Given that Estradiol is a hormone that is known for causing cancers, and with my sons predisposition of developing cancer/s (***in organs, that produce and regulate hormones!***), it seems like common sense that taking Estradiol and/or other similar hormones could be very dangerous to him. Yet, **he was prescribed Estradiol** on his very first visit **without any consultation** of his **Endocrinologist, Oncologist, Primary Care Physician nor his Genetic Counselor.**

Here is a bit of our family health history:

- B's father was diagnosed with **kidney cancer at age 32!** One of B's cousins was diagnosed with **kidney cancer and paraganglioma tumors, also at age 32**, and he **passed away within four years** of diagnosis! A second cousin developed **cancer at the age of 21 and died by the age 24!!** There have been many other family members with cancer and it is assumed they also had/have the genetic mutation. ****Estradiol can cause cancer!***
- There is a **very strong history** of heart disease in our family! B's father had a **heart attack at 47** years old, his maternal grandfather had a **heart attack at 34** and died on the fourth heart attack at 38 years old. Also, a second cousin died of a **heart attack at 31** years old! ****Estradiol can cause cardiovascular disease!***
- **Blood clots** (which can be hereditary) are also common in **both sides of our family!** Uncle's on from each side have had more than one blood clot at young ages. ****Estradiol can cause blood clots!***
- **Brain aneurysms** run in his family too! B's **grandmother had a brain aneurysm** that ruptured causing a hemorrhagic stroke. Her aneurysm lead to other family members being checked for aneurysms. **Myself and B's aunt also have/had brain aneurysms.** ****Estradiol can cause strokes!***
- Many family members have Diabetes. ***Estradiol can cause Type 2 Diabetes!***

****Link to estradiol side effects according to Mayo clinic:** <https://www.mayoclinic.org/tests-procedures/feminizing-hormone-therapy/about/pac-20385096>*

B suffers from **depression** and has been diagnosed with **ADHD** too. I do not believe that B was of sound mind and psychology stable when he went to Planned Parenthood but a Psychiatrist, nor Therapist, nor any mental health professional did an evaluation of him before prescribing hormones to him. Perhaps if B worked with professionals for his depression and ADHD he might feel differently about transitioning but this was not offered as a solution. Wouldn't it be smarter to first try a non-invasive treatment, especially with B's medical history?!

There needs to be more time for these doctors to thoroughly determine whether the patient should proceed down the path of medicalization. Synthetic hormones can have many detrimental side effects and everything should to be taken into consideration before patients are prescribed hormones.

Patients should be required to submit medical records, have family and friends testify that they are mentally stable and have a proper psychological evaluation done. Additionally, the doctor should provided proper statistics about people that have detransitioned and patients should be **fully** taken through the **risks of hormones, surgeries, etc.** They should not just given a consent form to sign with a bunch of legal information that no one ever reads. Especially, when working with a minor or a young adults whose brains are not yet fully developed to process all the ramifications.

With B's health history and the long list of family member's serious health issues, B should have been required to consult with an Endocrinologist, Oncologist, Primary Care Physician, Genetic Counselor, Neurosurgeon, Urologist, Cardiologist and a Psychiatrist prior to starting any hormones.

Instead, a **gynecologist** prescribed hormones to **my son** and within **four months** he ended up with **two brain tumors**, one in the pituitary gland the other in the left frontal lobe. I can provide mri scans from year prior to him taking hormones and mri 4 months after starting hormones. I am happy to provide medical records as well if you would like to see.

Dear Dr Vazquez:

As a physician for well over 30 years, I want to voice my concern about the danger of rapid gender transition of youth. The rapid process in my professional opinion leaves this vulnerable population in danger. In addition, the lack of informed consent in this population and the absence of input from the families of these minors is outrageous. I ask the State health Department to take a mature view and to tone down the ideological volume voiced by those who prefer ideology over science. Thank you for your timr.

Dear Florida Board of Medicine:

I am a Board certified Family medicine physician, and recently read that you will have meeting to consider implementing regulations related to sex based medicine practices. I am deeply concerned about “gender transition” of minors and the importance of informed consent and parental consent, especially when there is medical evidence of the long term harmful effects of those treatments, and that simple waiting and counseling help the gender confused patient. It is of utmost importance to restrict these misguided interventions and protect the youth of the state of Florida from unnecessary and lifelong harm that results from surgical and hormonal treatment, including physical and chemical castration, and the sterilization of minors which should be considered permanent. There is medical evidence that “gender-affirming care” treatments have dangerous and harmful effects that include cancer, osteoporosis, depression and increased risk of suicide. The vast majority of children with gender dysphoria will have a resolution of symptoms over time, with observation and counseling. We now know that in identical twin studies, the tendencies to have same sex attraction correlate with the sociocultural influences and the environment, and not with genetic information, and that over time there is a high probability of resolution. Our goal as physician is to help with healing and do no harm, and the “gender affirming care” is not a cure, but a harmful path of lifelong suffering.

Sincerely,
Joanne E. Castillo Rivera, MD

I am writing to support best care for children by protecting them from medicines and surgical procedures that would purport to help them affirm their true gender.

With more study and data, physicians have become increasingly aware that the effects of these therapeutics can be deleterious and not reversible as previously believed.

This is especially tragic, given that the majority of young people with feelings of gender dysphoria will eventually become comfortable with their biological sex.

Thank you,

Mary McCrossan, M.D.

Hi, Mr. Vazquez,

I am writing to you about gender affirming care and the lack of scientific approach associated with the whole process.

My 20 year old son was captured by the gender cult right before he celebrated his 19th birthday. Since then our family has been torn apart, my son's mental health deteriorated, quit his dream college and lost / cutoff almost all of his childhood friends. My husband and I also suffered mentally, physically and financially, so did his 14 year-old brother who had been caught in the crossfire. Thankfully, my son is finally sobering up after more than one year of psychotherapy and medication. He is examining his comorbid conditions and doing gender exploration therapy. As a result, he becomes more human vs. previously a gender ideation rhetoric repeating machine. While I am encouraged by his progress, I think nobody should have gone through this kind of excruciating pain trying to help your beloved child make a well-informed vs. impulsive decision, while the whole world seemed to be against you. The schools, the media, the medical professionals all blindly affirm. It's as if, the minute the word "gender" was mentioned, everyone turned into a machine that can only affirm no questions asked. I don't think this is scientific and I don't believe public funds should be spent as blindly and politically as this. But, you don't have to take my words for it. This research said it all. Please read this scientific paper.

" the outcomes omit one patient who died because puberty suppression dictated a riskier vaginoplasty. The fifth section pursues the British study designed to replicate the Dutch one; it was withheld from publication for some years, presumably because puberty suppression in this sample failed to improve gender dysphoria or psychological functioning. The poor quality of American studies is also noted. The final section evaluates evidence for the side effects of GnRHa. The negative effect on the accrual of bone mass is well studied, while there is increasing evidence for negative effects on cognitive and emotional development and on sexual functioning." <https://www.tandfonline.com/doi/full/10.1080/0092623X.2022.2121238?scroll=top&needAccess=true>

Thanks for your time!

Lily

Dear Sirs,

As a board-certified Emergency Physician with a masters in psychiatric nursing living in Pensacola I strongly encourage you to be conservative in the physical and hormonal interventions with these dysphoric youth. Chemical transitioning is adding greater confusion and in fact often great regret for many youth who are in no position to make these lifelong decisions while suffering dysphoria. For the last 15 years I have seen many of these regretful cases in the emergency room suffering worsening mental conditions, anxieties, depression and suicidality.

There is a lack of quality evidence to support transitioning and a strong research bias has prevented reporting on the long-term damage of these procedures. What you can find is that these unfortunate patients and their parents are currently suing the institutions and doctors who have so poorly informed and consented them for this treatment.

Sincerely

Vincent Dodge MD, MSN, FACEP

Paul A. Vazquez, J.D.
Executive Director
Florida Board of Medicine

Dear Mr Vazquez,
the Australian National Association of Practising Psychiatrists (NAPP) published on our website (napp.org.au) in July 2020 our Guide to managing gender dysphoria in young people (see attached). This Guide was developed with contributions from child and adolescent psychiatrists, psychotherapists, paediatricians, and general adult psychiatrists. It is informed by the medical literature available on this clinical topic and has been updated with new information as the field has developed. We believe it provides a compassionate, respectful, cautious, contemporary and evidence-based approach to the care of children and adolescents presenting with gender dysphoria. I hope you might take it into account when your Board is reviewing the guidelines for the management of gender dysphoria in Florida.

Yours sincerely,
Prof Philip Morris AM
President NAPP

Subject: Re: WPATH Standards of Care
Date: 17 September 2022 at 1:45:16 pm AEST

Dear All, perhaps the president of the American Academy of Pediatrics, Dr Szilagyi, might be given a copy of the NAPP Guide, given her pronouncements in her letter response to the Op-Ed in the Wall Street Journal in the screenshot below. Notice now how the term 'affirm' now means to 'de-stigmatise gender variance and promote the child's self worth', not affirm the child's demand to be or appear like a gender different to their birth-assigned gender. It seems to me, from what Dr Szilagyi said about the AAP advice that it does not push medical treatments or surgery, and for the vast majority of children, it recommends the opposite, the NAPP Guide could now become the policy of the American Academy of Pediatrics.

I also note the new edition of the WPATH guidelines include more cautious recommendations about use of medically affirming treatments in adolescents (see screenshots below), acknowledges the potential adverse effects on cognitive development of prolonged puberty blockade (see screenshot below), and the benefit of psychotherapy for children that addresses gender exploration, rather than gender affirmation (see screenshots below). Perhaps this last recommendation can be shown to the Queensland, ACT and Victorian governments with a request to make this recommendation part of their conversion therapy legislation.

Also, these issues are covered in my two interviews with ABC radio hosts (Paul Turton and Josh Szepe) on this topic available on the NAPP website (napp.org.au). Philip Morris.

OPINION | LETTERS

Academy of Pediatrics Responds on Trans Treatment for Kids

To 'affirm' a child or teen means destigmatizing gender variance and promoting the child's self-worth.

Aug. 21, 2022 12:37 pm ET

Regarding Julia Mason and Leor Sapir's op-ed "[The American Academy of Pediatrics' Dubious Transgender Science](#)" (Aug. 18): In its recommendations for caring for transgender and gender-diverse young people, the AAP advises pediatricians to offer developmentally appropriate care that is oriented toward understanding and appreciating the youth's gender experience. This care is nonjudgmental, includes families and allows questions and concerns to be raised in a supportive environment. This is what it means to "affirm" a child or teen; it means destigmatizing gender variance and promoting a child's self-worth. Gender-affirming care can be lifesaving. It doesn't push medical treatments or surgery; for the vast majority of children, it recommends the opposite.

WPATH guidelines

The following recommendations are made regarding the requirements for gender-affirming medical and surgical treatment (All of them must be met):

- 6.12- We recommend health care professionals assessing transgender and gender diverse adolescents only recommend gender-affirming medical or surgical treatments requested by the patient when:
- 6.12.a- The adolescent meets the diagnostic criteria of gender incongruence as per the ICD-11 in situations where a diagnosis is necessary to access health care. In countries that have not implemented the latest ICD, other taxonomies may be used although efforts should be undertaken to utilize the latest ICD as soon as practicable.
- 6.12.b- The experience of gender diversity/incongruence is marked and sustained over time.
- 6.12.c- The adolescent demonstrates the emotional and cognitive maturity required to provide informed consent/assent for the treatment.
- 6.12.d- The adolescent's mental health concerns (if any) that may interfere with diagnostic clarity, capacity to consent, and gender-affirming medical treatments have been addressed.
- 6.12.e- The adolescent has been informed of the reproductive effects, including the potential loss of fertility and the available options to preserve fertility, and these have been discussed in the context of the adolescent's stage of pubertal development.
- 6.12.f- The adolescent has reached Tanner stage 2 of puberty for pubertal suppression to be initiated.
- 6.12.g- The adolescent had at least 12 months of gender-affirming hormone therapy or longer, if required, to achieve the desired surgical result for gender-affirming procedures, including breast augmentation, orchiectomy, vaginoplasty, hysterectomy, phalloplasty, metoidioplasty, and facial surgery as part of gender-affirming treatment unless hormone therapy is either not desired or is medically contraindicated.

(Hembree et al., 2017). A compelling reason for earlier initiation of GAHT, for example, might be to avoid prolonged pubertal suppression, given potential bone health concerns and the psychosocial implications of delaying puberty as described in more detail in Chapter 12—Hormone Therapy (Klink, Caris et al., 2015; Schagen et al., 2020; Vlot et al., 2017; Zhu & Chan, 2017). Puberty is a time of significant brain and cognitive development. The potential neurodevelopmental impact of extended pubertal suppression in gender diverse youth has been specifically identified as an area in need of continued study (Chen et al., 2020). While GnRH

Statement 7.8

We recommend health care professionals consider consultation, psychotherapy, or both for a gender diverse child and family/caregivers when families and health care professionals believe this would benefit the well-being and development of a child and/or family.

Society, 2020; Telfer et al., 2018). Nevertheless, it is often appropriate and helpful to seek psychotherapy when there is distress or concerns are expressed by parents to improve psychosocial health and prevent further distress (APA, 2015). Some of the common reasons for considering psychotherapy for a gender diverse child and family include the following 1) A child is demonstrating significant conflicts, confusion, stress or distress about their gender identity or needs a protected space to explore their gender (Ehrensaft, 2018; Spivey and Edwards-Leeper, 2019); 2) A child is experiencing external pressure to express their gender in a way that conflicts with their self-knowledge, desires, and beliefs (APA, 2015); 3) A child is struggling with mental health concerns, related to or independent of their gender

Tishelman, 2018); and 4) provide the child an opportunity to further understand their internal gender experiences (APA, 2015; Barrow & Apostle, 2018; Ehrensaft, 2018; Malpas et al., 2018; McLaughlin & Sharp, 2018). It is helpful for HCPs

Gender dysphoria/incongruence in young people is a contested area of medical practice. This approach avoids political, social, religious and ideological positions.

This approach to developing guidelines for managing gender dysphoria [1] or gender incongruence [2] in children and adolescents aims to protect and safeguard the health, safety and welfare of the child. This guide prioritises the best interests of the child in accordance with human rights obligations under the International Convention of the Rights of the Child [3].

Specifically, this guide:

While respecting young people's views about their gender identity, it does so as part of the totality of their developmental and holistic clinical picture, and incorporates these into the clinical formulation. This approach requires that a comprehensive bio-psycho-social assessment of the young individual and their family be conducted before recommending specific treatment.

Acknowledges that childhood and adolescence is a time of rapid physical and psycho-social growth and profound personal development, during which young people may question their identity, sexual orientation and gender. As the child matures and progresses through puberty this questioning usually transforms and resolves, and the young person, in the majority of cases, accepts his/her biological sex and adult body [4, 5].

Understands that gender dysphoria/incongruence can be both a symptom and a syndrome. For a young person to have the syndrome of gender dysphoria/incongruence there must be a significant, established and prolonged pattern [2] of desire and behaviour that indicates the person insists they are a gender different to their biological sex and natal (birth assigned) gender.

Recognises that gender dysphoria/incongruence can often be a manifestation of complex pre-existing family, social, psychological, or psychiatric conditions or predisposing factors [6]. A holistic approach to assessment includes a comprehensive exploration for these potential conditions in order to more fully understand a child presenting with gender dysphoria/incongruence [7,8]. Where these conditions are presenting as gender dysphoria/incongruence, the treatment of the underlying condition is a priority.

Individualised psychosocial interventions (e.g., psychoeducation, individual therapy, school-home liaison, family therapy) should be first-line treatments for young people with gender dysphoria/incongruence. Exploratory psychotherapy should be offered to all gender-questioning young people to identify the many potential sources of distress in their lives in addition to their gender concerns. Clinicians can apply a range of psychological interventions (e.g., supportive psychotherapy, CBT, dynamic psychotherapy, and family therapy) to assist the young person clarify and resolve these contributory factors. Such approaches are consistent with established principles of comprehensive, systemic youth health care [7]. They should be undertaken before experimental puberty-blocking drugs [9] and other medical interventions (e.g., cross-sex hormones, sex reassignment surgery) are considered.

Psychotherapy for gender dysphoria in children and adolescents is a respectful, supportive and exploratory process that does not seek any particular outcome in relation to gender identity or sexual orientation. It seeks to understand the nature and meaning of the young person's gender distress and the context in which it has arisen. Psychotherapy addresses the multiple factors that contribute to the young person's difficulties, helping to address issues that resolve distress and support ongoing development and maturation. Conversion therapies, on the other hand, aim to achieve a pre-determined outcome, such as gender normativity or heterosexual orientation. Psychotherapy for gender dysphoria must NOT be conflated with conversion therapies.

Medical interventions to block puberty and cross-hormone treatment to achieve feminization and masculinization according to the young person's perceived gender are not fully reversible and can cause significant adverse effects on physical, cognitive, reproductive and psychosexual development [9,10,11,12,13,14,15,16].

Currently, while some individuals report a successful transition, we are not aware of published long-term outcome studies that have followed up adults who have undergone childhood or adolescent transition that show substantial benefit. As a consequence, there is no consensus that medical treatments such as the use of puberty-blocking drugs, cross-sex hormones or sexual reassignment surgery lead to better future psychosocial adjustment [17,18,19,20].

Increasing numbers of individuals who have undergone hormonal treatment and surgical interventions subsequently report experiencing regret and a wish to de-transition [21]. They describe significant psychological and physical suffering, including loss of fertility and sexual function as a consequence of decisions made when younger [22,23,24,25,26,27].

Medico legal considerations must be fully appreciated in this area of clinical practice. Health professionals are exposed to significant legal risk:

- If a child or adolescent is found not to have been competent to give an informed consent,
- If in children under age 16 years both parents have not agreed to puberty suppression and cross-hormone treatment,
- If gender affirming treatment is not preceded by a comprehensive psycho-social assessment, that considers and excludes alternate diagnoses, or
- If the patient was not informed of all the risks of puberty blockers and cross-hormone treatment including their experimental nature [9].

Clinicians should therefore reflect carefully before recommending treatments for gender dysphoria/incongruence.

The still unproven risks and benefits of gender reassignment interventions make it imperative that parents and children under 18 years and young people over 18 years are made aware of the current evidence of potential harm regarding gender transition and provide fully informed consent before potentially damaging and irreversible treatment is commenced.

This cautious approach is also mirrored in general clinical guidance by national treatment advisory bodies in Finland, Sweden, France and the United Kingdom that recommend treatment methods for gender dysphoria in minors [28, 29, 30, 31]. In Finland, the recommendation is that among young people with gender dysphoria and significant psychiatric comorbidity no conclusions can be drawn on the stability of the gender identity of the child [28]. In the UK, the one specialised clinic in England (Tavistock Clinic) offering an affirmation approach to management of gender dysphoria in children and adolescents will be closed and replaced by regional clinics offering a more holistic model of care [32]. The author of the report that led to this decision (Dr Hilary Cass) raised substantial concerns about the effect of puberty blockers on developmental maturation and decision-making [32].

This guide adopts a personalised, non-ideological approach to the care of youth with gender dysphoria. As Dr Hilary Cass notes [33], the diagnostic process required by doctors who prescribe treatment for young individuals with this condition must include a diagnosis and differential diagnosis:

"I have also noticed some debate around the inclusion of the need for a diagnosis and differential diagnosis, and whether that means we are pathologising gender identity or seeing it as a mental health problem. I think it is worth clarifying what is meant by these terms.

Applying medical thinking to gender identity isn't required until and unless a young person needs treatment. The regulations are particularly tightly defined when a doctor is considering prescribing medication, and especially medication that may have some life-long effects. Doctors then have a professional obligation to go through a process of ensuring that it is appropriate for the health needs of the individual, which means making a positive diagnosis (what the condition is) and a differential diagnosis (what the condition isn't). This applies in all areas of medicine.

The process of differential diagnosis is neutral in terms of outcome - it's not about preferring one diagnosis over another; it's just about getting it right. It isn't about trying to rule out every conceivable explanation before confirming any particular diagnosis - only about ruling out other diagnoses that might be likely for that individual, or where getting it wrong and missing another diagnosis could have serious consequences. Achieving this involves taking a holistic, considered approach to each individual about the possible causes of their distress and identifying the most appropriate pathway for them. This must always be done with sensitivity and in partnership with the young person and their family.

This same requirement is reflected in the internationally developed Endocrine Society gender dysphoria/gender incongruence guidance which recommends that health professionals responsible for diagnosing gender dysphoria should meet a range of criteria including "the ability to make a distinction between GD [gender dysphoria] /gender incongruence and conditions that have similar features".

In preparing this guide, advice was obtained from a number of senior medical colleagues in child and adolescent psychiatry, adult psychiatry, and forensic psychiatry, as well as from physicians and psychologists who have cared for young people experiencing gender dysphoria/incongruence, and legal practitioners who have experience in this field.

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of

WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

Dear Chair Diamond:

Thank you and the Florida Board of Medicine
for protecting Florida minors which prohibits children
and teens from receiving hormone therapy or
undergoing "gender" surgery. Your efforts, however
controversial they may seem to some people, are being
applauded in heaven by God almighty.
God will richly bless you for your efforts!

again thank you
Julien Stelly

Dear Chair Diamond:

Thank you and the Florida Board of Medicine
for protecting Florida minors without
prohibiting children and teens from receiving
hormone therapy or undergoing "gender surgery".
Your efforts, however controversial they may
be, people are being applauded for today
by God almighty.

God will richly bless you for your
efforts! -

Again Thank You

Dear Mr. Vazquez and the Florida Board of Medicine Rules Committee:

As a native Floridian who has recently returned to live in my home state, I'm exceedingly proud to know that the Board will be considering the vital issues regarding the practice of gender medicine at its upcoming meeting.

I'm hopeful that FL will lead the way and be on the right side of history regarding the worst medical catastrophe since the opioid crisis. The sterilization and mutilation of our youngest and brightest in the name of "affirmative care" for gender dysphoria.

My son, who has ADHD, OCD, who is extremely bright, socially awkward and has experienced trauma (all characteristics of youth presenting with gender dysphoria) told me four years ago that he was born in the wrong body. Not only that, he said that if I did not affirm that identity he may be taken from me (a crazy threat that turns out has happened to parents) or commit suicide. I did not know then that is a "script" that such youth are told my transgender activists. Needless to say, it knocks parents off their feet.

I took him to the pediatrician he had seen since birth, who told me to stay away from Boston Children's hospital and tried to help by referring me to non-affirming therapists, but those therapists were not taking new patients. This pediatrician is Harvard trained and did her residency at Massachusetts General hospital. She also cared for my older daughters since birth (33 years in total), lived in the same town as me, and my daughter and her daughter were friends. Thus, she knows my family intimately. She helped when my daughter had anorexia for which she was treated and is now recovered. She knew that the dramatic increase in youth presenting with gender dysphoria was not normal and she knew that I should not pursue transition for my child. I mention this because it seems like all pediatricians support transition. This is not true. **Many highly-trained pediatricians do not support transition but they are silenced by a society and a medical establishment that names anything other than full support "transphobic."**

My psychiatrist, a physician at Massachusetts General Hospital, immediately said my son was having an identity crisis when I told him about his sudden announcement of being transgender. He admits that one of the premiere gender doctors at MGH is an advocate for transgender people. Letting politics influence his medical advice. My

psychiatrist also finds it incredulous that many of these youth have autism and that the issue of social contagion is not being raised and examined in the medical field. He is incredulous that a clinic in Chicago diagnoses perfectly healthy males as having an endocrine disorder requiring cross-gender hormones as equivalent to saying that they have chromosome disorders. That same physician, who is now "brainwashed" by the hospital he works for that is making hundreds of thousands of dollars (maybe millions) off transgender care, has stepped back from that position and is now saying he is "remaining curious." **Many highly-trained psychiatrists do not support transition but they are silenced by a society and a medical establishment that names anything other than full support "transphobic."**

The individuals who "diagnosed" my son as having gender dysphoria were his high school guidance counselor and a very new therapist. They did so immediately after his declaration and immediately referred him to Boston Children's Hospital for puberty blockers. We never went.

There is scientific evidence that the male brain does not mature until age 25. Yet, we are listening to youth (who we freely say do stupid stuff in high school and college) that they need to medicalize themselves for life to escape mental anguish now.

I am a lawyer. I've already helped one detransitioner file suit against a major hospital and a group of doctors. This is the start of these lawsuits.

I am fighting for my child and the hundreds of thousands like him who have been influenced through the internet, peers, and some well-meaning adults that they are the other gender. Other progressive countries such as Finland, Sweden and the UK have woken up. We are like Iran who forces homosexual individuals to transition.

No youth can consent to elective, experimental treatments that will sterilize and medicalize them for life. No parent can consent on behalf of their minor children to elective, experimental treatments that will sterilize and medicalize them for life. Full stop.

I hope that the Florida Board of Medicine will do the right thing and prohibit transitioning care for gender non-conforming youth. I hope that it does so using science. Medicine should not be political. The treatments are irreversible. One better have high-quality longitudinal evidence that such treatments are necessary. There is none.

Best,

Subject: Please stop medically transitioning children

Hello Paul,

I am the mother of a previously trans identifying child. I was terrified to learn of the medical potential children are lead to by medical and mental health professionals. Puberty blockers, hormones and surgeries all have irreversible and very harmful effects on a child.

When we pulled our daughter away from all of the affirming influences in her life she desisted. I do not believe this would have happened had we not removed the influences from her life (internet, affirming friends, affirming school). She may have gone down a medical path that would have been wrong for her. In the old watchful waiting protocol most children grew to be comfortable with their sex. With all the influences in our culture today, (internet, friends, school, etc.) I believe there is no longer such a thing as watchful waiting.

Children are too young to consent to irreversible medical harms. There are now 40k in a detransitioner Reddit. This should be enough evidence that we need to pull back on these medical procedures.

We were lucky that we were able to help our child be comfortable with her sex. These are mistakes that children should not be allowed to make. The medical profession needs to hold to its oath to first do no harm. Please consider ending the medicalization of children in Florida.

Thank you,
Jennifer Krohn

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

Hello,

I am sending this email as a licensed mental health provider. I am in charge of a mental health agency in Utah with locations in three cities.

I have seen a tremendous increase in the number of adolescent girls seeking care at my agency over the last two years. The parents of these girls have brought them in after their daughters have suddenly wanted to use masculine names and shown confusion about their gender.

After these girls begin mental health therapy, we are seeing several underlying concerns such as: body image concerns, self-harm, anxiety, and depression.

Last year my own daughter suddenly chose a male sounding name and became confused about her gender after some others girls at school she associated with did the same thing.

As a mental health clinician (and also a mother) who is responsible for creating programs and cares about the mental well-being of these girls, I started to do some research.

Unfortunately, the increase in adolescent girls identifying as transgender is relatively new. Due to this, there is a surprisingly small amount of research on it.

I read some articles, including one in psychology today, which advocated for transitioning a youth as soon as they become gender dysphoric. In this same publication, they did acknowledge the increase in adolescents identifying as transgender has increased significantly in the past few years. In the same publication the researchers discussed how personality changes over time and we are not the same person in childhood, adolescence, and even through adulthood.

In addition, I read about the Supreme Court case in England for Kiera Bell, the banning of hormone treatments for youth in Finland and Sweden, as well the closure of Travistock for a more holistic approach to gender dysphoria in youth.

When I looked at the medical research, I saw that what is being used as a puberty blocker, has traditionally been used as chemical castration for sex offenders and in children with precocious puberty. I could not find any long term studies on the results of halting healthy puberty and having it return to normal in later adulthood when the medications were stopped. The closest thing I was able to find were cases where an adolescent had used puberty blockers then proceeded to cross sex hormones and became infertile.

I would like to encourage those with the authority to decide in Florida, to take a cautious

approach when it comes to affirmative care.

When one looks at all of the facts with regard to adolescent gender dysphoria, there is still much more research to be done. There are many unanswered questions. Why the sudden increase in gender dysphoric youth? Why do the vast majority of them have underlying mental health concerns? Why does it seem to appear in groups of girls? Why after exposure to gender oriented lessons/presentations, trans advocates online, or peers do adolescent girls seem to realize they were born in the wrong body? As well as many more questions.

When it comes to medical interventions, informed care is paramount. Even more so, permanent or possibly permanent inventions should be used with extreme caution. We do not allow minors to get tattoos or sign contracts. We do not schedule a hysterectomy as soon as an adolescent girl with painful periods decides she doesn't want to have them anymore and is convinced she won't want children later.

Every medication and every medical intervention has side effects. Every single one has pros and cons with it's use. In the cases of medical intervention with regard to affirmative care, we are halting a healthy and functioning process. We are interfering with the normal functioning of an adolescent's body. In my state, I have seen adolescent girls go to a gender clinic and get a prescription for hormones that same day without a note from that person's mental health therapist.

I don't have all the answers, but something is going on for our adolescents and, particularly, our adolescent girls. Please help the medical community to do it's due diligence in ensuring the research is conducted, evidence based inventions are used, and caution is used when providing treatment to minors for anything, but especially for something that could have lifelong consequences for them.

Thank you for your time in reading what I have written here today.

Florida Board of Medicine

Please be fair and recognize rights of all citizens and Florida residents- no one person should have more access to healthcare than another. stop trying to discriminate against Lesbian Gay and especially Transgender and Nonbinary citizens.

Your proposals and upcoming bills to deny citizens healthcare is not upholding relevant constitutional and national laws and guidelines. Using old outdated and debunked research is bogus attempt to sow fear and misinformation. Stop prejudice discrimination and hate + just stop attacking some citizens and showing favoritism to others. it is immoral and cruel to deny best practices in healthcare and to deny appropriate privacy between doctors and patients. Shame on you.

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically

appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

I was in the meeting on August 5 2022. There was one detransitioner that spoke. ONE. There were 50+ transgender people in the room that I personally know & have been able to solve this issue in their lives. This has been given the label of 'concern for well-being', whilst ACTING in a non-concerning manner. Their actions do not match 'do no harm'. Denying people healthcare DOES harm.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.” This is a key piece. Why involve government in medical decisions? Why do political actors feel they have more knowledge & expertise than the doctor & patient involved? Allow the patient & their doctors to manage these situations.

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically

appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of

WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

Even though I am not a citizen of Florida, I am appalled that the Florida Board of Medicine would take this step to restrict access to gender-affirming care rather than ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, the Florida Board of Medicine should at least take the position to DO NO HARM.

If Florida-specific standards of care are adopted, they must reflect the most current version of WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

Sincerely,
Marcela Howell

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

How could a medical board ignore the professional opinion of doctors and listen to hateful politicians instead? Ignore the AMA?

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

I have two friends with trans adult children, who were suicidal as minors until they received mental health care and hormone therapy. It was under constant care by a physician, and with much care and concern.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive

Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

As a citizen of Washington, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). One of my best friends came out as a transman. Henry is as precious as he ever was. It started with "if I had my life to do over again", but three years later he chose top surgery. He is so happy--a smile on his face all the time. I'd go very long way to do whatever I can to affirm his humanity.

We are talking about human beings here, not some abstraction or even an enemy. And if you haven't noticed, there are lots more transpeople coming out. You need to get on the right side of history. I would assume you are educated--which makes your sin even worse--you should know better.

To Whom It May Concern,

Minors suffering from sex dysphoria (that is, they feel they were “born in the sexed wrong body”) are at great risk of being victims of medical exploitation and malpractice. Puberty blockers completely block puberty from occurring and are being prescribed to physically healthy children as young as 10 years old, some even younger. Lupron, the commonly used puberty-blocking drug was given FDA approval to treat prostate cancer in men and endometriosis in women, not childhood psychological issues.

There have been no long-term clinical studies done on children. Puberty blockers are being used ‘off label’ to block kids’ healthy, natural development, with grave physical consequences. The few small studies we do have show that they don’t even provide any psychological benefit, and in fact may make things worse. The studies we do have show clearly that of these children (provided they go through puberty), 4 out of 5 experience complete alleviation of psychological distress. Most discover that they are same-sex attracted. Furthermore, over 90% of children who are put on puberty blockers move forward with cross-sex hormones. It is now clear that suicidality significantly *increases* in those who have been “affirmed” in this way. In addition, the long term effects of these drugs and hormones have sweeping deleterious effects on health and chain patients to a lifetime of medical intervention and drugs.

Gender ideology is a pseudo-religious movement which claims that children can be born in the wrong body. It teaches that we all have a ‘gender identity’ which takes precedence over our biological sex. It is entirely based on regressive stereotypes: Children are taught that it is their interests, hobbies, likes and dislikes which determine their gender. School materials literally say: if boys like Barbie dolls and dancing, they might actually be a girl. Girls struggling with adolescence, with puberty, with anxiety, etc. are especially vulnerable to this craze, as covered so well in Abigail Shrier’s book, ‘Irreversible Damage: The Transgender Craze Seducing Our Daughters’.

Instead of encouraging gender nonconformity, and rejecting regressive gender stereotypes, children are now taught to embrace the stereotypes to the point of physically harming their bodies. They are taught that they have boy brains or girl brains, or a gendered soul. This is wholly unscientific nonsense. Thousands of children are now being sent to gender clinics, where they receive ONLY affirmation of this idea, and they are quickly sent on a medical pathway which includes puberty blockers, opposite-sex hormones, and surgery.

State and federal governments must take a firm stand against pediatric “affirmative care” and the gender ideology being aggressively taught in schools (many starting in pre-K). It’s the biggest medical scandal in history and it’s being committed against our most precious

population — our children.

Thank you for your consideration of my opinion.

Best,
Suzy

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of

WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

Dear Mr Vazquez,

I am an experienced mentally health practitioner who also specialises in the area of the psychological treatment of children and young adults with GD. It was suggested that I should write to you with some of my experiences and knowledge for your upcoming meeting regarding the evidence base and ethical treatment models for children experiencing gender dysphoria.

Please let me know if this is sufficient, and if required for the Board I can supply substantially more information, research data and references.

Yours sincerely

Susan Evans

CV and Experience

I am trained as a Psychoanalytic Psychotherapist and currently work in private practice in the UK seeing children with gender identity issues. I am retired from the NHS which has allowed me to speak more freely regarding this issue.

I worked in the Tavistock Gender Identity Service in the NHS for several years. I trained as a state registered nurse and psychiatric nurse and have experience in many specialist areas of psychiatry/mental health since the 1980s. I was a Senior Clinical Lecturer at the Tavistock and Portman National Health Service Foundation Trust and Senior Fellow in Education, University of East London.

The Tavistock GIDS has recently been permanently closed, following many concerns raised by staff, parents, the law and the media. It received a poor report from the Care Quality Commission, which oversees standards of care in the NHS. NHS England in response, commissioned a report by Dr Hilary Cass, a consultant paediatrician and her team concerned with the evidence base, standards, and efficacy of approaches to the medical treatment and care of gender dysphoria in children.

Marcus Evans and I have authored a book on Gender Dysphoria which offers a potential holistic psychological understanding and treatment model to support children with gender dysphoria in their time of distress.

My involvement

Between 2004 and 2007 I became very concerned that the children who were presenting as patients in the GIDS were, in most cases, psychologically complex and many with co-morbidities. (It is estimated approximately 30% are on the autistic spectrum). I witnessed some being recommended for medicalised treatments on hormones, after as few as 4 assessment meetings, during which time very little psychological support or treatment could have occurred. In my clinical experience it takes much longer to make a full assessment of children and adolescents and a therapeutic alliance can take months to build. I was shocked by this superficial psychological approach, as it led to irreversible changes, both physical and mental, some of which, as yet, are unknown, due to the paucity of follow up data on the children receiving these treatments.

The UK Judicial review ‘Bell versus Tavistock

By 2019 the service had grown from approximately 80 referrals nationally per year to over 3,000 per annum. Certain staff at the unit whistle blew to Dr David Bell who was at the time a staff governor for the Tavistock Trust. He made a report for the Tavistock trust board, but the board decided to conduct their own review and many of the staff concerns were diminished or ignored. Meanwhile there was a growing awareness in the UK that all was not well in the growing political influence on medical and psychological approaches to treatment of gender dysphoria in children. There was a meeting organised by Lord Moonie in the House of Lords and from this several previously separate but concerned individuals came together. Following this I agreed with Mrs A, the mother of a teenage girl, with autism on the waiting list for the Tavistock GIDS, that we would take a judicial review to question whether children can give informed consent to this experimental form of medical treatment. Our team gathered witness statements from experts throughout the world and also from Keira Bell, a female who had been treated at GIDS as a 16-year-old, but subsequently de-transitioned. She became the main claimant in the Case.

At 23, Keira Bell felt that she should not have been able to embark on such a procedure because, in retrospect, she realised she had not had the maturity and understanding to give informed consent to the medicalised procedures. Mrs A, the other claimant, did not consider her daughter capable of understanding the attendant risks of undertaking gender reassignment treatment due to her autism diagnosis and other emotional conditions. The judicial review in the UK High Court was to challenge policies and practices based on unconditional “affirmation”

and the prescription of puberty blockers to children under 18 with gender dysphoria at the Gender Identity Development Service (GIDS), part of the Tavistock and Portman NHS Foundation Trust.

Our team submitted a huge amount of evidence which 3 high court judges were able to read prior to the hearing, along with any evidence that the Tavistock GIDS submitted.

In December 2020, three judges in the High Court ruled that it is doubtful that children under the age of 16 years are able to consent to treatment with hormone blockers

The 3 High Court judges stated "There will be enormous difficulties in a child under 16 understanding and weighing up this information and deciding whether to consent to the use of puberty blocking medication." The judgement said it was "doubtful that a child aged 14 or 15 could understand and weigh the long-term risks and consequences" of this treatment. It further ruled that it was "highly unlikely that a child aged 13 or under would be competent to give consent to the administration of puberty blockers."

They also considered the 16-18 group and said that most young people aged 16 or 17 will be able to consent to medical treatment. Some young people under 16 can also consent to their medical treatment. **However, competence to consent to a treatment is specific to the nature of that treatment.**

"There will be enormous difficulties in a child under 16 understanding and weighing up this information and deciding whether to consent to the use of puberty blocking medication."

In my clinical experience of working with this group of children, I have learned that many of these children are managing their anxieties through a system of rigid psychological defences. They often struggle to be able to think about their internal emotional world and their conflicts and confusions. It may feel anxiety provoking to explore this with the child, but a holistic empathetic approach can be utilised to help the child begin to be curious about themselves. If however, they are not supported to do so, the psychic discomfort is often channelled into the idea of making concrete changes to the body as if this will get rid of the difficult issues. The idea of 'puberty blockers' may be very appealing to put a stop to this adolescent development. (to the patients, parents and clinicians

because it appears to be an easier route out of the chaos and disturbance) The task of us all in life is to develop from a child into an adult. Adolescence and the accompanying chaos this age brings, is a very normal human experience. The anxieties which some children are hoping to avoid is often around their adolescent physical development and maturation, associated with a difficulty in negotiating sexuality and relationships. (I will not say more here but hope this offers the board some ideas for why puberty blocking is perhaps not only physically harmful but psychologically harmful as it interferes with ordinary human development in all areas).

The recent ICD11 has, in my view bowed to certain political pressures over diagnostic terms.

One small example is observing 'Insistence, Consistence and Persistence' taken to be diagnostic confirmations of gender dysphoria, and this might indeed describe the state of mind witnessed by the clinician, but for me these particular states of mind wave a red flag when I encounter them in children. As I said earlier, many of these children find themselves caught up in rigid psychic defence systems where there is no room for ordinary questioning or doubt about the huge decisions they are making for their future life. It is ordinary good mental health to question or have concerns and doubts about a serious life changing course of action. The lack of anxiety and doubt is of huge concern, not a green light of diagnostic confirmation in my opinion.

The Cass interim report found that gender identity involves a "complex range of issues", which are not sufficiently recognised in the WPATH Standards of Care.

Regret desistance and detransition

There is a very high level of desistance (between 75-95%) in children with gender dysphoria, if they are offered 'watchful waiting' but early evidence is suggesting that this rate lowers if children are socially and medically affirmed.

We have no true idea of the number of children who have given 'informed consent' to this medicalised route, received hormones and/or surgeries, but live to regret their transition and will suffer lifelong consequences of this experimental treatment. The Cass review evidenced that there is very little gold standard research and follow up data in this area of medicine. Sadly, 'de-transitioners' do not often go back to tell their medical 'transitioners' that they have, together, made an

irrevocable mistake and caused perhaps irreversible harms. Many of them speak of the wish that a professional had stopped them in their headlong run towards medical transition. The medical profession has an opportunity to look more closely at the potential harms being done and improve their practices in the care of gender dysphoric patients.

Dear Board Members,

I understand the Board is considering recommendations regarding medical transition for minors with gender dysphoria. I am sure that the Board is aware that the world's largest pediatric Gender Identity Development Service (GIDS) in the UK is planning to close to be replaced by clinics with a greater focus on mental health and general practitioner services. The literature review by Dr. Hillary Cass determined that their current medical transition model was not safe. It also determined it was not viable for the long term.

An important quote from her review demonstrates that the medical treatment of gender dysphoria has become more of a political issue than a medical one. From page 17, para. 1.14, "Primary and secondary care staff have told us that they feel under pressure to adopt an unquestioning affirmative approach and that this is at odds with the standard process of clinical assessment and diagnosis that they have been trained to undertake in all other clinical encounters." Further support for such politicalization of this issue comes from the fact that 35 psychologists resigned from NHS's GIDS over three years, complaining of over-prescribing the medicalization of gender dysphoric minors feeling they were unable to properly assess patients over fears they will be branded transphobic.

Further support for this politicalization from the Cass review includes the following:

- Page 17, para. 1.15, states " many of the children and young people presenting have complex needs, but once they are identified as having gender-related distress, other important healthcare issues that would normally be managed by local services can sometimes be overlooked."
- Page 17, para. 1.18, "From the point of entry to GIDS there appears to be predominantly an affirmative, non-exploratory approach, often driven by child and parent expectations and the extent of social transition that has developed due to the delay in service provision" "There is limited evidence of mental health or neurodevelopmental assessments being routinely documented, or of a discipline of formal diagnostic or psychological formulation."

Importantly, the Cass review states on page 18, "Evidence on the appropriate management of children and young people with gender incongruence and dysphoria is inconclusive both nationally and internationally." This review is not alone in that assessment.

The UK's National Institute for Health and Care Excellence (N.I.C.E) issued reviews in 2020 on puberty blockers and cross-sex hormones.

In regards to gonadotrophin releasing hormone analogues for children and adolescents with gender dysphoria, they concluded: "The results of the studies that reported impact on the critical outcomes of gender dysphoria and mental health (depression, anger and anxiety), and

the important outcomes of body image and psychosocial impact (global and psychosocial functioning), in children and adolescents with gender dysphoria are of very low certainty using modified GRADE. They suggest little change with GnRH analogues from baseline to follow-up.”

In regards to Gender-affirming hormones for children and adolescents with gender dysphoria, they concluded:

“Results from 5 uncontrolled, observational studies suggest that, in children and adolescents with gender dysphoria, gender-affirming hormones are likely to improve symptoms of gender dysphoria, and may also improve depression, anxiety, quality of life, suicidality, and psychosocial functioning. The impact of treatment on body image is unclear. All results were of very low certainty using modified GRADE.”

“Adverse events and discontinuation rates associated with gender-affirming hormones were only reported in 1 study, and no conclusions can be made on these outcomes.”

I recommend the Board be very cautious in their recommendations regarding the treatment of gender dysphoria in minors. I recommend such treatment only be performed with parental consent. I am not convinced parents can grasp the gravity and enormity of these decisions. Minors clearly cannot.

It appears the quality of evidence to support the medical treatment of gender dysphoria is poor at best and follow up on these treatments is clearly inadequate. Since the largest pediatric gender identity clinic in the world seems to be moving back towards a mental health emphasis in the treatment of gender dysphoria, it might be wise for Florida to follow suit.

Thank you for your consideration in these matters.

God bless you!

Sincerely,

Daniel Joyce, M.D.

Dear Mr. Vasquez,

I am a family medicine physician living in Clermont. I am writing to express my concerns about gender transition:

1. The evidence supporting the usefulness of this treatment for children is weak.
2. The risk of children taking puberty blockers is high.
3. The capacity of children to make a decision to transition is limited.
4. Encouraging gender transition in children without the knowledge and consent of the child's parents is criminal.

Gender transition in children is a dangerous procedure and should not be permitted in Florida, or anywhere in the world.

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of

WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

September 20, 2022

To: The Florida Board of Medicine

Re: Gender Affirming Care for Adolescents

I am a pediatrician with 37 years of experience. In recent years, I have seen a large increase in the number of adolescents asking for referral to our local Gender Clinic. The majority of these patients are pubertal young women. Most have not expressed concerns about their gender prior to puberty. Many have had prior anxiety and difficulty socially. They are looking for answers, and being “in the wrong gendered body” has become a much more common answer than previously.

Unfortunately, there are far too few resources for young people struggling with accepting the changes in their bodies associated with puberty. In the past, there were support groups we could refer these adolescents to. Now, it is easier to refer to the Gender Clinic. We are changing from a “body positive” approach to a “wrong body needing change” approach.

These adolescents need our support, but it is important that we study Gender Affirming Care before adopting it with no boundaries. Young people being treated medically for gender dysphoria should be part of well-designed studies. Any irreversible treatments, such as mastectomies (top surgery), should be particularly scrutinized.

Ideally, we should be doing studies comparing Gender Affirming Care with age appropriate support groups that promote self love and make puberty less daunting.

To be clear, there are some children who present at very young ages with gender variation. This small group started the movement to have Gender Clinics and they appear to be much more persistent in their gender identification. Their numbers have not increased at the same pace as the pubertal group.

Thank you for your consideration of this important topic.

Sincerely,

Robin Winokur, MD

Dear Dr. Vazquez and members of the Florida Medical Board,

I am a physician who has been practicing in Florida for 30 years and am writing to express concern about how the board will decide in its upcoming deliberation on recommendations for the availability, appropriateness, and standard of care for minors suffering from gender dysphoria who request so-called gender-affirming hormonal or surgical interventions.

Whereas in my own family, I have an adult nephew who has opted for such a transition, when it comes to minors, in my medical opinion, minors lack the cognitive developmental ability to render valid informed consent for such a life-altering transition that we know has potentially irreversible health consequences (e.g., thrombosis and stroke for those receiving estrogens; and potential infertility). Further, I have reviewed the medical literature on this question and find the evidence in support of medical and surgical transitions in minors to be scientifically weak, in critical areas inconclusive, and in other areas heavily biased. In longterm studies, a substantial number of patients who, as children, identify as the opposite sex later identify as their true biological sex, and there are cases of patients who later regret their transition. Further, the claim we sometimes hear that such treatments prevent suicide has been discredited.

At the very least, the medical profession should exercise due caution regarding unknown long-term impact of experimental drugs in minors. I fear that, one or two decades from now, a rational review of this social phenomenon will deliver a verdict not unlike that for frontal leukotomy.

Thank you for your consideration.

Cordially,

William P. Cheshire Jr., M.D.

I am writing because I am highly concerned that the Florida board of medicine is considering harming a subset of children and teens. Youth transition should not be allowed for many reasons, one being that > 85% of children and teens change their minds by age 20.

Please do not allow this fad and the activists who support it, to irreparably harm our children and teens!

Sincerely,

W. Matt Zban, MD, FACEP

I am grateful for the opportunity to provide comments regarding the Florida board of medicine evaluation of gender affirming care. My name is Tim McNicoll MD, I am board certified in family practice since 1984 with an additional year of residency training in Pediatrics, a certificate of added qualifications in geriatrics from the AAFP and ABIM and a masters degree in bioethics. I also practiced OB early in my career and have cared for patients from conception to death.

I have watched with some dismay over the last few years the rapid progression from gender insecurity to permanent gender transition in many youths. I have cared for children for the last 40 years and have witnessed how quickly they can progress through developmental stages acquiring and vacillating between new physical, psychological, emotional, and sexual identities. They are constantly and rapidly acquiring new skills but have mastered none of them. Their search for themselves often involves different clothing, different hair styles or color, different speech, and different peer groups. Some more potentially permanent or damaging changes include tattoos, anorexia, overeating, alcohol, smoking, drugs, self-harming behaviors, suicidal ideation and even suicide. These are often aggravated by anxiety, depression, and family dysfunction.

Gender insecurity seems to be another manifestation of the almost cataclysmic changes that result from general adolescent identity insecurity. One could conceive of this almost as a living suicide as you destroy a major part of who you have been throughout your life – and unlike the other developmental experiments listed above, you may never be able to return from this gender experiment. There are always exceptions to rules, and likely there are some who may always desire transition, but the tremendous recent increase in gender dysphoria seems to be more of a social trend rather than an inherent human characteristic. Hopefully, like anorexia, it will regress to a much smaller fraction of the adolescent population in 20 years. In the meantime, one has to wonder how many regrettable and irreversible changes will be made.

Other body altering surgeries such as bariatric surgery are rarely offered to adolescents and usually only after prolonged counseling and non-surgical medical treatments. Even adults must go through rigorous counseling and non-surgical weight loss treatments before undergoing such surgery. Breast augmentation again is rarely offered to adolescents and we now know after 50 years of the risks of autoimmune disease, potential cancer risks, difficulty with cancer detection, infection and prosthetic rupture associated with various breast implants.

It is likely a universal human characteristic that at times we all imagine being somebody or somewhere different. A place where all our troubles in life vanish. This is likely a more common and more powerful feeling in adolescence as we try to determine who we are and where we fit in. However, because of the rapid developmental changes that adolescents are constantly experiencing, we should take a long pause before embarking on gender transition treatments. As with driving, smoking, alcohol consumption, leaving high school campus without authorization, and even adults having sex with a minor, there are some activities that we should strictly limit or proscribe until adolescents have successfully navigated through a good part of their development. This is the least we can do for our children before they permanently alter the rest of their long life.

Grateful for your public service,

Tim McNicoll M.D., M.S. Bioethics

Dear Dr. Paul Vazquez and the FL BOM,

I am a Psychiatric APRN here in FL.

Please protect the children and adolescents in FL from the irreversible effects of puberty blockers, cross sex hormones and surgery.

As a Psych NP, I have had several encounters with transgender individuals. One adult wanted me to sign off on a hysterectomy that an OB/GYN surgeon would not do without psychiatry approval. She told me initially that the surgeon needed to do the surgery because of polycystic ovarian syndrome. When I questioned surgery as a treatment for Polycystic Ovarian surgery she said that she is transgender. I then asked if she was planning to have mastectomies and she said she was. However, prior to asking for approval from me as a Psych NP for a hysterectomy, she had never mentioned any of this is the few times I had seen her. When I mentioned that it would be difficult for me to agree to this as it would be a liability if she changes her mind at some point in time, she got angry and hung up. She did not schedule another appointment. Unfortunately, her insurance had lapsed and I was never paid for that appointment. This is an adult who did not tell me the truth initially. She did not tell me she had changed insurance or that it had lapsed. She did not in any way present as male. She had been in the psych hospital many, many, many times and was extremely mentally ill.

It is well known that adolescents brains do not fully develop until age 25. They are not allowed to drink until 21 or buy a gun. Should they be allowed to make a decision about something that has not been clearly researched and studied and is a trend among the youth causing irreversible damage to their young bodies? I do not think so. Twenty-five should be the minimum age to give such a consent. Until then, psychological care and living several years as the opposite sex should be required first as it was in the past for trans surgeries.

I had another trans young man in his early 20s. "He" had had a complete hysterectomy and mastectomies and had been in the hospital due to suicidal ideation after the surgeries. In spite of this psych hospitalization, his parents took him back to Texas to have a phalloplasty. After returning, "his" girlfriend broke up with him and he ended up in the psych hospital again. Thankfully, he did not return to my office which was a relief to me as it was very traumatic to me to care for this young girl who had had such body altering surgery at such a young age and was clearly not mentally stable when they did the phalloplasty. "He" had just been in a psych hospital the month before the surgery.

What I see is that no one is assessing the psychological problems these young people have. I only see adults so I have not had anyone younger than 18 but a psychologist colleague of mine is seeing many, many young transgender clients in the hospital for suicide attempts, etc.

Fund a huge research study. You will have more than enough young people willing to sign up. I don't know what the State of FL or BOM liability would be if you would do such a study. Can it pass a Do No Harm, Informed Consent process to ethically do such a study? Puberty blockers were never studied long term in transgender individuals. It is being used totally off label along with the cross sex hormones in adolescent young people who will never recover.

I do not believe any insurance that I might be paying for, including Medicaid which is funded by my taxes should be paying for these damaging, experimental treatments. If someone wants to pay cash, as has always been the case in the past, and they are 25 years old, then it can be up to them.

Please protect the consciences of those like myself, who are not comfortable with this experimental treatment. I have been a member of the Christian Medical and Dental Association since 1989 before I graduated as an NP in 1990. They have an ethics statement on transgender issues. See items D&E below

for the negative effects of hormone blockers, cross-sex hormones and surgery. I apologize the references did not copy clearly. The original is attached.

Thank you for your time in reading this.

CMDA Ethics Statement Transgender Identification

Preamble

A novel way of thinking about one's body has entered into popular culture. "Transgender" individuals refer to their "gender" as a sexual identity that may be male or female, something in between, or neither. This self-identification differs from, and takes priority over, their biological sex as recognized in their chromosomal DNA and innate physical sexual characteristics. The naming of gender as a category set apart from sex is an idea foreign to the holistic view of the person as understood within Christianity. Christians affirm the biblical understanding of humankind as having been created male and female, with the two sexes having equal dignity and a complementary relationship to each other.

At the heart of disagreement over transgenderism is a difference in worldviews. If the human body is nothing more than the product of mindless, random, purposeless physical forces, then one may do with it what one wishes, even to demand medical and surgical cooperation in projects to alter, amputate, or reconstruct normal tissue to conform to the patient's revised psychological sense of identity. If, on the other hand, our bodies are an inseparable aspect of our true selves and are a good gift from God, who has designed the sexes to be wonderfully paired, and who has a purpose for humanity, then respecting the gift of given sexual identity and the ensuing moral obligations to our neighbors is the surest path to human flourishing. Both worldviews share the recognition that humanity is broken and in need of renewal, but they look to different answers for healing. Christians seek not a reconfiguring of the body, but a spiritual transformation of the mind to become more like Christ; not rejecting the gifts of God, but welcoming God's purposes and demonstrating God's love by loving our neighbors. This love of neighbors includes loving our transgender neighbors as persons who, like all people, are created in God's image. However, loving them and validating them as people does not mean agreeing with their ideologies or use of language.

The Christian Medical & Dental Associations (CMDA) believes that healthcare professionals should not be forced to violate their conscientious commitment to their patients' health and welfare by being required to accept and participate in harmful gender-transition interventions, especially on the young and vulnerable. CMDA affirms the obligation of Christian healthcare professionals caring for patients struggling with gender identity to do so with sensitivity and

compassion, consistent with the humility and love that Jesus modeled and commanded us to show all people.

Introduction

CMDA affirms that all human beings are created in the image of, and beloved by, God. All human beings are our “neighbors”, and are to be loved by us as we love ourselves. All human beings possess intrinsic dignity and are worthy of equal respect and concern from Health Care Professionals.

CMDA considers “sex” (i.e., male or female) to be an objective biological fact (see section B.1. below). CMDA affirms the historic understanding of gender as referring to biological sex and the enduring biblical understanding of humankind as having been created male and female and that this is good. CMDA acknowledges the current cultural use of the word “gender” to refer to one’s sense of identity as male or female. CMDA cannot support the recent usage of the term “gender” to emphasize an identity other than one’s biological sex, that is, a subjective sense of self based on feelings or desires leading to identifying somewhere on a fluid continuum of gender identity.^{1,2,3,4} (See Glossary at the end of this document)

CMDA cannot support the prevailing culture’s acceptance of an ideology of unrestrained sexual self-definition that, in celebrating gender fluidity and gender transition efforts, is indifferent to biological reality and opposed to the biblical understanding of human sexuality. Further, CMDA is alarmed that some proponents of transgender ideology, through activism and intimidation, are insisting that healthcare professionals cooperate with and affirm their beliefs in gender fluidity, even if the healthcare professionals believe that such cooperation and affirmation would be doing harm to their patients. This violates the most fundamental core value of medicine since Hippocrates, that of caring only for the good and benefit of the patient while abstaining from all unnecessary harm. The evolving scientific and medical facts demonstrate that the mutilation of normal tissue and profound disruption of normal physiology that occur during gender transition procedures are very difficult to justify, as this constitutes deliberate harm.

CMDA affirms the obligation of Christian healthcare professionals caring for patients struggling with gender identity to do so with sensitivity and compassion. CMDA holds that attempts to radically reconstruct one’s body surgically or hormonally for psychological indications, however, are medically, ethically, and psychologically inappropriate. These measures alter healthy tissue and increasingly are not supported by scientific research evaluating behavioral, medical, and surgical outcomes.^{5,6,7,8,9,10,11}

Accordingly, CMDA opposes medical assistance with gender transition on the following grounds:

A. Biblical

1. God created humanity as male and female (Gen 1:27, 5:2; Matt 19:4; Mark 10:6). God's directives – to have dominion over the earth and to fulfill his goals of procreation, union, fellowship, and worship – are given to men and women together (Gen 1:26-28, 2:18-24).
2. Men and women are morally and spiritually equal (Gal 3:28) and are created to have roles that are in some respects alike and in other respects wonderfully complementary (Eph 5).
3. All people are loved by God (John 3:16-17). All struggle with moral failure and fall short of God’s standards (Rom 3:10-12) and, therefore, need the forgiveness that God provides through Christ alone (John 3:36; Rom 3:22-24; Col 1:15-22; 1 Tim 2:5-6).
4. For the Christian, all of ethics, grounded in God’s moral law, is based upon the first and

second greatest commandments: to love God with all our heart, soul, and mind, and to love our neighbors as ourselves (Matt 22: 37-40). If we encourage others to sin sexually, just as if we sin sexually ourselves, we are violating these two commandments. We violate the first greatest commandment by failing to love God in his holiness, wisdom, and rightful place as our Creator, and we violate the second greatest commandment as we fail to respect ourselves and each other by abetting lives of disobedience, deception and unholiness (1 Cor 6: 13b-20). Love may include a corrective component that should be applied in an appropriate and timely manner; affirmation can be enablement.

5. We live in a fallen world (Gen 3), and we all come into this world as fallen creatures with a sinful nature. (Rom 3:9-12). The fall is expressed in nature and in humanity in many ways, including sexuality. Confusion of gender identity is but one example of the fall, as are also marital breakdown and sexual immorality (Rom 1:24-32; Eph 5:3).
6. A lifestyle that is directed by pursuing sexual desires, or driven by personal sexual fulfillment, misses the divinely ordained purpose of sex, which is for procreation, bond creation, and re-creation¹² and for facilitating unity in the lifelong commitment of marriage, which is defined as being between one man and one woman. Heterosexual marriage fosters a secure and nurturing environment for children and it reflects the unity of Christ and the Church (Exod 20:1-18; Lev 20:10-21; Rom 1; Eph 5:23-33) (see also CMDA Statement on Homosexuality).
7. Believers in Christ, though having inherited the sinful nature common to all humanity, also receive a new nature in Christ. As the old nature, being crucified with Christ, dies, our new redeemed nature, sealed by Christ's bodily resurrection, is actively transforming our minds and hearts to be more and more like Christ. This transformation is spiritual, not sexual, and is God's work, not something of our own design (Psalm 100:3; Rom 12:2; Col 1:27).

B. Biological

1. Sex is an objective biological fact that is determined genetically at conception by the allocation of X and Y chromosomes to one's genome, is observable at birth, is found in every nucleated cell, and is immutable throughout one's lifetime. Sex is not a social construct arbitrarily assigned at birth and cannot be changed at will.^{2,3,13}
2. Human beings are sexually dimorphic. Male and female phenotypes are the outworking of sex gene expression, which shapes sex anatomy, determines patterns of sex hormone secretion, and influences sex differences in the development of the central nervous system and other organs.^{2,3,14}
3. Procreation requires genetic contributions from both one man and one woman.^{15,16}
4. CMDA recognizes that exceedingly rare congenital abnormalities exist in which phenotypic sex characteristics are not what is expected from the genotype.^{1,2} These disorders of sex development are of a diverse nature, but usually impair fertility.³ Treatment (including non-intervention) of these disorders differs categorically from transgender interventions, which are performed on persons with no inherent defect in sex organ development, function, or fertility. Anomalies of human biological sex are conditions rather than identities, something one has rather than who

one is. Disorders of sex development are not the fault of the patient, do not invalidate God's design in creation, and do not constitute a third sex.^{17,18,19,20}

5. Gender dysphoria²¹, the condition of experiencing discomfort or distress at one's sex and preferring a different "gender" identity, has not to date been linked to a genetic cause and

is a psychological disorder of unclear and complex origin.^{22,23,24} Gender dysphoria may cause profound distress. It should not be confused with transient gender-questioning that can occur in early childhood.^{25,26,27,28,29,30}

C. Social

1. CMDA recognizes that gender identity issues are complex. The inclination to identify with the opposite sex or as some other gender identity along a spectrum may have non-genetic biological,³¹ familial,^{32,33} and social ^{27,28,34} causes that are not personally generated by particular individuals.²¹⁻³⁰
2. In our current social context, there is a prevailing view that removing traditional definitions and boundaries is a requirement for self-actualization. Thus, Christian healthcare professionals find themselves in the position of being at variance with evolving views of gender identity in which patients or their subcultures seek validation by medical professionals of their transgender desires and choices through medical or surgical solutions to gender dysphoria. Although such desires may be approved by society at large, they are contrary to a biblical worldview and to biological reality and thus are disordered.
3. In contrast to the current culture, CMDA believes that finding one's identity within God's design will result in genuine human flourishing. CMDA believes, moreover, that social movements which assert that gender is a choice are mistaken in defining gender as something independent of sex. Authentic personal identity consists in social gender expression that is congruent with one's natural biological sex but not limited to stereotypes. CMDA recognizes that this traditional view has become counter-cultural; however, CMDA affirms that God's design transcends culture.
4. CMDA opposes efforts to impose transgender ideology on all society by excluding, suppressing, marginalizing, intimidating, or portraying as hateful those individuals and organizations that disagree on scientific, medical, moral, or religious grounds. Such attacks are contrary to the freedoms of speech and religious liberty that lie at the very foundation of a just and democratic society.
5. There is a social contagion phenomenon luring young people into the transgender culture.^{32,33}
6. CMDA opposes efforts to compel healthcare professionals to grant medical legitimacy to transgender ideologies.^{35,36,37,38,39,40} Cooperation with requests for medical or surgical gender reassignment threatens professional integrity by undermining our respect for biological reality, evidence-based medical science, and our commitment to non-maleficence (see CMDA Statement on Healthcare Right of Conscience).
7. Promotion of transgender ideology by educational institutions and teachers to children

as young as 5 years of age is a danger to the health and safety of minor children (for medical reasons elaborated in the next section).^{41,42,43,44,45,46,47} Education should respect the value of every human being; in supporting and affirming the student, it need not affirm every desire.

8. No educational institution or teacher should ever block parents from supervising their child's education or withhold from them knowledge of the educational content.

D. Medical

1. Transient gender questioning can occur during childhood. Most children and adolescents who express transgender tendencies eventually come to identify with their biological sex during adolescence or early childhood.^{48,49,50,51,52,53} There is evidence that gender dysphoria is influenced by psychosocial experiences and can be exacerbated by promoters of transgender ideology.^{27,33} Early counseling for children expressing gender dysphoria is critical to treat any underlying psychological disorders, including depression, anxiety, or suicidal tendencies, and should be done without promoting attempts for gender transitioning.

2. Hormones prescribed to a previously biologically healthy child for the purpose of blocking puberty inhibit normal growth and fertility, cause sexual dysfunction, and may aggravate mental health issues. Continuation of cross-sex hormones, such as estrogen and testosterone, during adolescence and into adulthood, is associated with increased health risks including, but not limited to, high blood pressure, blood clots, stroke, heart attack, infertility, and some types of cancer.^{51,54,55,56,57,58,59,60}
3. Although some individuals report a sense of relief as they initiate the transitioning process, this is not always sustained or consistent over time. Some patients regret having undergone the transitioning attempt process and choose to detransition, which involves additional medical risk and cost.^{56,61,62,63,64}
4. Among individuals who identify as transgender, use cross-sex hormones, and undergo attempted gender reassignment surgery, there are well-documented increased incidences of depression, anxiety, suicidal ideation, substance abuse, and risky sexual behaviors in comparison to the general population.^{21,22,23,61,65,66,67} These health disparities are not prima facie evidence of healthcare system prejudice. These mental health co-morbidities have been shown to predate transgender identification.^{24,25,26,27,28,34,68} Patients' own gender- altering attempts and sexual encounter choices (or, in the case of children, their parents' choices on their behalf) are among the factors relevant to adverse outcomes in transgender-identified patients.
5. Although current medical evidence is incomplete and open to various interpretations, some studies suggest that surgical alteration of sex characteristics has uncertain and potentially harmful psychological effects and can mask or exacerbate deeper psychological problems.^{7,8,9,69} Evidence increasingly demonstrates that there is no reduction in depression, anxiety, suicidal ideation, or actual suicide attempts in patients who do undergo surgical transitioning compared to those who do not.^{7,70} The claim that sex-reassignment surgery leads to a reduction in suicide and severe psychological problems is not scientifically supported.^{64,71,72,73}
6. A patient has died because the medical records conveyed only the individual's gender

preference, and not their biological sex, leading to misdiagnosis and medical catastrophe.^{74,74}

E. Ethical

1. Restoring and preserving physical and mental health are goals of medicine, but assisting with or perpetuating psychosocial disorders are not. Accordingly, treatment of anomalous sexual anatomy is restorative.⁷⁵ Interventions to alter normal sexual anatomy and physiology to conform to identities arising from gender dysphoria are disruptive to health.^{9,76}
2. Medicine rests on science and should not be held captive to desires or demands that contradict biological reality. Sex reassignment operations are physically harmful because they disregard normal human anatomy and function. Normal anatomy is not a disease; dissatisfaction with natural anatomical and genetic sexual makeup is not a condition that
can be successfully remedied medically or surgically.
3. The medical status of gender identity disorder (currently termed gender dysphoria) as a mental or psychosocial disorder should not be discarded.
4. The inability of men, including men who identify as women, to bear children is not an illness to be remedied by medical or surgical means, such as uterine transplantation.⁷⁷ Uterine transplantation into biological men cannot be justified medically (See CMDA Statement on Enhancement and CMDA Statement on Transplantation).
5. Fundamentally, it is unrealistic to remove or mutilate normal organs and tissue and to disrupt normal physiology, and then to expect normal function. This illustrates the reality that complete gender transitioning is not medically possible.
6. Christian patients struggling with transgender inclinations face not only the psychological distress of a desire for a gender identity different from their biological sex, but may also face the spiritual distress that comes to anyone who follows a path in life that departs from God's design for humanity. Hormonal or surgical interventions cannot resolve spiritual distress but may lead to further spiritual turmoil. These, our neighbors, need and deserve the spiritual, psychological, and social support of the Christian community.
7. CMDA is especially concerned about the increasing phenomenon of parents enabling their gender-questioning children or adolescent minors to receive hormones to inhibit normal adolescent development. Children and adolescents lack the developmental cognitive capacity to assent or request such interventions, which have lifelong physical, psychological, and social consequences.⁵⁶ Facilitating hormonal or surgical transitioning interventions for those who have not reached the age of majority is a form of child endangerment and abuse.⁶⁴ Highly affirming parents have been shown to not improve the mental health statistics of transgender-identified children.⁷⁸
8. Many diseases affect men and women differently, according to biological sex

phenotype. Transgender designations may conceal biological sex differences relevant to medical risk factors, the recognition of which is important for effective healthcare and disease prevention. As accurate documentation is necessary for good patient care, healthcare professionals should document the patient's biological sex and any alterations of gender characteristics in the medical record.^{2,13,54,57,79,80,81} It is appropriate and should not be interpreted as disrespectful for healthcare professionals to discuss their patients' biological sex with them as part of their medical care.^{80,81}

9. For the overall health of the patient, the healthcare professional should be forthright with the patient that addressing the individual's sexual reality is necessary for appropriate medical care and should not be interpreted as disrespect.

CMDA Recommendations for the Christian Community

1. A person questioning or struggling with gender identity should evoke neither scorn nor enmity, but rather the Christian's concern, compassion, help, and understanding. Christians must respond to the complex issues surrounding gender identity with grace, civility, and love.
2. Christians should avail themselves of opportunities to help the larger society understand that male/female sexes are complementary and permanent. Both are good and part of the created order. For the reasons elaborated above, CMDA believes that attempting to define gender as fluid and changeable through technical means will have grave spiritual, emotional, cultural, and medical repercussions.
3. The Christian community, beginning with the Christian family, must resist stereotyping or rejecting individuals who do not fit the popular norms of masculinity and femininity. At the same time, parents should guide their children and adolescent minors in appropriate gender identity development. For children and adolescents experiencing gender dysphoria, the Christian community should provide appropriate role models and biblically informed guidance.
4. The Christian community must condemn hatred and violence directed against those struggling with questions of gender identity.
5. Since Christians are to love their neighbors as themselves, they are to love those struggling with gender dysphoria or incongruence of desired gender with biological sex. Love for the person does not condone or facilitate gender transitioning treatments.
6. In obedience to God who commands his followers to love one another, and for the sake of the common good, Christians should welcome inclusion of transgender-identified individuals into their communities, as we are all broken and sinners, not more or less valuable than each other. Transgender-identified individuals have the same rights shared by all other humans. We oppose granting special rights and privileges based on transgender identification. These special rights can negatively impact the rights of others (e.g., bathroom designations that allow biological males access to shared female restrooms or showers, female athletic competitions that give participating biological males an unfair physiologic advantage, affirmative actions, or claims for unnecessary

medical interventions).

7. The Christian community is to be a refuge of love for all who are broken – including the sexually broken – not to affirm their sin, nor to condemn, but to shepherd them to Jesus, who alone can forgive, heal, restore, and redirect to a godly, honorable, and virtuous way of life. God provides the remedy for all moral failure through repentance and faith in Jesus Christ and the life-changing power of the Holy Spirit. Though healing may be incomplete on earth, the promise of complete healing for those who are in Christ will ultimately be fulfilled in heaven.

CMDA Recommendations for Christian Healthcare Professionals

1. CMDA advocates that all Christian healthcare professionals provide ethically and medically competent care to all patients, including those who identify as transgender. Such care requires compassion, an open and trusting dialogue, a genuine effort to understand and respond to the patient's psychological distress when present, and acceptance of the person without agreeing with the person's ideology or providing a requested sex-altering intervention.
2. CMDA believes that the appropriate medical response to patients with gender dysphoria is to help them understand that they are people God loves and who are made in his image, even when their choices cannot be validated. Christian healthcare professionals should validate their right as individuals in a free society to make decisions for themselves. This right, however, does not extend to obligating Christian and other healthcare professionals to prescribe medication or perform surgical procedures that are harmful (see CMDA Statement on Healthcare Right of Conscience).
3. CMDA believes that Christian healthcare professionals should not initiate hormonal and surgical interventions that alter natural sex phenotypes. Such interventions contradict one of the basic principles of medical ethics, which is that medical treatment is intended to restore and preserve health, and not to harm.
4. CMDA believes that prescribing hormonal treatments to children or adolescents to disrupt normal sexual development for the purpose of attempting gender reassignment is ethically impermissible, whether requested by the child, the adolescent, or the parent (See CMDA Statement on Limits to Parental Authority in Medical Decision-Making, and CMDA Statement on Abuse of Human Life).
5. Supporting a patient's pursuit of gender transitioning procedures is neither loving nor the best means to help that individual who is experiencing gender dysphoria.

CMDA Recommendations Regarding Nondiscrimination

1. Mutual respect and civil discourse are cornerstones of a free society, and so is truthfulness. In the context of health care, identification of sex and gender has both interpersonal and medical implications. In regard to medical documentation, the medical record should document the sex observed at birth even when the patient expresses a different gender preference or has obtained a legal change in gender status.
2. Christian healthcare professionals, in particular, must care for their patients with gender identity disorders in a non-judgmental and compassionate manner, consistent with the

humility and love that Jesus modeled and commanded us to show all people. When questioning transgender ideology, Christian healthcare professionals should do so with an attitude of humility and love.

3. Those who hold to a biblical or traditional biological view of human sexuality, including CMDA members, should be permitted to question transgender ideology free from exclusion, oppression, or unjust discrimination. Healthcare professionals who hold the position that transgender identification is harmful and inconsistent with the will of God should not be stigmatized or accused of being bigoted, phobic, unprofessional, or discriminatory because of their desire to adhere to biological and medical reality as a sincerely held (and widely shared) belief.
4. To decline to provide a requested gender-altering treatment that is harmful, or is not medically indicated, does not constitute unjust discrimination against persons. CMDA affirms that Christian and other healthcare professionals should not be coerced or mandated to provide or refer for services they believe to be morally wrong or medically harmful to patients (See CMDA Statement on Healthcare Right of Conscience).
5. Healthcare professionals must not be prevented from providing counseling and support to patients with gender dysphoria and who request assistance with accepting and maintaining their biologic sex and gender identity.

GLOSSARY

Person and Image of God

According to the Bible, human persons (as opposed to divine and angelic persons) are embodied from conception onward. At conception, at least one genetically unique human person is formed (twinning may occur during the first two weeks of pregnancy). So the psalmist offers a hymn to God in Psalm 139, “you created my inmost being, you knit me together in my mother’s womb. I praise you because I am fearfully and wonderfully made; your works are wonderful, I know that full well. My frame was not hidden from you when I was made in the secret place, when I was woven together in the depth of the earth, Your eyes saw my unformed body; all the days ordained for me were written in your book before one of them came to be” (13-16 NIV). Human persons are, however, the only persons who are made in the *imago Dei* (image of God). Thus,

Jesus—fully God and fully human—is “image of the invisible God, the firstborn over all creation” (Colossians 1:15). Likewise, according to Genesis, “God created mankind in his own image, in the image of God he created them, male and female he created them” (Genesis 1:27).

Sex

Human sex and sexuality are aspects of God’s good, well-ordered creation. From the beginning he made humans sexual beings (Genesis 2:15-25). Humans are sexual beings who procreate through sexual reproduction. Sex is objective, identifiable, immutable, determined at conception, stamped on every nucleated cell, and highly consequential.^{82,83,84,85}

There are 2 sex cells or gametes, sperm and ova. There is no third. Human fallenness incurred pervasive distortions in humanity, including disorders of sexual biology, none of which limits either God’s love for each of us, or the inestimable value of creation in His image.

Sexuality

Human sexuality is a “very good” component of God’s well-ordered creation (Genesis 2:15-25). Sexuality is a broad and easily confusing term usually requiring contextualization for clear communication. As noted by McHugh and Mayer, sexuality incorporates desires,

attractions, behaviors, and/or identity.¹⁶ Furthermore, sexuality may vary regarding timing, intensity, consistency, and exclusivity. Its elements may be sporadic, temporary, pervasive, or long-term. Sexual expression may be healthful or unhealthful.

Because of human fallenness, sexuality has become disordered. The goods of sexuality are often distorted by pathologies in biology, psychology (e.g., sexual addiction or adultery), and society (e.g., sexual revolution and polyamory). Redeeming sex requires the reordering of human desires and practice. Celibacy outside of marriage, sexual fidelity within heterosexual marriage between one man and one woman, and the presumption in favor of procreation are ways human sex and sexuality may be redeemed.

Christian Worldview

A worldview is a way of seeing and understanding the phenomenon of the world around us. Like lenses of eyeglasses, one's worldview provides a set of interpretive assumptions that enable us to make sense of our experience. One's worldview is how one answers the big questions of life, such as: Is the world real? What is the nature of reality? Is there a God? What can we know about God? How do I know anything at all? Is matter all there is? Is there a supernatural? The orthodox Christian worldview is grounded on certain theological affirmations found in the Bible, which Christians believe to be the revealed word of God, and summarized in the great confessions in the history of Christianity, for instance, in the Nicene (325 AD) and Apostles (390 AD) Creeds.

The Fall and Human Fallenness

Rather than remaining faithful to God's will and purposes, Adam and Eve fell from their original righteous state through disobedience (i.e., sin). Their sin brought with it not only immediate deleterious consequences for them (Genesis 3), but for the entire created order thereafter. Those well-ordered desires to love God and love another have become disordered by human depravity. Love for God and others was replaced with hatred, envy, and murder (as in the case of Cain and Abel). The goods of honest labor were turned into toil and struggle in a creation that is now filled with corruption, death, disease, pain, and hardship. After the fall, human beings are born with a propensity to disobedience, selfishness, and sin.

Intrinsic Dignity

Because human beings are made in God's image, they possess an intrinsic dignity. They should never be used as a means to an end, but as ends in themselves. Their lives have sacred value and they should not be harmed without just cause. This dignity is intrinsic and equal for all human beings, not varied and dependent on level of function, cognitive or physical, presence or absence of injury or disability, age, or other traits or features for which human beings tend to impute upon others value or worth. Human dignity has been the foundation of Western ethics and jurisprudence and has been enshrined in secular language in the Nuremberg Code and global treaties in science, medicine, and public policy since that time.

Love

Christians are called to love God with all their hearts, souls, minds, and body and to love their neighbors as themselves (Deut 6:5; Lev 19:18; Mark 12:29-31). Love is a disposition of heart and life that impels one person to treat another person with respect and dignity quite apart from ethnicity, economic, social status, or what the individual can exploit or receive from the other. Furthermore, love seeks the best for another individual without the expectation any kind of recompense or remuneration.

Holiness

With respect to God, holiness is the supreme attribute of all of God's attributes, setting the God of the Bible apart from all other deities. The Triune God is holy in his love, righteousness, justice, wrath, and mercy (among other attributes). With respect to human beings and objects, holiness is being set apart for sacred use (as with the Old Testament

Temple). Christian holiness is the aspiration to live a life “set apart” from the corruptions of the world, and instead committed to fidelity, trust, and dependence on God, patterning ourselves after Jesus Christ.

Repentance

Repentance is a response to the recognition of harm done, either by commission or omission. The word used in the New Testament (metanoia) means to “turn and go in the other direction.” To repent, then, is to acknowledge one’s sin and turn back toward God. Turning back toward God may include ceasing to perform or pursue sinful acts, reconciling with those who have been harmed, or restoring items or relationships that have been damaged through one’s behavior. Repentance is not a one-time event, but a disposition of character.

Faith

Faith is the virtue of trust and dependence on God and his promises, believing and acting in ways consistent with that confidence (Hebrews 11).

Sexual Orientation

Orientation essentialism – the belief that a person has a given sexual orientation, be it innate or resulting from various combinations of biology and environment -- is an ideological position that has gained strong purchase in modern culture.

Per academics McHugh and Diamond, polar opposites in many ways:

Psychiatry professor Paul McHugh states, “Sexual orientation is a complex and amorphous phenomenon There is no scientific consensus on how to define sexual orientation, and the various definitions proposed by experts produce substantially different classes.”⁸³

Psychology professor Lisa Diamond, “There is currently no scientific or popular consensus . . . that definitively ‘qualify’ an individual as lesbian, gay, or bisexual.”⁸⁵

Genetic essentialism, like its orientation counterpart, is similarly ideological.

- • In a 2011 *Psychological Bulletin* Dar-Nimrod and Heine define genetic essentialism as,
“The tendency to infer a person's characteristics and behaviors from his or her perceived genetic makeup” (p. 801).⁸⁴ “Much of the ways that genes relate to human conditions can be described as weak genetic explanations” (p. 802).
- • Eric Turkheimer of UVA states, “...the amount of influence that genes have on behaviors is considerably smaller than one might think.”⁸⁴ And, “...genetic essentialists were wrong about gay genes and similar nonsense.”⁸³ Diamond and Rosky: “In essence, the current scientific revolution in our understanding of the human epigenome challenges the very notion of being “born gay,” along with the “born” with *any* complex trait. Rather, our genetic legacy is dynamic, developmental, and environmentally embedded.”⁸⁵

Same-sex attraction

Sexual attraction to members of the same sex. The propensity and degree may vary from near exclusive to occasional attraction, and is shown to potentially change over time. It does not preclude the same individual from experiencing varying degrees of attraction to members of the opposite sex.

Fornication

Per theologian Robert Gagnon “fornication,” likewise *porneia* in Greek, is frequently an overarching reference to sexual sin as defined in Torah. In more common usage, fornication is sexual intercourse between two people not married to each other. Sex between male and female is implied in the term’s reference to anatomy, fornix being

the curved vaginal recess created by the cervix and the term also being Latin for “arch.”

Fornication is separate from adultery or rape.

Temptation

A trial, being put to the test.

It is not yet sin, but an invitation to it.

Jesus “was in all *points* tempted as *we are*, yet without sin.” Hebrews 4:15. It is inherent to the fallen human condition.

“No temptation has overtaken you except such as is common to man; ...” I Corinthians 10:13.

God tests individuals.

Abraham (Genesis 22:1), Job (Job 23:10), I Corinthians 11:32, Hebrews 12:4-11, etc.

Satan tempts individual to sin.

Matthew 4:3, I Thessalonians 3:5. God provides means of rescue.

“*then* the Lord knows how to deliver the godly out of temptations...” 2 Peter 2:9. “...but God *is* faithful, who will not allow you to be tempted beyond what you are able, but with the temptation will also make the way of escape, that you may be able to bear *it*.” I Corinthians 10:13.

Scripture describes temptation as something to be avoided if possible: “And do not lead us into temptation...” Matthew 6:13.

“Watch and pray, lest you enter into temptation.” Mark 14:38.

Sexual Fantasy - when does it cross into sin?

Temptation is not yet sin. Everyone has a sex drive and the duty to manage it.

Experiencing sexual thoughts is not yet fantasy, or lust, unless willingly pursued. Some have compared the appearance of sexual thoughts to a bird flying over one’s head, thus out of our control; and fantasy or lust is compared to the equivalent of allowing that bird to build a nest on our head, something clearly in our power to resist.

Same-sex attraction chaste life - does it include avoidance of kissing? Is this equal to homosexual celibacy?

This is a multi-faceted question.

1. Scripture speaks of greeting each other with “a holy kiss” (Romans 16:16, I Corinthians 16:20), which is a salutation, something non-sexual.

Greeting with a kiss is a pervasive practice in the general cultures of several nations to this day. 2. The kissing implicit in the stated question is sexual, romantic.

There is no part of homosexual practice that is endorsed in scripture; it is condemned without exception.

3. Though we mean abstinence from homosexual practices when we say, “homosexual celibacy,” the application of the term “celibate” to same-sex sexual practice is Biblically problematic. Lifetime celibacy is referred to as a “gift” by the Apostle Paul in I Corinthians 7:7-9.

A Celibate person is giving up the God-ordained institution of marriage (exclusively between one man and one woman in scriptural standards) along with its God-ordained sexual practice. God gifts, or graces, that person with something else God-ordained in its place. But a person setting aside same-sex sexual practice is abstaining from or repenting of a sinful practice, which is both commanded and its own benefit. We wish to avoid canonizing homosexual temptation.

Same-sex lifestyle

The willing practice of same-sex sexuality.

Gay culture

Any assemblage of like-minded people creates a culture. Culture itself is a neutral term that gains a moral dimension in its practice. Gay culture endorses the ideological concept of gay identity along with its practices.

Scripturally and scientifically, we hold that sexuality is a verb and not just a noun. Gay and straight are category errors and false identities. Homosexuality by any name is a practice and not an identity, what one does and not who one is.

Likewise, “gay Christian” language canonizes temptation behind a false identity. Any name preceding “Christian” is an implicit priority, contravening Paul’s instruction to the Galatian church (Gal. 3:28).

Homophobia, -ic

Homophobia is an ideological and pejorative term that has gained common usage. It is often an accusation made against an individual failing to sufficiently celebrate same-sex sexuality, practices and politics.

But per MayoClinic.org: “A phobia is an overwhelming and unreasonable fear of an object or situation . . . a phobia is long lasting, causes intense physical and psychological reactions, and can affect your ability to function normally at work or in social settings.”

Disagreement is clearly not a phobia.

Linguistically, “homophobia” is somewhat nonsensical, meaning “fear of the same thing.”

Gender vs Sex

Sex is biological and stamped on every nucleated cell in a person’s body from conception onward. It is immutable down to the level of brain cells, so it is impossible to have “a man’s brain in a woman’s body,” for example.

Gender, in its common current usage, is an engineered term leveraging linguistics against biology; it is ideological and self-declared.

Historically, however, per theologian Christopher West:

“The root “gen”—from which we get words such as generous, generate, genesis, genetics, genealogy, progeny, gender, and genitals—means “to produce” or “give birth to.” A person’s gen-der, therefore, is based on the manner in which that person is designed to gen-erate new life. Contrary to widespread secular insistence, a person’s gender is not a malleable social construct. Rather, a person’s gender is determined by the kind of genitals he or she has.”⁸⁶

But ideology does not bow to history. Sex is biology, and gender is ideology.

Gender Identity

Gender identity is a feeling, a self-perception, of how one identifies with their biological sex or not, and it is often a sex stereotype. It is subjective, self-declared and fluid. Psychologist Dr. John Money of Johns Hopkins initiated its use in professional journals in 1955, referring to “the identity of the inner sexed self.”⁸⁷

Gender Confusion/Dysphoria

Gender identity confusion/dysphoria is a feeling/self-perception that one’s biology is not as one

wishes it to be or not as one identifies most comfortably as. Sechner notes, “A gender-dysphoric youth experiences a sense of incongruity between the gender expectations linked to her or his biological sex and her or his biological sex itself.”⁸⁸

The greater the discomfort/dissonance, the greater the dysphoria. Gender dysphoria is not synonymous with transgenderism, the latter being an umbrella term within which gender dysphoria fits, but to which transgenderism is not limited.

Gender - Should we be using that term or is there a better term? If so, how is it best defined?

The answer to that depends on the application and one must be careful.

Gender is an engineered term leveraging linguistics against biology; it is ideological and self-

declared. Sex is biological, right down to each human cell containing a nucleus. Though gender is sometimes used synonymously with sex (e.g., in forms asking if someone is male or female), ideologically it is considered separate and distinct from sex (e.g., “your sex is irrelevant to your gender identity”) in a manner that is quite Gnostic (i.e., the “higher knowledge” that transcends lowly biology).

Therefore, it is best to mean what you say and say what you mean in context. Using phrases like “identified gender,” “identifies as,” “gender incongruence,” “gender dysphoria,” “transgender identified,” etc. work well, don’t surrender reality to a claim, and do not imply agreement.

Best terminology for gender transition?

That depends on the intended usage.

“Transition efforts” or “transition-affirming treatments/procedures” are both quite clear and do not surrender to ideology as compared to terms like “gender-affirming” or “gender confirming” treatments and procedures.

Best terminology for transgender identity?

“Transgender-identified” or “transgender identification” are well understood and non-capitulating.

A final comment on language

Terms should be as descriptively accurate as possible while avoiding ideological programming. For instance, because an individual’s intrinsic sex cannot be changed, and gender is essentially a biologically meaningless term or concept aside from biological sex, terms such as “transgender identity,” as if it were an objective reality, should be replaced by “transgender-identified, - identifying, or -identification,” which are descriptively accurate. Similarly, because “gender transition” is not ontologically or biologically possible, more descriptively accurate terms, such as, “attempted transition efforts,” or “attempted transition-affirming treatments or procedures,” are more accurate and preferred.

CMDA Ethics Statement

Transgender Identification

Preamble

A novel way of thinking about one's body has entered into popular culture. "Transgender" individuals refer to their "gender" as a sexual identity that may be male or female, something in between, or neither. This self-identification differs from, and takes priority over, their biological sex as recognized in their chromosomal DNA and innate physical sexual characteristics. The naming of gender as a category set apart from sex is an idea foreign to the holistic view of the person as understood within Christianity. Christians affirm the biblical understanding of humankind as having been created male and female, with the two sexes having equal dignity and a complementary relationship to each other.

At the heart of disagreement over transgenderism is a difference in worldviews. If the human body is nothing more than the product of mindless, random, purposeless physical forces, then one may do with it what one wishes, even to demand medical and surgical cooperation in projects to alter, amputate, or reconstruct normal tissue to conform to the patient's revised psychological sense of identity. If, on the other hand, our bodies are an inseparable aspect of our true selves and are a good gift from God, who has designed the sexes to be wonderfully paired, and who has a purpose for humanity, then respecting the gift of given sexual identity and the ensuing moral obligations to our neighbors is the surest path to human flourishing.

Both worldviews share the recognition that humanity is broken and in need of renewal, but they look to different answers for healing. Christians seek not a reconfiguring of the body, but a spiritual transformation of the mind to become more like Christ; not rejecting the gifts of God, but welcoming God's purposes and demonstrating God's love by loving our neighbors. This love of neighbors includes loving our transgender neighbors as persons who, like all people, are created in God's image. However, loving them and validating them as people does not mean agreeing with their ideologies or use of language.

The Christian Medical & Dental Associations (CMDA) believes that healthcare professionals should not be forced to violate their conscientious commitment to their patients' health and welfare by being required to accept and participate in harmful gender-transition interventions, especially on the young and vulnerable. CMDA affirms the obligation of Christian healthcare professionals caring for patients struggling with gender identity to do so with sensitivity and compassion, consistent with the humility and love that Jesus modeled and commanded us to show all people.

Introduction

CMDA affirms that all human beings are created in the image of, and beloved by, God. All human beings are our “neighbors”, and are to be loved by us as we love ourselves. All human beings possess intrinsic dignity and are worthy of equal respect and concern from Health Care Professionals.

CMDA considers “sex” (i.e., male or female) to be an objective biological fact (see section B.1. below). CMDA affirms the historic understanding of gender as referring to biological sex and the enduring biblical understanding of humankind as having been created male and female and that this is good. CMDA acknowledges the current cultural use of the word “gender” to refer to one’s sense of identity as male or female. CMDA cannot support the recent usage of the term “gender” to emphasize an identity other than one’s biological sex, that is, a subjective sense of self based on feelings or desires leading to identifying somewhere on a fluid continuum of gender identity.^{1,2,3,4} (See Glossary at the end of this document)

CMDA cannot support the prevailing culture’s acceptance of an ideology of unrestrained sexual self-definition that, in celebrating gender fluidity and gender transition efforts, is indifferent to biological reality and opposed to the biblical understanding of human sexuality. Further, CMDA is alarmed that some proponents of transgender ideology, through activism and intimidation, are insisting that healthcare professionals cooperate with and affirm their beliefs in gender fluidity, even if the healthcare professionals believe that such cooperation and affirmation would be doing harm to their patients. This violates the most fundamental core value of medicine since Hippocrates, that of caring only for the good and benefit of the patient while abstaining from all unnecessary harm. The evolving scientific and medical facts demonstrate that the mutilation of normal tissue and profound disruption of normal physiology that occur during gender transition procedures are very difficult to justify, as this constitutes deliberate harm.

CMDA affirms the obligation of Christian healthcare professionals caring for patients struggling with gender identity to do so with sensitivity and compassion. CMDA holds that attempts to radically reconstruct one’s body surgically or hormonally for psychological indications, however, are medically, ethically, and psychologically inappropriate. These measures alter healthy tissue and increasingly are not supported by scientific research evaluating behavioral, medical, and surgical outcomes.^{5,6,7,8,9,10,11}

Accordingly, CMDA opposes medical assistance with gender transition on the following grounds:

A. Biblical

1. God created humanity as male and female (Gen 1:27, 5:2; Matt 19:4; Mark 10:6). God’s directives – to have dominion over the earth and to fulfill his goals of procreation, union, fellowship, and worship – are given to men and women together (Gen 1:26-28, 2:18-24).
2. Men and women are morally and spiritually equal (Gal 3:28) and are created to have roles that are in some respects alike and in other respects wonderfully complementary (Eph 5).
3. All people are loved by God (John 3:16-17). All struggle with moral failure and fall short of God’s standards (Rom 3:10-12) and, therefore, need the forgiveness that God provides through Christ alone (John 3:36; Rom 3:22-24; Col 1:15-22; 1 Tim 2:5-6).
4. For the Christian, all of ethics, grounded in God’s moral law, is based upon the first and

second greatest commandments: to love God with all our heart, soul, and mind, and to love our neighbors as ourselves (Matt 22: 37-40). If we encourage others to sin sexually, just as if we sin sexually ourselves, we are violating these two commandments. We violate the first greatest commandment by failing to love God in his holiness, wisdom, and rightful place as our Creator, and we violate the second greatest commandment as we fail to respect ourselves and each other by abetting lives of disobedience, deception and unholiness (1 Cor 6: 13b-20). Love may include a corrective component that should be applied in an appropriate and timely manner; affirmation can be enablement.

5. We live in a fallen world (Gen 3), and we all come into this world as fallen creatures with a sinful nature. (Rom 3:9-12). The fall is expressed in nature and in humanity in many ways, including sexuality. Confusion of gender identity is but one example of the fall, as are also marital breakdown and sexual immorality (Rom 1:24-32; Eph 5:3).
6. A lifestyle that is directed by pursuing sexual desires, or driven by personal sexual fulfillment, misses the divinely ordained purpose of sex, which is for procreation, bond creation, and re-creation¹² and for facilitating unity in the lifelong commitment of marriage, which is defined as being between one man and one woman. Heterosexual marriage fosters a secure and nurturing environment for children and it reflects the unity of Christ and the Church (Exod 20:1-18; Lev 20:10-21; Rom 1; Eph 5:23-33) (see also CMDA Statement on Homosexuality).
7. Believers in Christ, though having inherited the sinful nature common to all humanity, also receive a new nature in Christ. As the old nature, being crucified with Christ, dies, our new redeemed nature, sealed by Christ's bodily resurrection, is actively transforming our minds and hearts to be more and more like Christ. This transformation is spiritual, not sexual, and is God's work, not something of our own design (Psalm 100:3; Rom 12:2; Col 1:27).

B. Biological

1. Sex is an objective biological fact that is determined genetically at conception by the allocation of X and Y chromosomes to one's genome, is observable at birth, is found in every nucleated cell, and is immutable throughout one's lifetime. Sex is not a social construct arbitrarily assigned at birth and cannot be changed at will.^{2,3,13}
2. Human beings are sexually dimorphic. Male and female phenotypes are the outworking of sex gene expression, which shapes sex anatomy, determines patterns of sex hormone secretion, and influences sex differences in the development of the central nervous system and other organs.^{2,3,14}
3. Procreation requires genetic contributions from both one man and one woman.^{15,16}
4. CMDA recognizes that exceedingly rare congenital abnormalities exist in which phenotypic sex characteristics are not what is expected from the genotype.^{1,2} These disorders of sex development are of a diverse nature, but usually impair fertility.³ Treatment (including non-intervention) of these disorders differs categorically from transgender interventions, which are performed on persons with no inherent defect in sex organ development, function, or fertility. Anomalies of human biological sex are conditions rather than identities, something one has rather than who one is.⁴ Disorders of sex development are not the fault of the patient, do not invalidate God's design in creation, and do not constitute a third sex.^{17,18,19,20}
5. Gender dysphoria²¹, the condition of experiencing discomfort or distress at one's sex and preferring a different "gender" identity, has not to date been linked to a genetic cause and

is a psychological disorder of unclear and complex origin.^{22,23,24} Gender dysphoria may cause profound distress. It should not be confused with transient gender-questioning that can occur in early childhood.^{25,26,27,28,29,30}

C. Social

1. CMDA recognizes that gender identity issues are complex. The inclination to identify with the opposite sex or as some other gender identity along a spectrum may have non-genetic biological,³¹ familial,^{32,33} and social ^{27,28,34} causes that are not personally generated by particular individuals.²¹⁻³⁰
2. In our current social context, there is a prevailing view that removing traditional definitions and boundaries is a requirement for self-actualization. Thus, Christian healthcare professionals find themselves in the position of being at variance with evolving views of gender identity in which patients or their subcultures seek validation by medical professionals of their transgender desires and choices through medical or surgical solutions to gender dysphoria. Although such desires may be approved by society at large, they are contrary to a biblical worldview and to biological reality and thus are disordered.
3. In contrast to the current culture, CMDA believes that finding one's identity within God's design will result in genuine human flourishing. CMDA believes, moreover, that social movements which assert that gender is a choice are mistaken in defining gender as something independent of sex. Authentic personal identity consists in social gender expression that is congruent with one's natural biological sex but not limited to stereotypes. CMDA recognizes that this traditional view has become counter-cultural; however, CMDA affirms that God's design transcends culture.
4. CMDA opposes efforts to impose transgender ideology on all society by excluding, suppressing, marginalizing, intimidating, or portraying as hateful those individuals and organizations that disagree on scientific, medical, moral, or religious grounds. Such attacks are contrary to the freedoms of speech and religious liberty that lie at the very foundation of a just and democratic society.
5. There is a social contagion phenomenon luring young people into the transgender culture.^{32,33}
6. CMDA opposes efforts to compel healthcare professionals to grant medical legitimacy to transgender ideologies.^{35,36,37,38,39,40} Cooperation with requests for medical or surgical gender reassignment threatens professional integrity by undermining our respect for biological reality, evidence-based medical science, and our commitment to non-maleficence (see CMDA Statement on Healthcare Right of Conscience).
7. Promotion of transgender ideology by educational institutions and teachers to children as young as 5 years of age is a danger to the health and safety of minor children (for medical reasons elaborated in the next section).^{41,42,43,44,45,46,47} Education should respect the value of every human being; in supporting and affirming the student, it need not affirm every desire.
8. No educational institution or teacher should ever block parents from supervising their child's education or withhold from them knowledge of the educational content.

D. Medical

1. Transient gender questioning can occur during childhood. Most children and adolescents who express transgender tendencies eventually come to identify with their biological sex

during adolescence or early childhood.^{48,49,50,51,52,53} There is evidence that gender dysphoria is influenced by psychosocial experiences and can be exacerbated by promoters of transgender ideology.^{27,33} Early counseling for children expressing gender dysphoria is critical to treat any underlying psychological disorders, including depression, anxiety, or suicidal tendencies, and should be done without promoting attempts for gender transitioning.

2. Hormones prescribed to a previously biologically healthy child for the purpose of blocking puberty inhibit normal growth and fertility, cause sexual dysfunction, and may aggravate mental health issues. Continuation of cross-sex hormones, such as estrogen and testosterone, during adolescence and into adulthood, is associated with increased health risks including, but not limited to, high blood pressure, blood clots, stroke, heart attack, infertility, and some types of cancer.^{51,54,55,56,57,58,59,60}
3. Although some individuals report a sense of relief as they initiate the transitioning process, this is not always sustained or consistent over time. Some patients regret having undergone the transitioning attempt process and choose to detransition, which involves additional medical risk and cost.^{56,61,62,63,64}
4. Among individuals who identify as transgender, use cross-sex hormones, and undergo attempted gender reassignment surgery, there are well-documented increased incidences of depression, anxiety, suicidal ideation, substance abuse, and risky sexual behaviors in comparison to the general population.^{21,22,23,61,65,66,67} These health disparities are not *prima facie* evidence of healthcare system prejudice. These mental health co-morbidities have been shown to predate transgender identification.^{24,25,26,27,28,34,68} Patients' own gender-altering attempts and sexual encounter choices (or, in the case of children, their parents' choices on their behalf) are among the factors relevant to adverse outcomes in transgender-identified patients.
5. Although current medical evidence is incomplete and open to various interpretations, some studies suggest that surgical alteration of sex characteristics has uncertain and potentially harmful psychological effects and can mask or exacerbate deeper psychological problems.^{7,8,9,69} Evidence increasingly demonstrates that there is no reduction in depression, anxiety, suicidal ideation, or actual suicide attempts in patients who do undergo surgical transitioning compared to those who do not.^{7,70} The claim that sex-reassignment surgery leads to a reduction in suicide and severe psychological problems is not scientifically supported.^{64,71,72,73}
6. A patient has died because the medical records conveyed only the individual's gender preference, and not their biological sex, leading to misdiagnosis and medical catastrophe.^{74,74}

E. Ethical

1. Restoring and preserving physical and mental health are goals of medicine, but assisting with or perpetuating psychosocial disorders are not. Accordingly, treatment of anomalous sexual anatomy is restorative.⁷⁵ Interventions to alter normal sexual anatomy and physiology to conform to identities arising from gender dysphoria are disruptive to health.^{9,76}
2. Medicine rests on science and should not be held captive to desires or demands that contradict biological reality. Sex reassignment operations are physically harmful because they disregard normal human anatomy and function. Normal anatomy is not a disease; dissatisfaction with natural anatomical and genetic sexual makeup is not a condition that

- can be successfully remedied medically or surgically.
3. The medical status of gender identity disorder (currently termed gender dysphoria) as a mental or psychosocial disorder should not be discarded.
 4. The inability of men, including men who identify as women, to bear children is not an illness to be remedied by medical or surgical means, such as uterine transplantation.⁷⁷ Uterine transplantation into biological men cannot be justified medically (See CMDA Statement on Enhancement and CMDA Statement on Transplantation).
 5. Fundamentally, it is unrealistic to remove or mutilate normal organs and tissue and to disrupt normal physiology, and then to expect normal function. This illustrates the reality that complete gender transitioning is not medically possible.
 6. Christian patients struggling with transgender inclinations face not only the psychological distress of a desire for a gender identity different from their biological sex, but may also face the spiritual distress that comes to anyone who follows a path in life that departs from God's design for humanity. Hormonal or surgical interventions cannot resolve spiritual distress but may lead to further spiritual turmoil. These, our neighbors, need and deserve the spiritual, psychological, and social support of the Christian community.
 7. CMDA is especially concerned about the increasing phenomenon of parents enabling their gender-questioning children or adolescent minors to receive hormones to inhibit normal adolescent development. Children and adolescents lack the developmental cognitive capacity to assent or request such interventions, which have lifelong physical, psychological, and social consequences.⁵⁶ Facilitating hormonal or surgical transitioning interventions for those who have not reached the age of majority is a form of child endangerment and abuse.⁶⁴ Highly affirming parents have been shown to not improve the mental health statistics of transgender-identified children.⁷⁸
 8. Many diseases affect men and women differently, according to biological sex phenotype. Transgender designations may conceal biological sex differences relevant to medical risk factors, the recognition of which is important for effective healthcare and disease prevention. As accurate documentation is necessary for good patient care, healthcare professionals should document the patient's biological sex and any alterations of gender characteristics in the medical record.^{2,13,54,57,79,80,81} It is appropriate and should not be interpreted as disrespectful for healthcare professionals to discuss their patients' biological sex with them as part of their medical care.^{80,81}
 9. For the overall health of the patient, the healthcare professional should be forthright with the patient that addressing the individual's sexual reality is necessary for appropriate medical care and should not be interpreted as disrespect.

CMDA Recommendations for the Christian Community

1. A person questioning or struggling with gender identity should evoke neither scorn nor enmity, but rather the Christian's concern, compassion, help, and understanding. Christians must respond to the complex issues surrounding gender identity with grace, civility, and love.
2. Christians should avail themselves of opportunities to help the larger society understand that male/female sexes are complementary and permanent. Both are good and part of the created order. For the reasons elaborated above, CMDA believes that attempting to define gender as fluid and changeable through technical means will have grave spiritual, emotional, cultural, and medical repercussions.
3. The Christian community, beginning with the Christian family, must resist stereotyping or

rejecting individuals who do not fit the popular norms of masculinity and femininity. At the same time, parents should guide their children and adolescent minors in appropriate gender identity development. For children and adolescents experiencing gender dysphoria, the Christian community should provide appropriate role models and biblically informed guidance.

4. The Christian community must condemn hatred and violence directed against those struggling with questions of gender identity.
5. Since Christians are to love their neighbors as themselves, they are to love those struggling with gender dysphoria or incongruence of desired gender with biological sex. Love for the person does not condone or facilitate gender transitioning treatments.
6. In obedience to God who commands his followers to love one another, and for the sake of the common good, Christians should welcome inclusion of transgender-identified individuals into their communities, as we are all broken and sinners, not more or less valuable than each other. Transgender-identified individuals have the same rights shared by all other humans. We oppose granting special rights and privileges based on transgender identification. These special rights can negatively impact the rights of others (e.g., bathroom designations that allow biological males access to shared female restrooms or showers, female athletic competitions that give participating biological males an unfair physiologic advantage, affirmative actions, or claims for unnecessary medical interventions).
7. The Christian community is to be a refuge of love for all who are broken – including the sexually broken – not to affirm their sin, nor to condemn, but to shepherd them to Jesus, who alone can forgive, heal, restore, and redirect to a godly, honorable, and virtuous way of life. God provides the remedy for all moral failure through repentance and faith in Jesus Christ and the life-changing power of the Holy Spirit. Though healing may be incomplete on earth, the promise of complete healing for those who are in Christ will ultimately be fulfilled in heaven.

CMDA Recommendations for Christian Healthcare Professionals

1. CMDA advocates that all Christian healthcare professionals provide ethically and medically competent care to all patients, including those who identify as transgender. Such care requires compassion, an open and trusting dialogue, a genuine effort to understand and respond to the patient's psychological distress when present, and acceptance of the person without agreeing with the person's ideology or providing a requested sex-altering intervention.
2. CMDA believes that the appropriate medical response to patients with gender dysphoria is to help them understand that they are people God loves and who are made in his image, even when their choices cannot be validated. Christian healthcare professionals should validate their right as individuals in a free society to make decisions for themselves. This right, however, does not extend to obligating Christian and other healthcare professionals to prescribe medication or perform surgical procedures that are harmful (see CMDA Statement on Healthcare Right of Conscience).
3. CMDA believes that Christian healthcare professionals should not initiate hormonal and surgical interventions that alter natural sex phenotypes. Such interventions contradict one of the basic principles of medical ethics, which is that medical treatment is intended to restore and preserve health, and not to harm.
4. CMDA believes that prescribing hormonal treatments to children or adolescents to

disrupt normal sexual development for the purpose of attempting gender reassignment is ethically impermissible, whether requested by the child, the adolescent, or the parent (See CMDA Statement on Limits to Parental Authority in Medical Decision-Making, and CMDA Statement on Abuse of Human Life).

5. Supporting a patient's pursuit of gender transitioning procedures is neither loving nor the best means to help that individual who is experiencing gender dysphoria.

CMDA Recommendations Regarding Nondiscrimination

1. Mutual respect and civil discourse are cornerstones of a free society, and so is truthfulness. In the context of health care, identification of sex and gender has both interpersonal and medical implications. In regard to medical documentation, the medical record should document the sex observed at birth even when the patient expresses a different gender preference or has obtained a legal change in gender status.
2. Christian healthcare professionals, in particular, must care for their patients with gender identity disorders in a non-judgmental and compassionate manner, consistent with the humility and love that Jesus modeled and commanded us to show all people. When questioning transgender ideology, Christian healthcare professionals should do so with an attitude of humility and love.
3. Those who hold to a biblical or traditional biological view of human sexuality, including CMDA members, should be permitted to question transgender ideology free from exclusion, oppression, or unjust discrimination. Healthcare professionals who hold the position that transgender identification is harmful and inconsistent with the will of God should not be stigmatized or accused of being bigoted, phobic, unprofessional, or discriminatory because of their desire to adhere to biological and medical reality as a sincerely held (and widely shared) belief.
4. To decline to provide a requested gender-altering treatment that is harmful, or is not medically indicated, does not constitute unjust discrimination against persons. CMDA affirms that Christian and other healthcare professionals should not be coerced or mandated to provide or refer for services they believe to be morally wrong or medically harmful to patients (See CMDA Statement on Healthcare Right of Conscience).
5. Healthcare professionals must not be prevented from providing counseling and support to patients with gender dysphoria and who request assistance with accepting and maintaining their biologic sex and gender identity.

GLOSSARY

Person and Image of God

According to the Bible, human persons (as opposed to divine and angelic persons) are embodied from conception onward. At conception, at least one genetically unique human person is formed (twinning may occur during the first two weeks of pregnancy). So the psalmist offers a hymn to God in Psalm 139, "you created my inmost being, you knit me together in my mother's womb. I praise you because I am fearfully and wonderfully made; your works are wonderful, I know that full well. My frame was not hidden from you when I was made in the secret place, when I was woven together in the depth of the earth, Your eyes saw my unformed body; all the days ordained for me were written in your book before one of them came to be" (13-16 NIV). Human persons are, however, the only persons who are made in the *imago Dei* (image of God). Thus,

Jesus—fully God and fully human—is “image of the invisible God, the firstborn over all creation” (Colossians 1:15). Likewise, according to Genesis, “God created mankind in his own image, in the image of God he created them, male and female he created them” (Genesis 1:27).

Sex

Human sex and sexuality are aspects of God’s good, well-ordered creation. From the beginning he made humans sexual beings (Genesis 2:15-25). Humans are sexual beings who procreate through sexual reproduction. Sex is objective, identifiable, immutable, determined at conception, stamped on every nucleated cell, and highly consequential.^{82,83,84,85}

There are 2 sex cells or gametes, sperm and ova. There is no third. Human fallenness incurred pervasive distortions in humanity, including disorders of sexual biology, none of which limits either God’s love for each of us, or the inestimable value of creation in His image.

Sexuality

Human sexuality is a “very good” component of God’s well-ordered creation (Genesis 2:15-25). Sexuality is a broad and easily confusing term usually requiring contextualization for clear communication. As noted by McHugh and Mayer, sexuality incorporates desires, attractions, behaviors, and/or identity.¹⁶ Furthermore, sexuality may vary regarding timing, intensity, consistency, and exclusivity. Its elements may be sporadic, temporary, pervasive, or long-term. Sexual expression may be healthful or unhealthful.

Because of human fallenness, sexuality has become disordered. The goods of sexuality are often distorted by pathologies in biology, psychology (e.g., sexual addiction or adultery), and society (e.g., sexual revolution and polyamory). Redeeming sex requires the reordering of human desires and practice. Celibacy outside of marriage, sexual fidelity within heterosexual marriage between one man and one woman, and the presumption in favor of procreation are ways human sex and sexuality may be redeemed.

Christian Worldview

A worldview is a way of seeing and understanding the phenomenon of the world around us. Like lenses of eyeglasses, one’s worldview provides a set of interpretive assumptions that enable us to make sense of our experience. One’s worldview is how one answers the big questions of life, such as: Is the world real? What is the nature of reality? Is there a God? What can we know about God? How do I know anything at all? Is matter all there is? Is there a supernatural? The orthodox Christian worldview is grounded on certain theological affirmations found in the Bible, which Christians believe to be the revealed word of God, and summarized in the great confessions in the history of Christianity, for instance, in the Nicene (325 AD) and Apostles (390 AD) Creeds.

The Fall and Human Fallenness

Rather than remaining faithful to God’s will and purposes, Adam and Eve fell from their original righteous state through disobedience (i.e., sin). Their sin brought with it not only immediate deleterious consequences for them (Genesis 3), but for the entire created order thereafter. Those well-ordered desires to love God and love another have become disordered by human depravity. Love for God and others was replaced with hatred, envy, and murder (as in the case of Cain and Abel). The goods of honest labor were turned into toil and struggle in a creation that is now filled with corruption, death, disease, pain, and hardship. After the fall, human beings are born with a propensity to disobedience, selfishness, and sin.

Intrinsic Dignity

Because human beings are made in God's image, they possess an intrinsic dignity. They should never be used as a means to an end, but as ends in themselves. Their lives have sacred value and they should not be harmed without just cause. This dignity is intrinsic and equal for all human beings, not varied and dependent on level of function, cognitive or physical, presence of absence of injury or disability, age, or other traits or features for which human beings tend to impute upon others value or worth. Human dignity has been the foundation of Western ethics and jurisprudence and has been enshrined in secular language in the Nuremberg Code and global treaties in science, medicine, and public policy since that time.

Love

Christians are called to love God with all their hearts, souls, minds, and body and to love their neighbors as themselves (Deut 6:5; Lev 19:18; Mark 12:29-31). Love is a disposition of heart and life that impels one person to treat another person with respect and dignity quite apart from ethnicity, economic, social status, or what the individual can exploit or receive from the other. Furthermore, love seeks the best for another individual without the expectation any kind of recompense or remuneration.

Holiness

With respect to God, holiness is the supreme attribute of all of God's attributes, setting the God of the Bible apart from all other deities. The Triune God is holy in his love, righteousness, justice, wrath, and mercy (among other attributes). With respect to human beings and objects, holiness is being set apart for sacred use (as with the Old Testament Temple). Christian holiness is the aspiration to live a life "set apart" from the corruptions of the world, and instead committed to fidelity, trust, and dependence on God, patterning ourselves after Jesus Christ.

Repentance

Repentance is a response to the recognition of harm done, either by commission or omission. The word used in the New Testament (metanoia) means to "turn and go in the other direction." To repent, then, is to acknowledge one's sin and turn back toward God. Turning back toward God may include ceasing to perform or pursue sinful acts, reconciling with those who have been harmed, or restoring items or relationships that have been damaged through one's behavior. Repentance is not a one-time event, but a disposition of character.

Faith

Faith is the virtue of trust and dependence on God and his promises, believing and acting in ways consistent with that confidence (Hebrews 11).

Sexual Orientation

Orientation essentialism – the belief that a person has a given sexual orientation, be it innate or resulting from various combinations of biology and environment -- is an ideological position that has gained strong purchase in modern culture.

Per academics McHugh and Diamond, polar opposites in many ways:

Psychiatry professor Paul McHugh states, "Sexual orientation is a complex and amorphous phenomenon There is no scientific consensus on how to define sexual orientation, and the various definitions proposed by experts produce substantially different classes."⁸³

Psychology professor Lisa Diamond, “There is currently no scientific or popular consensus . . . that definitively ‘qualify’ an individual as lesbian, gay, or bisexual.”⁸⁵

Genetic essentialism, like its orientation counterpart, is similarly ideological.

- In a 2011 *Psychological Bulletin* Dar-Nimrod and Heine define genetic essentialism as, “The tendency to infer a person's characteristics and behaviors from his or her perceived genetic makeup” (p. 801).⁸⁴ “Much of the ways that genes relate to human conditions can be described as weak genetic explanations” (p. 802).
- Eric Turkheimer of UVA states, “...the amount of influence that genes have on behaviors is considerably smaller than one might think.”⁸⁴ And, “...genetic essentialists were wrong about gay genes and similar nonsense.”⁸³ Diamond and Rosky: “In essence, the current scientific revolution in our understanding of the human epigenome challenges the very notion of being “born gay,” along with the “born” with *any* complex trait. Rather, our genetic legacy is dynamic, developmental, and environmentally embedded.”⁸⁵

Same-sex attraction

Sexual attraction to members of the same sex. The propensity and degree may vary from near exclusive to occasional attraction, and is shown to potentially change over time. It does not preclude the same individual from experiencing varying degrees of attraction to members of the opposite sex.

Fornication

Per theologian Robert Gagnon “fornication,” likewise *porneia* in Greek, is frequently an overarching reference to sexual sin as defined in Torah. In more common usage, fornication is sexual intercourse between two people not married to each other. Sex between male and female is implied in the term’s reference to anatomy, fornix being the curved vaginal recess created by the cervix and the term also being Latin for “arch.”

Fornication is separate from adultery or rape.

Temptation

A trial, being put to the test.

It is not yet sin, but an invitation to it.

Jesus “was in all *points* tempted as *we are*, yet without sin.” Hebrews 4:15.

It is inherent to the fallen human condition.

“No temptation has overtaken you except such as is common to man; ...” I Corinthians 10:13.

God tests individuals.

Abraham (Genesis 22:1), Job (Job 23:10), I Corinthians 11:32, Hebrews 12:4-11, etc.

Satan tempts individual to sin.

Matthew 4:3, I Thessalonians 3:5.

God provides means of rescue.

“*then* the Lord knows how to deliver the godly out of temptations...” 2 Peter 2:9.

“...but God *is* faithful, who will not allow you to be tempted beyond what you are able, but with the temptation will also make the way of escape, that you may be able to bear *it*.” I Corinthians 10:13.

Scripture describes temptation as something to be avoided if possible:

“And do not lead us into temptation...” Matthew 6:13.

“Watch and pray, lest you enter into temptation.” Mark 14:38.

Sexual Fantasy - when does it cross into sin?

Temptation is not yet sin. Everyone has a sex drive and the duty to manage it.

Experiencing sexual thoughts is not yet fantasy, or lust, unless willingly pursued. Some have compared the appearance of sexual thoughts to a bird flying over one's head, thus out of our control; and fantasy or lust is compared to the equivalent of allowing that bird to build a nest on our head, something clearly in our power to resist.

Same-sex attraction chaste life - does it include avoidance of kissing? Is this equal to homosexual celibacy?

This is a multi-faceted question.

1. Scripture speaks of greeting each other with “a holy kiss” (Romans 16:16, I Corinthians 16:20), which is a salutation, something non-sexual.

Greeting with a kiss is a pervasive practice in the general cultures of several nations to this day.

2. The kissing implicit in the stated question is sexual, romantic.

There is no part of homosexual practice that is endorsed in scripture; it is condemned without exception.

3. Though we mean abstinence from homosexual practices when we say, “homosexual celibacy,” the application of the term “celibate” to same-sex sexual practice is Biblically problematic.

Lifetime celibacy is referred to as a “gift” by the Apostle Paul in I Corinthians 7:7-9.

A Celibate person is giving up the God-ordained institution of marriage (exclusively between one man and one woman in scriptural standards) along with its God-ordained sexual practice.

God gifts, or graces, that person with something else God-ordained in its place. But a person setting aside same-sex sexual practice is abstaining from or repenting of a sinful practice, which is both commanded and its own benefit. We wish to avoid canonizing homosexual temptation.

Same-sex lifestyle

The willing practice of same-sex sexuality.

Gay culture

Any assemblage of like-minded people creates a culture. Culture itself is a neutral term that gains a moral dimension in its practice. Gay culture endorses the ideological concept of gay identity along with its practices.

Scripturally and scientifically, we hold that sexuality is a verb and not just a noun. Gay and straight are category errors and false identities. Homosexuality by any name is a practice and not an identity, what one does and not who one is.

Likewise, “gay Christian” language canonizes temptation behind a false identity. Any name preceding “Christian” is an implicit priority, contravening Paul's instruction to the Galatian church (Gal. 3:28).

Homophobia, -ic

Homophobia is an ideological and pejorative term that has gained common usage. It is often an accusation made against an individual failing to sufficiently celebrate same-sex sexuality, practices and politics.

But per MayoClinic.org: “A phobia is an overwhelming and unreasonable fear of an object or situation . . . a phobia is long lasting, causes intense physical and psychological reactions, and can affect your ability to function normally at work or in social settings.”

Disagreement is clearly not a phobia.

Linguistically, “homophobia” is somewhat nonsensical, meaning “fear of the same thing.”

Gender vs Sex

Sex is biological and stamped on every nucleated cell in a person’s body from conception onward. It is immutable down to the level of brain cells, so it is impossible to have “a man’s brain in a woman’s body,” for example.

Gender, in its common current usage, is an engineered term leveraging linguistics against biology; it is ideological and self-declared.

Historically, however, per theologian Christopher West:

“The root “gen”—from which we get words such as generous, generate, genesis, genetics, genealogy, progeny, gender, and genitals—means “to produce” or “give birth to.” A person’s gen-der, therefore, is based on the manner in which that person is designed to gen-erate new life. Contrary to widespread secular insistence, a person’s gender is not a malleable social construct. Rather, a person’s gender is determined by the kind of genitals he or she has.”⁸⁶

But ideology does not bow to history. Sex is biology, and gender is ideology.

Gender Identity

Gender identity is a feeling, a self-perception, of how one identifies with their biological sex or not, and it is often a sex stereotype. It is subjective, self-declared and fluid. Psychologist Dr. John Money of Johns Hopkins initiated its use in professional journals in 1955, referring to “the identity of the inner sexed self.”⁸⁷

Gender Confusion/Dysphoria

Gender identity confusion/dysphoria is a feeling/self-perception that one’s biology is not as one wishes it to be or not as one identifies most comfortably as. Sechner notes, “A gender-dysphoric youth experiences a sense of incongruity between the gender expectations linked to her or his biological sex and her or his biological sex itself.”⁸⁸

The greater the discomfort/dissonance, the greater the dysphoria. Gender dysphoria is not synonymous with transgenderism, the latter being an umbrella term within which gender dysphoria fits, but to which transgenderism is not limited.

Gender - Should we be using that term or is there a better term? If so, how is it best defined?

The answer to that depends on the application and one must be careful.

Gender is an engineered term leveraging linguistics against biology; it is ideological and self-declared. Sex is biological, right down to each human cell containing a nucleus.

Though gender is sometimes used synonymously with sex (e.g., in forms asking if someone is male or female), ideologically it is considered separate and distinct from sex (e.g., “your sex is irrelevant to your gender identity”) in a manner that is quite Gnostic (i.e., the “higher knowledge” that transcends lowly biology).

Therefore, it is best to mean what you say and say what you mean in context. Using phrases like “identified gender,” “identifies as,” “gender incongruence,” “gender dysphoria,” “transgender identified,” etc. work well, don’t surrender reality to a claim, and do not imply agreement.

Best terminology for gender transition?

That depends on the intended usage.

“Transition efforts” or “transition-affirming treatments/procedures” are both quite clear and do not surrender to ideology as compared to terms like “gender-affirming” or “gender confirming” treatments and procedures.

Best terminology for transgender identity?

“Transgender-identified” or “transgender identification” are well understood and non-capitulating.

A final comment on language

Terms should be as descriptively accurate as possible while avoiding ideological programming. For instance, because an individual’s intrinsic sex cannot be changed, and gender is essentially a biologically meaningless term or concept aside from biological sex, terms such as “transgender identity,” as if it were an objective reality, should be replaced by “transgender-identified, -identifying, or -identification,” which are descriptively accurate. Similarly, because “gender transition” is not ontologically or biologically possible, more descriptively accurate terms, such as, “attempted transition efforts,” or “attempted transition-affirming treatments or procedures,” are more accurate and preferred.

Hello,

Please accept my input on the regulation of the practice of medicine to protect children in FL.

First, what concerns the most about this issue is the increased suicide rate of transgender people. Even when supported by society like in Sweden they have a high suicide rate. Children can't make that far reaching a decision and a parent should not be allowed to make it for them. The surgery can be done when they are adults if they haven't changed their mind. The problem is not life threatening other than suicide and there is no evidence that their suicide rate returns to normal after the surgery. What we have is an elective surgery that can happen any time after they are 18. However, it would be very hard to reverse once it is done. In essence, a ton of harm and minimal good can be created by allowing doctors to change the sex of the child.

Sincerely,

Stephen Guffanti, MD

Subject: Gender dysphoria in minors

Dear Sir, I hope all will remember the axiom “first do no harm” when considering the issue of medical and surgical treatment of gender dysphoria in minors. The experience of adverse outcomes of this treatment in minors in the U.K. and Sweden should be evidence that more needs to be learned before recognizing these treatments as being of value.

Taking this uncertainty into account, we should not leave this decision up to the adolescent lacking the ability to understand long term consequences which even the medical establishment finds unclear at present.

Thank you for your attention to this matter.

As a Board certified Family physician I am horrified at the devolution of medical care away from sound principles of biological and to allow mentally unhinged individuals to dictate what constitutes medical care.

Certainly we need to carefully evaluate every person who has questions about their gender to include karyotyping when indicated and to help people to accept their gender in every truly supportive way, but we can never foster the lie that people can choose their gender irrespective of biology.

Florida Board of Medicine

Dear Mr. Vazquez and the Florida Board of Medicine Members,

I am writing as the parent of a trans-identified child in order to give my input as a person who has been navigating the system of gender affirming care for many years. First, I would like to state that I am politically center left- a Democrat, and I am not writing with a political agenda. I want you to know that I am very grateful that this medical board has turned its attention to this matter, and I truly thank you from the bottom of my heart, for making this a priority since all other American institutions have decided to turn a blind eye to a system that is clearly corrupt and ideologically captured.

The idea that any medical model should be 'client driven' is radical, but it becomes absurd when it is applied to children. My child began identifying as non-binary around her 13th birthday, following a difficult puberty, a diagnosis of Asperger's, and a long period of self-harming and depression that was brought on when she identified as EMO (a culture she described as "hating yourself" and which she discovered online). Prior to this, she was a happy, energetic, curious, interested and self-loving child who never displayed any discomfort with her physical self.

It cannot be a coincidence that most teenage girls who identify as transgender seem to have a similar trajectory. At the time of the trans identification, my child was being treated by a group of doctors at NYU Children's Hospital, and had outside DBT and ASD specialist. I was unable at the time to comprehend how these doctors, who were treating her for self harm and social communications disorder, just accepted my child's sudden and inexplicable change of name and pronouns, asserting that though they were recommending an in-patient therapeutic program, that this one thing about herself- that she was non-binary- was the only one true thing my child knew about herself. Leaving it at that, my child was affirmed

and no further cause or issue regarding identity was further investigated or challenged.

At the time, I was naive and I thought she would explore this identity and move on, but then by the interventions of staff at the above mentioned program, the identity changed to gay boy. It was not long after that that my child's mental and physical health got worse and did not seem to recover until many years later when I started pushing back on the ideology by asking questions. This trajectory also appears to be common amongst this cohort, as I've found out from talking to a lot of parents.

This is a long story to say that in my experience with affirmation, including allowing children to decide their sex, names, pronouns and to socially transition- especially in a medical setting, triggers an unspooling of mental health disorders, achieving the opposite of what it purports to do. Moreover, as I realized in horror after doing some research, none of those interventions are neutral, and in actuality seem to forfeit a child's ability to feel comfortable with themselves.

Doctors, teachers, neighbors, do-gooders, and even family members who 'affirm' a person's transgender identity before said person has had a chance to investigate and question the origins of the identification, are doing great harm. It is my experience that they tend to do so for their own good, as it makes them feel progressive and supportive of someone under the LGBT banner, without understanding any of the harms they cause. I have many friends whose intrusive family members or friends have been instrumental in turning their kids against them.

Doctors, allies, and teachers who affirm other people's children without parent consent have no understanding of all the unhealthy and negative cultural and ideological forces that belie the identification. While gender ideologues and affirmation proponents like to paint a picture of self-acceptance, healthy development, and everything that is rosy with rainbows and glitter, the reality is that most of us at home who look into what our children are doing online, in school GSA and LGBT groups, and in that culture, come to understand that the identity is often tied to pornography, sexual fetishes, inappropriate contact with adults who pose

as a 'glitter family,' and a lot of coaching inner self-talk about being 'born in the wrong body.'

To many of us, it is obvious that the trans identification triggers an iatrogenic development of gender dysphoric feelings that cause our children to reject their body and their past selves. This must be studied and researched carefully by a set of neutral scientists interested in really helping this cohort. In the case of my child, after 4 years of refusing to move lest she 'feels' herself, she now suffers from obesity, pre-diabetes, and metabolic disorder. Someone who was average weight all her life, was a dancer, a swimmer, a lover of movement and of herself, is now an unhealthy young adult who is immobile, obese, and who needs a plethora of medications that make her feel ill all the time.

The various pediatricians, psychiatrists, psychologists, therapists, endocrinologists, and other doctors that are entrusted with our children's care don't understand or don't want to see that affirmation is problematic. For example, not one of my child's many doctors ever questioned fallacies in her recollections of when this disorder set in, or her false memories that we knew had not occurred. Though I made them aware of the horrendous materials she had accessed online, they never bothered to question or help her explore what all of that meant, and to this day, most people and professionals will dismiss the possibility that online content can influence our children.

Affirmation appears to function as the imposition of an ideology or outside personal beliefs onto the developing minds of innocent and vulnerable children and adolescents. It must be studied: what effect does it actually have? especially when used by doctors or therapists who have an outsize influence on their patients. There is NO evidence that social transition, cross-dressing, using affirmative drugs and medical treatments, actually heal or help these children in any way. Considering the lack of evidence base to support it, is actually mind-boggling that this practice has been unfurled and is so widely practiced.

It is my opinion that the Florida Board of Medicine should look closely at the following issues and phenomena in order to fully understand what is appropriate medical care and what is simply activist directive designed to

provide cover for a lot of unhealthy and predatory actors (including unethical doctors, charities, private citizens, paraphilic men, misguided parents, and mentally ill persons):

1. WPATH and USPATH- Why is an organization made up of activists and the very doctors who work in the field allowed to dictate the standards by which the treat patients? My insurance booklet states that WPATH is an activist, not a medical organization- so why are we allowing activists who will benefit financially and socially to determine treatment protocols? especially because they tend to do poor science and seem to have an agenda? How is this legal?

They are so unfettered by reality and feel so untouchable that they had the gaul to add the identity of eunuch to the SoC8, released last week. How can a child even identify as a eunuch when the condition requires that one has already become an adult This really makes me wonder about the mental capacity and judgment of this group of people.

2. Informed consent clinics, including Planned Parenthood, Community LGBT+ service centers, and virtual providers such as Plume and Folx Health. These businesses have had a great influx of investor money and NGO funding and they are sending out hormones with very little medical case management, proper blood testing, or proper informed consent. Often times they do not even adhere to the WPATH's laughable SoC.

1. Regarding PP: When my child turned 18, she insisted that she wanted hormones. Though I opposed this, I did support her and took her to see her psychiatrist and endocrinologist. Both doctors explained to her that hormone therapy is still experimental, and that especially for people on the autism spectrum, it is better to wait until the brain is fully developed and the person has tried other ways to find relief. The endocrinologist aded that her metabolic panel and current weight anyways disqualified her for hormones because it is contraindicated for obese people who have high cholesterol due to chances of stroke. About 6 months later, on the urging of some friends, my child made a virtual appointment at Planned Parenthood, where she was seen by a midwife! My daughter was affirmed, but luckily, she did not chose to go on hormones. A month later, my child received a bill for \$370, though she had originally been told that the consultation was only

\$40. If Planned Parenthood is unable to clearly explain their pay structure to a young person on the spectrum, how can they possibly ever hope to give proper medical care and get informed consent correctly? If my child had decided to go ahead with taking hormones as prescribed by PP, she may have suffered a stroke or other consequences.

I have heard many such stories for mothers about Planned Parenthood, and I think they are going to destroy their brand with these shenanigans. I am adding below some more information about PP's practices, including some stories by detransitioners about the bad care they received there. I believe that their practices need to be considered carefully by the medical board:

7. <https://4thwavenow.com/2019/08/13/how-mental-illnesses-become-identities-tumblr-a-callout-post-part-2/>

7. Illegal services that send hormones to kids without prescription and the adults who enable it. One example is from a friend of mine whose kid ordered elicit hormones from this website: <https://steroidify.com>

The child is a minor and they paid via crypto following instructions from an online forum. The drugs were shipped to the home of an adult 'aly' who deemed herself this child's savior. This parent's rights were completely undermined by not only strangers online, but also a porous US customs process that allowed these drugs in from the eastern Europe to be delivered to a third person. This must be stopped.

8. There should also be an investigation into record keeping practices at all informed consent clinics as well as hospitals that provide surgery. Data reporting in this field should be mandated in the same way that the CDC mandates reporting from fertility clinics. The government should initiate an audit of clinic outcomes thus far, and require future reporting on all intakes and outcomes. Currently, there seems to be no record keeping or follow up, and when patients come with problems and complications the doctors ignore them, pass them over to other doctors, or mistreat them, as per the testimony of many detransitioners. Vaginoplasty and phalloplasty have horrifically high rates of complications and negative outcome rates. This data needs to be reported, and these procedures need to be kept to the SAME standards as any other surgical procedure:

<https://www.statsforgender.org/surgery/>

9. Researching detransition. The input from patients who were medically harmed by current practices, including affirmative care and informed consent models, are a good way to inform what has gone wrong and what needs to change.

10. Debunk the suicide myth of trans people:

<https://www.statsforgender.org/suicide/>

11. Investigate the large NGOs and charities that put out an incredible amount of disinformation that is unhealthy for LGBT+ individuals because they are based on propaganda and lies:

- <https://www.aclu.org/issues/lgbtq-rights/transgender-rights>
- <https://www.glaad.org>
- <https://www.thetrevorproject.org>
- <https://www.hrc.org>
- <https://pflag.org>
- <https://www.lambdalegal.org>

This form of medical practice is so broken and so dysfunctional, that I can go on forever. There is so much more to say and look at, but I will leave you with the thought that having done a preliminary review of the medical literature, you are well aware that this medicine is not sound. The USA as a world leader, must join other progressive countries such as Sweden, the UK, France and Denmark in putting science before activism and going back to the drawing board to figure out what really IS the best way to help these people. I don't think I am advocating for the end of transgenderism by asking that any surgery or medical intervention performed on anyone in this group be based on safe and sound practices that have been developed with purpose, discipline, and rigor. What is transphobic, homophobic, and misogynist is the current practice of experimenting on this vulnerable and often desperate population without care or respect for the patient.

Thank you again for your interest, your time, and your hard work in this matter.

Sincerely,

Rosita Weissberg

Dear Sirs,

This letter is to reject gender identification process being considered before you. In my medical opinion with a degree of medical certainty, gender dysphoria corrects in due time and any interference in medical or surgical treatment is irreversible and counterproductive to natural health. Thank you for your consideration.

Good afternoon,

Although I am a physician in Tennessee, I want to write to you to encourage the Florida Board of Medicine to restrict any misguided interventions and medical practices that encourage gender transition. The evidence does not support these kinds of intervention which ultimately appear to lead to irreparable long-term harm. Please do whatever is necessary to protect the youth of your state from unnecessary and lifelong harm. Thank you.

Sincerely,

Michael Ferri, MD
Franklin, Tennessee

Dear Florida Board of Medicine,

Although I do not practice medicine in Florida, I have been made aware of the Board's upcoming discussions on transgender issues especially regarding transitioning of youth away from their biological sex identified at birth. You are at the forefront of what every state medical association will be facing in the near future. You may well set a precedent. For this reason, I am writing you this short email.

I am not in favor of the chemical and physical mutilation of children. It makes no sense to allow youths to make life-altering decisions with mental complications (19-fold increase in suicides) and reproductive complications (permanent infertility), to name a few. And this at a point when the decision-making capacity of the brain is woefully underdeveloped and will remain so for several more years.

The medical literature is clear about the harmful effects and that over 90% of children and adolescents adopt their biological sex as they mature. Additionally, the experiences in European countries have caused, in recent times, more reticence in offering transition therapies. I pray the guiding principle of 'do no harm,' be the basis of your decisions.

Thank you. Sincerely,

Peter Rosario MD

Dear Florida Board of Medicine,

The Catholic Medical Association has informed its members of the intent of the Florida Board of Medicine to promote gender transition treatment for adolescents and children.

This is a very dangerous move and seems unethical for the following reasons. There is no evidence that gender transition actually solves the problem of gender dysphoria for children or adults. This type of treatment is exploiting the children, adolescents and families for the benefit of the researcher and provides monetary gain for the persons directing the transition treatment. The attainment of informed consent for adolescents and children must be through the parents. The assent for treatment is by the adolescents and children. Since the outcomes of such treatment are not known it would be impossible for the treating entity to gain informed consent from the parents or assent from the children. It is impossible to justify gender transition treatment in an ethical and responsible manner.

Sincerely,
Diana M. L. Newman, Ed.D.,RN

As a Developmental and Behavioral Pediatrician, I have been trained to understand both the physiology and the psychology of children. That is why I implore you to please RESTRICT rapid gender transition for children and adolescents. Most children who have gender dysphoria resolve their struggles and uncertainty by the end of adolescence, and thus it is essential that we allow them to work through this struggle in the proper timeline before making a permanent decision that involves hormone disruption and/or surgical intervention.

In fact, many European nations are CLOSING their gender transition clinics because their long-term, real life experience is that many who transition at a young age return with immense regret and a desire to transition back to their biological sex.

I am happy to be of assistance if you would like further explanation of how the process of gender dysphoria proceeds.

Sincerely,
Karen Landmeier, MD

To the Board of Directors:

I am writing to express my deep concern about the consideration of the Florida Board of Medicines gender affirming care. This push to accept such care is clearly ideologically driven and not based in either reason or sound medical evidence.

There is excellent evidence coming from our European colleagues that such treatment fails to show improvement in youth experiencing gender dysphoria. In the UK an Independent systematic review of the data concluded that evidence was very low regarding hormonal interventions in gender dysphoric youth disorder. Finland, as a country, adopted a position of early transitioning of pediatric patients and they too showed a lack of improvement in mental health and have now moved to psychotherapy as first line therapy.

As a recent Medscape article pointed out by Dr William Malone Endocrinologist

- “Most cases of early childhood-onset gender dysphoria self-resolve. [Eleven out of 11 studies](#) that followed the trajectory of gender-variant youth show that the most common outcome is natural resolution of gender dysphoria [around or after puberty](#). Among those diagnosed as having gender identity disorder, 67% no longer met the diagnostic criteria as adults; among those subthreshold for diagnosis, [93% were not gender dysphoric](#) as adults. Gender dysphoria in childhood is a far better predictor of future homosexuality than of future trans identity.
- The future trajectory of people whose transgender identity emerged during or after puberty is entirely unknown. No one has studied future trajectories of patients whose transgender identity emerged for the first time after the onset of puberty — a previously rare but now increasingly common presentation. Growing numbers of young detransitioners and

desisters are precisely from this demographic, suggesting that a transgender identity that emerges in adolescence may not be durable.

- Social transition does not improve mental health outcomes. Recent studies show that while socially transitioned children can thrive in the short term, they [do not fare any better](#) than their non-socially transitioned dysphoric peers. It appears that [peer relations](#), not the social transition status, predict mental health in gender-dysphoric children. We don't yet know the long-term trajectories of socially transitioned minors, but [emerging evidence](#) suggests that they may [be more likely to persist](#) with gender-related distress rather than outgrow it, as previously observed. This in turn necessitates decades of invasive and risky medical interventions. In fact, the Dutch researchers who pioneered the protocol used to medically transition minors (see Box) [explicitly and strongly discouraged](#) social transition of children and early adolescents.
- Nearly 100% of children who begin puberty blockers will proceed to cross-sex hormones and surgeries. The two main studies that have [evaluated the effects of puberty blockers](#) on mental health found [no improvements](#) or [improvements of marginal clinical significance](#). Both studies are also at critical risk of bias due to the absence of control groups. [Four additional studies looking](#) at the mental health effects of puberty blockers were plagued by [design limitations](#) and also [failed](#) to show any convincing positive effects on psychological health. However, one effect of puberty blockers has been consistently replicated: [At least four studies show](#) that [virtually all of the children who start puberty blockers proceed to cross-sex hormones](#). This suggests that rather than being a pause button, puberty blockers may serve as the "gas pedal" for gender transition.
- Most of the long-term health risks are largely unknown. No long-term studies exist of patients who underwent medical transition as teens or young adults. Therefore, our ability to assess risks vs benefits is limited. Puberty blockers have been demonstrated to [significantly impair bone health](#), and it is not clear whether this will result in future [osteoporosis](#). Cross-sex hormones are associated with [roughly 3-5 times the risk](#) for [heart attacks and strokes](#), though long-term studies are of insufficient quality for accurate risk assessments. Other risks associated

with these endocrine interventions will come to light as the practice continues to scale and as young people spend years and decades on these interventions. The risks to fertility are largely unknown, but it is almost certain that if puberty blockers are given at the early stages of puberty and followed by cross-sex hormones, sterility will result.

- The medical pathway of "affirmative care" rests on a single Dutch study that is not applicable to the current populations of gender-dysphoric youth. Most of the youth presenting for care today would have been explicitly disqualified by the original Dutch protocol, as most have significant mental health comorbidities and post-puberty onset of trans identities. This fact has been recognized by the principal investigators of the Dutch protocol itself, who have [recently begun to sound the alarm](#) about the [potential misapplication of their protocol](#) and who suggest that psychotherapy — rather than gender reassignment — is more appropriate for many of the currently presenting cases.”

The fundamental principle in good medical practice is “do no harm”. The evidence clearly shows that harm is being done by these hormonal transitions and should not be encouraged or promoted. An individual is born either male or female and this accords with both reason and common sense. We as physicians should be working for the wholeness and well being of your patients and not contributing to further distress.

I appreciate your consideration of my comments in your deliberations.

Sincerely,

Margaret J. Hart, DO, FAAFP

Chandler, Arizona

Paul A. Vazquez, J.D.
Executive Director
Florida Board of Medicine

Mr. Vazquez,

The foundation for so-called "gender medicine" is that there is such a thing as "gender identity" and it is innate and immutable. This claim is without scientific merit. I respectfully submit to you an essay (in two parts) I have recently completed which addresses this question. Please include it in the record of submissions related to your upcoming discussions on these matters.

Thank you.

Yours,

Phillip Penna

Gender Identity

Fruitful Hypothesis

or

Dangerous Delusion?

Part I

By Phillip Penna, MA

Environment and Community Program

Antioch College Seattle

17 July 2022

Many scientific hypotheses take origin from flights of the imagination which at first seem wild, but which later stand up to sober scrutiny and detailed proof. Newton's notion that gravity was a universal which acted at enormous distances was a leap of the imagination which must have seemed absurd until he was able to demonstrate it mathematically. Kekulé's discovery of the ring structure of organic molecules originated from a dream-like vision of atoms combining in chains which then formed into coils like snakes eating their own tails. Einstein's special theory of relativity depended upon his being able to imagine how the universe might appear to an observer travelling at near the speed of light. These are examples of phantasies which, although originating in the imagination, nevertheless connected with external world in ways which illumined it and made it more comprehensible.

Other phantasies giving rise to supposedly scientific hypotheses have lacked this connection with the external world. Such creations of the imagination are ultimately discarded as delusions. Throughout the eighteenth century, for example, the standard explanation of combustion was the theory of phlogiston. Phlogistan was considered to be the material principle of combustibility. When something burned, it was supposed to lose phlogiston, which was thought of as an [imponderable fluid](#)¹. It was finally demonstrated that phlogiston existed only in the imagination, that nothing in the external world corresponded to it.

We see, therefore, that in the field of science, there are two kinds of phantasy. The first reaches out to the external world and, by maintaining a connection with the world which corresponds to its real workings, becomes a fruitful hypothesis. The second, making no such connection with the external world, is ultimately dismissed as [a delusion](#).²

Gender Identity: Fruitful Hypothesis or Dangerous Delusion?

In my first essay, I argued that the term "Gender Identity" was essentially meaningless because the word "Gender" was being improperly used. "Gender" formally speaking, is a grammatical term denoting

the classification of words, or the class to which a word belongs by virtue of such classification, according to the sex of the referent (natural gender) or according to arbitrary distinctions of form and syntax (grammatical gender). Modern English has few traces of grammatical gender, but Latin nouns all have gender, masculine, feminine or neuter, often contradicting natural gender. Adjectives and articles have gender insofar as they change form to agree with the noun they qualify...³

¹ "These imponderable fluids were mere names, and these forces were suppositions, representing no observed facts." From https://en.wikipedia.org/wiki/Imponderable_fluid accessed 8 April 2022.

² Storr, Anthony. *Solitude: A Return to the Self* (New York: Ballantine Books, 1988), pages 67-68.

³ *The New Lexicon Webster's Encyclopedic Dictionary of the English language Canadian Edition* published in 1988 main dictionary section copyright 1972 Librarie Larousse as Larousse Illustrated International Encyclopedia and Dictionary Revised and updated 1988.

The argument I made can be summed up as follows: it is not possible for someone to be “Transgender” because people don’t have “gender,” only words do.⁴ Terms such as “Transgender” and “Cisgender” are nonsense words that one would find in “nonsense poetry” which employ “fanciful language and meaningless, [made-up words](#).”⁵ Sadly, we now have laws which have enshrined these “made-up words” in the criminal code. Nietzsche was wrong: God is not dead, language is; as Frank Zappa sang

*You can't even speak your own f***ing language
You can't read it anymore
You can't write it anymore
Your language
[The future of your language](#)...*⁶

In this brief reflection I will consider “Gender Identity” as a scientific hypothesis, simply stated as follows:

1. Everyone has a “Gender Identity.”
2. “Gender Identity” is innate (and immutable) both in terms of psychology and biology.
3. Only the person themselves can verify their Gender Identity, their individual “innermost sense of [their own gender](#).”⁷

More descriptively, the “Gender Identity” scientific hypothesis is this:

- If a person “senses” that they are a woman, then they are a woman, and vice-versa, and somehow neither (among other seemingly endless options).
- Furthermore, this “innermost sense” is in fact the only determining factor of whether or not someone is a man, woman, both, neither, or something else together (like a cat).
- The argument is this: if a person who has a penis “senses” that they are a woman then they are in fact a woman and the scientific verification of this is this person’s own “innermost sense” because (so goes the hypothesis) this “sense” is immutable, part of your biological make-up, that is, one can only have that “sense” of being a woman if you were a woman, a man if you were a man, neither if you were neither, both if you were both, etc.
- What we would normally rightly call the human body has nothing to do with this. Gender Identity alone determines what you are and it, somehow, is inherent to you and is itself biological.

⁴ “Sex” is biological and “Gender” is grammatical.

⁵ <https://www.best-books-for-kids.com/nonsense-poems.html>, Accessed 2 April 2022.

⁶ Zappa, Frank. “[The Blue Light](#)” from the Album *Tinseltown Rebellion Band* originally released in 1981.

⁷ I recognize that Queer Theorists will disagree with the statement at Gender Identity is understood to be an innate psychological state rooted in biology. They would argue that Gender Identity is “performative” like when a couple gets married and the officiant states “I now pronounce you man and wife”, that is, when someone says that they are non-binary then they are non-binary. I am not addressing their conception of Gender Identity in this essay. I am addressing those who present Gender Identity in scientific terms.

Here is an example of this scientific hypothesis employed by Canadian Centre for Ethics in Sport Expert Working Group who wrote in a 2016 document in which they state they acknowledge

*“the concern that transwomen athletes who grew up biologically male and who do not undergo hormonal intervention may be at a competitive advantage when competing in high-performance women’s sport. Nonetheless **it is recognized that transfemales are not males who became females. Rather these are people who have always been psychologically female, but whose anatomy and physiology, for reasons as yet unexplained, have manifested as male.**”⁸*

In other words, according to the CCES EWG,

- We know these “transwomen” are women, not because of their “anatomy and physiology” but because of their psychological make-up, *that* is why they are women.
- Their psychological make-up should have resulted in them having a different biology reality; that is, because they are “psychologically female” they really should have been born with what we know to be a female body, but for some scientifically unknown (and [imponderable](#)⁹) reason this is not what happened. But despite this *in utero* mix-up, we know they are females because these “transwomen” tell us they are.

Who knew that a baby was formed in the womb and then born would have a body based on the child’s “psychological” make-up? Well, we don’t know this. It is simply a hypothesis, namely, that psychology is *the* biological force which determines what you are even if your body disagrees; and, again, according to the CCES EWG, we can confidently claim that this is true even though we don’t know why a body would disagree as the body has nothing to say about the matter. [This is quite a hypothesis](#).¹⁰

This hypothesis was [first articulated by Dr. John Money in the 1950’s](#), and has increasingly been acted upon since then. For the past 10-15 years, it has been deemed by political, academic, medical, and corporate establishments to have been verified and true. We now teach this to children starting at age 4 and we have seen an explosion of medical clinics offering medical products and procedures ([in the US there was 1 ten years ago and now there are more than 300 in North America](#))¹¹ which we are told affirm people’s “gender identity”, this “scientific reality” which is verified by someone simply saying that they are “transgender.” With the thousands of (mostly) young people, particularly young females, having accessed these services over the past ten years (and [tens of thousands more hoping to do so](#)),¹² this “*reaching out to the external world*,” we should now be able to accurately see and state whether or not this hypothesis has been fruitful or delusional. What does the evidence reveal? Does it “*stand up to sober scrutiny and detailed proof?*”

⁸ Canadian Centre for Ethics in Sports, “Creating Inclusive Environments for Trans Participants in Canadian Sport: Guidance for Sport Organizations,” August 15, 2016, <https://cces.ca/sites/default/files/content/docs/pdf/cces-transinclusionpolicyguidance-e.pdf>; quotation found in *Unsporting: How Trans Activism and Science Denial are Destroying Sport*, by Linda Blade and Barbara Kay (2020 Rebel News Network Ltd.), page 87.

"You need to have a really, really good evidence base in place if you're going straight to an invasive treatment that is going to cause permanent changes to your body"¹³

"Surely medical organisations and children's hospitals wouldn't endorse these treatments without rock-solid evidence."¹⁴

1. **"Sweden drastically changes protocol, prioritizes psychotherapy"**¹⁵

The National Board of Health and Welfare is currently working to update the knowledge support for care of young people with gender dysphoria that was established in 2015. This is happening in stages and now the authority comes with new recommendations regarding puberty blocking and cross-sex hormone treatment in this group.

The National Board of Health and Welfare therefore calls for restraint with treatment in persons under 18 years of age. According to the authority, the risks of hormone treatment currently outweigh the possible benefits for the group as a whole.

The National Board of Health and Welfare relies, among other things, on a review of relevant studies on the effect and safety of hormone treatment carried out by the Swedish Agency for Medical and Social Evaluation (SBU). In the report¹⁶ . . . the SBU concludes that it is not yet possible to draw any definite conclusions regarding this.

Hormone treatment should henceforth be given within the framework of research, according to Thomas Lindén, head of department at the National Board of Health and Welfare. (**Emphasis mine**)

2. **"National Academy of Medicine in France Advises Caution in Pediatric Gender Transition"**¹⁷

*The National Academy of Medicine in France has issued a press release in which it cautions medical practitioners that the growing cases of transgender identity in young people are often socially-mediated and that great caution in treatment is needed. The Academy draws attention to the fact that hormonal and surgical treatments carry health risks and have permanent effects, and that **it is not possible to distinguish a durable trans identity from a passing phase** of an adolescent's development. (**Emphasis added**)*

¹³ "Doctors Have Failed Them, Say Those Who Regret Transitioning" By Alicia Ault 22 March 2022, <https://www.webmd.com/sex-relationships/news/20220322/doctors-have-failed-them-say-those-who-regret-transitioning>

3. UK – “[Cass Review Interim Report published](#)”¹⁸

The report says . . . the unquestioning affirmative approach is flagged in several places in reports from clinicians and therapists who feel that this is at odds with their professional training and standards:

“Some secondary care providers told us that their training and professional standards dictate that when working with a child or young person they should be taking a mental health approach to formulating a differential diagnosis of the child or young person’s problems. However, they are afraid of the consequences of doing so in relation to gender distress because of the pressure to take a purely affirmative approach. Some clinicians feel that they are not supported by their professional body on this matter. Hence the practice of passing referrals straight through to GIDS is not just a reflection of local service capacity problems, but also of professionals’ practical concerns about the appropriate clinical management of this group of children and young people.” (Emphasis added)

4. “[Finland Issues Strict Guidelines for Treating Gender Dysphoria](#)”¹⁹

Western countries around the world are grappling with how to treat the exponentially growing number of children and adolescents being referred to gender clinics for puberty blockers, cross-sex hormones and gender-affirming surgery. Finland recently issued very strict clinical guidelines for the treatment of children with gender dysphoria.

- *There is clear differentiation in treatment guidelines between early-onset childhood gender dysphoria and adolescent-onset gender dysphoria.*
- *The guidelines acknowledge and recognize that identity exploration is a natural phase of adolescence and restrict medical interventions until “identity and personality development appear to be stable”.*
- *There is a prioritization of psychotherapeutic non-invasive interventions as the first course of action “due to variations in gender identity in minors”.*
- *Hormone therapy is initiated only if it is ascertained that “identity as the other sex is of a permanent nature and causes severe dysphoria” (ie medically necessary).*
- **A requirement that there be “no contraindications” prior to initiation of puberty blocker or cross-sex hormone interventions.**
- *No surgical interventions are allowed for children under the age of 18.* (Emphasis added)

5. Australia and New Zealand:

*In an updated **position statement**, the Melbourne-based Royal Australian and New Zealand College of Psychiatrists last year **underscored the importance of mental health evaluations of gender dysphoric youth** over an “[affirmation only](#)” approach.*²⁰ (Emphasis added)

¹⁸ <https://www.transgendertrend.com/cass-review-interim-report/> accessed 5 April 2022.

¹⁹ <https://genderreport.ca/finland-strict-guidelines-for-treating-gender-dysphoria/> accessed 5 April 2022

²⁰ “Hitting the brakes on transgender treatments for youth: International medical groups call for caution on hormonal and surgical interventions”, by Mary Jackson; Posted 14 March, 2022 https://wng.org/roundups/hitting-the-brakes-on-transgender-treatments-for-youth-1647283935?fbclid=IwAR1IScNqt_S6oW001NK7K8xpXcGJtzjG-L-QOouMRazRnOJRX8degQn1q38

6. Detransitioners:

"I was a child, allowed to destroy my body permanently, under the assurance that I can always change my mind, and that it's a beautiful, harmless process," wrote Lgbtcos in February. "The informed consent model is a lie, because we are just guinea pigs to a medical experiment, my life is permanently afflicted, and I was not informed."

*The missive was on the Detrans subreddit, which currently has **23,000** members.*

...

[Athena] recently wrote on Reddit: "I'm gonna tell u from experience the coddling of transgender ppl and their delusions ... You are going against fundamentals of nature, immutable stuff, and damaging yourself!!! no such thing as sex change, only sterilization. people won't want to date you. your health declines. your body suffers. your social life suffers."²¹ (Emphasis added)

7. Back to the UK: **Sajid Javid inquiry into gender treatment for children - Health secretary compares political fears over trans issue to silence during Rotherham scandal**

Javid is said to be particularly alarmed by [Hilary Cass'] finding that some non-specialist staff felt "under pressure to adopt an unquestioning affirmative approach" to transitioning and that other mental health issues were "overshadowed" when gender was raised... "This has been a growing issue for years and it's clear we're not taking this seriously enough," an ally of the health secretary said. "If you look at Hilary Cass's interim report, the findings are deeply concerning and it's clear from that report that we're failing children."... "That overly affirmative approach where people just accept what a child says, almost automatically, and then start talking about things like puberty blockers — that's not in the interest of the child at all," the ally said. The Tavistock & Portman NHS Foundation Trust sees 2,500 children a year — 200 of whom access hormones. Referrals have increased 50-fold in the past decade, with far more female-born children now coming forward in a reversal of previous trends.

8. **Florida** (which seems to be well aware of everything I have noted above):

Systematic reviews on hormonal treatment for young people show a trend of low-quality evidence, small sample sizes, and medium to high risk of bias. A paper published in the International Review of Psychiatry states that 80% of those seeking clinical care will lose their desire to identify with the nonbirth sex. One review concludes that "hormonal treatments for transgender adolescents can achieve their intended physical effects, but evidence regarding their psychosocial and cognitive impact is generally lacking."²²

9. And the list goes on.

²¹ "We are just guinea pigs: Women describe trauma of transitioning as teenagers" 21 March, 2022 by Tori Richards, <https://www.washingtonexaminer.com/restoring-america/community-family/we-are-just-guinea-pigs-women-describe-trauma-of-transitioning-as-teenagers>

²² https://www.floridahealth.gov/documents/newsroom/press-releases/2022/04/20220420-gender-dysphoria-guidance.pdf?utm_source=floridahealth.gov&utm_medium=referral&utm_campaign=newsroom&utm_content=article&url_trace_7f2r5y6=https://www.floridahealth.gov/newsroom/2022/04/20220420-gender-dysphoria-press-release.pr.html accessed 2-May-2022.

If the Gender Identity hypothesis was true, then there would not be this retreat both at the institutional and individual levels. All one needs to do is listen to the four women on the [“Detrans 101: What You Need to Know”](#) panel to recognize that this hypothesis, when acted by and upon them, did not produce the results hypothesized, but rather produced more and irreversible harm.²³

Clearly the hypothesis has fallen short. In the words of Storr, having reached out to the external world, this phantasy made no connection with it and therefore should be *“dismissed as a delusion.”*

Should we be surprised by this? Not at all. The evidence of this hypothesis being wrong was provided to us by the work of [Dr. John Money](#) himself. His work with the Riemer twins of Winnipeg, Manitoba was clearly a abject and tragic failure. Despite this, he himself never admitted that the implementation of his “gender theory” with these twin boys to be so. This lack of acknowledging this failed experiment is tantamount to lying.²⁴ Everything that has happened in this field since then is based on this original lie, on the denial of the truth, the perpetuation of a failed hypothesis that should be *“dismissed as a delusion.”*

So why is this hypothesis still being acted upon as if it were not so? **Vested interests**

Vested interest #1: Trans Activists:

Why are bad experiences with gender medicine stigmatized, suppressed, discouraged, etc., by the trans community? As part of the push to “depathologize” being transgender, activists are now pushing for an informed consent model as an alternative to the diagnostic process. This removes all of the “gatekeeping” measures that were in place to try and manage regret and other negative experiences with transition.

So this is the dilemma for trans activists: if too many people report negative experiences with transition, health care providers will be forced to reassess whether the current model of care is ethical.

It is in their interest to keep this model, so it is in their interest to downplay negative experiences. The idea that a trans identity could be socially influenced is stamped out. The possibility that a young person might wrongly interpret symptoms of developmental disabilities or other mental health disorders as “gender dysphoria” must be suppressed. They repeat over and over that getting it wrong is very rare, and many of the people claiming to be detransitioners are just liars.

This is why I keep finding myself at odds with trans activists. Fully understanding all of the possible outcomes, including the negative ones, is essential to informed consent. You are not for “informed consent.” You are for getting what you want immediately when you want it — regretters be damned.

*Ultimately, the stigmatizing of negative experiences — removing the ability to provide true informed consent when choosing medical transition — harms **every single person** who transitions. You were all failed by professionals and by the community just as much as I was.²⁵ (**Emphasis added**)*

Vested Interest #2: Money and Power

Why do we have laws such as Bill C-4 in Canada, the NCAA allowing males to compete and win in the female category, President Biden using terms such as 'Transgender kids', and more? I make the following hypothesis my own: it is because *"humanity is far more profitable as parts than we are as whole sexed beings. Corporate capitalism, already having colonized the entire planet and left a wasteland of our waterways, our soil, the air we breathe, and most other species, has [now come for us](#)."*²⁶

More to the point, they have [come for our kids](#).²⁷

*"...you have these big corporatists on their social media platforms like gender surgeons marketing their wares, their operations to young people. They don't understand the power of this. Transgenderism has been made cool, that's why they're doing it, that's part of why they're doing it, but they're dissociated; they're dissociated because also there's a lot of porn on their platforms. They're being sexually traumatized [in] an effort to get them to dissociate. **This is all about capturing the youth; they don't give a crap about us, you know, it's really the youth that they want. Any totalitarian regime goes after the youth because they'll take it into the next generation and children that don't know who or what they are are just vulnerable.** They're going to be like little drones for the state, for the corporate state ... and it's not my imagination. It's not that oh I've been like down this rabbit hole so long I think 'oh they're coming after the kids.' I have the receipts; Arcus Foundation, Denton's International, largest international law firm, Open Society Foundation; they're making these legal edifices for constructing this apparatus which is not true. **It's not real. There are no transgender children because there's no transgender. It's an ad. People have got to get that down. I just want to like do a chant like "it's an ad, it's an ad, [it's an ad campaign](#)."**"²⁸ (Emphasis added)*

In conclusion, both my first and my second essays agree: "Transgender" is neither scientifically verifiable nor linguistically accurate. Like phlogiston, it is a mere name, a supposition, *"representing no observed facts."* Experience in the real "external world" has shown this does not exist, and will continue to be shown to be so. Why? Because as Athena has told us:

*"You are going against fundamentals of nature, immutable stuff, and damaging yourself!!!
[no such thing as sex change, only sterilization](#)."*²⁹

As the old saying goes, "A rose by any other name is still a rose."

But [there is money to be made](#)³⁰ and politics to be won, so who cares?

²⁹ "'We are just guinea pigs': Women describe trauma of transitioning as teenagers" 21 March, 2022 by Tori Richards, <https://www.washingtonexaminer.com/restoring-america/community-family/we-are-just-guinea-pigs-women-describe-trauma-of-transitioning-as-teenagers>

And you might say, “It’s not my kid.” Are you sure about that? Apparently, only they can tell you and when they do, you *must* agree. It’s science after all. Just ask the CCES Expert Working Group who adopted this hypothesis even though they lacked the scientific expertise to make such an assessment.

Since the very reason for the committee’s existence involved contemplating a potential dramatic disruption of sport’s existential paradigm of biological categories, you would expect at a minimum, for example, to see the name of at least one disinterested biologist from a top Canadian university on the list of EWG members.

There was no biologist. The only representative from the domain of science was a medical doctor. Dr. Stephen Feder is head of the adolescent Health Clinic at the Children’s Hospital of Eastern Ontario, and a proponent of expeditious affirmation for youthful transition, a highly contested practice amongst sexologists and therapists specializing in the field of gender dysphoria. That’s one single scientist.

And by virtue of his work, he is far from a disinterested observer. Moreover, no one else on that committee except a biologist could have credibly interrogated from a scientific perspective the theories on which this [one medical doctor’s opinion](#) rests.³¹

O well, just forget the science! There are 40,000 young females raising money on GoFundMe to get [double mastectomies](#).³² It’s a bonanza and there is money to be made! Let’s go “get” while the “gettin” is good!

Gender Identity

Fruitful Hypothesis

or

Dangerous Delusion?

Part II

Further Reflection on the

Canadian Centre for Ethics in Sport Expert Working Group

2016 Statement

By Phillip Penna, MA

Environment and Community Program

Antioch College Seattle

17 July 2022

*“The [Canadian Centre for Ethics in Sport Expert Working Group] acknowledges the concern that transwomen athletes who grew up biologically male and who do not undergo hormonal intervention may be at a competitive advantage when competing in high-performance women’s sport. Nonetheless **it is recognized that transfemales are not males who became females. Rather these are people who have always been psychologically female, but whose anatomy and physiology, for reasons as yet unexplained, have manifested as male.”**¹*

Further to my comments in Part I of this essay, this statement deserves further scrutiny as it comes from a document which set the stage and forms the basis for so-called “Transgender Inclusion” policies being implemented by sports organizations throughout Canada. Though it has carried political weight, can the same be said for it intellectually? If not, then it behooves sporting organizations across Canada to – at a minimum - put a pause on these policies so a thorough and proper rethinking of the matter can be undertaken. Let us begin:

1. They use the term “transfemales.” This is important.
 - a. The word “woman” is a noun and means “adult human female.”
 - b. The word “female” is an adjective which means “the sex in animals or plants that produces or is capable of producing eggs or bearing young.” In other words, “female” is a biological term. So, the CCES EWG is making an appeal to *biology* when using this new term “transfemale.”
2. In sports, there are two categories for participation: male and female. Within each category, there are divisions based on age and skill (for example, boys AAA hockey; girls junior high school soccer).
3. The statement in question does not challenge this male/female binary for sports. Instead, what it does is offer a new definition for what determines someone to be “male” or “female.” More precisely, **they state emphatically, though without proof, that there is a heretofore unknown biological feature which determines the sex of a person.**
4. The statement directly speaks to the group of people who “grew up biologically male” but (they say) are actually female, or, as they refer to these people, “transfemales.” According to the CCES EWG these so-called “transfemales” are not males, rather they are females; what they mean by this is that they are *biologically female*² even though they have penises, larger bones and greater bone density, higher levels of testosterone, etc. The CCES EWG stated these people are and always have been females; always - from conception to the present. This is because they are, so they claim, “psychologically female.” The CCES EWG is arguing that it is *this* and nothing else which actually determines whether or not someone is female or male.
5. They base this argument on the claim this “female (and male) psychology” is part of everyone’s biological make-up. How do we know this is what they are stating? How else can one explain the following statement: **“these are people who have always been psychologically female, but whose anatomy and physiology, for reasons as yet unexplained, have manifested as male.”** (*emphasis mine*) In other words:

¹ Canadian Centre for Ethics in Sports, “Creating Inclusive Environments for Trans Participants in Canadian Sport: Guidance for Sport Organizations,” August 15, 2016, <https://cces.ca/sites/default/files/content/docs/pdf/cces-transinclusionpolicyguidance-e.pdf>; quotation found in *Unsporting: How Trans Activism and Science Denial are Destroying Sport*, by Linda Blade and Barbara Kay (2020 Rebel News Network Ltd.), page 87.

² We should not have to use these two words together. “Female” is biological term. “Biologically female” is redundant. O well...

- a. They are claiming these people should have had a female body because they have “always” – from conception onward – been psychological female;
 - b. Logically it is clear that they are stating that this psychological state is a biological reality because it should have had the impact on the developing fetus such that they should have had female anatomy.
 - c. Again, logically they are saying those people who have female anatomy and who say they are female have said female anatomy because the (hypothesized) biological principle of “female psychology” worked its magic properly.
 - d. But for some (or many) imponderable reason, this biological process did not work out for them and they were born with male anatomy.
6. It is clear, therefore, that the CCES EWG is not arguing for males to be included in and participate in female categories (or vice-versa) because, according to them, these people are in fact females, biologically, and therefore should be participating in the female category based on the (hypothesized and imponderable) biological principle of Gender Identity, their “inner sense” that they are female.
7. Indeed, all people who say they are female can only say that because of this inner sense. According to the CCES EWG, that is the foundation for sex determination, not DNA.

Is there a consensus in the scientific community that this is what determines sex? Is there verifiable proof that this is the reason why females who have female bodies are females, that is, because of Gender Identity? Like DNA, has this “inner sense” been isolated in a laboratory and proven to exist? If it has not, then how can it be claimed that it does exist? If it does exist, then we should be able to describe how it works to make a female body, and from there we should be able to determine why it sometimes does not do so. Then we could develop a test so as to be able to verify claims to be female, made by people with male bodies, are true.

But we don’t have this test, and we don’t have this test because we don’t know how Gender Identity actually works biologically to create babies that correspond to this Gender Identity, and since we do not know how it works biologically, can we – like the members of the CCES EWG have done - say with any kind of scientific confidence that it is in fact Gender Identity which determines sex? Let me pose this question more directly: on what scientific grounds have so many sports organizations across Canada come to agree with what the CCES EWG has proposed in this statement?

Let’s restate this differently:

1. If Gender Identity usually produces the correct body, what is the means of it doing so? If we do not know the means of it doing so, then how can it be said with any confidence that it does so? Indeed, how can we say with any confidence that it even exists?
2. We know DNA exists, and we have a pretty thorough knowledge of how DNA works. We know how disruptions in DNA can cause physical anomalies, and we even know how those disruptions happen; indeed, we have developed many tests to see and determine if some of these disruptions are present even while the child is *in utero*. Can any of this be said for Gender Identity?
3. The only proof offered is the person’s claim. It is argued that a person would only make such a claim if it was true. This is circular logic, and such an esteemed group of people such as the

members of the CCES EWG should be more than a little embarrassed to use such logic. Therefore, the answer to both of the above questions is negative.

4. Since the answer is negative, how can we “recognize” that these people with male bodies who say they are “psychologically female” are in fact females as is claimed? There is no test to determine if this is biologically true, and therefore the very claim that they are “psychologically female” is at best suspect and certainly should not be a determining factor for who gets to participate in the female category of sporting activities.

Let's go one step further and apply the logic of the statement as if we were speaking of people who claim to be non-binary:

it is recognized that [transgender/non-binary individuals] are not males [or females] who became [non-binary]. Rather these are people who have always been psychologically [non-binary], but whose anatomy and physiology, for reasons as yet unexplained, have manifested as male [or female].

What exactly would that non-binary physiology look like coming out of the womb? Has there ever been an example in history of a person's body being non-binary, that is, either having fully intact and working gonads of both female and male genitalia or of not having any vestiges of either that we can appeal to so as to make the case for a non-binary psychology, a non-binary Gender Identity? The answer is obvious: we do not have such an example.

Though this is enough to demonstrate the statement made by the CCES EWG, and as a result the whole document from which it comes, is without merit, I will discuss one more thing so as to drive home the point that this statement is woefully lacking; and all sports organizations in this country who have taken direction from this document and, acting upon it, implemented “transgender inclusion” policies (like Ringette Canada³) should be embarrassed to have done so.

The word “manifested”, what does it mean?

manifest (adjective): man·i·fest | \ 'ma-nə-, fest \

1: readily perceived by the senses and especially by the sense of sight

Their sadness was manifest in their faces.

2: easily understood or recognized by the mind: OBVIOUS

manifest (verb): manifested; manifesting; manifests

transitive verb

: to make evident or certain by showing or displaying

evident (adjective): ev·i·dent | \ 'e-və-dənt , -və-, dent \

: clear to the vision or understanding⁴

The CCES EWG says that these so-called “transfemales” anatomically “manifested as male.” If that is true, then, according to the definition of the word Manifest (a transitive verb), the evidence displays that they are Male. Further to this (as an adjective), it is readily (quickly, easily) perceived by the senses and recognized by the mind (it is obvious) that they are Male. In other words, what is being

³ <https://www.ringette.ca/trans-inclusion-policy-and-resources/> accessed 7 April 2022.

⁴ See <https://www.merriam-webster.com/>

made evident (verb) and easily understood (adjective) is that these people are Male. And since the CCES EWG is not arguing against the sex binary for participation in sports, these people should play and compete with other males like they themselves are. There is no counter-evidence that is easily perceived (or even difficult to perceive) to prove biologically (as they claim) to say that we can “recognize” (their word) them as females. Furthermore, as noted above, there is no way to prove that they are not males because there is no way to prove that there is such a thing as Gender Identity or that it is the foundation for the determination of sex. The CCES EWG making the claim that this is so is not enough to make it so. Saying “The Emperor is wearing clothes” does not make it to be so.

Thus we can see that there are two competing theories at play in this one paragraph: The first is that Gender Identity is a biological principle and it is responsible for determining sex (no matter the anatomical features of a person’s body); the second, is that DNA is the biological principle which determines sex. I have shown that the first is not verifiable while the second is easily so. Yet, the CCES EWG has chosen to side with the former. This goes against the basic and essential scientific and philosophical principle of Occam’s Razor,

*the maxim that, given a choice between two hypotheses, the one involving the fewer assumptions should be preferred. In other words, one should apply the law of parsimony and choose simpler explanations over more complicated ones. See also **elegant solution**. [William of **Occam** or **Ockham** (c. 1285–1347), English Franciscan monk and Scholastic philosopher]*

Elegant Solution

a solution to a question or a problem that achieves the maximally satisfactory effect with minimal effort, materials, or steps. In terms of theories or models of behavior, an elegant solution would be one that satisfies the requirements of the law of parsimony.

Law of Parsimony

*the principle that the simplest explanation of an event or observation is the preferred explanation. Simplicity is understood in various ways, including the requirement that an explanation should (a) make the smallest number of unsupported assumptions, (b) postulate the existence of the fewest entities, and (c) invoke the fewest unobservable constructs. Also called **economy principle; principle of economy; principle of parsimony**.⁵*

Principle of Parsimony

The principle of parsimony recommends that from among theories fitting the data equally well, scientists choose the simplest theory. Thus, the fit of the data is not the only criterion bearing on theory choice. Additional criteria include parsimony, predictive accuracy, explanatory power, testability, fruitfulness in generating new insights and knowledge, coherence with other scientific and philosophical beliefs, and repeatability of results. The principle of parsimony has four common names, also being called the principle of simplicity, the principle of economy, and Ockham's razor (with Ockham sometimes Latinized as Occam).

⁵ From the APA Dictionary of Psychology <https://dictionary.apa.org/> accessed 7 April 2022.

*Parsimony is an important principle of the scientific method for two reasons. First and most fundamentally, parsimony is important because the entire scientific enterprise has never produced, and never will produce, a single conclusion without invoking parsimony. Parsimony is absolutely essential and pervasive.*⁶

There was and is no necessity (that is, no compelling evidence) for the CCES EWG to prefer the more complex hypothesis - rife with assumptions and invocations of “unobservable constructs” - of Gender Identity over the simple hypothesis of DNA. The latter can be and has been verified; whereas the former has not, nor, because of its imponderability, can it ever be so. The CCES EWG, and every other sports organization which has followed their lead, making this preference was and is in error. This is a big problem. As Thomas Aquinas correctly remarked, “a little error in the beginning leads to a great one in the end.”⁷ In this case, these errors work themselves out in individual lives with physically irreversible consequences. Sports organizations who have implemented “Trans Inclusion” policies have made themselves accountable for these consequences. (Perhaps they should start getting ready for the lawsuits, like all the parties who were involved with the Canadian residential school system.)

Post-script

It is clear that the CCES EWG made an appeal to biology when making the case in favour of the possibility that people can be “trans.” They had to, because it is sports we are talking about and it is bodies that play sports. As I have shown, their appeal to biology fails because there is no biological proof for what they have claimed and because it fails to meet the standard of Occam’s Razor.

It must be noted that their explanation for what makes for a person being “trans” is not at all what others state, namely, “gender distinction (male and female) stems from the soul rather than from the body.”⁸ In 1964, Psychoanalyst Robert Stoller first coined the term itself and defined it as “a complex system of beliefs about oneself: a sense of one’s masculinity and femininity. It implies nothing about the origins of that sense (e.g., whether the person is male or female). It has, then, psychological connotations only: one’s subjective state.”⁹

*Like some quasi-religious movement, the transgender community is bound together by faith in gender identity — the idea that we all have a soul-like essence that determines whether we are men or women.*¹⁰

So, on one hand, Gender Identity is presented as biological and innate - physical and objective - and on the other it is presented as “a system of beliefs,” something metaphysical and subjective. Which is it? In either case, both are presented as belief statements because neither camp can produce proof of its existence save the person saying they are “transgender.” In addition to this there are the Queer

⁶ PARSIMONY AND EFFICIENCY, Published online by Cambridge University Press: 05 March 2015, Hugh G. Gauch Jr, <https://www.cambridge.org/core/books/abs/scientific-method-in-practice/parsimony-and-efficiency/F8327BE6D73C3D00214B65AC04D350F2> accessed 7 April 2022.

Paul A. Vazquez, JD

Executive Director

Florida Board of Medicine

Dear Mr. Vazquez,

I am a retired Ob/Gyn with many years of service to young people in my practice. I have done extensive reading and research into this new transgender “craze,” and I am amazed at the lack of quality medical evidence to support the radical treatments being considered for patients who are still children and have not reached an age at which they can provide informed consent.

I am also aware of the recent efforts by the British Medical Service to review the literature on puberty blockers and cross-sex hormones. The findings of both of these reviews reveal that the quality of studies supporting the use of puberty blockers and cross-sex hormones are low quality.

These reviews have led not only the British Medical Service but also the medical systems within Sweden and Finland to change their approach to minors with gender dysphoria.

Please protect the children of Florida from experimentation that can cause irreparable harm to their ability to have children in the future. They deserve the best medical science can provide.

Sincerely,

Jeff Barrows, DO, MA (Ethics)

To whom it may concern,

As the Florida Board of Medicine considers regulations regarding gender-affirming care for minors, please be aware that there is no scientific evidence that supports a benefit to minors who undergo medical and surgical gender-affirming care. There are, however, a growing number of detransisters who regret undergoing irreversible medical and surgical therapies without the intellectual capacity to understand the long-term effects of the care they chose or, in some cases, without the knowledge that such therapies are usually sterilizing and permanent.

To whom it may concern,

My name is Andrew Mullally and I am a family physician. I am concerned about your upcoming meeting regarding sex based medicine practices in Florida.

Gender affirming care is not evidence based. If anything, there is growing evidence of the short term and long term harms that this treatment strategy confers on patients. As you are likely aware there is a significant increase in suicide and depression in patients even after gender affirming care and a large majority of those with this treatment regret their transition as they age. Gender dysphoria is showing itself to largely be a self limited condition for most patients. Additionally, it is well documented that this diagnosis is very regional and not consistent in a population. For these reasons and others, many of the European countries that pioneered this treatment strategy are moving away from gender affirming models -- it is bad medicine.

Please do not move to advance the gender affirming care model in Florida.

Thank you,

Andrew Mullally, MD

Please, listen to empiricism and reason in your decision making process. Do not support or allow children to medically transition. It is harmful to them on every level possible and contrary to simple reason. If you can't arbitrarily identify as a 21 year old at age 14 or african american despite no such lineage then how is identifying as the opposite sex any different?

Thank you,

Javier Ocariz

To: Paul.Vazquez@flhealth.gov
Subject: Youth transition and the informed consent process

TO: Paul Vazquez

There have been very rapid developments in Florida that are worrisome to me as a pediatrician . As you are aware, your Florida Board of Medicine will be meeting very soon to consider implementing regulations related to sex based medicine practices in Florida. The Board is specifically concerned about “youth transition” and the “informed consent process”.

It is my understanding, I those who support so-called “gender-affirming care,” including rapid gender transition for children and adolescents, have inundated the Board of Medicine with their comments. As medical professionals (CMA), we feel compelled to make sure you are aware the medical and evidence-based studies of these methods do not support such claims. Rather, the short and long term harm of these interventions is clear.

I am a Cuban American. My father was a pediatrician in Camaguey. I went to schools in Miami for over 3 yrs before moving to West Virginia. I even swam in the Florida Jr Olympics qualifying meet. I practiced general pediatrics for 37 yrs prior to retirement.

I strongly believe children are incapable of making life long decisions till mid twenties. Much medical evidence proves this. Please allow children to be children. Don't allow the approval of politically driven, unethical, child experimentation procedures or drug treatments with lifetime consequences.

Sadly, if allowed, we'll live to regret it, and many children will have to live with the horrible consequences, physical and emotional.

To whom it may concern:

The field of transgenderism is very new and so there is much that is unknown regarding its foundational ideology. Especially unknown are the psychological and corporal effects of the so called "therapies" because there is little data. Therefore great care must be taken when applying these therapies to minors and young adults because they are the most likely to not fully understand the consequences of the chemical and surgical interventions involved in "transitioning". It is almost certain they do not realize that the effects of many of these interventions are permanent and will irrevocably alter their lives. I believe that is why we are now seeing young individuals who have gone through all or part of this "transitioning" now regret what they did and are desperately trying to reverse the effects. I earnestly ask you to be very slow and deliberate in your study of this issue and not to rush any decisions. I ask you to make a thorough study of the results of those youth who have participated both in the U.S. and abroad to see how they have fared especially those who are speaking out in regret. Please do not affirm any "rapid transition" plans until you have completed your study. The very lives of our children are at stake.

Sincerely,

David P. Martinez M.D.

Good afternoon,

In preparation for the upcoming Florida Board of Medicine meeting, I hope the members will consider the experience from other countries. Other countries have many years of (not good) experience with gender transitions. A few scholarly articles include:

1. Bränström R, Pachankis JE. Reduction in Mental Health Treatment Utilization Among Transgender Individuals After Gender-Affirming Surgeries: A Total Population Study. *Am J Psychiatry*. 2020 Aug 1;177(8):727-734. doi: 10.1176/appi.ajp.2019.19010080. Epub 2019 Oct 4. Erratum in: *Am J Psychiatry*. 2020 Aug 1;177(8):734. PMID: 31581798.
2. Dhejne C, Lichtenstein P, Boman M, Johansson AL, Långström N, Landén M. Long-term follow-up of transsexual persons undergoing sex reassignment surgery: cohort study in Sweden. *PLoS One*. 2011 Feb 22;6(2):e16885. doi: 10.1371/journal.pone.0016885. PMID: 21364939; PMCID: PMC3043071.

I hope the Board is committed to providing truly evidenced based and holistic care for all patients.

Kind regards,
Dr Thomas Nienaber

Dear Members of the Florida Medical Board,

I am the Director of Pediatric Gastroenterology at University of California Davis, a retired Army Colonel and have 31+ years of experience caring for children and in the training of young physicians. I am writing to you to express my VERY great concern and disgust that any healthcare professional who truly cares for the mental and physical health of children AND who has experienced the confusion of their own adolescents, would remotely consider in his/her right mind that it is a loving or noble act to engage in and promote so called "Gender" affirming medical and surgical treatments for children.

The only rationale for such therapies that hold some supposed weight is the supposition, based on sloppy research, that such therapies would in some way decrease the known high rate of suicide among gender dysphoric adults. Not only is this demonstrably untrue (as recognized by our European colleagues who have all but squashed these misguided efforts, among others), it is obvious to anyone with a grain of common sense that those engaged in providing such "therapies" are permanently and egregiously harming the individuals seduced by the lie that is being promoted by "gender affirming physicians".

As a pediatric gastroenterologist a large part of my clientele are otherwise healthy adolescents with abdominal pain caused by their Irritable Bowel Syndrome complicated by the excessive anxiety they endure in the midst of a world that is full of contradictions. A subgroup of these adolescents are the gender dysphoric kids who are engaged in various gender affirming therapies. These therapies NEVER lead to well balanced emotionally healthy situations. Rather, all these kids seem to spiral into a never ending life of anxiety and depression.

Any ethical leader with any sense will put very vigorous restrictions to such therapies in children.

Good Luck,

Arthur J. De Lorimier, MD, COL (US Army retired)
Clinical Professor of Pediatrics
Director Pediatric Gastroenterology UC Davis

To whom it may concern, and colleagues,

As a licensee of the State of Florida, and a conscientious physician and surgeon, I am writing to express my concerns over enacting laws in FL that would facilitate rapid care for gender affirming care and surgery, especially amongst our young. Medical literature does not support this type of care for children and adolescents, and the push to do this is strictly based on emotion and politics. I would ask that you protect our developing and vulnerable young people and allow this type of care for adults who have affirmed these decisions after extensive counselling. Many patients change their minds on these unalterable treatments, and are done irreparable harm by it, even after care consideration, much less facilitated and rapid care.

My best,

Brian Burkey MD

September 19, 2022

To: Florida Board of Medicine

My daughter's story has been shared around the world, including at The Heritage foundation, as well as The House of Lords in England. The fact that I love my daughter is part of the Congressional record. I was part of high-level meetings in Washington, D.C., to no avail. I provided my daughter's medical records of her mastectomy and hysterectomy to Dr. Joseph Ladapo, to whom I am forever grateful. Please note that both surgeries were done on an outpatient basis, after which she was discharged to homelessness. My daughter was first indoctrinated into the gender cult in school, starting at age 13, unbeknownst to me. At age 14, she announced her new male identity, with names that changed over time. She was only 16 when a pediatric endocrinologist in Arizona skirted the law and taught her how to inject herself with testosterone. I grieved when I realized I would never hear my sweet daughter's voice again, which was only the beginning of the trail of utter terror. My daughter was only 17 when diabolical, unethical surgeons wielded shiny scalpels to slice off her breasts and remove her entire reproductive system. She was just 19 when doctors performed a radial forearm phalloplasty, despite my desperate attempts to stop it. For years now, I have been fighting against a well-funded army of Goliaths, with my only weapon being nothing more than a slingshot of love. Will you have the courage to fight the army of Goliaths too? I cannot change anything that happened to my precious daughter, my only child. Yet I will tell her story a thousand times over if it prevents even one child from falling victim of the sacrifice to the gods of gender identity.

I beg of you to be on the right side of history on this subject, knowing that one day, humans will look back in horror at the medical atrocities committed against children who needed help, just as we now look in horror at past medical practices of treating the mentally ill and developmentally disabled with torturous methods. As I have done before, I speak for thousands of desperate parents. Our children are being led down an unnecessary pathway of medical dependence, of which there is little chance of turning back. Beyond the wrong sex hormones, beyond the disfiguring surgeries, our children are further poisoned with multiple drugs to counteract the ill effects of the unnecessary medicine and medical procedures assigned to them at "re-birth." My daughter does not have a dead name. She can never be my son. She lives in a world of delusion, pain, poverty, and unhappiness. She was once a beacon of light but now lives in dark despair. My only reprieve is sleep and the rare dream of my daughter as the sweet child she once was. I desperately needed help with my daughter; instead, doctors sterilized and mutilated her.

Thank you, in advance, for your wisdom in decision-making on this matter.

Kind regards,

Amy Atterberry

To the Florida Board of Medicine:

I strongly urge you to not endorse so-called "gender affirming care".
The medical and evidence-based studies do not support making these life altering changes.
Please restrict these misguided interventions, and protect the youth of your state

Sincerely,

Andrew P. Brayer, M.D.

My name is Abel Garcia, I was born in 1997 to a Mexican family who came to the US illegally. Due to my parents being in the US illegally I was raised by my grandparents because my parents were working non-stop so they could support me. Growing up I was a very shy, quiet, and timid boy, I was and still am an overthinker. With my father working non-stop, I did not have a male role model in my life growing up. As a kid, I did not feel comfortable as a boy because I was not the most masculine boy growing up, that plus my mind that over thinks, I believed that I must have been a girl since I was not the most typical boy growing up.

Even though I had issues with what it meant to be a boy or a man while confusing my different nature as a girl/woman, I did not know what the word "transgender" was until I was much older and found the word through YouTube. Not knowing much and assuming that was what I was, especially with my childhood, I believed I was transgender. But because I was a minor I did not move forward on those thoughts, and I just put them in the back of my mind. It was not until after I left high school that I decided to transition from male to female.

I came out as transgender to my friends who were all supportive of my decision, I then came out to my mother a few months later in December of 2015. My mother broke down crying when I came out to her as transgender, she then asked me many questions mostly regarding what if I made a mistake or what if I realized I wasn't transgender, I informed my mother then that I knew this is what I wanted and that I could not be wrong regarding this. A few months later I went to see a therapist regarding my identity as a transgender woman at my local LGBT center, I received a female therapist. This Therapist did not know how to handle transgender patients so, after three sessions with her, she then transferred me to her supervisor who had more experience with transgender patients.

The next therapist that I spoke with, immediately affirmed me as a transgender woman and informed me that she had my letter to transition during my first session with her. When I asked her how come I was ready to transition during my first session with her, I was informed that she did not want to gatekeep me from my transition. Even though I wanted to transition then I waited a couple of months before I accepted the letter to transition, I had a part of me tell me that this could be irreversible and due to that possibility, I took a bit longer to start my transition and gave myself a plan regarding surgeries. My original plan was to wait five years before I received top surgery aka breast implants and ten years before I got bottom surgery aka penile inversion/neo-vagina.

Before accepting my letter to start hormones, my father had learned about my plans to transition from male to female. My father being Mexican did not approve of my choice and decided to fix me because at this point in my life I had not been in a relationship with a woman. My father's idea to fix me was for me to have a relationship with a woman, I was taken to Mexicali by my father under the guise that he needed a backup driver to return from Mexico back to the United States. May 2016 was when my father and I went to Mexico under pretense, later in the day after doing everything my father needed to do, we parked in a parking lot in Mexico. My father then left me alone in the car claiming to find a restaurant

and check out their menu, at this moment I had a bad feeling in my gut, but I was unsure of what to do. My father then returned to the car and informed me that he found the restaurant and he found the food to be good. While I walked to the “restaurant” with my father, my gut kept giving me a bad feeling the closer we got to the restaurant that my father found. Eventually, we found the restaurant that he found, but when we finally stopped, we arrived at a black building.

The building was painted black both inside and outside, it even had tinted windows, the windows were so tinted that you could not see anything inside if you were looking from outside the building. Once we went inside this restaurant, my gut feelings were confirmed of something that was not safe for me or somewhere that I should be. Unfortunately, I went along with my father because I was in a country where I did not know nor knew how to stand up for myself. After arriving inside the building, I took a seat down, looking at my phone wondering what the building was because I did not know any restaurant that was built and looked like the one, I was in. After a few minutes of sitting down, I heard my father’s voice telling me to stand up and pick a woman, and that was what I was having. At that moment I realized that I was not at a restaurant but instead at a Brothel.

I looked up and noticed a row of younger women, it was about five to eight women who looked to be in their 20s. While looking at my father confused, he told me to pick one of the ladies, not knowing what to do I picked a random lady from the group. After picking one of them, the rest of the women left, and I started to walk inside alone with the woman I had picked. But before going inside, my father told the woman that I had picked to hold on to as he wanted to speak with her before she left with me, I was told to go on ahead without her. But I ignored what I was told and hid around the corner, and I overheard my father informing the young lady “take care of him, it’s his first time”. After my father and the woman who I was supposed to have intercourse with finished their conversation, the woman walked toward me, and together we walked into a room.

Not long after entering the room with this woman, I do not recall the entire event. Not because I was drugged or anything, but because I have chosen to repress those memories as they did traumatize me. I do recall a few parts of the event, I recall after entering the room, she informed me that I needed to undress and that she was going to give me a massage. I believed her and did as they instructed, after laying down on a table, she returned completely nude and started to give me a massage. Eventually, we went from the massage table to the bed, I do not recall exactly what happened, but I am aware that I could not perform with her, and eventually, our time ended. But before we left the room and went back to my father, I asked her to lie to my father that we had a great time and that it went very well. While I did not enjoy the incident, the woman covered for me and lied to my father about what we did inside and that I did great for the first time. Once my father and I went back to our car, I finally realized what my father did to me and what I went through. I was utterly disgusted by the event, but when I looked at my father knowing that he was lied to, he believed what he was told. I acted like I enjoyed the event at the brothel and with the woman. I then noticed that my father was proud of me, and he probably suspected that I no longer wished to be a transgender woman after this incident.

I did not know it at the time, but this incident that I was involved in was the point in my life when I decided that I did want to become a transgender woman as I was dealing with trauma. The trauma was caused by my father who believed that was doing something right in his life but instead it backfired unknowingly which caused me to down a path of self-destruction. I eventually spoke with my therapist informing her of the incident in Mexico, but because she was a gender-affirming therapist who worked with transgender patients, she did not attribute my accepting the hormones to the recent trauma that I had just experienced and continued to affirm me as a transgender woman.

At this point, I continued to see my therapist for five more months before I finally moved out of my parent's house and a month later, I started hormones. But before I could start hormones, I needed to see my doctor and get cleared before I started. When I arrived at the doctor's office, I was informed that I could become a woman, I just needed hormones and surgeries, I sadly believed the lies that I was told. Especially because my doctor had brought in a transgender activist to inform me that I was not just a feminine man, but I was a transgender woman with the proportions of my body.

Once I started hormones, I was happy that I was finally able to be my true authentic self, I was affirmed by everyone who knew that I was transgender. A few months later I got my name and sex marker changed on all my documents and recognized as a woman legally. A year after I started hormones, I got my letter to get both top and bottom surgery approved, during that session I had only requested top surgery, but I did not want to get bottom surgery yet. I did not know it at the time, but I was given both letters of approval, I only found out when I got a letter from my insurance company saying that I am good to meet up with my surgeons for both top and bottom surgery. I ignored the letter for the bottom, but I choose to accept the letter for the top surgery.

In May 2018, I went into surgery, and I got top surgery completed, I was very happy with the results of my surgery but looking back it was because I was on heavy painkillers, and I had a couple of events to attend for friends and family. Three months after I got surgery, I got a wake-up call from reality, I realized that I made a mistake and that this was not for me. After realizing my mistake and waking up from the lies, I realized how much I had damaged my body, I had to then accept that I would always be a man even if I continued to go down this path of self-destruction. I then had to look at my body, that I was just a man, but I was a man who was in the process of being mutilated to appear as a woman, now as a decoy/caricature of what I believed a woman looked like.

When I reached out for help from the therapist who signed off on my transition, I was met with pushback when I brought up the idea of detransitioning back from a trans woman to a man as I was born. My therapist informed me that my current thoughts of detransitioning were caused by childhood trauma and due to the excitement that I was feeling since I recently had breast implants. At this moment I knew that I would receive affirmative care instead of the proper help I needed. After being

failed by my therapist I looked for a new one through my medical clinic. I was provided a new therapist, unknowingly this therapist was as worse as the last one maybe even worse.

At this point, I knew that I could not detransition without giving a good enough reason to a therapist. This was late 2018, early 2019 when I decided that probably joining the military was a good reason to have a therapist sign off on my detransition because at the time you could not enlist in the military if you were trans unless you detransitioned or finished your transition. I choose to use the military as an excuse to detransition, and I had been talking to a recruiter to enlist but also to detransition. My new therapist did not like that I was willing to throw away my progress regarding my transition because of the military and instead told me to look at other avenues that did not require me to detransition. He informed me that I should not be too cavalier regarding my detransition as it could have irreversible damage to my body and be dangerous. Early into seeing this therapist, I had known he also would have not allowed me to detransition, so while still seeing him I looked for another therapist but instead of finding one, I found a detransitioner by the name of Walt Heyer.

Mr. Heyer is a detransitioner in his 80s but when I reached out to him, I told him that I had nowhere to look for help and I felt hopeless. After telling Heyer my story and where I lived, he informed me that he had a friend and therapist in my area who could help me fix my life. A few months later I was finally able to see Walt's friend my final therapist and the one who was able to help me transition. During the first session I had with this therapist, he informed me that because we were in California, everything we were talking about and doing, was of my own free choice and not of his doing, because if the state were to find out they would accuse him of conversion therapy and strip him of his license.

A few months later we found out how we could start the process so I could transition back to being a man. The process required me to find two medical professionals to sign off on my detransition, submit it to my health insurance and then find a surgeon who would perform the surgery on me to remove my implants. Finding two medical professionals was a bit challenging even though we only needed one as my therapist was the first one to sign off on it but finding a second medical professional was a bit tougher than we thought because it was during the covid 19 pandemic, and no professional was willing to accept a new patient and possibly risk their career with the state going after them due to conversion therapy. Months passed and I was eventually able to find a second medical professional to sign off on my detransition, but this was after pinpointing who was covered by my insurance and explaining my story to the medical professional and his staff until I was given an appointment. Once we secured both letters for my detransition, next we had to submit them to my insurance company which was easier said than done.

Once we submitted the documents to my insurance company, we waited. Eventually, we got a response regarding my detransition, unfortunately, it was a letter of denial, but fortunately, I was able to apply for an appeal to their decision which would have taken thirty days. A little over thirty days I got an update,

which was an approval to have my breast removed with the information of the surgeon who would perform the surgery, luckily for me it was the same surgeon who gave me the implants in 2018.

I eventually got my implants removed in December of 2020, at last, I could finally start my detransition, but this was only the start of it. I had to then fight the state of California to allow me to change all my documents back to male, which took a total of 6 months to have everything changed. I then spent the next year and two months wearing a chest binder, which is the same product that young women must wear if they choose to transition from female to male to make their chest appear flat. I had to wear on because I had developed gynecomastia due to hormones, being overweight, and having implants added and removed. Fast forward to February of 2022 I had one final surgery to finalize my detransition, I had my chest reconstructed to be flat and removed all the excess skin that I had developed. Unfortunately, I could not reverse everything done to my chest, I now have a chest with scars reminding me of my past choices.

Looking back to these last seven years, I am a young man in his mid-twenties who has damaged his body for a lie that was given to him. As of today, I do not know all the harmful side effects done to my body, but I can confirm that my genitals have developed atrophied which means that they have shrunk to a size much smaller than they were before I transitioned. Due to the atrophy, I have difficulties relieving myself in the bathroom, and from time to time I will experience pain in my genitals when I attempt to relive myself. I do not know my fertility status as of now, but I do not suspect to be fertile due to being on estrogen for two and a half years while compressing my genitals with tight clothes and the atrophy. I have also spoken with multiple people and informed them of a shaking that has developed on the left side of my body, mostly affecting my shoulder and face that was not present before I took hormones, I've been told it is more than likely MS, Multiple Sclerosis. I also have numbness in my chest due to the multiple surgeries.

Practice Standards for Gender Dysphoria

As a practicing General Surgeon in New York, who is also licensed in Florida, I have many concerns with respect to what will constitute practice standards for gender dysphoria.

To date there have been no long-term studies that have demonstrated either the safety or efficacy of puberty blockers, cross-sex hormones or surgeries for transgender youth. Thus, at best, many of the hormonal and surgical interventions are experimental.

Puberty blockers and hormones are very powerful drugs with significant psychological and physical risks. Puberty blockers, such as Lupron, have been associated with depression, mood disorders, cognitive impairment, stunting of growth, osteoporosis, headaches and seizures. When combined with cross-sex hormones, sterility can result. Other long-term risks are myocardial infarction, stroke, diabetes, blood clots and cancers.

Testosterone, given in the doses required for women to have the same levels as men, can potentially lead to psychiatric disorders such as mania, hypomania, severe depression and psychotic symptoms. Estrogen, given in doses for men to have the same levels as women, can also result in depression and anxiety.

Blocking puberty results in depriving children of a natural and healthy developmental period that is necessary for some to become comfortable with and accept their bodies. Another effect is that they will also fall behind their peers both in physical and brain development.

Sweden officially ended the practice of prescribing puberty blockers and cross-sex hormones to minors in 2021 recognizing that it is experimental. Recently, this year, the British National Health Service shut down and is radically remaking its gender identity clinic for young people due to the emphasis that was put on “affirmation” and lack of mental health support for those presenting to the clinic.

Many of the effects of puberty blockers are irreversible and permanent. All of the effects of surgical interventions are irreversible and permanent. They leave permanent physical scars and deep psychological wounds. They also fail to address the underlying cause of the disorder. Gender dysphoria is the only psychiatric disorder that physicians are attempting to treat with surgery.

Would we ever perform liposuction on an anorexic? Perform amputations or sever the spinal cord on one with body integrity identity disorder? Then why would we ever consider that removing healthy breasts, ovaries, testicles or the uterus or the penis from transgendered youths are rational treatments for gender dysphoria.

Interventions, such as phalloplasty and vaginoplasty, have high complication rates (as high as 32.5%) especially those involving the urinary tract. Some individuals will develop devastating complications such as recto-neovaginal fistula and horrific wound infections. Mastectomies leave large permanent scars. Depression rates after surgery are as high as 62%. Long term rates of suicide ideation and suicide are much higher in those who undergo surgery compared to those who did not. The real-world experience at Johns Hopkins with surgery for gender dysphoria led to shutting down of the program.

Most gender distressed teens are anxious, depressed, traumatized, uncomfortable with their bodies and struggle with their identity. Gender dysphoria is a result of a complex combination of psychosocial factors, dysfunctional familial relationships and adverse childhood events.

Children are incapable of giving informed consent to these types of treatments given their immaturity especially with respect to cognitive ability and brain development.

The best treatment is affirming their biological sex. 80-90% children will desist or grow out of it with counseling and allowing puberty to occur naturally. Treatment for gender dysphoria should focus on better understanding the psychological factors leading to this disorder, and providing the necessary individual, and in some cases familial, psychotherapy and counselling in order to have successful outcomes.

Dear Sir,

I beg you not to push through the implementation and regulations related to sex-based medicines. As a clergy, I have a special concern about the "youth transition" and the "informed consent process. God created us males and females. We cannot alter God creation to change sex of a certain individual by surgery. As Pope Benedict once said, 'this is a manipulation of gender'. Thank you for listening.

In Christ,

Deacon Victor Lopez

The risks of gender transition are substantial. They include blood clots, which can be fatal, cancer, accelerated atherosclerosis, depression, suicide, and infertility. This is neither a safe nor prudent action to do to our minors. Damian E. Birchess M.D.

My child, may not be a “child” by definition of age, She is 21. However, the prefrontal cortex of the brain does not fully develop until age 25. From Wikipedia ... **“This brain region has been implicated in [executive functions](#), such as [planning](#), [decision making](#), [short-term memory](#), personality expression, moderating social behavior and controlling certain aspects of speech and language.[4][5][6] Executive function relates to abilities to differentiate among conflicting thoughts, determine good and bad, better and best, same and different, future consequences of current activities, working toward a defined goal, prediction of outcomes, expectation based on actions, and social "control" (the ability to suppress urges that, if not suppressed, could lead to socially unacceptable outcomes).”**

In October of 2021, Our daughter made the declaration to us that she was going to start taking testosterone and that Planned Parenthood would be the one providing and helping her with all of this. We were shocked and devastated but most of all, confused and deeply concerned.

In 20 years of this child’s life not once has she ever questioned asked shown displayed anything about her gender until following the pandemic and returning to college in Florida.

We tried having conversations with her to ask - what she knew about the side effects of taking extremely high doses of synthetic hormone and why or where did this all of the sudden desire come from These conversations were met with script-like rhetoric of gender narrative/ideology. Nothing, not one thing was based on fact.

This is a bulleted list of what we have encountered since

- our child sought out an LGBTQ therapist from a website of “lgbtq resources “.
- Our child -at 20 years old who had the same therapist for the last EIGHT years, all of a sudden dropped her for this new LGBTQ choice bc she thought she could get an easy and quick letter of recommendation for her planned parenthood hormone appointment.
- It was discovered that this “ child “ had completely LIED to this new therapist on multiple levels presenting false info. Had I, her mother, not happened to call and leave a message stating I had concerns it would have gone in checked
- The child dropped this therapist after the therapist asked her about the truth and refused to write a letter (THIS therapist did the right thing BUT ONLY bc I happen to have found her and left a phone message about our concerns
- The child found NEW “non-binary “ providers in some sort of clinic in st Pete Florida that provides resources for this
- These therapists are NOT doing due diligence and contacting any former medical or mental health professionals involved in these children's lives - there MUST be extreme due diligence when it comes to mental health care and health care when it comes to

these patients who are children - even up to age 25!!!!

- There are numerous advocacy Organizations online where we found that what was going on with our daughter is an alarming trend among this age group! It's an astonishing and HUGE red flag. Research it!
- I am a South Carolina resident and I have currently been down in Sarasota Florida since the beginning of July after my daughter took herself to check into a mental health institution for fear of self-harm. This is the child that wants to take male hormones, that wants to not become a man but in her words "be a female that has male characteristics" because this has been born out of some social media /college / who knows what else influence for this age group, it is so disturbing! She attends a very very small extreme liberal college(has we known this it would not have even been an option and especially because she is using a full Florida prepaid college plan this state is paying for this indoctrination from the school) various people attend the school who are not friends who do not belong in the same social circles do not have any classes together nor the same area of study and these kids are espousing the same exact rhetoric like it has been fed to them from a script which is such a huge red flag.
- Historically if any of us walked into a therapist or psychologist or psychiatrist's office and said to them I want to be a tree or I want to be someone else, we would not receive affirming supportive validation along with help to further that problematic request. How in the hell has it become the case when it comes to children? That they can walk in and say they want to be another sex and there is no due diligence and ethics followed to help this person work through the root cause of why they are feeling this way and how to accept themselves in the dysphoria that they are experiencing.
- This is alarming and dangerous and will Have tremendous consequences that ultimately the systems of the government will be responsible for because who is going to pay for the medical consequences and side effects and detrimental health consequences that come of these things and the mental health care that will be necessary for life ... if you look at the evidence that we DO have (because there is so much evidence that we do not have) we can see thus far that the people who have successfully followed through with these transitions STILL have a suicide rate higher than the dysmorphia before and a suicide rate that is confounded with carrying through with it resulting in deaths
- PLEASE PLEASE STOP these detrimental practices And provide a very strict code of ethics that is consequential with the law if it is breached. Healthcare providers of any kind have a code of ethics and due diligence that they are required to follow by law otherwise there are consequences. This should be no different.
- I implore you - kids' lives are at stake!

Dear Florida Board of Medicine,

I am an obstetrician and gynecologist and am writing to you in support of the cautious approach the board has taken in regards to the care of gender diverse children and adolescents. This is not settled science, and systematic reviews of the evidence have not found that the benefits outweigh the risks of a medicalized approach to affirmative care for gender diverse people. As a physician licensed in the state of Florida, I commend your ongoing consideration in how best to safely care for our vulnerable patients who are gender diverse, especially children and adolescents, by preservation of their functional bodily integrity.

Respectfully,

Angela Thompson MD, MPH, FACOG

BOM.MeetingMaterials@flhealth.gov

Paul A. Vazquez, J.D.
Executive Director
Florida Board of Medicine

Dear Dr. Vazquez:

I am a psychiatrist in Canada, and have been in practice since 1998. I currently practice in Victoria, British Columbia, but attended medical school and completed residency in Toronto, Ontario, where I spent the first five years of my career. In addition to being a psychiatrist, I completed a Master's of Education (in health professional education) in 2003. I have worked since 2004 in Victoria at the USTAT (Urgent Short Term Assessment and Treatment) Clinic and have a private practice with where I provide long term psychotherapy, with a focus on psychodynamic psychotherapy. I have an appointment at the University of British Columbia, as Victoria is a satellite site for the psychiatry residency program. Since 2017, I have held the position of Associate Director of Curriculum for the Department of Psychiatry at UBC.

When I was in residency on my child psychiatry rotation, I was privileged to have conversations with Dr. Susan Bradley about gender dysphoria in children. Together with Dr. Ken Zucker, she ran the gender dysphoria clinic for children and youth at the Hospital for Sick Children. She gifted me a copy of their book on childhood gender dysphoria, published in 1995 (Gender Identity Disorder and Psychosexual Problems in Children and Adolescents). The thoughtful and careful approach described made sense to me regarding the patients I was seeing with gender dysphoria. When I trained at the Clarke Institute of Psychiatry (now part of CAMH – the Centre for Addiction and Mental Health), I was introduced to adults with gender dysphoria. Some had already transitioned, and some were in the beginning stages of seeking transition. With adults, the approach was also slow and careful. Adults had to live in public as their desired gender for at least a year (it may have been 2 years, but I cannot recall the specific details) before cross sex hormones would be considered. I met a number of patients who were refused access to cross sex hormones as their mental health was not deemed stable enough.

During the years I have been working in Victoria I have noticed an exponential increase in the

number of youth and young adults (as an adult psychiatrist, I treat 17 year olds in the ER and 18 and up in the clinic) with gender dysphoria. I have had discussions with many psychiatry colleagues, and they have noticed the same trend. They also shared my concern these youth seemed to be able to quickly access cross sex hormones under the gender affirmation model, and their underlying mental health conditions were rarely taken into consideration by the prescribing physicians.

From our detailed psychiatric assessments, we have come to understand that there are multiple pathways to gender dysphoria, and often it is a symptom of other conditions such as anxiety and depression, and not the cause. Many youth and young adults that we treat are still in the process of separation and individuation, and have not yet developed a stable sense of self. Many think that changing gender will solve their problems. Unfortunately, this is not what we have seen. In fact, changing gender can become the focus of all of their energy, and it can foreclose our efforts to engage them in exploring any of their other issues.

Discussions about the gender affirmation model have taken place in private. Because we were aware that there were strong trans activist lobbying groups, we were worried about what would happen if we spoke up about our concerns. Although we were not prescribing hormones, we felt uncomfortable in our complacency. The slower and more careful “watch and wait” models for gender dysphoria that I had been trained in, that included treating any underlying mental health issues, had been lost.

My interest in the area increased, as family, friends and colleagues began to tell me of their teenagers, with no history of gender dysphoria, suddenly coming out as transgender. This led me to do research. What I found out, particularly about the very poor evidence base for these treatments compelled me to speak up publically. As a result, I began to write letters to editors (LTE's) to various journals (on my own, and with others who shared my concern) when I saw content that I did not think was balanced. For example, earlier this year the British Columbia Medical Journal published 6 articles on the gender affirmation model. I wrote [2 LTE's](#) in response to these articles. I also wrote an LTE to the [Journal of Pediatrics](#) in response to a study that claimed to disprove the existence of Rapid Onset Gender Dysphoria (a term coined by [Dr. Lisa Littman](#), as a result of her research into the phenomenon of the increasing numbers of youth presenting with gender dysphoria.) The final LTE was in response to an article on puberty blocking medication in the [Journal of the American College of Clinical Pharmacy](#).

In addition, I did a grand rounds presentation at Vancouver Island Health Authority on June 7, 2022, titled [Gender Dysphoria: A Changing Landscape](#). I encourage you to watch the rounds as it is a good summary of the research and some of the concerns that I have.

I would like to clearly state that I am very sympathetic to trans people. They deserve careful,

nuanced care that takes into account the entirety of their biopsychosocial presentations. I am concerned that the gender affirmation pays lip service to psychiatric evaluations and psychiatric care. The vast majority of children with gender dysphoria (over 80%), if not socially transitioned, desist during puberty. I think we simply do not know enough about the causes and natural history of ROGD to justify the irreversible treatments that many teenagers are opting for.

To summarize, these are some of my concerns regarding the current gender affirmation model of care for gender dysphoria:

- There is a very poor evidence base for puberty blockers and cross sex hormones, as per 4 systematic reviews, with 4 European countries changing course as a result.
- Brain maturation typically doesn't occur until age 25 or above.
- Children and youth (which may include up to 25) may not have the cognitive and emotional capacity to consent to treatment.
- Puberty blockers and cross sex hormones can have irreversible effects such as infertility, anorgasmia, bone disease, cardiac disease and other as yet unknown consequences of these medications used long term.
- There is a paucity of good research and a lack of research regarding long term outcomes regarding medication, surgery and mental health.
- We know very little about the new group of mostly natal teen girls who are presenting with gender dysphoria. Providing them with therapy first may help them understand their gender dysphoria and make truly informed treatment decisions. Having worked with many youth in therapy, I think it is probable that the desistance rate could be as high as the rate in children if they are not provided medication or surgery. I suspect desistance would occur as they naturally enter another psychological stage in their lives in their early to mid 20's, with a more established sense of identity.
- The numbers of detransitioners is increasing, and this is likely the tip of the ice berg.

In sum, rather than the current affirmation model proposed by WPATH, I would propose a much more slow and cautious approach to the treatment of gender dysphoria in children and youth. This approach should favour psychotherapy, and only involve medication and/or surgery if part of a research protocol or if there are extenuating circumstances.

To: Dr. Paul Vazquez
J.D. Executive Director
Florida Board of Medicine

Dear Dr. Vazquez and all concerned Board Members:

Picture in your mind a happy toddler running towards a hot burning stove, getting ever so closer to severely burning his little hands. Do you let him do it?

Of course not!!!

Unthinkable, right?

Well, every parent writing to you and testifying about their kids' experience with gender confusion, Rapid Onset Gender Dysphoria and "detransitioning" is precisely making you aware of the unthinkable.

The unthinkable, unethical and immoral misleading of vulnerable teens and youth into cult-like behaviors and life-altering, mutilating surgeries that result in irreversible damage and a life of pain, suffering and permanent sterilization.

How is this even happening? How did we as a society get here?

With careful, quiet and well-funded international lobbying. Look it up. As soon as gay marriage was approved, all the millions in funding that were still available to LGBT lobbyists were diverted into lobbying for "trans rights". Still are. From 2015 on there has been a disproportionate rise in "trans" cases, particularly in girls. Here is just one example from *Trans*, a book by Helen Joyce, page 91:

In 1989 the famous Tavistock gender clinic opened in Great Britain. They had two cases that year. TWO. Both boys.

Numbers stayed low for years.

By 2020, there were 2,378 referrals!! Over TWO THOUSAND, almost three quarters of them being girls.

Thank God this clinic was just closed this year, and is now facing multi-million dollar law-suits.

Any search of hospitals or places where they offer gender care here in the U.S. reflects the same disproportionate rise in cases, and the same statistics (in other words, majority of the increase is in girls).

How could adults let this happen? How could anyone in their right-frame-of-mind let that toddler run full-force into that burning stove - or in this case - a young girl or boy go ahead with taking dangerous amounts of drugs, and even perform surgeries?

With methodic and systematic lobbying, gradually changing the contents of Public Libraries, School Libraries and curricula, and lobbying that changed even medical thinking in doctor's offices, clinics and Hospitals.

The hot burning stove is what is referred to as "Gender Affirming Care". Teachers, medical professionals, etc. were led to believe by "gender experts" that if a kid - no matter their age or circumstances - simply *says* they are "trans", it must be accepted as truth, no questions asked, no need to involve the parents who most likely are "trans-phobes" and will make matters worse. Kids usually will have had months of "recognition" from their schools before the parents find out. The old marching orders were: protect the kid by socially affirming immediately and start calling them by their new name and their new pronouns; Don't involve the parents.

This is exactly what happened to us with our 13 year old daughter (now almost 14). We learned the hard way what new research is showing: that in cases of Rapid Onset it is precisely the so-called Gender Affirming Care what makes these kids suicidal. During our daughter's first Hospitalization (April, 2022), the new Guidelines from the US Dept of Health and the Florida Dept of Health came out, recommending AGAINST social and gender affirming practices:

<https://content.govdelivery.com/accounts/FLDOH/bulletins/3143d4c>

She had two more hospitalizations (June and July, 2022) and is technically still under suicide watch. After a long search we have found a great Psychiatrist and Therapist team that is working on undoing the damage. Too soon to tell if her life will be saved, but working on it with all our strength.

The new guidelines have made a HUGE difference for us. During her first hospitalization, the Psychiatrist and team at the hospital said "of course "he" is

suicidal, "he" is trans and needs to take Testosterone immediately so they can start being prepped for surgery!!" Kid you not.

For the other two hospitalizations, as soon as we showed the new guidelines and showed that she had several diagnoses and was being treated for those, their attitude and care changed immediately. They were supportive, understood that we were not "trans-Phobes" and why we were not allowing others to head blind into a burning stove.

So what are we asking of you today?

1. Ensure that practices all over Florida are not blindly socially transitioning anyone without proper counseling and without their parents knowledge (unless abuse is suspected).
2. Help ensure that minors cannot have access on their own to hormone blockers, Testosterone treatments and surgeries. Sure, it might be the law...but it is happening.
3. Publish and distribute guidelines to every medical practice, library and school so that the symptoms of Rapid Onset are widely known. That alone can save lives.

The symptoms/requirements to confirm Rapid Onset Dysphoria in teenage girls are:

- very low self-esteem,
- some trauma in her life that led to self-harm
- other parallel conditions (sensory issues, anxiety, food issues, defiance & anger management issues, high-functioning Autism),
- frequent feeling of being down, difficulty socializing feeling that everyone is better than her, that friends reject her, etc
- having never before manifested any inclinations of dysphoria or same sex attraction
- influence from other teen girls "going trans"
- misled by an inappropriate therapist

ALL of these paired with propaganda online, on social media, and with Gender Affirming Practices, leads these vulnerable girls into thinking they are

transgender.

To be clear, it is our belief that a truly, genuinely trans youth *needs* Gender Affirming Care, starting with the Social Gender Transitions: new name, haircuts, binders, clothes, pronouns, etc. After proper counseling and parent involvement, **Not providing GAF and treatment to a genuine trans case would be inhumane.**

But to blindly impose GAC as the blanket solution for all teens with other disorders is even more inhumane. This no longer needs to be the case.

Thank you for your time, interest and dedication to saving lives.

Elena Torrey, for the Torrey family

To whom it may concern,

Many children are being mutilated without mindful consent through affirmative care gender ideology. Adolescents and younger do not have a developed pre-frontal cortex. Many gender confused/fixated/dysphoric youth present with co-existing mental health issues such as autism, ADHD, and traumas from causes such as bullying and abuse. Most do not have adequate psychological counseling, and in many jurisdictions it is outlawed. I'm almost 50 years of age and never in my life have I witnessed such mass failure of policy. This issue affects every child of every nation that encourages the flourishing of gender ideology. The promotion that a girl can be a boy and vice-versa, is in one word, evil. Gender discontent is a social contagion, just as anorexia was, and is being fed by it's promoters, including WPATH. This organization has members who benefit financially from people changing genders, and they're affiliated with people who promote child castration and claim eunuchs are a valid gender identity. This extension of sado-masochism is who is guiding world nations on treatment for gender dysphoria. Florida has an opportunity to display to the world, what real child care looks like. This issue is beyond sad or ridiculous. This issue in many nations is somehow oddly not even challenged for debate. Why? When all evidence suggests at bare minimum, there should be swift change in sex/gender law, to rule on the side of caution. Studies suggest the vast majority of youth will naturally outgrow gender dysphoria/distress- and verified by thousands of years of human history. A study also showed that suicide rates of post-medical trans patients is over 19 times higher than their peers. The sharp rise in gender dysphoric youth in the last decade is not a natural genetic mutation. It is a social contagion, whose roots, I believe should be criminal. Please do all you can to protect children and give them proper care, to make them feel at peace with their bodies, and free them from the evil that pushes them to defy themselves and gaslights them to believe it's right. It is not right. It is evil and we all have an opportunity to do what we can, for what we believe is right. Thank you for reading my message and considering my thoughts.

Respectfully,

Mark Corkum

As a member of the Catholic Medical Association, I urge and encourage the Florida Board of Medicine to restrict these misguided interventions and to protect the youth from unnecessary lifelong harmful effects of gender affirming transition care/procedures. As a psychiatrist , I have witnessed the deleterious effects not only in their physical but also in their psychological well being. I have seen cases where initially the intentions were that of the relief of perceived sufferings on these individuals who have homosexual issues, after they had gone through sex affirming procedures, they regretted and came to find out that it did not solve their problems and led to even more issues such as severe depression that led to self injurious behaviors and suicide. I hope that serious considerations be upheld as this could be a major impact on healthcare throughout the country especially on our youth , the future of our country.

Mr. Vazquez,

Thank you for the opportunity to comment on the topic of gender affirming care.

I am Chuck Stuart of 1385 Lakewood Lane, Fleming Island Florida. I am a retired Navy Captain of 27 years, most recently serving as the Chief Executive of the Naval Aviation Depot in Jacksonville, Florida, a \$950 million annual operation. Most importantly, however, I am a parent of three daughters, the youngest of which is 17.

It was not too long ago that any form of physical gender-altering surgery on a minor would be considered child abuse. Truly, I am not sure what has changed. It is well-documented that people under the age of 18 are still developing physically, mentally and especially emotionally. They should not be able to make these decisions until much later in life. To think that we are even considering allowing people in this age range to make life-altering decisions on their anatomy without the full consideration, deliberation and protection of their parents is appalling,

At a less-invasive level than surgery is gender-affirming counseling. Just as with physical surgery, psychological treatments on adolescents must have the consent and support of parents. The only exception should be if the parents were found unfit or abusive. There is a system in place for that determination, and that system must be allowed to run its full course before medical practitioners should step in and assume the role of the parents.

In all these situations, the emotional development of the adolescent needs to be a primary driver. Over the course of life, it seems prudent to wait until the adolescent has developed into a full adult before making these kinds of life-altering decisions.

Again, thank you for the opportunity to comment. I pray that you make decisions consistent with the values I have raised in this letter.

Respectfully,

Chuck Stuart

Dear Mr. Vazquez,

I am a licensed Florida physician practicing internal medicine and geriatrics for over 30 years. During the last 8 years, I have cared for patients that have been hospitalized for complications after transgender surgery or are in the process of pursuing gender surgery for gender dysphoria.

In some cases, there are life threatening complications I have treated working as a Hospitalist.

Surgeons that have performed these operations are often from other states. Florida surgeons I've consulted are not anxious in helping to correct surgical complications that have occurred.

It is disturbing and against my Hippocratic oath for me when I engage in the initial and ongoing treatment required to achieve gender reversal and maintain gender change .

I have read much of the available research done by others and I'm convinced that hormonal manipulation and transgender surgery has not demonstrated long term clinical benefit for most of those undergoing these treatments.

It is also known that many who undergo the surgery (1/3) especially male to female often will seek reversal of their surgery or hormonal manipulation after not achieving the expected benefits.

John Hopkins Hospital surgeons had a department and performed this surgery in the past but discontinued doing transgender surgery in the 1980's.

There may be some there who continue doing these operations, I do not know.

Evaluating patients in the Medical clinic requesting treatment for gender dysphoria or hormonal manipulation renewal in their early 20's in the medical clinic is also morally troubling for me.

I believe my right of conscience as a physician is violated asking me to engage in prescribing or renewing hormones for those patients.

I generally defer the treatment of these patients to qualified Endocrinologists who have extensive experience in management of gender dysphoria.

This referral is problematic in itself due to the small number of specialists in West Florida who do this, insurance issues, or months of waiting for these patients to establish care.

I urge all engaged in developing medical legislation to pursue extreme caution in the development of any laws or transgender treatment recommendations. that would encourage or require Florida physicians to participate in this transgender surgery or hormonal treatment for gender dysphoria.

Sincerely,

Dr. Robert E. Ebert, III

Dear Florida Board of Medicine,

As a family medicine doctor practicing in Tampa, I write to you to encourage you to restrict gender-affirmation procedures in our state in order to protect our youth from unnecessary and lifelong harm. Scientific evidence suggests that sex reassignment does not appropriately address the psychosocial challenges faced by people who identify as transgender. Even when the procedures are technically and cosmetically successful, these patients still face poor outcomes.

The Guardian summarized the results of a review of more than 100 follow-up studies of post-operative transsexuals by Birmingham University's Aggressive Research Intelligence Facility:

"[The Aggressive Research Intelligence Facility], which conducts reviews of health care treatments for the [National Health Service], concludes that none of the studies provides conclusive evidence that gender reassignment is beneficial for patients. It found that most research was poorly designed, which skewed the results in favor of physically changing sex. There was no evaluation of whether other treatments, such as long-term counseling, might help transsexuals, or whether their gender confusion might lessen over time.

We have a serious need to restrict these procedures in our state. Our young patients going through their teenage years may at times question their gender identity, and in many cases, this is short-lived and may in part be due to hormonal changes and psychosocial stressors. Gender-altering procedures do not address these concerns and may in fact be harmful in the long-term, as many of these procedures are irreversible. I trust that you have the best interests of our youngest patients and will restrict these procedures in this patient population.

My name is Dr. Franklin Smith, I am a physician of 35 years. I am offering my strong opposition to the Florida Board of Medicine's consideration of implementing regulations related to sex based medicine.

This subject is controversial and sensitive, as it deals with one's personal identity, but we need the ability to speak and listen to each other calmly.

First, we must insist that, no matter what state they find themselves, every individual deserves dignity and respect as a human person. We must always address and prevent bullying and other discriminatory behaviors.

Gender affirming therapy is based on a theory that even though over 99% of humans are born with functioning sexual organs, that *perfectly match* the genes expressed within every single cell of their body – *either male **or** female* – biology may have got it wrong. Medical and surgical treatment is then based on a state of mind: to what gender do you identify?

Unfortunately when this "gender identity" doesn't correspond with biological sex, the new approach proposed is to initiate lifelong medical treatment and surgery rather than psychological care alone. This is **supposedly** accepted by the entire medical community.

But actually, doctors around the world are asking themselves, Is this good medical care, that in this ***one and only condition***, we ask the patient "what is your diagnosis?" and then with chemicals and surgeries eliminate their reproductive ability, change their bodies and expose them to lifelong treatments and complications? Doctors interpret studies and hang so much weight on the **hope** that "gender affirming care" might lower rates of suicide, (even though these studies have small numbers and are considered flawed by some).

In Europe, the major transgender clinics are being closed or put under strict experimental restrictions. But here in the US, medical societies continue to push an ideology, rather than look at things objectively.

There is no doubt in my mind that future generations will observe the damage to children and adults and will judge this approach as harmful and regrettable. I recommend the state medical board should not engage promoting harmful medicine to treat psychological distress. Thank you.

Dear Mr. Vazquez & Respectfully Members of the Board

I am the mother of a child that has grown into an adult with gender dysphoria. One thing that you must remember and keep in the forefront is there are no mature adults with gender dysphoria, there are only vulnerable people. Gender Dysphoria started with my daughter around age 15, I was told to use "watchful Waiting" I was told she would get past it on her own. Wachful waiting is impossible in a world where young adults are bombarded with thousands of images telling females how inadequate they are and online tests that will tell you in 5 questions or less that you are transgender. I battled for years trying to get a non affirmative objective therapist - I literally circled the globe and faced wait lists that were years and years long.

At 18 she received approval for breast removal and testosterone in a 30 minute session with a Social Worker. I was able to convince her to delay. My time ran out quickly as she gathered supporters, my sister and her father. Also the support of online "friends" online people who she never met in person. At 21 she managed to convince her Aunt to help pay for her private mastectomy. Her family doctors refused surgical fitness without a complete psychiatric assessment. The private clinic advised her to go to a walk-in clinic- who approved her for a voluntary breast amputation in less than 15 minutes - no psychiatric evaluation needed. The private surgeon was provided a diagnostic letter that showed she had 5 mental disorders, one of which was Gender Dysphoria, adolescent onset. He ignored it and performed the amputation. All those who cheerleaded this surgery were too busy to attend. Me who was against it, was left to reluctantly go. I sat in a parking garage while my daughter's organs were tossed in a garbage can.

You might think at this point that this young adult must be really unstable, troubled and an under performer. At this stage she had graduated from College - Deans and President list - a former National medal winner in baseball - a former Female athlete of the year - she had a bright future.

You need to understand young people with mental disorders can be high functioning. Where is she now - She is on antipsychotic medication for acute psychosis and just came home after a

30 day involuntary stay at a Psychiatric ward - Homeless , jobless, little friends, in massive debt and trying to recover from Mania. Mom picking up the pieces again - leaving my job and cashing out my retirement to survive. This is a set pattern with Kids with GD, she is one many with the same trajectory and outcomes. It's almost at a predictable level.

Why did this happen - because she was sold a bill of goods that amputation would solve her Gender Dysphoria, putting her in an even more fragile state - one of 40% who suffer increased mental disorder after a double mastectomy -

Florida nor anywhere else has the magnitude and level of quality mental health care needed - to take care of these minors who get to legal age to make their own decisions. It is not possible to have informed consent, not possible to agree to anything that has such poor outcomes, not possible to have informed consent when you have Gender Dysphoria, and physicians are telling you, you can be a man instead of a woman. It is a factual lie. It is a disorder that testosterone, estrogen and surgeries can not solve and only psychotherapy can.

You need to ask yourself how Florida will prepare to take the onslaught of mental health cases that will appear in the next few years - who are the failed promises of risks they can not understand or conceive "that it will happen to them". You need to think how your economy will suffer, you need to figure out how you will take care of babies who do not have breast milk and are allergic to formula - you have a lot to figure out.

I have summed up my story due to time- I would be happy to discuss my story should you desire.

Sincerely
Lesley. MacNeil
Nova Scotia Canada

Dear Mr. Vasquez and Florida Board of Medicine:

Although I am not a medical professional, I am a mother and a grandmother. Little children are highly impressionable, suggestable and exploitable, not all-knowing gurus who possess the knowledge one would need to proceed with amputating or mutilating healthy organs of the body. Even a highly experienced surgeon considers every alternative therapy before resorting to amputation, even of a diseased body part.

Claims are made that treatment with puberty blockers and cross sex hormones are fully reversible so there is no harm to children. But are these claims exaggerated or outright deceptive? Aren't the possible consequences of infertility and loss of sexual function and satisfaction for a lifetime too weighty to lay on the shoulders of a child? For physicians to advise parents let the child do whatever he or she wants, without a heavy dose of caution and informed consent, seems to this Florida citizen like malpractice. Please protect Florida children and parents from this madness which has so suddenly infected our society.

A tidal wave of regret and malpractice lawsuits are already on the way. As you are probably aware, Europe's cutting edge Tavistock gender clinic has been shutdown. <https://www.dailymail.co.uk/news/article-11101661/Tavistock-transgender-clinic-facing-mass-legal-action-1-000-families.html>

There are a thousand good reasons to proceed with caution and require respect for the healthy development of children's bodies. Threats of suicide by children suffering from gender dysphoria certainly must be compassionately addressed. At the same time, the reckless promotion of fashionable gender ideologies, even in our public schools (possibly in pediatric well-child visits!), should also be strongly discouraged for the danger it presents for social contagion.

Please do not abdicate your professional responsibility to evidence-based medicine for fear of a woke lynch mob. That would be cowardly and committing a malpractice sin of omission.

Remember, "First, do no harm."

Wishing you all the best as you deliberate on this important matter.

Irene Doyle Sandler
Orlando, Florida 32812

PS One more thing...the term "gender affirming" therapy only makes sense if it refers helping children feel more connected to and appreciative of the healthy body they have. "Gender defeating" therapy is a more accurate descriptor of medical and surgical interventions against normal puberty.

Hello Dr. Vasquez,

My name is Matt Peck, I practice emergency medicine in Ohio, and I am emailing with regards the current debate ongoing gender affirming care, especially with regards children.

I have seen in my practice severe anxiety, depression, and suicidality in patients who are status post gender affirming interventions, and I find the evidence supporting these interventions to be rather limited. Until such data (particularly long-term data) is available it is almost certainly best to limit such interventions to highly selected populations and to avoid them entirely in children.

I appreciate your willingness to take the time to read this,

To whom it may concern:

Please stop rapid gender transition among children and adolescents. At such a tender age, executive function capacity is very much immature and as a result, their decision-making may not be carefully thought-out. We are well aware of the statistics among teens regarding reckless driving, teen pregnancies, illicit drug use. Why would we let our youth provide informed consent revolving such a life-altering decision without having a full perception of possible consequences, of irreparable damage as they get older?

If full-grown adults make mistakes, how much more among children and adolescents? This “gender-affirming care” abuses the innocence of our children and adolescents. This is child abuse. Please stop!

Pseudonym: Sal A. Mander
Date: September 2022

I had always been gender atypical compared to my male peers. I was feminine in my mannerisms, and I was always drawn to toys marketed for girls. My first memory of confusing myself for a girl was when I was in kindergarten, when I went onto the girls line and a teacher corrected me by placing me back on the boys line. I first came to believe I was trans 17 years ago when, at the age of 14, I came to learn of the concept of being “born into the wrong body.” To my adolescent, under developed mind, it made sense. To me, it explained why I felt so different from my male peers.

Soon after coming out a year later, I received what I now view as inadequate and misguided healthcare by a doctor who immediately affirmed my trans identity and created a plan for me to get onto hormones and transition. The therapists I worked with also affirmed my identity and failed to implement a developmentally informed psychological and exploratory approach that took into account environmental factors and trauma history. For twelve years, including all of my twenties, I lived my life as a stealth transwoman, believing that I had been born into the wrong body and had done what needed to be done to be who I truly was. I put the trans thing behind me. I didn’t immerse myself in trans communities, I developed a robust social life, a successful professional life, I passed seamlessly and I never experienced transphobia. My transition had been a success. All the while, though, my physical and mental health was deteriorating.

For years I struggled to find a solution, seeking counsel from various allopathic doctors, psychiatrists, and naturopathic physicians. I’d spent hundreds of dollars on specialized blood tests to try and find the root cause of my suffering, as well as herbal treatments, massage, yoga, breathwork in an attempt to manage it. A year ago, in desperation, I began to supplement a small dose of testosterone. Doing so was the one thing I tried that finally restored my declining health, inspiring research into what happens to a male body that is deprived of its natal hormone...long story short: its not good. When it became clear that my “gender affirming” treatments had been making me sick, I embarked on a deep personal inquiry.

How’d I get here?

I guided myself through an investigation of my youth that therapists ought to have supported me in as a young person. I brought curiosity to why I had become so convinced at 14 that I had been born into the wrong body. I began to understand it all as a trauma-induced delusion that doctors

and therapists colluded with, that then got encased in a lot of physical, social, and legal pressure following transitioning. Growing up in a homophobic environment, a younger version of me did everything he could to shield himself and, as a result, I fell asleep to a huge part of who I was. I had been gay. That is why I felt so different from my peers. Not that I had been born into the wrong body.

At the time, the reasons behind my trans identification was unconscious, of course, and it's incredible to see how creative the human mind will become in its self-protection. Throughout the history of human psychology, we have established that there is so much that happens unconsciously. And yet, WPATH doesn't mention the unconscious mind at all. Nor are therapists allowed these days to engage in explorative, non-affirmative approaches that allow for curiosity and potential discovery of unconscious motivations driving the desire to transition. But that, in retrospect, is what I needed.

Instead, I lost myself for over a decade and garnered serious health issues that I'll have for life. Despite my transition being successful in the sense that I passed, had a robust social life, and was professionally successful, transitioning did not address the root emotional issues that I was struggling with. When we don't address the root cause of emotional distress, but rather address it with superficial band aids, eventually things will become dysfunctional. And they did. I came to a breaking point where I could not go on any further and needed to detransition.

Now that I have detransitioned, I feel healthier, stronger, and more emotionally grounded and centered than I ever have. Detransitioning helped me to begin addressing the root cause of my emotional pain and accept myself as a gay male. But now I have breasts that need to be surgically removed (which I have to pay 12k for out of pocket), a chronic endocrine disorder that requires me to inject myself weekly with testosterone because I no longer have testicles, severe urinary incontinence, and the inability to have normal sex with ease. I also have tremendous grief and a sense of loss for my body being altered in ways that are irreversible, and the life that I could have lived as a gay man all throughout my twenties.

My experience has taught me that no child can consent to these interventions, and that the earlier you start them, the higher the chance of someone's healing and acceptance of themselves being delayed, resulting in loss of years on the wrong path and physical and psychological harm.

September 19, 2022

Paul A. Vazquez, J.D.
Executive Director Florida Board of Medicine

Dear Dr. Vazquez,

Where do I begin? I am the aunt of a young man who is receiving gender-affirming care and the mother to an adult on the Autism Spectrum. Please kindly allow me, in this email, to describe my observations and thoughts on gender-affirming care as well as the social-influential component that is affecting kids/adults on the Autism Spectrum.

Let me begin with the gender-affirming care. My nephew, a bright-handsome-young man, went off to a university, away from home, and within a few weeks of being there called my sister and brother-in-law to tell them that he was a "woman."

To summarize, he explained that while in the university he met a young man that was having a lot of anxiety and could not figure out what was wrong with him. My nephew, a caring young man, decided to help him by researching the source of this anxiety. Along with his new friend and the help of Google, they discovered that his friend must be transgender, and his friend went on his quest to receive gender-affirming care. My nephew, enthralled with his research to help his friend and now alone in a university, away from home, soon discovered that he too was feeling odd and not sure of himself.

After further research, he concluded that he too must be a transgender and after "trying out" the different pronouns, he landed on the conclusion that the label that fit him the best was that of a transgender woman. After that realization, he sought out psychological care to help him decipher what he was feeling.

Every psychologist, psychiatrist, and general doctor provided gender-affirming care, immediately, without questioning his feelings/motives or thinking. Not one of them even considered that it could be something else. However, they all agreed that once he began his gender-affirming care, he will feel great. Well guess what? He did not feel great. He began having extreme anxiety. What did they do next? They added anxiety medications to his hormone therapies.

A few months later, he began feeling depressed, guess what happened next? That is correct, they added antidepressant medications. In summary, what started out as an "odd feeling about himself/insecurities" turned into gender affirming care, anxiety, and antidepressant medications. Did the odd feelings go away? No, in fact he feels worse than ever, and he has been completely brainwashed by the internet and doctors who failed to believe that perhaps he was facing other issues, instead. My nephew and our entire family have been destroyed by this gender-affirming care.

Second point, my daughter who has Autism, is constantly bombarded with ads, tv shows, internet, social groups which push the transgender agenda as the answer to her unique ways of being. Most recently, I have heard say, "I do not like wearing make-up nor dresses." I take a deep breath and believe, like every physician in the medical field should, that she is just going through a phase, and it is no big deal. Unfortunately, after my nephew's experience, my heart skips a beat. I fear for those parents, that being in a similar situation, would take their child to see a psychologist/psychiatrist to only be told that they need gender-affirming care.

In conclusion, gender-affirming care should not be the first answer to a young person's insecurities. The medical field needs to explore, listen, and ask questions instead of allowing these young men/women to dictate a diagnosis based on social norms of the times.

In our experience, the gender-affirming care did not solve the problem, it had the opposite effect. My nephew now suffers from anxiety, depression, and still feels "odd." Please do not allow for another family to go through, what we have gone through. Your medical team has the opportunity to listen to the concerns of multiple families who are suffering, daily, please listen and open your hearts and eyes to what is truly happening.

Thank you for your time and patience. May God guide your resolutions on this matter.

Sincerely,

Silvia Bolivar

Dear Sir, I hope all will remember the axiom “first do no harm” when considering the issue of medical and surgical treatment of gender dysphoria in minors. The experience of adverse outcomes of this treatment in minors in the U.K. and Sweden should be evidence that more needs to be learned before recognizing these treatments as being of value.

Taking this uncertainty into account, we should not leave this decision up to the adolescent lacking the ability to understand long term consequences which even the medical establishment finds unclear at present.

Thank you for your attention to this matter.

To the members of the Florida Board of Medicine,

It has come to my attention that you will be meeting very soon to consider implementing regulations related to sex based medicine practices in Florida, specifically concerning “youth transition” and the “informed consent process.” The medical and evidence-based studies of these methods do not support their claimed benefits. Rather, the short and long term harm of these interventions is clear.

Please restrict these misguided interventions and protect the youth of Florida from unnecessary and lifelong harm.

About: Your deliberations concerning the medical care of trans-identified children and adolescents

Date: September 22 2022

I am the first author of the *Reconsidering Informed Consent for Trans-identified Children, Adolescents, and Young Adults* which was published online on March 17, 2022 and as of today has been downloaded 35, 500 times, making it in the top 5% of all scientific articles downloaded among over 22 million articles. I presume you have had access to this work by E. Abbruzzese and J.M. Mason and me, if not by clicking on this doi the article will appear (DOI: [10.1080/0092623X.2022.2046221](https://doi.org/10.1080/0092623X.2022.2046221) More than I can briefly communicate, the article provides a comprehensive view of the profound ethical and legal problems of putting young people, who have questionable cognitive maturity to make life-altering decisions, on developmental path that includes risks of sterility, sexual dysfunction, unstable interpersonal relationships, shortened life expectancy and a plethora of discriminations.

The fundamental problem is that hormonal and surgical treatment of the young are not based on replicated science. Independent reviews from Sweden, Finland, UK, and McMasters University in Canada have found the existing evidence of very low quality. Instead of following the principles of Evidence-Based Medicine, trans affirmative practitioners have been unknowingly caught up in Eminence-Based Medicine in which professional organizations view the civil rights of individuals to self-define as the guiding principle of care. Consequently, if a person with a diagnosis of Gender Dysphoria desires puberty blockers, cross sex hormones or mastectomies, genital reconstruction, or facial feminization surgery and they are not conspicuously mentally ill, they can efficiently access these treatments. The Principles of Medical Ethics instruct physicians that their therapeutic actions must be based on science. The teaching of clinical care to our profession's young, be they medical students or residents, rest heavily on a chain of trust that high quality science has established the preponderance of benefits to risks for the intervention. In trans health care, the train of trust is untrustworthy; our young are being misled into thinking that the science is settled. This is very far from correct. While a culture war surrounds such care based on differing political and moral values, I assert that for medicine the issue is a scientific one. My view is that science with its various methods of research has thus far has not been seriously considered as the guide to treatment in this complex developmental arena.

All aspects of human identity—including gender identity-- are subject to evolution throughout the life cycle. To think that some medical professionals "know" that their pre-adolescent and adolescent patients' current gender identity is immutable, even when numerous studies have shown that cross-gender identification in these eras of life only predicts an adult homosexual orientation. These doctors still want to make irreversible changes to their patients' bodies because they were taught that this was only viable treatment. In the meantime, Sweden, France, Finland, and the UK have each recommended a policy that psychotherapy is to be the first treatment of this increasingly prevalent problem. It is imperative that state medical boards

weigh in on this contentious matter as there are many indicators that the quality of adult trans lives is generally poor.

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of

WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

18 September 2022

Paul A. Vazquez, J. D., Executive Director
Florida Board of Medicine
BOM.meetingmaterials@flhealth.gov
Paul.Vazquez@flhealth.gov

Dear Mr. Vazquez,

As a former physician I agree completely with the testimony expressed below by two experienced pediatricians from Miami, FL. I ask you to take into consideration their statement and the fact that many other doctors think the same way as we do.

Fr. Juan R. Velez, MD.

Gender dysphoria (GD) in children is diagnosed when children show gender confusion. When GD occurs in the pre-pubertal child, it resolves spontaneously in 80-90% after the children naturally develop through puberty. A high proportion of children with GD have other neuropsychiatric disorders such as autism and anorexia. GD is considered a body integrity disorder and ought to be treated by a mental health specialist.

The treatment recommended for this disorder is affirmation of the confusion exhibited by the child, suppression of puberty with hormones, high dose cross hormones (testosterone for the girls estrogen for the boys) and mutilating surgeries.

Puberty is an essential milestone in the development of the child. Puberty blocking medications like Lupron (most used) cause a disease state. Harms include impaired brain maturation, decreased bone density with risk of later

fractures, sexual dysfunction, and infertility. Are puberty blocking effects reversible? No. Time lost from developing together with peers and reaching important milestones can never be regained.

High dose cross hormones can result in heart disease, hypertension, diabetes, and cancer.

Once a child is given a puberty blocker, the majority go on to mutilating surgeries. Girls as young as 14 have had completely healthy breasts removed. Surgeries for males include dissecting the penis and inverting into a pelvic wound. For girls, removal of skin of the forearm and attachment to the pelvis to simulate a penis.

There are no long-term studies that show that gender changing therapies done to children have any beneficial effects. Suicide risk among trans-identified youth is the same as for other at-risk groups, such as depression, autism, and anorexia. Prevention of suicide ought to be the same as for other youth: talk therapy and FDA approved psychiatric medications. Psychiatrists in the US and Europe agree that there is no evidence that gender transition reduces gender dysphoric children likelihood of killing themselves.

Studies of transgender adults show a high incidence of depression and suicide. In Sweden, a 30 year follow up of sex-reassigned adults showed rates of suicide 20 times greater than the general population.

Acts which are performed by doctors which mutilate, sterilize or otherwise harm children such as blocking puberty, high dose cross sex hormones, and sex organ removal are not healthcare, but are atrocities. *Especially when the children diagnosed with GD resolve their confusion as they grow naturally through puberty and align their perceived gender with their biological sex by late adolescence.* Our children are the victims of this terrible experiment, as confused adults impose their disordered ideology onto the most innocent and vulnerable.

An Open Letter to the Florida Board of Medicine

To Whom it May Concern:

We write to you in response to your planned public meetings on September 30th, 2022, in Tallahassee, FL to discuss proposed rules and regulations regarding the medical care of gender variant youth.

First, we agree that all children deserve the best evidence-based medical treatments. This extends to children who are diverse in their gender expression and those so distressed by their bodies that they are diagnosed with gender dysphoria. Children, like all people, are complex beings with immense value, dignity and worth. As pediatric endocrinologists and pediatric endocrine nurse practitioners, and some of us also clinical scientists involved in pediatric research, we are deeply concerned that the current scientific evidence for “gender-affirming” care, which heavily relies on the off-label use of puberty blockers and cross-sex hormones, is simply lacking. There are limited data from prospective, controlled trials, which are the gold-standard by which we judge any therapeutic intervention. The Endocrine Society issued updated guidelines addressing the care of transgender individuals in 2017 and rated the evidence as mostly low quality and largely expert opinion [1, 2], which is among the lowest level of medical evidence.

Yet, the American Academy of Pediatrics (AAP) have nonetheless issued their own policies [3] that recommend what is described ‘gender affirming therapies’ in early adolescence, which is notably undefined precisely in the AAP policy statement but could be as young as 10-13 years of age. The AAP policy also calls for the use of puberty blockers (GnRH analogues) until 16 years of age [3]. This has led to a rapid proliferation of a myriad of clinics and programs where many of these children are prescribed these therapies on demand with little to no in-depth assessment of the psychological needs of these youngsters. The AAP and others, however, have stifled debate and honest critiques in this critical topic, even though data are lacking on the long-term safety and efficacy of the prescribed treatments, often labeling any honest dissent in gender dysphoria-related treatments as “extremist” (<https://www.aap.org/en/news-room/aap-voices/why-we-stand-up-for-transgender-children-and-teens/>). Sweden, Finland, France and UK are already restricting the use of puberty blockers and cross-sex hormones in children less than 18 years of age, concluding that the science and research regarding optimal treatments for children diagnosed with gender dysphoria is far from settled (<https://www.socialstyrelsen.se/globalassets/sharepoint-dokument/artikelkatalog/kunskapsstod/2022-3-7799.pdf>). We believe this should also be the approach in the U.S. until more robust data are published in the peer-review literature.

We commend the development of the largest longitudinal interventional trial funded by the NIH in 2015 in U.S. transgender youth known as the Trans Youth Care Study (TYC) (R01HD082554). This two-year prospective trial enrolled 497 subjects by 2018, of whom 95 are receiving puberty blockers, 316 subjects are receiving cross-sex hormones and ~86 are receiving no hormones at all. This critically important trial is taking place in four of the largest pediatric gender clinics in the USA (Los Angeles, San Francisco, Chicago, and Boston). While the researchers have published twice regarding their plans to track anthropometric, physiologic, and mental health outcomes in 2019 [4, 5], the actual outcomes data have not yet been published, now four years after these studies were initiated. It is noteworthy, that TYC investigators used as a justification for the study, the significant gaps in knowledge regarding medical therapies in gender dysphoric children [4]. In their 2019 publication, *Impact of Early Medical Treatment for Transgender Youth: Protocol for the Longitudinal, Observational Trans Youth Care Study*, the authors wrote about the 30-year experience of the “Dutch Model,” on which the so called ‘gender affirmative’ model is based, stating the following:

An Open Letter to the Florida Board of Medicine

“Although these guidelines [the Endocrine Society’s] have informed care at academic and community centers across the United States, they are based on extremely limited data. Furthermore, there is minimal available data examining the long-term physiologic and metabolic consequences of gender-affirming hormone treatment in youth. This represents a critical gap in knowledge that has significant implications for clinical practice across the United States.”

They then went on to observe that gender-affirming hormones are now prescribed at younger ages than used in the Dutch Model and concede that “there are only minimal data supporting the earlier use of gender-affirming hormones in transgender adolescents.” [4]. Yet, the AAP asserts hormonal interventions to be “evidence-based” already. This assertion by the AAP is incorrect, resulting in hundreds of clinics in the USA implementing these treatment pathways carte blanche outside of well-regulated and well-designed research protocols.

We have witnessed children being prescribed cross-sex hormones after a single brief visit to clinics, at times by physician and non-physician providers with limited expertise and minimal to no involvement by well-trained psychologists. This is deeply alarming since these are unproven medical interventions with serious potential risks including lifelong medicalization as seen in studies of transgender adults. Among transgender adults, long-term cross-sectional data suggests that for a substantial number, their quality of life remains immensely difficult even after medical transition [6]. Cross-sectional studies in transgender adults in Sweden, for example, have demonstrated persistently high rates of suicide, depression and premature death when compared to the general population. The survival curves in this retrospective Swedish cohort over a 30-year period, did not observe changes in mortality until about 10 years after these “gender affirmative surgeries” [6]. To date, we have no long-term prospective data in gender-diverse children in the literature who have received hormonal therapies in childhood.

To understand the state of evidence, the Florida Department of Health commissioned two researchers from McMaster University where the term “evidence-based medicine” was coined, for a systematic review of available evidence (<https://ahca.myflorida.com/letkidsbekids/>). The review included sixty-one systematic reviews of transgender research, including two studies of puberty blockers, four of cross-sex hormones and eight of surgery, which were of adequate quality and therefore worthy to inform an evidence-based decision-making determination. The review concluded that “this evidence alone is not sufficient to support using or not using these treatments.”

Given the absence of solid scientific data, we recommend the implementation of a judicious pause in hormonal interventions in gender dysphoric youth in the State of Florida in general medical practice. We also support that such interventions should only be ethically permitted in the context of high-quality research protocols approved by an IRB, overseen by a data safety monitoring board and capable of producing quality data prospectively targeting long-term pre-determined outcomes. This recommendation is congruent with the new policy of the National Board of Health and Welfare in Sweden and at the Karolinska Institute in Stockholm (<https://www.socialstyrelsen.se/globalassets/sharepoint-dokument/artikelkatalog/kunskapsstod/2022-3-7799.pdf>), and to the restructuring and new guidelines for gender dysphoria clinics being implemented by Dr. Hilary Cass in the UK, after her systematic review for the National Health Service (<https://cass.independent-review.uk/publications/interim-report/>).

We also support the expansion of competent expert psychological support with rapid implementation of nonjudgmental exploratory psychodynamic therapy in gender-dysphoric youth [7-11].

As we thoughtfully debate the science of these medical treatments, we must be clear that violence in any form cannot be condoned or tolerated whether against those providers treating children with

An Open Letter to the Florida Board of Medicine

gender dysphoria with hormonal treatments, nor against those that, like us, prefer a more conservative approach in children (<https://www.childrenshospitals.org/news/newsroom/2022/08/cha-supports-the-health-and-wellbeing-of-transgender-youth>). Any such threat should be reported immediately to the Florida Department of Law Enforcement (**1-855-FLA-SAFE**).

It is a sad commentary that it has become politically incorrect to raise any issues of concern when dealing with children and adolescents with gender dysphoria and transgender youth and that raising any such concerns gets automatically labeled as transphobic. This has silenced many physicians who thoroughly agree with our expressed concerns but that also fear retaliation.

We believe children and adolescents that are gender dysphoric and that identify themselves as transgender require respect and support in a non-judgmental, non-discriminatory way. We also believe these children can seldom make these overwhelming, life-changing decisions regarding hormone use and surgery, many of them irreversible, at such an early age. We are now seeing young adults that are openly expressing regret, while detransitioning in a variety of ways. These observations highlight the need for holistic examination of the individual gender-dysphoric person and their environment, to better understand their dysphoria in its full context while providing adequate time be given before any irreversible decisions are made.

A group of physicians, psychologists, risk-management experts, ethicists, and lay people on a medical board should be able to assess the evidence, while also advising on a proper standard of care as opposed to legislative and political bodies. These decisions are too critical and important for young children to make as they cannot easily comprehend the long-term ramifications.

Lastly, without adequate oversight and regulation by the Board of Medicine, the financial costs of the current approach could be large. More importantly, we must address the human suffering not alleviated by hormonal therapies or surgeries in these vulnerable youth. We appreciate the Florida Board of Medicine's careful consideration of our concerns.

Sincerely,

Matthew R. Benson, MD

To the Joint/Rules and Legislative Committee Members,

This letter is being written on behalf of the Florida Academy of Dermatology in reference to the agenda for September 30, 2022. Our statement relates to the access to medical care for any patient, including those who are transgender, gay or have gender dysphoria. As physicians, we believe that medical treatment decisions should rest with the patient, their families, and their specialized medical care team. We are neither agreeing nor disagreeing with the treatments in question, but rather expressing our concerns that medical decisions should be made by those best trained and qualified in the conditions in question.

Thank you,

Joely Kaufman MD FAAD for the Florida Academy of Dermatology Board and its medical members

Dear Florida Boards of Medicine and Osteopathic Medicine Joint Rules/Legislative Committee, As a Certified Safety Professional and a PhD in Space Physics, my background is mostly non-medical; however, I work as an expert witness in safety, and I use the Scientific Method all the time. Gender Medicine raised a number of red flags in these fundamental fields. Medicine is not exempt from experimental ethics or safety. What I found is written below in two parts (the next part begins after the References).

Thank you for your time.

Sincerely,

Elizabeth A. Jensen, PhD, PE, CSP
Spring, TX 77373
(832) 279-3619

Medical Safety: Risk Study of Gender Medicine, Part 1

[Elizabeth Jensen](#)

How many Gender Medicine doctors knew or should have known that they were experimenting outside of experimental safeguards and with no intention of collecting results or modifying their hypotheses?

One of the fundamental issues with Gender Medicine is the lack of rigorous research to support how it is being practiced (see references within Expert Report of Dr. James Cantor; Cantor, 2022 Report to Florida). The best research with respect to children is that the treatment approach to Gender Identity issues is “watchful waiting” (e.g. Levine et al., 2022). However, that’s with the classic pre-puberty presentation of gender dysphoria. Research is almost entirely lacking with the new teenage presentation which has not prevented permanent medical treatments to unknown causes (also Levine et al., 2022; Kaltiala-Heino et al., 2018). With respect to adults, the best research is showing that the suicide rate either doesn’t change from 0.03-0.04% BEFORE treatment or increases by a significant factor AFTER treatment* (e.g. Dhejne et al., 2011; Wiepjes et al., 2020). So this article and the next are a 2-part series that begins to look at the questions: **Where are the safety controls to Gender Medicine practices? How does the suicide rate change when Gender Medicine is involved, and why is our information so bad if it is so important politically? (Not to mention medically and ethically important, too.)**

If medicine is a scientific discipline, then the Scientific Method must be applied to medicine. To quote from the Encyclopedia Britannica, “In a typical application of the scientific method, a researcher develops a hypothesis, tests it through various means, and then modifies the hypothesis on the basis of the outcome of the tests and experiments. The modified hypothesis is then retested, further modified, and tested again, until it becomes consistent with observed phenomena and testing outcomes. In this way, hypotheses serve as tools by which scientists gather data. From that data and the many different scientific investigations undertaken to explore hypotheses, scientists are able to develop broad general explanations, or scientific theories.”

To highlight the disconnect between research and practice in the field of Gender Medicine, Levine et al. (2022) discusses the Dutch Experiment (de Vries et al., 2011 and 2014). “The interventions described in the study are currently being applied to adolescents who were not cross-gender identified prior to puberty, who have significant mental health problems, as well as those who have non-binary identities—all of these presentations were explicitly disqualified from the Dutch protocol. Despite these limitations, the Dutch clinical experiment has become the basis for the practice of medical transition of minors worldwide and serves as the basis for the recommendations outlined in the 2017 Endocrine Society guidelines..” To summarize what this statement is saying: **Practice guidelines/standards have been adopted for children who do not have the illness characteristics of the studied population.** If we were to translate this to a safety paradigm, it is saying that the procedures that are being examined for a trench operation are equally valid for a confined space with a toxic atmosphere. Doing that when you know better can get an OSHA Willful Citation: “A willful violation is defined as a violation in which the employer either knowingly failed to comply with a legal requirement (purposeful disregard) or acted with plain indifference to employee safety.”

This point is qualitatively made in other ways. For example Dahlen et al. (2021) states, “Some extracted statements [from WPATH SOC] might have been intended as recommendations or standards, but many were flexible, disconnected from evidence and could not be used by individuals or services to benchmark practice. After discussion of this incoherence within WPATH [World Professional Association for Transgender Health] SOCv7 and our inability therefore to compare recommendations across all CPGs [clinical practice guidelines], it was decided not to revisit inclusions post hoc but to abandon this protocol aim.” This means that the guidelines published by WPATH were “disconnected from evidence” and incoherent, a.k.a. unscientific.

When medical practice deviates from research in this way, it is similar to using PPE (personal protective equipment) in a way that it wasn’t designed to be used. In the case of the American Psychological Association (APA) adopting WPATH guidelines (which include recommendations for children), this is like obtaining the operators manual for your PPE from a 3rd party because the current manual is very poorly written and narrow in scope for the PPE’s *potential* uses. The Endocrine Society’s guidelines while advocating for Gender Medicine at least acknowledge that the “true effect maybe” or “is likely to be substantially different from the estimate” (Balsheem et al., 2011) as summarized by Cantor (2022), “In every category [each Endocrine Society guideline for pediatric Gender Medicine], without exception, the research quality was rated [by the Endocrine Society] as ‘low’ or ‘very low’..” **To take this into a safety paradigm, this is like providing fall protection to a worker in which its effectiveness is unknown.** There are other Endocrine Society guidance that are similarly ranked this poorly for effectiveness; however, the measure for how problematic this is depends on the effect of the treatment. Gender Medicine impacts the entire body and is permanent (e.g. Lesbians United, 2022). So the result is that Endocrinologists working in Gender Medicine based on these guidelines are doing so unscientifically and unsafely; they know how poor the estimate for a positive outcome is, and they know the risk is a lifetime of potential damage to the entire patient’s body. What else do they know?

Keeping in line with the safety analogy, the effect of advocating for the 3rd party operator’s manual and wide-spread sales of the PPE is that beta-testing is now occurring through the entire customer base. Obviously this is not safe. The hazards to health are serious (e.g. brain development impacts, early-onset osteoporosis, sterility, auto-immune issues, and more) and the

extent of these problems developing over time is unknown (e.g. Cass Review). Drafting guidelines/standards without supporting research also is not scientific. Cantor (2019) discusses how the American Academy of Pediatrics (AAP) proceeded with their Gender Medicine guidelines/standards without rigorous review. The “experimental” results from these Gender Medicine practices are no longer being collected in order to modify the hypothesis when this happens. The situation has been created where researchers, who ordinarily would not be able to conduct an experiment on this scale with this population for ethical reasons, are now ad-hoc attempting to collect data on how effective/harmful unscientifically-practiced Gender Medicine is.

As Cantor (2022) states, “The initial enthusiasm for medical blocking of puberty followed largely from early reports from the Dutch clinical research team suggesting at least some mental health improvement. It was when subsequent research studies failed to replicate those successes that it became apparent that the successes were due, not to the medical interventions, but to the psychotherapy that accompanied such interventions in most clinics, including the Dutch clinic.” Recall that the Dutch Experiment is the basis for pediatric Gender Medicine; subsequent research showed that it wasn’t the invasive medical treatments that were effective, and Cantor argues that it was the psychotherapy. The guidelines/standards discussed previously which were adopted by the APA, AAP, and Endocrine Society are all built on a fundamentally flawed, low quality, research experiment, a research experiment that permanently altered the children’s bodies on a cellular level. **This means they expanded a poorly designed experiment with serious risks and unlikely benefits into the population as whole, and no results are being collected to modify the hypothesis.**

With Gender Medicine practices unscientifically disconnecting from research, the implication is that the public as a whole becomes an unconstrained experiment. However, unlike an actual scientific experiment, the results are susceptible to the full spectrum of organizational responses, some of which I’ve identified as Organizational Failure (ACS, 2022). To reiterate the elements of Organization Failure: (1) Conflict of Interest (Col) among medical practitioners, (2) medical practitioners making decisions based on emotional preference as opposed to known data, (3) medical practitioners suppressing/punishing workers/clients investigating the outcome of these emotional decisions, (4) Clients/Workers are perceived with hostility/malignant condescension, and (5) Insular training of medical practitioners. Col appears when the providers of Gender Medicine receive financial rewards from businesses selling the medical treatments or some other form of emotional reward (e.g. Richardson, 2008-2009). Organizational Failures (2), (3), and (4) all contribute the failure to collect or maintain data necessary for evaluating the results of Gender Medicine practices, the failure to properly respond to incidents of harm, and the failure to properly conduct valid scientific research (a.k.a. “cooking the data”). These will be discussed in more detail in the following article on pre-/post-medicalization suicide rates. Finally, Organizational Failure (5) consists of unscientific practices being taught to medical practitioners. While there are examples of (5) available across media, none meet the higher standard of court record or peer review here in the United States (e.g. Irvine et al. 2022 Letter; Isaac, 2021; Kimberly, 2022 Letter). Further sworn testimony and legally admissible evidence is expected in the near future.

Gender Medicine as currently practiced is unrestrained by the unsound guidelines/standards that have been adopted (e.g. Mahfouda et al., 2018; Milrod, 2014; Milrod and Karasic, 2017; Olson-Kennedy, 2018). Treatment research that previously could have been halted due to risks to their subjects can now be conducted with subjects that are already experiencing a treatment. For example, a widely adopted treatment across schools is called “Social Transitioning” which likely increases dysphoria rather than relieving it (e.g. Zucker, 2020 and references therein). **When a treatment is harmful rather than helpful, it is iatrogenic; regardless, social transitioning has become widely adopted** (e.g. Health and Human Services, Office of Population Affairs, 2022). This enabled a low quality research study that attempted to measure the effect of this practice. How the study was designed suffered from fundamental flaws which are worth discussing to understand what makes the guidelines/standards unsound.

“Gender Identity 5 Years After Social Transition” by Kristina R. Olson, PhD *et-al*/ was published in 2022. It suffered from many flaws (Society for Evidence Based Gender Medicine, 2022 Public

Release Statement), and a few of the most concerning are listed below:

- The study participants did not represent the socially gender transitioning population “the ratio of natal boys to girls in this study is approximately 2:1 [most transitioning children are natal girls]...early age of social transition (average 6.5 years) [most are teens]...excellent mental health function [most do not have this level of mental health, e.g. Autism]”. While all this could be considered caveats, the fact that results from this study don’t apply generally to pediatric Gender Medicine isn’t sufficiently emphasized (e.g. Cass Review; Kaltiala-Heino, 2018).
- The participants were filtered. No children were in the study who had been socially transitioned for less than 1.5 years. “Thus, it is likely that the study under-represents families where the child had experienced a briefer period of social transition and who then detransitioned [note Olson uses ‘retransition’ instead of ‘detransition’].”
- The drop out rate from the study is unknown. My personal note: Every study of gender identity **MUST** include an accounting for whether former participants died as opposed to leaving the study. As I show in the next article, the suicide rate for transition medicine (AFTER medicalizing) has significant error bars but **the question of the treatment being uniquely fatal needs to be investigated.**
- Limitation in hypothesis. The researchers’ “main concern with early social gender transition is that the process of re-identifying with their natal sex following a period of social transition may be distressing to a child”. However, “the researchers noted that in many cases the “distress” criterion, necessary for the DSM-5 [gender dysphoria] diagnosis, was not met. This allows for the inclusion of children with a certain parent profile: one who is heavily invested in the idea that their child is transgender even if they don’t meet diagnostic.”
- “The children and adolescents’ pattern of sexual attraction/ orientation is not noted. This is an important omission, as gender incongruence in childhood is strongly associated with future homosexuality. If a significant proportion of the youth in the study are attracted to the individuals of their natal sex, it would suggest that early social transition poses risks of iatrogenic harm to LGB youth by exposing them to highly invasive and unnecessary medical interventions.”
- Commingling of interventions and lack of control group. In the Scientific Method, a control group enables establishing whether a difference developed; if not, then no conclusions can be made. Also, making social-transition-impact conclusions when many subjects have moved on to medicalization (60%) eliminates being able to distinguish the effect of social transition alone.

How did such a fundamentally flawed study get approval? This leads to three questions: **(1) What are the safety standards for experimenting on humans? (2) Assuming they failed in this situation, where was the failure? (3) What can we learn about these safety practices to address the situation of unscientific guidelines/standards?**

“Institutional Review Boards (IRBs) are federally-mandated, locally-administered groups charged with evaluating risks and benefits of human participant research at their institution.” As many IRB members are aware, federal regulations make clear that an IRB must have the “. . . professional competence necessary to review specific research activities . . .”, and that an IRB may invite input from “. . . individuals with competence in special areas to assist in the review of issues which require expertise beyond or in addition to that available on the IRB” [45 CFR 46.107 (a) and (f)].

Health and Human Services (HHS) has guidance for IRBs to follow Federal law (see Office for Human Research Protections reference) . Relative to Gender Medicine in general and the social transitioning study specifically, the following IRB concerns require further inquiry:

- Was an IRB involved in the social transitioning study?

- If an IRB reviewed the proposed research, what are:
 1. Its members' experience?
 2. Meeting minutes?
 3. Assurance that Federal standards on human experimentation are met?
 4. A copy of the Informed Consent provided to participants in the research?
 5. The risk/benefit analysis of the research?
 6. Any materials concerning the fair and equitable selection of participating subjects?
 7. Research design is appropriate?
 8. Copies of the assent form provided to children and the permission form provided to their parents/guardians?
 9. Conflict of Interests identified and addressed?

I reached out to multiple institutions regarding IRBs. It is concerning that the ones which did not respond to my request for more information include: (1) National Institute of Health (nihfoia@mail.nih.gov), (2) Stanford University (officesupportstaff@lists.stanford.edu), and (3) Massachusetts General Hospital (kkpiper@mgh.harvard.edu). One IRB staff member was available for questions and to discuss how generally this safety practice works at their institution. The outcome from the discussion is that research such as the Olson et al. (2022) study described above would require convincing IRB members of the validity of the science. In other words, the state of the Gender Medicine practices and research has to be presented as rigorous and strong; a presentation that is false. **IRB members would have to independently go through the cited materials to assess the accuracy of their citations and be sufficient experts in the field to recognize what is missing from the discussion of the hypothesis.** Cantor (2022) goes in to this in detail when discussing the expert witness reports filed by Drs. Brady and Antommaria. This is probably what went wrong with the Olson IRB.

Conflict of Interest takes many forms. A discussion of how to strengthen IRBs against Col was published by the APA and hopefully implemented by all applicable institutions (Eissenberg, 2004). In the case of Gender Medicine research, there are two forms to be watchful for: (a) Researchers attempting to structure the experiment to achieve a desired outcome (e.g. Lett et al., 2022) and (b) Non-researchers attempting to prevent the experiment out of concern of an undesired outcome.

This article began with discussing how Gender Medicine is being practiced without a scientific basis. I then transitioned to discussing research in Gender Medicine and issues with how it is being conducted. This led to learning about Institutional Review Boards and their critical importance to safety in human experimentation. I then discussed where they can fail. So what needs to be done?

According to Merriam-Webster, hearsay evidence is evidence based not on a witness's personal knowledge but on another's statement not made under oath. One issue that I see reoccurring is detransitioners stating that lawyers will not take their cases. The explanation given is that it was "experimental". As discussed previously, an experiment follows the Scientific Method. These detransitioners make no other statements indicating that they were participating in an official IRB-safety-evaluated experiment. So here are the final questions: **(1) How many Gender Medicine doctors who were involved with the unscientific guidelines/standards being adopted were aware of the IRB safety protocol? (2) How many Gender Medicine doctors who are not adhering to the guidelines/standards are aware of the IRB safety protocol? (3) How many Gender Medicine researchers are misrepresenting the status of the field to their IRBs?**

How many Gender Medicine doctors knew or should have known that they were experimenting outside of experimental safeguards and with no intention of collecting results or modifying their hypotheses?

Author's Request: I am looking to collect Informed Consent documents from patients.

Footnote

*Calculated from 4 suicides/100,000 human hours; another issue to be discussed in the next article is how to measure this and what is available to measure.

Medical Safety: Risk Study of Gender Medicine, Part 2

[Elizabeth Jensen](#)

Statements that Gender Medicine is “life-saving” and addresses the suicide rate are unsubstantiated by any data here in the USA; furthermore, no effort is being made to collect this data scientifically. What data is available indicates that Gender Medicine is ineffective at impacting the suicide rate. Based on the material that I have reviewed, my education, training, and experience, I find that Gender Medicine as currently described by WPATH (2022) is hazardous. The World Professional Association for Transgender Health (WPATH) leadership is grossly incompetent. WPATH (2022) is grossly negligent in providing its assessment of suicide in Gender Medicine to practitioners using its “standards”.

In the previous part of this two-part series, I discussed how Gender Medicine was being conducted without any safety controls for this type of experimentation. This conduct would not necessarily meet the definition of “experiment”, because no results are being systematically collected to modify the hypotheses (Jensen, 2022). This part examines the claim for why this approach is appropriate: suicide (WPATH, 2022). The claim that this is necessary includes the term “life-saving” as well (Becerra, 2022).

Recall from Part 1 that I listed ways in which the Institutional Review Board safety practice could be subverted, including the misrepresentation of current research. Herein we evaluate the relevance of the claim that Gender Medicine improves suicide rates by comparing the citations in two overarching sources: (1) Levine et al. (2022) “Reconsidering Informed Consent for Trans-Identified Children, Adolescents, and Young Adults” and (2) WPATH (2022) “Standards of Care for the Health of Transgender and Gender Diverse People, Version 8”.

Recall from Part 1 that I listed ways in which the Institutional Review Board safety practice could be subverted, including the misrepresentation of current research.

To summarize the rigorous research that has taken place into the question of whether or not Gender Medicine improved outcomes on suicide, the following quality control criteria were applied: (1) The study’s methodology was not contradicted by a peer reviewed article; (2) The study produced some form of quantifiable data on the topic; and (3) The study passed a consistency inspection on its basic statistics, logic, and calculations. If a study is not included, these numbers provide the criteria item where it failed. These are noted as “**Fail #**” in the text below.

Variables in Suicide

My summer sociology class at Texas A&M University (circa 1994-1998) featured studying Durkheim’s (1897) text “Suicide”. The short summary is that he found statistical patterns to the practice after studying data across multiple countries, religions, mental health, age, sex, marriage status, etc.; for example, a single mom is less likely to commit suicide than a teenager home alone with nothing to do. Suicide is also a socially spread contagion, spread through thought rather than biology (Gould and Lake, 2013). Finally, suicide is a secondary side effect of various pharmaceuticals with depression as a side-effect (Qato et al, 2018). Note that depression is not caused by low serotonin (Moncrieff et al, 2022). When discussing approaches to address suicide, it is important to recognize that multiple factors can be involved and isolating their contribution is quite complicated.

There are two more issues relative to understanding the research into the effectiveness (or not) of Gender Medicine on suicide. The first is terminology relative to concrete evaluation. Specifically, Clayton et al (2021) states,

“There is also unclear use of the term suicidality, which exaggerates the implication of Turban et al.’s findings. Suicidality is a broad term, which is comprised of suicide attempts, plans, and ideation, and indeed this was the manner it was used by Turban et al. It is also important to note that Turban et al. made no assessment of completed suicides. Turban et al. assessed six areas of suicidality (including recent and lifetime

suicide attempts, recent ideation with plans, recent and lifetime ideation) and found no association between puberty blockers and suicidality measures on five of the six areas [before AND after interventions]. The only association was with “lifetime suicidal ideation.” Of course, any suicidal ideation is concerning, but suicide attempts are generally considered of higher concern, in terms of suicide risk assessment, than suicidal ideation.”

(My additional information for the reader is in []’s.) Note that WPATH (2022) failed to include the Clayton reference in its materials.

Suicide Completion Rates

Figure 1 shows the quality of evidence in the suicide research that we will be discussing. One of the best studies cited by Levine et al. (2022) was Dhejne et al. (2011), a population-wide study from Sweden 1973-2003. The study analyzed records from more than a 30-year time span, and it found that (summary from Levine et al, 2022)

“adults who underwent surgical transition were 19 times more likely than their age-matched peers to die by suicide overall, with female-to-male participants’ risk 40 times the expected rate”

The suicide rate was 0.3% (2.7/1000 person years). WPATH (2022) cites this study only once in its “Mental Health” chapter as a supporting reference that a higher prevalence of *suicidality* occurs among “those requiring medically necessary gender-affirming medical treatment”. This is problematic because Dhejne et al. (2011) shows no improvement in suicides nor *suicidality*. The impact of gender-affirming treatment on changing the suicide rate was not measured.

Levine et al. (2022)’s second reference on the topic, Wiepjes et al. (2020), examined the charts of the population in their Amsterdam clinic and found no change in the suicide rate before, during, or after medicalization. The ratio of suicides was 0.5%.

Biggs (2022), Levine et al. (2022)’s last citation on suicide, analyzed England, Wales, and Northern Ireland children referred for Gender Medicine from 2010 to 2020; 0.03% died from suicide. Due to the extent of the wait list (2 years) for this population, the change in suicide rate prior to and after medicalization was studied, and there was no significant statistical difference. Note that in the realm of the statistics of small numbers, comparisons between data sets are complicated. Biggs (2022) discusses the Dhejne et al. (2011) and Wiepjes et al. (2020) studies in terms of suicides per 100,000 people for comparing these statistics.

Due to the extent of the wait list (2 years) for this population, the change in suicide rate prior to and after medicalization was studied, and there was no significant statistical difference.

WPATH (2022) does not discuss Wiepjes et al. (2020) nor Biggs (2022) at all. I would like to note that the Levine et al. (2022) is also not mentioned in WPATH (2022). This is concerning, because Levine et al. (2022) raised extremely serious ethics issues in current practices.

WPATH Citations

It is clear that WPATH (2022) did not provide the medical community with information that is consistent with Levine et al. (2022). In discussing the citations WPATH (2022) provided, the difference between “*suicidal*” and “suicide” needs to be re-emphasized. Cantor (2022) states, “Psychological research importantly distinguishes completed suicide—which occurs primarily among biological males and involves the intent to die—from *suicidal* ideation, gestures, and attempts—which occur primarily among biological females and represent psychological distress and cries for help.” Also refer to the discussion by Clayton et al. (2021) in this article (paragraph 3).

A search through the WPATH (2022) material for discussions on suicide brought up references such as Craig et al., 2017; Green et al., 2020; Turban, Beckwith et al., 2020 and D'Angelo et al., 2020 in the "conversion therapy"-suicide relationship section. First of all, the American Psychological Association (2022) loosely defines "conversion therapy" as, "a highly controversial, ethically questionable, and generally discredited process intended to change individuals of same-sex or bisexual orientation to heterosexual orientation." I interpret this to mean sexual orientation relative to the individual's being female/male, genetically; all of these details can be objectively measured. In contrast, gender identity is purely subjective.

Finding of note: Given how concentrated homosexual/bisexual people are among the gender dysphoric population (e.g. Levin et al., 2022), Gender Medicine practices could be defined as conversion therapy.

Among WPATH (2022)'s citations related to *suicidality*, Craig et al. (2017) is inappropriate for Table 1 as it does not actually tally any data from the survey that quotes were drawn from (**Fail #2**).

D'Angelo et al. (2020) questions the methodology in Turban, Beckwith et al. (2020), so this will be left out of Table 1 (**Fail #1**).

Finally Green et al. (2020) is a selection-biased survey in which respondents who claim to have undergone Sexual Orientation and Gender Identity Change Efforts (SOGICE) were asked about *suicidal* thoughts and attempts. Table 1 in Green et al. (2020) had the following issue: 58.5% of the SOGICE respondents were "cisgender". There is a major difference between a LGB person experiencing SOGICE and a transgender person not having their identity affirmed (Stella O'Malley, 2022). Without Green et al. (2020) distinguishing *suicidality* between transgender and cisgender respondents in Table 2, it provides no insight into the *suicidality* relative to LGB SOGICE versus transgender identity non-affirmation (**Fail #3**). The labels in Table 3 are meaningless without "cisgender" among them to make this separation of variables possible given the extremely limited description provided of the "adjusted" logistic regression model(s) involved. Finally, it is not explained in the text why the number of respondents changed between Tables 1 and 2.

Other WPATH (2022) references include de Graaf (2022), summarized by Levine et al. (2022) as, "...*suicidality* of trans-identifying teens is only somewhat elevated compared to that of youth referred for mental health issues unrelated to gender identity struggles"; this reference is added to Table 1.

Keo-Meier et al. (2015) looked at adult *suicidality* during the 3 months after medicalization; this is temporarily beneficial so it isn't included in Table 1 (**Fail #1**). Levine et al. (2022) points out,

"Clinicians working with trans-identified youth should be aware that although in the short-term, gender-affirmative interventions can lead to improvements in some measures of *suicidality*, neither hormones nor surgeries have been shown to reduce *suicidality* in the long-term."

The Levy (2003) reference, concerned with discussing pharmaceutical effects, is not being included in Table 1 as studying suicide was not one of the article's objectives (**Fail #2**).

Turban, King et al. (2020) and Rew et al. (2020) were methodologically criticized by Clayton et al. (2021). Turban, King et al. (2020) was methodologically criticized by Biggs (2020), too. Neither Turban, King et al. (2020) nor Rew et al. (2020) will be included in the table below (**Fail #1**). Note that WPATH (2022) failed to include both the Clayton reference and the Biggs reference in its materials.

Bauer et al. (2015)'s selection-biased survey somehow has 110 individuals that attempted suicide out of 433 total survey respondents consisting of "11.2%" of the population; it's 25.4%. As how

this was accomplished is not explained, this study is not included in the table below **(Fail #3)**.

Finally in another selection-biased survey, Brumer et al (2015), which should read Perez-Brumer et al. (2015), somehow analyzes the sample size of 1060 individuals which is larger than the total survey group of lifetime suicide attempts (355). This indicates that the population size was too small for the analysis that was conducted, so this study is also not included in the table below **(Fail #3)**.

Recall what I said in Part 1:

In other words, the state of the Gender Medicine practices and research has to be presented as rigorous and strong; a presentation that is false. **IRB members would have to independently go through the cited materials to assess the accuracy of their citations and be sufficient experts in the field to recognize what is missing from the discussion of the hypothesis.** Cantor (2022) goes in to this in detail when discussing the expert witness reports filed by Drs. Brady and Antommaria. This is probably what went wrong with the Olson IRB.

Levine et al. (2022) had superior citations to WPATH (2022), and the quality of the WPATH (2022) citations were very weak for supporting the points they were attempting to make in their "standards of care". What is the effect of WPATH (2022) misrepresenting the state of research?

Four Risk and Safety issues are relevant here:

1) It is not unusual to make policy changes to address small populations which are at risk (e.g. USDA, 2017); however, these changes are debated in terms of the expected impacts on other people (see the comments on the proposed change). In the absence of data (Jensen, 2022), my educated guess is that the number of transgender people who commit suicide is smaller than most populations on which major policy changes are directed. This is important for the upcoming safety discussion.

2) Gender Medicine does not change the suicide rate/ratio. In other words, it is not "life-saving". The WPATH (2022) document claims the reverse and then fails to discuss the studies in Table 1 that contradict that assertion.

3) Where suicide has patterns relative to the individual, as a social contagion, and as a side effect of certain pharmaceuticals, it is impossible to isolate one versus another with the available research.

Levine et al. (2022) warns practioners,

"Providers of gender-affirmative care should be careful not to unwittingly propagate misinformation regarding suicide to parents and youths. They should also be reminded that any conversations about suicide should be handled with great care, due to its socially contagious nature."

The necessity of this warning suggests to me that practitioners, particularly in promulgating the transition-or-die misinformation, could themselves be socially spreading suicide.

Also, Gender Medicine involves lifetime consumption of off-label use pharmaceuticals (American Medical Association, 2016). Dresser and Frader (2009) warn about the weak evidence base for these sorts of prescriptions,

"More than half the respondents in a survey of academic medical centers reported that innovative off-label prescribing raised concerns in their institutions, such as lack of data, costs, and unfavorable risk-benefit ratios. When substantial uncertainty exists about off-label applications, patients are at risk of receiving harmful or

ineffective treatments.”

The side effects from Gender Medicine pharmaceuticals is not discussed here, but their off-label status and uncertainty in effectiveness in suicide cannot be dismissed.

4) The suicide completion data on these Gender Medicine patients is not being collected here in the USA (Jensen, 2022). Green (2022) makes an estimate on effectiveness by comparing pediatric suicide data against pediatric access to Gender Medicine pharmaceuticals, for example.

Conclusion

In Part 1 of this Medical Safety series, I discussed how Gender Medicine is being conducted on an experimental basis without any of the safety controls for human experimentation. In fact, the term “experimentation” is not the correct description of the practice as no effort is being made to systematically collect results and modify the hypotheses. The explanation for this approach has been that the Gender Medicine patients have extreme suicide rates. In Part 2 of this series, I examined this claim by comparing two overarching Gender Medicine publications and found that the available data suggests that the suicide rate doesn’t change.

Finding for a court of law: Statements that Gender Medicine is “life-saving” and addresses the suicide rate are unsubstantiated by any data here in the USA; furthermore, no effort is being made to collect this data scientifically.

Finding for a court of law: What data is available (Table 1) indicates that Gender Medicine is ineffective at impacting the suicide rate.

Finding for a court of law: Based on the material that I have reviewed, my education, training, and experience, I find that Gender Medicine as currently described by WPATH (2022) is hazardous.

Opinion for a court of law: WPATH leadership is grossly incompetent.

Opinion for a court of law: WPATH (2022) is grossly negligent in providing its assessment of suicide in Gender Medicine to practitioners using its “standards”.

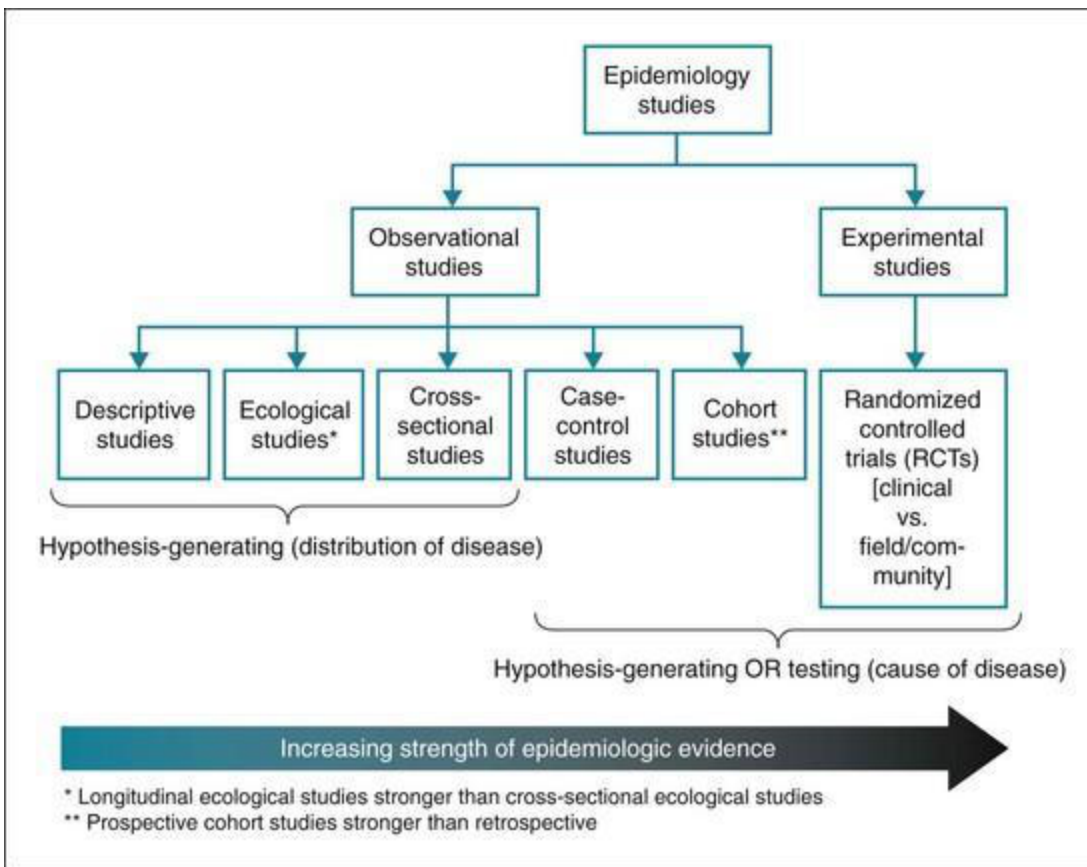

Figure 1: *Epidemiologic study designs and increasing strength of evidence (from BasicMedical Key, 2016).*

Table 1: *Advantages and Disadvantages of Common Types of Studies Used in Epidemiology (from BasicMedical Key, 2016) with studies of note in this article listed.*

Studies	Advantages	Disadvantages	Studies
Qualitative research	Generates hypotheses and initial exploration of issues in participants' own language without bias of investigator	(i) Cannot test study hypotheses (ii) Can explore only what is presented or stated (iii) Has potential for bias	
Cross-sectional surveys	(i) Are fairly quick and easy to perform (ii) Are useful for hypothesis generation	(i) Do not offer evidence of temporal relationship between risk factors and disease (ii) Are subject to late-look bias (iii) Are not good for hypothesis testing	

Ecological studies	(i) Are fairly quick and easy to perform (ii) Are useful for hypothesis generation	(i) Do not allow for causal conclusions to be drawn because the data are not associated with individual persons (ii) Are subject to ecological fallacy (iii) Are not good for hypothesis testing	
Cohort studies	(i) Can be performed retrospectively or prospectively (ii) Can be used to obtain a true (absolute) measure of risk (iii) Can study many disease outcomes (iv) Are good for studying rare risk factors	(i) Are time-consuming and costly (especially prospective studies) (ii) Can study only the risk factors measured at the beginning (ii) Can be used only for common diseases (iv) May have losses to follow-up	Dhejne et al. (2011); Wiepjes et al. (2020); Biggs (2022)
Case-control studies	(i) Are fairly quick and easy to perform (ii) Can study many risk factors (iii) Are good for studying rare diseases	(i) Can obtain only a relative measure of risk (ii) Are subject to recall bias (iii) Selection of controls may be difficult (iv) Temporal relationships may be unclear (v) Can study only one disease outcome at a time	de Graaf et al. (2022)
Randomized controlled trials	(i) Are the “gold standard” for evaluating treatment intervention (clinical trials) or preventative intervention (field trials) (ii) Allow investigator to have	(i) Are time-consuming and usually costly (ii) Can study only interventions or exposures that are controlled by investigator (iii) May have problems	

	extensive control over research process	related to therapy changes and dropouts (iv) May be limited in generalizability (v) Are often unethical to perform at all	
Systematic reviews and meta-analysis	(i) Decrease subjective element of literature review (ii) Increase statistical power (iii) Allow exploration of subgroups (iv) Provide quantitative estimates of effect	(i) Mixing poor quality studies together in a review or meta-analysis does not improve the underlying quality of studies	
Cost-effectiveness analysis	Clinically important	Difficult to identify costs and payments in many health care systems	

Safety Implications

Significant policy changes have been enacted to protect transgender people based on the largely unmeasured phenomena discussed above. For example, a professor at the UC Berkeley School of Law testified at the Senate Judiciary Committee, “I want to recognize that your line of questioning is transphobic and it opens up trans people to violence by not recognizing them... [asked to clarify]...I want to note that one out of five transgender persons have attempted suicide” (C-span, 2022). There is no evidence to support this assertion, and there is no intention among USA Gender Medicine community leadership to study this scientifically. So accommodations in the form of limits on free speech are being implemented because of this small, virtually unstudied risk (e.g. Meriwether, 2021). How do other policy accommodations impact safety?

First of all, there are fundamental biological differences between females and males that are critical to acknowledge in the health care setting (search “female” in American Medical Association, 2021). While the nursing home court case, *Taking Offense* (2021), was not concerned with patient safety insofar as receiving the correct care, this is a developing issue as sex-specific definitions fall under scrutiny (e.g. American Medical Association, 2021). Also, recall that the definition of transgender does not require any form of medicalization; it is a subjective identity. Impact sports become unnecessarily hazardous if females play against males (e.g. World Rugby, 2022). Imprisoning females with males is particularly dangerous (e.g. *Chandler v CDCR*, 2022). Then there are various activities, such as bathing, in which the presence of a naked male is inherently threatening (e.g. Hoyt, 2021; note it is concerning that the wider media did not follow-up on the safety issues in this incident after the suspect’s criminal history became known). These are a small sampling of the incidents, injuries, and close-calls that are being experienced by the policies intended to protect transgender people from suicide. For comparison, the USDA (2017) regulation change was based on a measured issue, worker safety for chicken farmers. It is concerning that in comparison to this USDA regulation that was not modified, Gender Identity based regulation changes are occurring across the breadth of the federal government in the

absence of an objective measure of harm and to whom (e.g. Title IX, 2022).

Just as measuring the full suicide rate has not been conducted here in the USA, documentation of these safety incidents in health care, sports, prison, and facilities for partial or full-nudity are similarly under-sampled. The safety risks to females is significantly greater under these policies, but they also impact all Gender Medicine patients when it comes to health care. My educated guess is that the size of the population put at risk by these changes far exceeds the population at risk without these protections. Also note that due to the complexity of suicide, social contagion and pharmaceutical secondary side-effects in particular, there is no data suggesting that these policy changes will have any impact regardless.

Finally, current research on detransitioners, Gender Medicine's patients who regret medicalization, found that they experience negative interactions with the LGBT community (Vandenbussche, 2022). Safety concerns that transgender people raise also apply to those who medicalized yet no longer identify as transgender; however, no policies are being developed to support this growing population.

Summary

Based on the material that I have reviewed, my education, training, and experience, I find that Gender Medicine as currently described by WPATH (2022) is hazardous. Based on the available data, the suicide risk shows no improvement for those who medicalize. I also briefly summarized the most dangerous policy accommodations which developed on these unfounded assumptions of suicide risk. The safety risks to females is significantly greater, but they also impact all Gender Medicine patients when it comes to health care.

Subject: Gender-Affirming Care Is Life Saving Health Care
Date: Wednesday, September 28, 2022 4:41:00 PM

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of

WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

As someone with a dear trans friend in Florida, and as someone who is a citizen of Earth, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

Dear Director Paul Vazquez,

I am sure that you have already received letters from researchers and clinicians (e.g., physicians, psychologists, etc.) who are extremely knowledgeable – more so than I am – about clinical work and research on gender dysphoria and, more broadly, gender medicine. You can also find such research on segm.org, statsforgender.org, and other places, including the Cass Review (cass.independent-review.uk), which led to the UK's NHS decision to close their gender dysphoria treatment service at the Tavistock Center as of this coming spring 2023. You are probably also aware that other European countries, including Sweden and Finland, announced earlier this year that they decided to (nearly) eliminate the prescription of puberty blockers to children, due to research and clinical findings sowing doubt on the previously-held hypothesis/belief that puberty blockers – and their common sequelae, cross-sex hormones and surgery – were “medically-necessary” in order to treat gender dysphoria.

I also imagine that you have already received letters from persons who underwent some form(s) of the aforementioned medical interventions for gender dysphoria and then later detransitioned, oftentimes re-identifying with their natal sex and regretting their medical transition. To my knowledge of the research about detransitioners and desisters, as well as pieces detailing their stories (e.g., on Substack), a common theme is that medical and mental health providers failed them. That is, medical and mental health providers did not adequately evaluate or treat them for other co-morbid psychiatric disorders, attempt to understand the origins of their dysphoria, or conduct a thorough informed consent process prior to providing medical intervention. Many detransitioners and desisters report that no one (except their parents) ever questioned them, and they were “affirmed every step of the way.” Furthermore, they say that medical and mental health providers indicated that medical treatment was “the solution” to their gender dysphoria.

You are probably also aware that nearly 55,000 “gender-affirming” surgeries were done in the US between the years 2015 and 2020 (www.plasticsurgery.org/news/plastic-surgery-statistics). Following trends, it is reasonable to extrapolate that that number could have grown to 90,000 by now. I highly, highly doubt that all of these young people have finally found their true selves.

You might also be aware that gender-affirming surgical practice is considered to be a market, with a compound annual growth rate of 14.4% from 2019 thru 2027. A market.
<https://www.grandviewresearch.com/industry-analysis/us-sex-reassignment-surgery-market>

The fact that nullification surgery has now been available in the United States for over a year suggests that major medical organizations (e.g., American Medical Association) are allowing these surgeries to occur under the umbrella of “gender-affirming care.” If “gender-affirming care” was really, truly about the arguably noble goal of helping someone who strongly believes they were born in the wrong body, i.e., born in the body of the opposite sex, then medical options would end (at the most extreme) with penectomy/orchiectomy and vaginoplasty for natal males and hysterectomy/oophorectomy plus phalloplasty for natal females, combined with life-long dependence on cross-sex hormones. But, now with the availability of nullification surgery, it is obvious that the goal of “gender-affirming care,” in all of its possibilities and permutations, is not noble, if it ever was. In other words, relieving the tortured existence of someone who feels they were born in the wrong body is not what “gender-affirming care,” broadly speaking is really about.

I only recently – this past April – became aware of the current state of affairs regarding gender medicine as currently practiced in the United States, i.e., readily available medical intervention for gender dysphoric youth and young adults, with very few safeguards. I had heard of Abigail Shrier's book, *Irreversible Damage*, a year or so ago, but (regrettably) did not read it. At that time, I understood that the gist of her book was that a skyrocketing number of girls were suddenly gender dysphoric and some were undergoing medical intervention that led to irreversible changes/harm to their bodies, but I recall thinking something along the lines of "Wow, that's really strange and sad that so many girls suddenly feel uncomfortable in their bodies but I'm sure the medical and mental health professionals are doing their due diligence to make sure these girls are getting the care they need, and unfortunately maybe some rare mistakes are being made, as we don't have a crystal ball."

In short, I trusted. I trusted that, regardless of any other pressures (e.g., from social media), trends, well-meaning school counselors, parents, or other influences, that the medical and mental health professionals would be "the adults in the room." That is, no matter how uncomfortable a teen girl might be in her body and how much she says she wants medical intervention, medical and mental health professionals would say "no," or at least "not yet," except in very extreme, carefully chosen cases.

Many words describe my feelings upon finding out that this isn't – and hasn't been – the case for many years now. Shocked. Appalled. Disillusioned. Betrayed. Angry. Heartbroken.

Now, one might think that perhaps I'm being unfair and judgmental of such providers and had never encountered a person struggling with gender dysphoria or otherwise not completely identifying as cisgender. That is not the case. Prior to this past April – before I found out that I was "supposed to" have been practicing "gender-affirming" care – female patients happened upon my private practice describing themselves as "transgender." My gut response was "ok, let's explore and talk about that." It did not occur to me to have any other reaction. So finding out that, for the last several years, many medical and mental health providers have NOT had that reaction and instead have affirmed the young person's gender identity, oftentimes encouraging medical intervention that may result in irreversible physical changes – to say nothing of the psychological impact of all of this – has shattered my faith in the medical and mental health professions.

As I see it, medical and mental health providers have a small, but quickly disappearing, window of opportunity to retain and rebuild trust. Most media outlets and politicians, at least in the U.S., have served gender-affirming clinicians well: most of the public has been in the dark about this.

Florida has an opportunity – like Sweden, Finland, France, and the UK – to lead on this. Please take action to stop sending children down a gender-affirming road that ends in the operating room.

Sincerely,

Kristen Farrell-Turner, Ph.D.

To: Florida Board of Medicine

Regarding the transgender issue and so-called
"gender-affirming care" for youth;
in deciding how to proceed regarding its regulation, I recommend that
the FL Board of Medicine focus be on GENESIS - Chapter 1: 27;

" God created man in the image of himself,
in the **image of God** he created him,
male and female he created them. " (Emphasis added).

Thus, ' the Bible tells us so ' regarding the ancient truth that there are only two sexes.
It's also basic, common sense biology.

So-called "gender-affirming care" methods distort/destroy bodily integrity in vulnerable
children
experiencing the confusion of gender dysphoria. There is no rightful place for these within
authentic healthcare.

Social transitioning (including ' preferred gender expression ') conflicts with biological
reality.

Use of puberty blockers, cross sex hormones and disfiguring surgeries
in gender dysphoric children should be prohibited from the practice of medicine.

" Do No Harm " is not a worn-out cliché; it remains the foundational principle of good,
Hippocratic medicine.

The children of Florida need and deserve protection
against all forms of child abuse including that under the guise of medical practice.

Diane Gowski, MD
President, Florida Catholic Medical Association, Inc.

Dear Florida Board of Medicine,

Thank you for taking on the important issue of regulating the medical treatment of youth and young adults with gender dysphoria.

As your own review of research has found, there is no biological basis for a transgender identity and there are no longterm studies that show that medicalizing a transgender identity will result in better mental health outcomes. (segm.org/studies)

If puberty blockers are started there is an almost 100% chance that a child will go on cross-sex hormones and will end up sterile and without sexual function. Sterility and sexual function are also compromised in those who start cross-sex hormones in adolescence, especially for those who later have genital surgeries.

Since a large portion of the youth who are claiming a transgender identity have one or more of the following conditions (autism, ADHD, homosexuality, trauma, depression, and other mood disorders) the current medical model of treating gender dysphoria is effectively eugenics for our most vulnerable populations of youth.

Like you I care about the physical and mental health of the next generation. As well, my family is a victim of medicalization of a transgender identity - my daughter has lost her voice and become insulin resistant within a month of being prescribed cross-sex hormones by Planned Parenthood at age 18.

Thank you for your efforts in protecting our vulnerable youth from this horrendous medical experiment.

-Ann Pond

To the Florida Board of Medicine,

As a physician who practices medicine in Florida, I appeal to you to safeguard our children and young adults by prohibiting and restricting 'gender-affirming care'.

Medical and Evidence-based studies of such measures do not support their claims; Rather, there are clear serious short-term and long-term harms from such misguided interventions.

In Gender Dysphoria, children exhibit confusion regarding their gender. These youths typically suffer from mood disorder, anxiety disorder, depression, eating disorders/anorexia, schizophrenia, substance abuse, and suicide attempts. Gender dysphoria is a Body Integrity disorder, similar to Anorexia. It is imperative to treat this Body Integrity disorder and concomitant psychiatric disorders by skilled psychiatrists. Affirming the children's confusion by irreversibly suppressing puberty with puberty-blocking medications (Lupron), administering high dose cross hormones (Estrogen, Testosterone), and performing mutilating surgeries (sex organ removal) are physically and mentally harmful to children and offer no long-term beneficial effects. The Suicide risk among children with Gender dysphoria remains high especially after their gender-transition.

As Gender confusion typically resolves spontaneously when the child develops through natural puberty by late adolescence, I entreat the Medical Board of Florida NOT to subject our youths/young adults to hormonal puberty-blockers and/or gender mutilating surgeries. Such acts would victimize our youths and young adults and constitute maleficence per the Hippocratic Oath we professed, to DO NO HARM to our patients including our children. Please prohibit and restrict these misguided interventions and protect our youths and young adults from unnecessary and lifelong harm.

Sincerely,
Nadine Khouzam MD, FACP

Short statement

My name is Jet and I am a 22 year-old, Dutch, female detransitioner. I was treated at the Amsterdam gender clinic in the Netherlands, who were the first to medically transition children. My gender clinic pioneered these treatments and the Dutch clinicians played a prominent role in the development of gender medicine.

I arrived at the Amsterdam gender clinic in late 2015. After six conversations I was diagnosed with gender dysphoria. The circumstances leading up to my referral and the causes of my distress were not explored. If my psychologist had done this she would have discovered that: I had become estranged from my body after a major scoliosis surgery; I was socially isolated and spent all of my time on the Internet; I felt extremely alienated from my peers and family due to high intelligence, autism traits, sensory issues, anxiety, and depression; I felt like I failed at being a girl because I was very gender non-conforming; I had been bullied by other girls; I only had older brothers and male friends; I had no female role models to look up to; and I was ashamed of my same-sex attraction as a bisexual girl.

None of this was taken into account. Furthermore, I was sent down the medical pathway despite not meeting the criteria of the Dutch Protocol. I did not experience gender dysphoria in childhood. I only started to hate my sex as a teenager after spending time on the Internet. I had co-morbid mental health issues. They ignored this and did not follow their own protocol.

At age 16 I went on puberty blockers, which ruined the cognitive and emotional functioning of my brain. I became severely depressed, developed an anxiety disorder, insomnia, anorexia, became underweight, and eventually became suicidal and almost took my own life. This was extremely traumatic, and continues to have a negative impact on my psychological functioning. I was on testosterone for five years, from age 17 to 22. I developed serious physical health problems, and my mental health worsened. I suffered from vaginal atrophy, chronic stomach pain, lower back pain, pain in my hips and knees, muscle tenseness, chronic headaches, extreme irritability, emotional numbness, an inability to think clearly or focus, and I was very easily overwhelmed and distraught. My voice is permanently lowered and I have facial hair. At age 18 I had a mastectomy, which means I will never be able to breastfeed my future children.

Because I felt so horrible about myself and my body, I actively avoided friendships and relationships. I missed out on normal teenage social and emotional development. This was not due to intolerance. My entire environment accepted my trans identity. Instead, my misery was caused by social and medical transition. My self-hatred and emotional instability were caused by being told that there was something wrong with me and my body. What I needed was support and guidance to help me grow into a healthy and strong young woman. I should not have been medicalized. Children cannot consent.

Longer statement

How I was introduced to ‘transgender’

In June 2014, at age 14, I had a 12-level spinal fusion surgery for scoliosis. My entire life fell apart: my body was ruined, I was traumatised, could not attend school much, and could not maintain friendships. I was very socially isolated. In late 2014 I became increasingly depressed and anxious, I began experiencing panic attacks, and started to self-harm. As I was still in recovery from scoliosis surgery, I spent most of my time at home in bed, alone. I received no psychological or emotional support. My family did not know what to do. I felt like a problem, like a burden.

I spent virtually all of my waking hours on the internet in early 2015. Most of this time was spent on YouTube, Tumblr, and Twitter. On Tumblr I was introduced to the ideas around gender and transition, and on YouTube I watched every transgender-related video I could find (back then, there wasn't very much). I was obsessed. As I read and listened to people talking about the distress they experienced about their sexed body, these ideas crept into my own mind. The more content I consumed, the more I read about gendered stereotypes, and the more stories of transgender people that I related to, the more I became convinced that this could be me. Being transgender seemed like a logical explanation for my life experiences.

I related to transgender men (female to male). I too hated my body. I had always been gender non-conforming. I hated being grouped with girls, and gendered expectations around my sex. I had always felt that I failed at being a girl. The idea of not having to grow up into a woman was appealing to me. A large part of my distress related to growing up; to the loss of my childhood in which I was ‘one of the boys’. In adolescence this was no longer possible, and I foresaw that in adulthood these differences between myself and males would only increase. As I had never felt like ‘one of the girls,’ puberty, and becoming a woman made me very anxious.

In May 2015, my parents asked me whether I was transgender or lesbian. They had noticed I had been distressed about something. I was terrified they would even suggest I may be lesbian. I was bisexual, and repulsed by myself for it, and scared I would end up becoming more same-sex attracted than I was. I did not want to be lesbian. I did at the time think that I may possibly be transgender, so I told them. My parents took me to the only gender clinic in the Netherlands at the time, and put their trust into the medical experts at the VUmc in Amsterdam.

The VU medical centre in Amsterdam, the Netherlands

The VUmc in Amsterdam houses the gender clinic where the Dutch Protocol was developed under the lead of Peggy Cohen-Kettenis. She pioneered child transition, together with Louis Gooren and Henriette Delemarre-van de Waal. The first time GnRHa, or hormone blockers, were used to treat gender dysphoria was at the VUmc in 1987. Over the course of two decades, the Dutch followed the first cohort of 70 adolescents whose puberty they suppressed. Their studies on this cohort have been shown to be flawed, as 15 patients dropped out, one

patient died, and different gender dysphoria measurement scales were used before and after treatment. There has not been a follow-up study on this cohort since 2014. The concept of child transition rests on the two studies that have been published on this group.

Diagnosis

I arrived at the Amsterdam clinic in November of 2015. I had my first intake with the head psychiatrist. After my intake I was assigned a personal gender psychologist and entered the diagnostic phase. This lasted six months, during which I had a single one-hour conversation each month.

Some things which should have been discussed, but were ignored, include: how my scoliosis and spinal fusion surgery had affected my relation to my body, my social isolation, my educational trajectory being ruined, having been bullied by other girls as a child, my shame for my same-sex attraction, my bad relationship with my parents, my self-loathing, and that I had no female role models. Autism should have been considered more seriously as my brother has Asperger's and I have quite a bit of ASD in my family. A trait I have that is often linked to autism is sensory sensitivity. This caused me to despise girl's clothes, having my hair tied up, and wearing jewellery, as I found these things physically uncomfortable. Unexpected changes overwhelmed me, I preferred sameness, and I was very sensitive. I was also prone to obsession, and overthinking everything. As a teenager I had become increasingly analytical and self-critical. I did not understand myself, and I wanted to fix whatever was wrong with me, whatever it was that made me different from others.

My psychologist should also have taken into consideration that I was a gender non-conforming, bisexual girl, who had always had male friends, only had three older brothers, had not gone through a typical female socialisation, and that I did not have any female role models to look up to – and that these could be reasons I was distressed about my sex. Other factors that caused me to struggle socially were high intelligence and the fact that I was on average 1.5 years younger than my peers at school as I had skipped a grade as a child. I was intellectually ahead, but emotionally and physically behind. All of my life experiences and character traits combined caused me to feel extremely alienated, from everyone. I did not relate to any of my peers. I felt like a stranger in my own family.

Instead of discussing any of these problems, the conversations with my gender psychologist were about gender. I was asked how I had felt in relation to other girls and to boys, to gender stereotypes, and my body throughout my life, and how I felt now. I felt awful, obviously, and without clarifying any causes for the post-pubertal onset of my bodily distress, my psychologist diagnosed me with gender dysphoria after the standard six months diagnostic phase. During this time I saw the psychiatrist once more, for a psychiatric assessment. Later on in 2016, after my diagnosis, I was seen by a different psychologist once. The psychiatrist and this other psychologist did not examine the causes for my gender dysphoria either.

Protocol was ignored

I did not meet criteria number one and two of the Dutch protocol: I did not have early onset gender dysphoria, and it did not worsen at the onset of puberty. I did not hate my sexed body until after puberty had started. My psychologist did not examine the development of my gender dysphoria. I had been honest and told her that I did not want to be a boy in childhood. I had been fine as a child because gendered expectations were less rigid. I said the start of puberty was uncomfortable, but I had been okay up until age 14.5. Protocol was ignored.

Criterion number three is that the adolescent should not have any co-morbid mental health issues. I told my psychologist I was struggling with anxiety and depression. She told me she could not help, and that I should seek extra support from a local psychologist. This did not work out, but my psychologist at the VUmc did not mind. I had no formal diagnoses at the time, but I would argue that my mental health problems should have disqualified me from treatment. My mental health issues were ignored: protocol was ignored. I was later, at age 18, diagnosed with depressive mood disorder, social anxiety disorder, and post-traumatic stress disorder, which I believe to have all suffered from since age 14, before I developed gender dysphoria, and before I arrived at the VUmc.

Puberty blockers

As I was afraid to come out as transgender at school, I requested to first be put on puberty blockers. Potential harms were downplayed. I barely received any information. I was told puberty blockers were reversible and that I would have some hot flashes, but not more than that. We now know that blocking puberty may potentially stop the brain from maturing, and we know it can have severe adverse health effects. Even though I was already 16 years old, the idea was that blocking the production of my sex hormones would ease my distress. However, the opposite happened. About three months after starting puberty blockers my depression and anxiety worsened. My cognitive abilities and motor skills declined, I felt stupid, my memory broke down, I was forgetful, and emotionally dysregulated. I began to self-harm more, and developed insomnia. I often could not sleep at all, and I was mentally and physically exhausted whether I did sleep or not. Likely as a coping mechanism, I developed Anorexia, and rapidly became underweight. My brain did not function, I spiralled, and after six months I was actively suicidal. I felt like I was losing my mind, and I was not allowed to stay home alone. My parents feared that I would take my own life.

This suicidal episode ruined my relationship with my parents, and it traumatised me. I was afraid to detransition for years, because I thought that if I did I would again become as suicidal as before starting testosterone. Every winter, in January and February, I seem to go through some sort of trauma response related to my time on puberty blockers. My mental health worsens severely, I spiral, and all of these memories resurface. I then want to hurt myself and experience suicidal ideation. Some years I also relapse into anorexia, or I drink too much. Six years on, my experiences with puberty blockers continue to have a negative effect on my psychological functioning.

Testosterone

I started testosterone in early 2016, just before turning 17. I was told about the cosmetic effects, and some emotional effects. Potential harms were again downplayed and the medication was not discussed as the extreme medical intervention that it is. Some of the effects I experienced which were not mentioned to me as possible health consequences were: vaginal atrophy, stomach problems (pain, nausea, bloating), headaches, extreme hypersensitivity to sensory stimuli (I am sensitive by nature and testosterone made my brain function less well; so I had a more difficult time processing (sensory) information on testosterone), muscle pain, joint pain (lower back, hips, knees, shoulders, and neck), inflexibility of my body in general (women are naturally more flexible and testosterone ruins this), severe acne (which I had to take Accutane for), skin issues (dry, irritable, folliculitis around leg hair), symptoms of polycythemia (bad circulation, headaches, red skin, tiredness, dizziness, stomach pain, bloating, numbness/tingling in hands and feet, shortness of breath), orgasms hurt, higher libido than I expected (which is unfortunate when you are affected by vaginal atrophy and painful orgasms), more irritability and anger than I expected, restlessness, increase of nerve damage pain (I have skin nerve damage over a large portion of my back as a result of scoliosis surgery), emotional numbness, difficulty processing emotions, decreased verbal fluency, and my brain processed (sensory) information differently. Testosterone affects every part of your body. After about four years I realized how bad my health had gotten. I was very concerned about my future. I quit testosterone after five years. Within two weeks all of the above-mentioned health problems disappeared. My body healed rapidly, and I began to feel comfortable in my own skin. I feel healthy for the first time in six years.

From age 16, when I started puberty blockers, to age 22, I suffered from health problems every single day, which were caused by these treatments. This was unnecessary and cruel. This should not have happened to me. My healthy body should not have been made sick. I should have been able to enjoy life as a young person. Instead I was often confined to bed, did not undertake much, was in pain every day, and I became sicker and sicker as time progressed.

Mastectomy

At age 18 I underwent a periareolar-type double mastectomy. The harms this would cause my body were again downplayed. No one sat me down and explained I would never – never – be able to breastfeed my own children, if I would have children in the future. No one sat me down and made sure that I knew this was forever. I could not oversee this at age 18. I had very little breast tissue as a result of puberty suppression and testosterone, and I wanted the surgery, because ‘I would have to have it someday, so I better have it now, as soon as possible.’ I wasn’t even very distressed by my breasts. But going down the medical trajectory, this was just another thing that seemed to apply to me. I thought that having a flat chest would make me feel more comfortable in my body; that I would again feel as comfortable in my body as I did before puberty, when I was a flat-chested child. The removal of my secondary sex characteristics was in part a cry for my childhood, and to a time before medical trauma, and social isolation, and everything horrible that had accompanied puberty. I saw it as ‘going back in time.’

As a result of my mastectomy I will never be able to breastfeed my future children. I occasionally have shooting pains in my chest as a result of nerve damage. I very much regret having the surgery and wished I still had my breasts. I should not have been allowed to make this decision at 18. I was too young and could not oversee the consequences it would have on my body and my life.

Long-term consequences of medical transition

There are irreversible effects of medical transition. What I worry most about physically, are the negative health consequences of puberty blockers and testosterone on my body that I may not know about. What I do know, is that I now live with a lowered voice, facial hair, body hair, and no breasts. I am often still read as male by strangers. It causes me anxiety, and I avoid socialising. I have mental health problems, such as low mood, and emotional numbness. I often feel very negative about life, and I do not trust anyone.

What hurts most however, is having lost seven of the most formative years of my life to medical negligence, and to a world-wide experiment that is being performed on the bodies of children.

Hello Mr. Vazquez,

I hope this email finds you well. I am a female to male to female detransitioner who has experienced "gender-affirming care" firsthand, and I hope that you will consider this statement while determining the appropriate treatment model for trans-identifying minors in Florida.

All the best,
Tony

Dear Mr. Vazquez,

My name is Tony, and I am a 31-year-old female detransitioner – someone who took social and medical steps to attempt living as the opposite sex and later sought to reverse these measures. I recall suffering from gender dysphoria almost as early as I can remember but began identifying as a trans man at age thirteen, after accessing an online forum for transgender “female-to-male” individuals. It was packed with information wholly inappropriate for children, including how to “pass” as the opposite sex, bind one’s chest, access cross-sex hormones, request chest and genital surgery, and even how to have sex as a trans person. The adults on this forum claimed that genital surgery was safe, effective, and would result in functional male genitalia.

Prior to that (this was the early 2000s) I had never met a trans-identifying person and didn’t realize there was another option besides accepting that I was a girl. After accessing that forum, I was convinced I was transgender, and that as soon as I completed my medical transition, I would finally be happy. At this point I had had been diagnosed with a myriad of mental health issues (Anorexia Nervosa, Bulimia, clinical anxiety and depression, ADHD) in addition to gender dysphoria, but reading accounts from people who had transitioned suggested to me that my dysphoria was the root issue, and that treating it would make all my other problems go away.

Back then it was far less common or socially acceptable to be transgender. When I initially came out to my parents at 15, they didn’t affirm me. The only people I had in my life who supported my new identity were a couple of friends my age. Finally at 17, my parents took me to a gender therapist who suggested I start testosterone after three appointments. However, my family was concerned that my other issues were not being properly addressed and would not allow it.

Although at that time this made me furious, today I am extremely grateful I was made to wait until I was an adult to transition. Today, I likely would have been encouraged to transition not only by online communities or by a gender therapist, but by other students and teachers at my school. Had my parents taken the “affirmative” approach, which is being widely recommended by doctors nationwide, I would have risked ending up with osteoporosis, infertility, stunted brain development, or any number of other detrimental effects we have yet to discover, as a result of puberty blockers. As a teenager, I desperately wanted “top surgery” (a double mastectomy) and considered “bottom surgery” (hysterectomy and phalloplasty.) There is a serious lack of quality research into the safety and effectiveness of relying on any of these interventions as treatments for gender dysphoria, a mental health condition. New WPATH guidelines are recommending surgery and cross-sex hormones for younger and younger patients, despite there being no quality data suggesting these approaches improve mental health in the long-term.

These are invasive and irreversible procedures that should only be considered as a last resort, if at all. Surely when it comes to treating minors, the approach should be “unsafe until proven safe” rather than “safe until proven unsafe”, and there have never been clinical trials or controlled studies on delaying puberty in healthy children or on chest and genital surgeries for minors. Although I still transitioned and detransitioned as an adult and have suffered some irreversible changes (such as a permanently altered voice) the effects were far less severe and life altering than they would have been had I started at 13 or younger, as is being recommended for children now.

Children with gender dysphoria deserve love, care, and treatments backed by proper research. This “affirmation-only” approach is preventing research into less invasive treatment methods. As adult Americans, it is our responsibility to protect our youth and ensure they develop into healthy adults, and this widespread medical experimentation is in direct opposition to that. There are reasons we have laws against minors getting tattoos, drinking alcohol, or joining the military; underage people’s brains are not fully developed, and thus they are not equipped to fully consider the consequences of their choices. It is the responsibility of the medical community as well as legislators to safeguard minors from permanently and irreversibly harming themselves. As a detransitioner and former trans-identified teen, I urge the Florida Board of Medicine to put an end to the medical experimentation, sterilization, and mutilation of children and teenagers suffering from gender dysphoria.

Sincerely,

Tony M.

Dear Sir or Madam,

I am writing to express my opposition to the gender affirming care practice implementations the Florida Board of Medicine is considering to adopt/perpetuate.

As a physician and scientist I have attached two publications that clearly demonstrate that such proposed gender affirming care is UNSCIENTIFIC. By adopting this affirming care, you will weaken the public trust in the science of medicine and reduce our field of medicine into simply quackery.

Again I am strongly opposed and ask that you do not implement nor perpetuate gender affirming care as a standard of care.

Sincerely

David Chen MD

Abstract

INTRODUCTION: Across human societies and in both sexes, some 2 to 10% of individuals report engaging in sex with same-sex partners, either exclusively or in addition to sex with opposite-sex partners. Twin and family studies have shown that same-sex sexual behavior is partly genetically influenced, but previous searches for the specific genes involved have been underpowered to detect effect sizes realistic for complex traits.

RATIONALE: For the first time, new large-scale datasets afford sufficient statistical power to identify genetic variants associated with same-sex sexual behavior (ever versus never had a same-sex partner), estimate the proportion of variation in the trait accounted for by all variants in aggregate, estimate the genetic correlation of same-sex sexual behavior with other traits, and probe the biology and complexity of the trait. To these ends, we performed genome-wide association discovery analyses on 477,522 individuals from the United Kingdom and United States, replication analyses in 15,142 individuals from the United States and Sweden, and follow-up analyses using different aspects of sexual preference.

RESULTS: In the discovery samples (UK Biobank and 23andMe), five autosomal loci were significantly associated with same-sex sexual behavior. Follow-up of these loci suggested links to biological pathways that involve sex hormone regulation and olfaction. Three of the loci were significant in a meta-analysis of smaller, independent replication samples. Although only a few loci passed the stringent statistical corrections for genome-wide multiple testing and were replicated in other samples, our analyses show that many loci underlie same-sex sexual behavior in both sexes. In aggregate, all tested genetic variants accounted for 8 to 25% of variation in male and

female same-sex sexual behavior, and the genetic influences were positively but imperfectly correlated between the sexes [genetic correlation coefficient (r_g) = 0.63; 95% confidence intervals, 0.48 to 0.78]. These aggregate genetic influences partly overlapped with those on a variety of other traits, including externalizing behaviors such as smoking, cannabis use, risk-taking, and the personality trait “openness to experience.” Additional analyses suggested that sexual behavior, attraction, identity, and fantasies are influenced by a similar set of genetic variants ($r_g > 0.83$); however, the genetic effects that differentiate heterosexual from same-sex sexual behavior are not the same as those that differ among nonheterosexuals with lower versus higher proportions of same-sex partners, which suggests that there is no single continuum from opposite-sex to same-sex preference.

CONCLUSION: Same-sex sexual behavior is influenced by not one or a few genes but many. Overlap with genetic influences on other traits provides insights into the underlying biology of same-sex sexual behavior, and analysis of different aspects of sexual preference underscore its complexity and call into question the validity of bipolar continuum measures such as the Kinsey scale. Nevertheless, many uncertainties remain to be explored, including how sociocultural influences on sexual preference might interact with genetic influences. To help communicate our study to the broader public, we organized workshops in which representatives of the public, activists, and researchers discussed the rationale, results, and implications of our study.

Abstract

Twin and family studies have shown that same-sex sexual behavior is partly genetically influenced, but previous searches for specific genes involved have been underpowered. We performed a genome-wide association study (GWAS) on 477,522 individuals, revealing five loci significantly associated with same-sex sexual behavior. In aggregate, all tested genetic variants accounted for 8 to 25% of variation in same-sex sexual behavior, only partially overlapped between males and females, and do not allow meaningful prediction of an individual’s sexual behavior. Comparing these GWAS results with those for the proportion of same-sex to total number of sexual partners among nonheterosexuals suggests that there is no single continuum from opposite-sex to same-sex sexual behavior. Overall, our findings provide insights into the genetics underlying same-sex sexual behavior and underscore the complexity of sexuality.

Graphical Abstract

A genome-wide association study (GWAS) of same-sex sexual behavior reveals five loci and high polygenicity. Follow-up analyses show potential biological pathways; show genetic correlations with various traits; and indicate that sexual preference is a complex, heterogeneous phenotype.

Across human societies and in both sexes, some 2 to 10% of individuals report engaging in sex with same-sex partners, either exclusively or in addition to sex with opposite-sex partners (1–4). The biological factors that contribute to sexual preference are largely unknown (5), but genetic influences are suggested by the observation that same-sex sexual

behavior appears to run in families (6) and is concordant more often in genetically identical (monozygotic) twin pairs than in fraternal twin pairs or siblings (7).

With respect to genetic influences, several questions arise. First, what genes are involved and what biological processes do they affect? Previous reports of genetic variants associated with sexual orientation (8–10) were based on relatively small samples and did not meet current standards of genome-wide significance ($P < 5 \times 10^{-8}$). Identification of robustly associated variants could enable exploration of the biological pathways and processes involved in development of same-sex sexual behavior. One hypothesis suggests that sex hormones are involved (11–13), but little direct genetic or biological evidence is available. Second, to what extent are genetic influences the same or different for females and males; behavior, attraction, and identity; and heterosexuality and different same-sex sexual behaviors (such as bisexuality)?

In order to identify genetic variants associated with same-sex sexual behavior and explore its genetic architecture and underlying biology, we performed a genome-wide association study (GWAS) of same-sex sexual behavior. Analyses were conducted in the UK Biobank from the United Kingdom and a cohort of research participants from 23andMe, predominantly located in the United States, and replications were performed in three other smaller studies. This study is part of a preregistered research plan (Open Science Framework; <https://osf.io/357tn>), and we explain our deviations from that plan in (14).

Phenotypic characterization

The UK Biobank study comprises a sample of ~500,000 genotyped UK residents aged 40 to 70 years (tables S1 and S2) (14). Our primary phenotype of interest is a binary, self-reported measure of whether respondents had ever had sex with someone of the same sex (here termed “nonheterosexuals”) or had not (here termed “heterosexuals”) (Box 1).

In the UK Biobank sample, 4.1% of males and 2.8% of females reported ever having had sex with someone of the same sex (tables S1 and S2), with higher rates among younger participants (Fig. 1A). This binary phenotype follows from previous work proposing that sexual preference is taxonic rather than dimensional in structure, with individuals reporting exclusively opposite-sex preference differing from individuals reporting any same-sex preference (15). However, the binary variable also collapses rich and multifaceted diversity among nonheterosexual individuals (15), so we explored finer-scaled measurements and some of the complexities of the phenotype, although intricacies of the social and cultural influences on sexuality made it impossible to fully explore this complexity. The 23andMe sample comprised 23andMe customers who consented to participate in research and chose to complete a survey about sexual orientation (from many possible survey topics). Individuals who engage in same-sex sexual behavior may be more likely to self-select the sexual orientation survey, which would explain the unusually high proportion of individuals who had had same-sex sexual partners in this sample (18.9%) (table S3) (14).

We also performed replication analyses in three smaller datasets (14): (i) Molecular Genetic Study of Sexual Orientation (MGSOSO) ($n = 2308$ U.S. adult males), in which respondents

were asked about their sexual identity; (ii) Add Health ($n = 4755$ U.S. young adults), in which respondents were asked whether they ever had same-sex intercourse and whether they were romantically attracted to the same sex; and (iii) Child and Adolescent Twin Study in Sweden (CATSS) ($n = 8093$ Swedish adolescents), in which participants reported the degree of attraction to the same versus opposite sex.

We observed in the UK Biobank that individuals who reported same-sex sexual behavior had on average fewer offspring than those of individuals who engaged exclusively in heterosexual behavior, even for individuals reporting only a minority of same-sex partners (Fig. 1B). This reduction in number of children is comparable with or greater than for other traits that have been linked to lower fertility rates (fig. S1) (14). This reproductive deficit raises questions about the evolutionary maintenance of the trait, but we do not address these here.

Genetic architecture of same-sex sexual behavior

We first assessed whether same-sex sexual behavior clustered in families in a manner consistent with genetic influences on the phenotype. Among pairs of individuals in the UK Biobank related at full cousin or closer [as identified by genomic similarity (14); n pairs = 106,979], more closely related individuals were more likely to be concordant in terms of same-sex sexual behavior. By modeling the correspondence of relatedness among individuals and the similarity of their sexual behavior, we estimated broad-sense heritability—the percentage of variation in a trait attributable to genetic variation—at 32.4% [95% confidence intervals (CIs), 10.6 to 54.3] (table S4). This estimate is consistent with previous estimates from smaller twin studies (7).

To identify genetic variants [largely singlenucleotide polymorphisms (SNPs)] associated with same-sex sexual behavior, we performed a GWAS in the UK Biobank study ($n = 408,995$ individuals) (14). To increase power and generalizability of our results, we also performed a GWAS in the cohort from 23andMe using an equivalent variable (individuals who reported having had sex with “Other sex only” versus the other options on a seven-point scale regarding participants’ sexual partners) ($n = 68,527$ individuals, of which 12,933 reported same-sex sexual behavior) (table S3) (14). We estimated the genetic correlation (16) between different heritable traits to determine the degree of consistency of genetic influences on same-sex sexual behavior in the two studies, which was high [genetic correlation coefficient (r_g) = 0.87; 95% CIs, 0.67 to 1.06] (table S5) (14). Genetic correlations between same-sex sexual behavior and 28 different traits were largely similar in the correlations between same-sex sexual behavior and 28 different traits were largely similar in the UK Biobank and 23andMe (fig. S2) (14), although a few differences were observed; for example, in females, the genetic correlations between same-sex sexual behavior and anorexia were in opposite directions in the UK Biobank ($r_g = -0.36$; 95% CIs, -0.60 and -0.09) and 23andMe data ($r_g = 0.36$; 95% CIs, 0.08 to 0.65; Wald test P value for differences = 0.0001). Overall, these results indicate that the genetic influences on same-sex sexual behavior in the two samples is similar, although there is some suggestion of phenotypic heterogeneity. We meta-analyzed the two sample sets using MTAG (17), which

models their genetic correlation to determine the meta-analytic weights, yielding a total sample size of 477,522 individuals (26,827 individuals reporting same-sex sexual behavior).

After standard quality control checks (table S6) (14), we identified two genome-wide significant signals for same-sex sexual behavior (rs11114975–12q21.31 and rs10261857–7q31.2) (Fig. 2 and tables S7 and S8). We discuss these SNPs further in the section “In-silico follow-up of GWAS results.” To assess differences in effects between females and males, we also performed sex-specific analyses. These results suggested only a partially shared genetic architecture across the sexes; the across-sex genetic correlation was 0.63 (95% CIs, 0.48 to 0.78) (table S9). This is noteworthy given that most other studied traits show much higher across-sex genetic correlations, often close to 1 (18–21). Through the sex-specific analyses, we identified two additional signals in males (rs28371400–15q21.3 and rs34730029–11q12.1), which showed no significant association in females, and one in females (rs13135637–4p14), which showed no significant association in males. Overall, three of the SNPs replicated at a nominal P value in the meta-analyzed replication datasets (Wald test $P = 0.027$ for rs34730029, $P = 0.003$ for rs28371400, and $P = 0.006$ for rs11114975) (table S10), despite the much smaller sample size (MGSOSO, Add Health, and CATSS; total sample size = 15,156 individuals, effective sample size = 4887 individuals).

The SNPs that reached genome-wide significance had very small effects (odds ratios ~ 1.1) (table S7). For example, in the UK Biobank, males with a GT genotype at the rs34730029 locus had 0.4% higher prevalence of same-sex sexual behavior than those with a TT genotype (4.0 versus 3.6%). Nevertheless, the contribution of all measured common SNPs in aggregate (SNP-based heritability) was estimated to be 8 to 25% (95% CIs, 5 to 30%) of variation in female and male same-sex sexual behavior, in which the range reflects differing estimates by using different analysis methods or prevalence assumptions (table S11) (14). The discrepancy between the variance captured by the significant SNPs and all common SNPs suggests that same-sex sexual behavior, like most complex human traits, is influenced by the small, additive effects of very many genetic variants, most of which cannot be detected at the current sample size (22). Consistent with this interpretation, we show that the contribution of each chromosome to heritability is broadly proportional to its size (fig. S3) (14). In contrast to linkage studies that found substantial association of sexual orientation with variants on the X-chromosome (8, 23), we found no excess of signal (and no individual genome-wide significant loci) on the X-chromosome (fig. S4).

To test whether these aggregate estimates of genetic effects correlate with sexuality in other samples, we constructed polygenic scores for same-sex sexual behavior (14, 24). These polygenic scores were significantly associated with sexual identity in MGSOSO (Wald test, $P = 0.001$) and same-sex attraction in the Add Health ($P = 0.017$) and CATSS ($P = 3.5 \times 10^{-6}$) studies (tables S12, S13, and S14). In CATSS, polygenic scores were also significantly associated with sexual attraction in participants at age 15 years ($P = 6.4 \times 10^{-5}$), suggesting that at least some of the genetic influences on same-sex sexual behavior manifest early in sexual development. The purpose of these analyses is to further characterize the genetic influences on same-sex sexual behavior and not to predict same-sex sexual behavior on the individual level. In all cases, the variance explained by the polygenic scores was extremely

low (<1%); these scores could not be used to accurately predict sexual behavior in an individual.

Overall, these findings suggest that genetic influences on same-sex sexual behavior are highly polygenic and are not specific to the discovery samples or measures. All the SNPs measured, when combined, do not capture the entirety of family-based heritability (8 to 25% from GWAS versus 32% from family-based methods). In this, same-sex sexual behavior is similar to many other complex traits; the ratio between family-based heritability and SNP-heritability estimated in the same sample is consistent with empirical findings for the other 16 traits we tested (family heritability approximately three times larger than SNP-heritability) (Fig. 3) (14). There are many possible reasons for this discrepancy, including, but not limited to, variants not captured by genotyping arrays, nonadditive genetic effects, and phenotypic heterogeneity.

In silico follow-up of GWAS results

To explore the biological processes that may influence same-sex sexual behavior, we performed cell- and tissue-type enrichment analyses using the GWAS discovery dataset (14, 25). We did not find clear evidence of enrichment for any particular cell or tissue (fig S5). However, we did find that genes near variants associated with same-sex sexual behavior are more likely than chance to be highly constrained [having unusually low prevalence of loss-of-function variants, suggesting stronger evolutionary constraint (14, 26)], even after controlling for expression in the brain (table S15).

At the level of individual loci, we investigated biological pathways by integrating information from expression quantitative trait loci (eQTL) analyses (27), genome-wide association study (PheWAS) (table S16) (28), and gene-based analysis by using MAGMA (14, 29). A full report can be found in table S17. Here, we highlight findings relating to the two SNPs associated with male same-sex sexual behavior: rs34730029 and rs28371400. First, the locus encompassing rs34730029–11q12.1 contains a number of olfactory receptor genes (several of which were significantly associated with same-sex sexual behavior in a gene-based test) (fig. S6 and table S18). This SNP is correlated [linkage disequilibrium, coefficient of determination (R^2) = 0.70] with a missense variant (rs6591536) in *OR5A1* that has been reported to have a substantial effect on the sensitivity to certain scents (30). Second, rs28371400–15q21.3 had several indications of being involved in sex hormone regulation: The allele positively associated with same-sex sexual behavior is associated with higher rate of male pattern balding [in which sex-hormone sensitivity is implicated (31)] and is located ~20 kb upstream of the *TCF12* gene. *TCF12* is the primary heterodimerization partner for *TCF21*, a transcription factor essential for normal development of the gonads in mice (32), and is involved in the downstream actions of the *SRY* gene (which is responsible for the initiation of male sex determination) in humans (33).

Genetic correlations with other traits

Next, we explored the genetic correlations between same-sex sexual behavior and 28 other relevant traits chosen before the analyses, using summary statistics from other GWASs (Fig.

4 and table S19) (14). In particular, we included mental health traits because they are substantially heritable (34), and previous population surveys have shown elevated risk of adverse mental health outcomes (such as depression, anxiety, or substance use) in sexual minority populations, including individuals engaging in same-sex sexual behavior (35,36).

We found several personality traits (loneliness and openness to experience), risky behaviors (smoking and cannabis use) and mental health disorders, but not physical traits, to be significantly genetically correlated with same-sex sexual behavior. We found in both sexes that same-sex sexual behavior was positively genetically correlated with several psychiatric or mental health traits [for example, depression, $r_g = 0.44$ in females (95% CIs, 0.32 and 0.55), $r_g = 0.33$ in males (95% CIs, 0.22 and 0.43); schizophrenia, $r_g = 0.17$ in females (95% CIs 0.08 and 0.35), $r_g = 0.13$ in males (95% CIs, 0.05 and 0.26); all Wald test $P < 0.001$]. We emphasize that the causal processes underlying these genetic correlations are unclear and could be generated by environmental factors relating to prejudice against individuals engaging in same-sex sexual behavior, among other possibilities, which we discuss in (14). Some associations were sex specific. In particular, the genetic correlations with bipolar disorder, cannabis use, and number of sexual partners were significantly higher in females than in males (Wald test $P = 0.001, 1.47 \times 10^{-6}$, and 3.13×10^{-5} respectively) (table S19).

Last, given the potential roles of sex hormones in sexual behaviors, we directly explored whether there is a genetic correlation with serum sex-hormone-binding globulin (SHBG) levels (37), which are thought to be inversely related to bioactive testosterone and estrogen in females and males, respectively (38). There was a significant correlation in females ($r_g = 0.25$, Wald test $P = 0.03$) but not in males ($r_g = 0.10$, Wald test $P = 0.32$).

Complexity and heterogeneity

To maximize our sample size and increase the power to detect SNP associations, we defined our primary phenotype as ever or never having had a same sex partner. Such a measure fails to capture the multifaceted richness and complexity of human sexual orientation. To explore the consequences of this simplification, we pursued genetic analyses across different aspects of sexual orientation and behavior.

First, within participants reporting same-sex sexual behavior, we performed a GWAS on the proportion of same-sex partners to total partners, with a higher value indicating a higher proportion of same-sex partners (14). In the UK Biobank, this is measured directly from participants' reported number of same-sex and all partners, whereas in 23andMe, we used participants' raw responses to the item "With whom have you had sex?", which in individuals reporting same-sex sexual behavior could be "other sex mostly," "other sex slightly," "equal," "same sex slightly," "same sex mostly," or "same sex only." The UK Biobank and 23andMe variables were heritable (table S20A) and genetically correlated with each other ($r_g = 0.52$ and 95% CIs, -0.16 to 1.20 for females; $r_g = 0.73$ and 95% CIs, 0.18 to 1.27 for males) (Fig. 5A and table S20C), so we used MTAG to meta-analyze across the two studies for subsequent analyses.

We found little evidence for genetic correlation of the proportion of same-sex to total partners among individuals reporting same-sex sexual behavior (nonheterosexuals) with the binary same-sex sexual behavior variable [$r_g = -0.31$ (95% CIs, -0.62 to 0.00) for females and $r_g = 0.03$ (95% CIs, -0.18 to 0.23) for males] (table S20B). Further, this phenotype showed a markedly different pattern of genetic correlations with other traits, as compared with corresponding genetic correlations with the binary same-sex sexual behavior variable (Fig. 5B and table S21). These findings suggest that the same-sex sexual behavior variable and the proportion of same-sex partners among nonheterosexuals capture aspects of sexuality that are distinct on the genetic level, which in turn suggests that there is no single continuum from opposite-sex to same-sex sexual behavior. Interpretations of any one set of results in our study must consider this complexity.

With this in mind, we examined the possibility of different genetic variants distinguishing heterosexual behavior from differing proportions of same-sex partners within nonheterosexuals. To do so, we performed additional GWASs in the UK Biobank data on the following traits: those whose partners were (i) less than a third same-sex, (ii) between a third and two-thirds same-sex, (iii) more than two-thirds same-sex, and (iv) exclusively same-sex. Genetic correlations of the first three categories with the fourth were 0.13, 0.80, and 0.95 (table S22), indicating partly different genetic variants distinguishing heterosexual behavior from differing proportions of same-sex partners within nonheterosexuals.

Last, using additional measures from 23andMe, we showed strong genetic correlations (all $r_g \geq 0.83$) (Fig. 5C and fig. S7) of same-sex sexual behavior with items assessing same-sex attraction, identity, and fantasies (a full list of items is provided in table S5), suggesting that these different aspects of sexual orientation are influenced by largely the same genetic variants. The full set of results of phenotypic and genetic correlations for females, males, and the whole sample is available in fig. S7 and table S5.

Discussion

We identified genome-wide significant loci associated with same-sex sexual behavior and found evidence of a broader contribution of common genetic variation. We established that the underlying genetic architecture is highly complex; there is certainly no single genetic determinant (sometimes referred to as the “gay gene” in the media). Rather, many loci with individually small effects, spread across the whole genome and partly overlapping in females and males, additively contribute to individual differences in predisposition to same-sex sexual behavior. All measured common variants together explain only part of the genetic heritability at the population level and do not allow meaningful prediction of an individual’s sexual preference.

The knowledge that the variants involved are numerous and spread across the genome enabled us to leverage whole-genome analytic techniques to explore human sexual behavior in ways previously impossible. We determined that the genetic effects that differentiate heterosexual from same-sex sexual behavior are not the same as those that differ among non-heterosexuals with lower versus higher proportions of same-sex partners. This finding suggests that on the genetic level, there is no single dimension from opposite-sex to same-

sex preference. The existence of such a dimension, in which the more someone is attracted to the same-sex the less they are attracted to the opposite-sex, is the premise of the Kinsey scale (39), a research tool ubiquitously used to measure sexual orientation. Another measure, the Klein Grid (40), retains the same premise but separately measures sexual attraction, behavior, fantasies, and identification (as well as nonsexual preferences); however, we found that these sexual measures are influenced by similar genetic factors. Overall, our findings suggest that the most popular measures are based on a misconception of the underlying structure of sexual orientation and may need to be rethought. In particular, using separate measures of attraction to the opposite sex and attraction to the same sex, such as in the Sell Assessment of Sexual Orientation (41), would remove the assumption that these variables are perfectly inversely related and would enable more nuanced exploration of the full diversity of sexual orientation, including bisexuality and asexuality.

Although we emphasize the polygenicity of the genetic effects on same-sex sexual behavior, we identified five SNPs whose association with same-sex sexual behavior reached genome-wide significance. Three of these replicated in other independent samples whose measures related to identity and attraction rather than behavior. These SNPs may serve to generate new lines of enquiry. In particular, the finding that one of the replicated SNPs (rs28371400–15q21.3) is linked to male pattern balding and is nearby a gene (*TCF12*) relevant to sexual differentiation strengthens the idea that sex-hormone regulation may be involved in the development of same-sex sexual behavior. Also, that another replicated SNP (rs34730029–11q12.1) is strongly linked to several genes involved in olfaction raises intriguing questions. Although the underlying mechanism at this locus is unclear, a link between olfaction and reproductive function has previously been established. Individuals with Kallmann syndrome exhibit both delayed or absent pubertal development and an impaired sense of smell because of the close developmental origin of fetal gonadotropin-releasing hormone and olfactory neurons (42).

Our study focused on the genetic basis of same-sex sexual behavior, but several of our results point to the importance of sociocultural context as well. We observed changes in prevalence of reported same-sex sexual behavior across time, raising questions about how genetic and sociocultural influences on sexual behavior might interact. We also observed partly different genetic influences on same-sex sexual behavior in females and males; this could reflect sex differences in hormonal influences on sexual behavior (for example, importance of testosterone versus estrogen) but could also relate to different sociocultural contexts of female and male same-sex behavior and different demographics of gay, lesbian, and bisexual groups (43). With these points in mind, we acknowledge the limitation that we only studied participants of European ancestry and from a few Western countries; research involving larger and more diverse samples will afford greater insight into how these findings fare across different sociocultural contexts.

Our findings provide insights into the biological underpinnings of same-sex sexual behavior but also underscore the importance of resisting simplistic conclusions (Box 2)—because the behavioral phenotypes are complex, because our genetic insights are rudimentary, and because there is a long history of misusing genetic results for social purposes.

Materials and methods summary

Study samples—We used data from genotyped individuals from five cohorts (total $n = 492,678$) who provided self-report information using different questionnaire-based measurement scales. Informed consent was provided from all individuals participating in the studies, which were approved by their local research ethic committee.

Genetic association analyses

After standard quality control, we performed GWASs for “same-sex sexual behavior” (defined as ever versus never having had sex with a same-sex partner) in the UK Biobank and 23andMe samples, which we meta-analysed using MTAG (17). We also conducted GWASs separately by sex. Genome-wide significant SNPs were replicated in three independent samples. Also, using LD-pred (24), we derived polygenic score for same-sex sexual behavior according to the meta-analyzed GWAS results and tested the association between this polygenic score and same-sex sexual behavior in three independent samples. To explore diversity among individuals reporting same-sex sexual behavior, we also conducted GWASs in the UK-Biobank and 23andMe samples (meta-analyzed using MTAG) on the “proportion of same-sex to total number of sexual partners among nonheterosexuals.”

Heritability estimation

We estimated family-based heritability of same-sex sexual behavior on the basis of known familial relationships in the UK Biobank study. The relatedness between pairs of participants was estimated by using KING (44). Additive genetic effects as well as shared and unshared environmental variance components were estimated on the basis of the covariance between different pairs of relatives. Second, heritability explained by all measured common SNPs (SNP-based heritability) was estimated by using linkage disequilibrium (LD) score regression (45) and transformed to the liability scale (46). Using a similar approach, we also estimated the SNP-based heritability per chromosome and evaluated heritability enrichment across various tissues on the basis of Genotype-Tissue Expression (GTEx) gene-expression results (47).

In silico follow-up

The GWAS results for same-sex sexual behavior were followed up with gene-based tests of association in MAGMA (29) and an enrichment analysis of evolutionarily constrained genes by using partitioned LD score regression (45) and MAGMA. We also performed a PheWAS (28) to examine whether the SNPs we identified for same-sex sexual behavior have also been associated with other phenotypes and eQTL mapping (27) to link SNPs with gene expression.

Genetic correlations and phenotypic heterogeneity

Using cross-trait LD score regression (16), we estimated the genetic correlations of same-sex sexual behavior and proportion of same-sex to total number of sexual partners among nonheterosexuals with a range of traits, including mental health, personality, and sexually dimorphic traits. To examine heterogeneity of genetic influences, we looked at the genetic

correlations between sexes, between cohorts, and between different measures of sexual preference.

Science communication strategy

To communicate the results of the study to the broader audience, we engaged with different LGBTQIA+ (lesbian, gay, bisexual, transgender, queer, intersex, asexual, and other+) and science communication organizations and created multimedia materials for a lay audience.

Detailed materials and methods can be found in the supplementary materials (14).

Box 1.**Phenotype and sample definition and limitations.**

In this study, we use the term “same-sex sexual behavior,” which is defined as having ever had sex with someone of the same sex. Detailed descriptions of the variables used in the different cohorts can be found in the supplementary materials (14).

To aid in readability throughout the manuscript, in some places we refer to individuals who have ever had sex with someone of the same sex as “nonheterosexuals,” whereas we refer to individuals who have never had sex with someone of the same sex as “heterosexuals.”

We acknowledge that the grouping phrase “nonheterosexuals” has the potential to present messages of othering (that is, undesirable marginalization of another person or group on the basis of their sexual expression)—by defining an “outgroup” in reference to an “ingroup” and implying that “nonheterosexual behavior” may have a negative connotation, whereas “heterosexual behavior” may have a positive one. We wish to make clear that our choice of language is not meant to forward messages of othering on the basis of sexual behavior.

Throughout this manuscript, we use the terms “female” and “male” rather than “woman” and “man.” This is because our analyses and results relate to biologically defined sex, not to gender.

As is common in genetic analyses, we dropped individuals from our study whose biological sex and self-identified sex/gender did not match. This is an important limitation of our analyses because the analyses do not include transgender persons, intersex persons, and other important persons and groups within the queer community. We hope that this limitation will be addressed in future work.

Box 2.**Communication and interpretation.**

The topic explored in this study is complex and intersects with sexuality, identity, and attraction and potentially has civil and political implications for sexual minority groups. Therefore, we have

Engaged with science communication teams,

Engaged with LGBTQIA+ advocacy groups nationally and within our local institutions, and Tried to make clear the many limitations and nuances of our study and our phenotypes.

We wish to make it clear that our results overwhelmingly point toward the richness and diversity of human sexuality. Our results do not point toward a role for discrimination on the basis of sexual identity or attraction, nor do our results make any conclusive statements about the degree to which “nature” and “nurture” influence sexual preference.

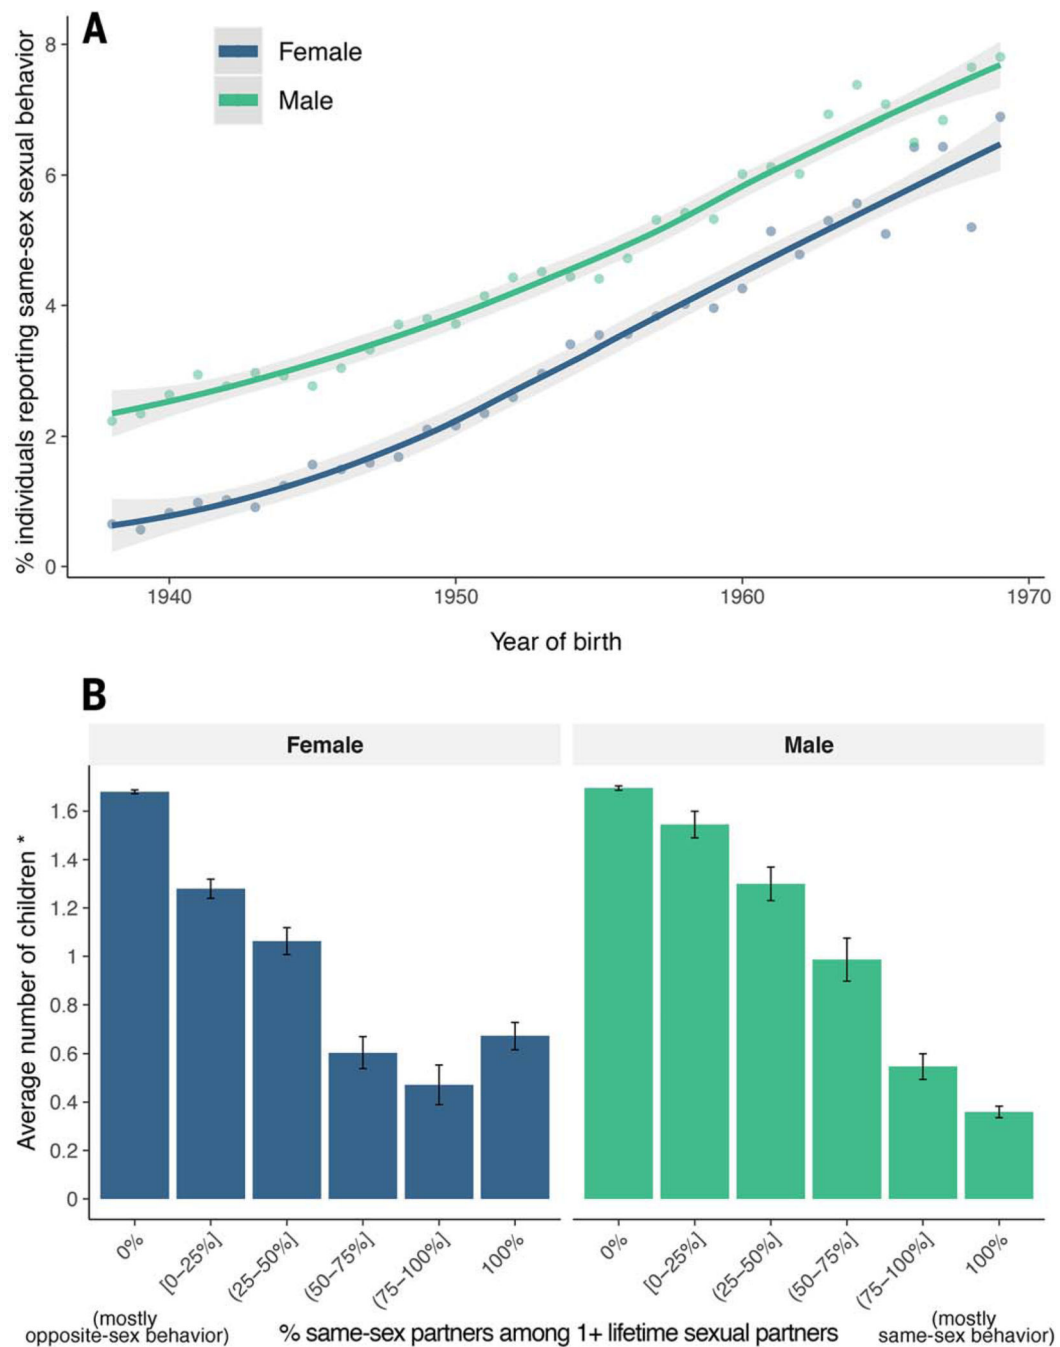

Fig. 1. Descriptive statistics regarding same-sex sexual behavior in the UK Biobank.

(A) The percentage of participants in the UK Biobank who reported having had at least one same-sex sexual partner (y axis) increased with participants' year of birth (x axis). (B) Among participants reporting at least one same-sex partner, those with a greater proportion of same-sex partners (x axis) have a larger reproductive disadvantage (lower birth-year adjusted number of children) (y axis). Vertical bars represent 95% CIs.

Fig. 2. Manhattan plot for a GWAS of same-sex sexual behavior.

Diamonds (red) represent genome-wide significant signals from analysis of males and females combined, and triangles represent genome-wide significant signals that are female (pointing up, blue) or male (pointing down, green) specific.

Fig. 3. SNP-based versus family-based heritability estimates for same-sex sexual behavior compared with a variety of other traits.

Heritability, h^2 ; same-sex sexual behavior, red dot; other traits, gray dots. The estimates for all traits are provided in table S23. Horizontal bars represent 95% CIs for the SNP-based estimate, and vertical bars represent 95% CIs for the family-based estimate. Dashed and solid lines represent the observed (obtained by linear regression) and expected relationship between family-based and SNP-based heritability, respectively.

Fig. 4. Genetic correlations of same-sex sexual behavior with various preselected traits and disorders, separately for males and females.

Males, green; females, blue. Yellow asterisks denote the genetic correlations that were experiment-wise significant ($P < 8.9 \times 10^{-4}$; references, definitions, and full results can be found in table S19). Wald test P values for the genetic correlations are reported above each dot. Horizontal bars represent 95% CIs.

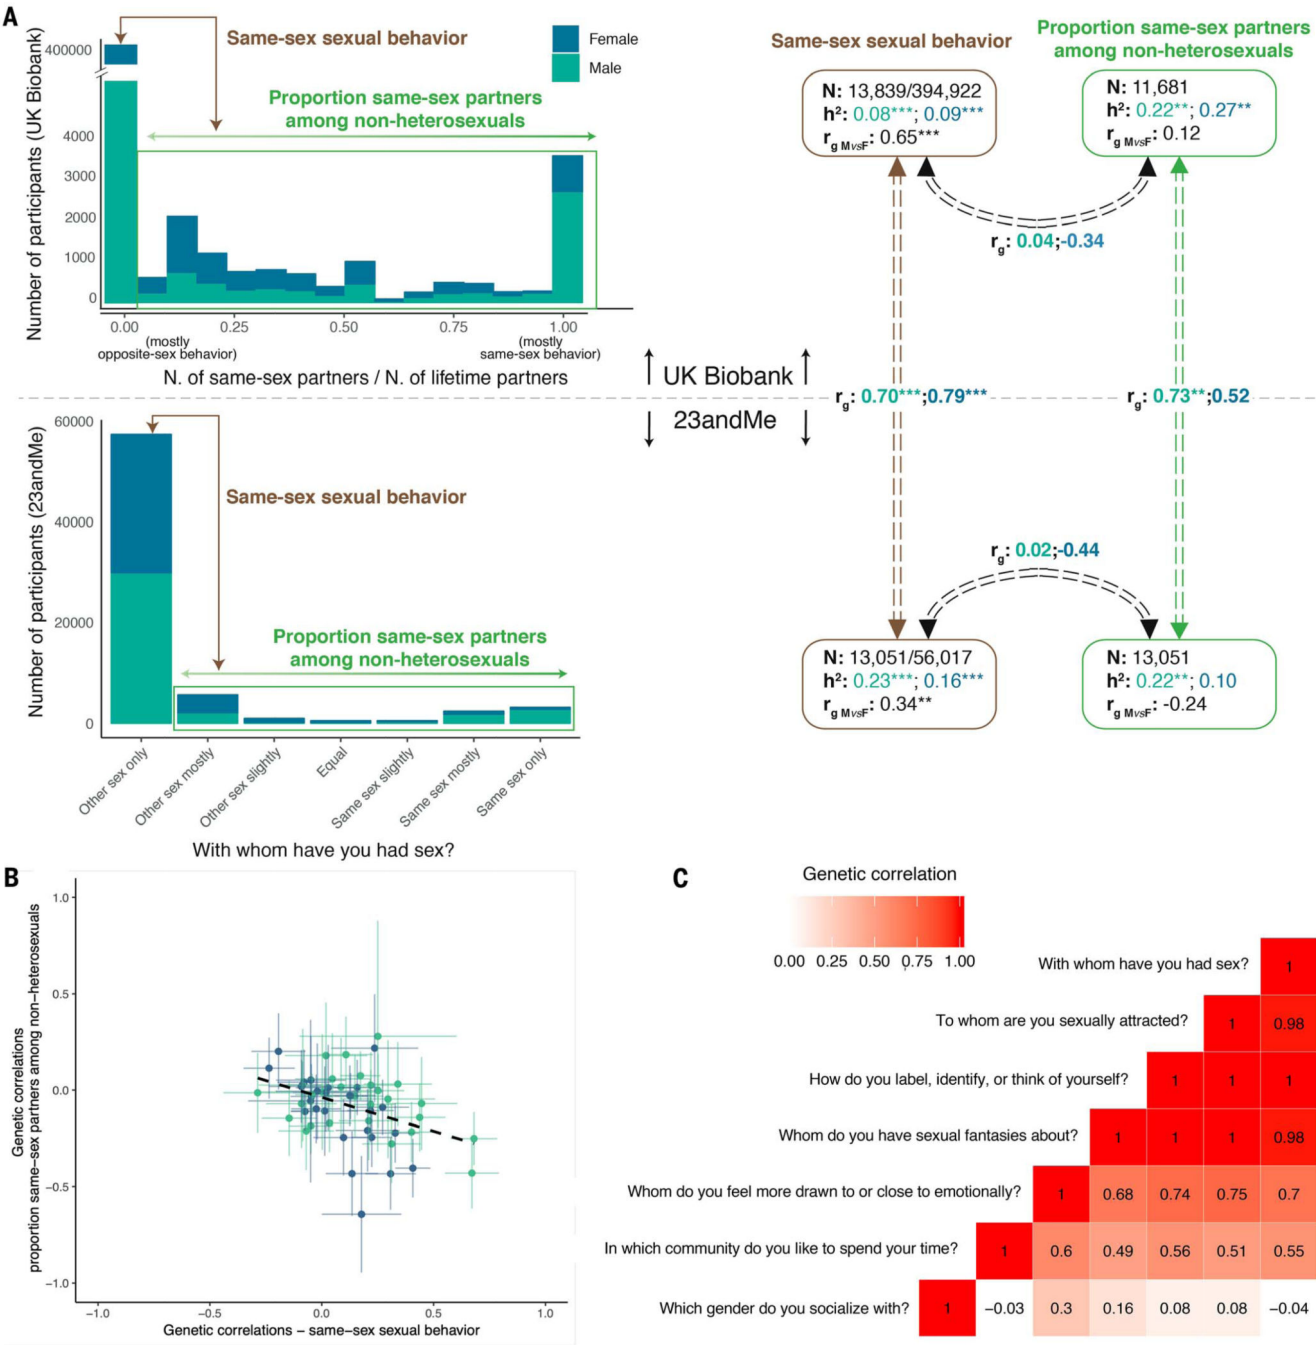

Fig. 5. Complexity and heterogeneity of genetic influences. (A) Genetic correlations between the main phenotype (same-sex sexual behavior; heterosexuals versus nonheterosexuals) and proportion of same-sex to total sexual partners among nonheterosexuals, in the UK Biobank and 23andMe samples. (B) Scatterplot showing genetic correlations of the main phenotype (x axis) and the proportion of same-sex to total partners among nonheterosexuals (y axis) with various other traits (table S21). (C) Genetic correlations among different sexual preference items in the 23andMe sample.

THE NEW ATLANTIS

A JOURNAL OF TECHNOLOGY & SOCIETY

NUMBER 50 ~ FALL 2016

Editor's Note: Questions related to sexuality and gender bear on some of the most intimate and personal aspects of human life. In recent years they have also vexed American politics. We offer this report—written by Dr. Lawrence S. Mayer, an epidemiologist trained in psychiatry, and Dr. Paul R. McHugh, arguably the most important American psychiatrist of the last half-century—in the hope of improving public understanding of these questions. Examining research from the biological, psychological, and social sciences, this report shows that some of the most frequently heard claims about sexuality and gender are not supported by scientific evidence. The report has a special focus on the higher rates of mental health problems among LGBT populations, and it questions the scientific basis of trends in the treatment of children who do not identify with their biological sex. More effort is called for to provide these people with the understanding, care, and support they need to lead healthy, flourishing lives.

Lawrence S. Mayer, M.B., M.S., Ph.D. is a scholar in residence in the Department of Psychiatry at the Johns Hopkins University School of Medicine and a professor of statistics and biostatistics at Arizona State University. *Paul R. McHugh, M.D.* is a professor of psychiatry and behavioral sciences at the Johns Hopkins University School of Medicine and was for twenty-five years the psychiatrist-in-chief at the Johns Hopkins Hospital. He is the author or coauthor of several books, including, most recently, *Try to Remember: Psychiatry's Clash over Meaning, Memory, and Mind* (Dana Press, 2008).

THE NEW ATLANTIS

A JOURNAL OF TECHNOLOGY & SOCIETY

The New Atlantis (1627) was the title Francis Bacon selected for his fable of a society living with the benefits and challenges of advanced science and technology. Bacon, a founder and champion of modern science, sought not only to highlight the potential of technology to improve human life, but also to foresee some of the social, moral, and political difficulties that confront a society shaped by the great scientific enterprise. His book offers no obvious answers; perhaps it seduces more than it warns. But the tale also hints at some of the dilemmas that arise with the ability to remake and reconfigure the natural world: governing science, so that it might flourish freely without destroying or dehumanizing us, and understanding the effect of technology on human life, human aspiration, and the human good. To a great extent, we live in the world Bacon imagined, and now we must find a way to live well with both its burdens and its blessings. This very challenge, which now confronts our own society most forcefully, is the focus of this journal.

It is printed by Global Printing and distributed by Ingram Periodicals, Inc.

Preface

This report was written for the general public and for mental health professionals in order to draw attention to—and offer some scientific insight about—the mental health issues faced by LGBT populations.

It arose from a request from Paul R. McHugh, M.D., the former chief of psychiatry at Johns Hopkins Hospital and one of the leading psychiatrists in the world. Dr. McHugh requested that I review a monograph he and colleagues had drafted on subjects related to sexual orientation and identity; my original assignment was to guarantee the accuracy of statistical inferences and to review additional sources. In the months that followed, I closely read over five hundred scientific articles on these topics and perused hundreds more. I was alarmed to learn that the LGBT community bears a disproportionate rate of mental health problems compared to the population as a whole.

As my interest grew, I explored research across a variety of scientific fields, including epidemiology, genetics, endocrinology, psychiatry, neuroscience, embryology, and pediatrics. I also reviewed many of the academic empirical studies done in the social sciences including psychology, sociology, political science, economics, and gender studies.

I agreed to take over as lead author, rewriting, reorganizing, and expanding the text. I support every sentence in this report, without reservation and without prejudice regarding any political or philosophical debates. This report is about science and medicine, nothing more and nothing less.

Readers wondering about this report's synthesis of research from so many different fields may wish to know a little about its lead author. I am a full-time academic involved in all aspects of teaching, research, and professional service. I am a biostatistician and epidemiologist who focuses on the design, analysis, and interpretation of experimental and observational data in public health and medicine, particularly when the data are complex in terms of underlying scientific issues. I am a research physician, having trained in medicine and psychiatry in the U.K. and received the British equivalent (M.B.) to the American M.D. I have never practiced medicine (including psychiatry) in the United States or abroad. I have testified in dozens of federal and state legal proceedings and regulatory hearings, in

most cases reviewing scientific literature to clarify the issues under examination. I strongly support equality and oppose discrimination for the LGBT community, and I have testified on their behalf as a statistical expert.

I have been a full-time tenured professor for over four decades. I have held professorial appointments at eight universities, including Princeton, the University of Pennsylvania, Stanford, Arizona State University, Johns Hopkins University Bloomberg School of Public Health and School of Medicine, Ohio State, Virginia Tech, and the University of Michigan. I have also held research faculty appointments at several other institutions, including the Mayo Clinic.

My full-time and part-time appointments have been in twenty-three disciplines, including statistics, biostatistics, epidemiology, public health, social methodology, psychiatry, mathematics, sociology, political science, economics, and biomedical informatics. But my research interests have varied far less than my academic appointments: the focus of my career has been to learn how statistics and models are employed across disciplines, with the goal of improving the use of models and data analytics in assessing issues of interest in the policy, regulatory, or legal realms.

I have been published in many top-tier peer-reviewed journals (including *The Annals of Statistics*, *Biometrics*, and *American Journal of Political Science*) and have reviewed hundreds of manuscripts submitted for publication to many of the major medical, statistical, and epidemiological journals (including *The New England Journal of Medicine*, *Journal of the American Statistical Association*, and *American Journal of Public Health*).

I am currently a scholar in residence in the Department of Psychiatry at Johns Hopkins School of Medicine and a professor of statistics and biostatistics at Arizona State University. Up until July 1, 2016, I also held part-time faculty appointments at the Johns Hopkins Bloomberg School of Public Health and School of Medicine, and at the Mayo Clinic.

An undertaking as ambitious as this report would not be possible without the counsel and advice of many gifted scholars and editors. I am grateful for the generous help of Laura E. Harrington, M.D., M.S., a psychiatrist with extensive training in internal medicine and neuroimmunology, whose clinical practice focuses on women in life transition, including affirmative treatment and therapy for the LGBT community. She contributed to the entire report, particularly lending her expertise to the sections on endocrinology and brain research. I am indebted also to Bentley J. Hanish, B.S., a young geneticist who expects to graduate medical school in 2021 with an M.D./Ph.D. in psychiatric epidemiology.

He contributed to the entire report, particularly to those sections that concern genetics.

I gratefully acknowledge the support of Johns Hopkins University Bloomberg School of Public Health and School of Medicine, Arizona State University, and the Mayo Clinic.

In the course of writing this report, I consulted a number of individuals who asked that I not thank them by name. Some feared an angry response from the more militant elements of the LGBT community; others feared an angry response from the more strident elements of religiously conservative communities. Most bothersome, however, is that some feared reprisals from their own universities for engaging such controversial topics, regardless of the report's content—a sad statement about academic freedom.

I dedicate my work on this report, first, to the LGBT community, which bears a disproportionate rate of mental health problems compared to the population as a whole. We must find ways to relieve their suffering.

I dedicate it also to scholars doing impartial research on topics of public controversy. May they never lose their way in political hurricanes.

And above all, I dedicate it to children struggling with their sexuality and gender. Children are a special case when addressing gender issues. In the course of their development, many children explore the idea of being of the opposite sex. Some children may have improved psychological well-being if they are encouraged and supported in their cross-gender identification, particularly if the identification is strong and persistent over time. But nearly all children ultimately identify with their biological sex. The notion that a two-year-old, having expressed thoughts or behaviors identified with the opposite sex, can be labeled for life as transgender has absolutely no support in science. Indeed, it is iniquitous to believe that all children who have gender-atypical thoughts or behavior at some point in their development, particularly before puberty, should be encouraged to become transgender.

As citizens, scholars, and clinicians concerned with the problems facing LGBT people, we should not be dogmatically committed to any particular views about the nature of sexuality or gender identity; rather, we should be guided first and foremost by the needs of struggling patients, and we should seek with open minds for ways to help them lead meaningful, dignified lives.

LAWRENCE S. MAYER, M.B., M.S., Ph.D.

Executive Summary

This report presents a careful summary and an up-to-date explanation of research—from the biological, psychological, and social sciences—related to sexual orientation and gender identity. It is offered in the hope that such an exposition can contribute to our capacity as physicians, scientists, and citizens to address health issues faced by LGBT populations within our society.

Some key findings:

Part One: Sexual Orientation

- The understanding of sexual orientation as an innate, biologically fixed property of human beings—the idea that people are “born that way”—is not supported by scientific evidence.
- While there is evidence that biological factors such as genes and hormones are associated with sexual behaviors and attractions, there are no compelling causal biological explanations for human sexual orientation. While minor differences in the brain structures and brain activity between homosexual and heterosexual individuals have been identified by researchers, such neurobiological findings do not demonstrate whether these differences are innate or are the result of environmental and psychological factors.
- Longitudinal studies of adolescents suggest that sexual orientation may be quite fluid over the life course for some people, with one study estimating that as many as 80% of male adolescents who report same-sex attractions no longer do so as adults (although the extent to which this figure reflects actual changes in same-sex attractions and not just artifacts of the survey process has been contested by some researchers).
- Compared to heterosexuals, non-heterosexuals are about two to three times as likely to have experienced childhood sexual abuse.

Part Two: Sexuality, Mental Health Outcomes, and Social Stress

- Compared to the general population, non-heterosexual sub-populations are at an elevated risk for a variety of adverse health and mental health outcomes.
- Members of the non-heterosexual population are estimated to have about 1.5 times higher risk of experiencing anxiety disorders than members of the heterosexual population, as well as roughly double the risk of depression, 1.5 times the risk of substance abuse, and nearly 2.5 times the risk of suicide.
- Members of the transgender population are also at higher risk of a variety of mental health problems compared to members of the non-transgender population. Especially alarmingly, the rate of lifetime suicide attempts across all ages of transgender individuals is estimated at 41%, compared to under 5% in the overall U.S. population.
- There is evidence, albeit limited, that social stressors such as discrimination and stigma contribute to the elevated risk of poor mental health outcomes for non-heterosexual and transgender populations. More high-quality longitudinal studies are necessary for the “social stress model” to be a useful tool for understanding public health concerns.

Part Three: Gender Identity

- The hypothesis that gender identity is an innate, fixed property of human beings that is independent of biological sex—that a person might be “a man trapped in a woman’s body” or “a woman trapped in a man’s body”—is not supported by scientific evidence.
- According to a recent estimate, about 0.6% of U.S. adults identify as a gender that does not correspond to their biological sex.
- Studies comparing the brain structures of transgender and non-transgender individuals have demonstrated weak correlations between brain structure and cross-gender identification. These correlations do not provide any evidence for a neurobiological basis for cross-gender identification.

- Compared to the general population, adults who have undergone sex-reassignment surgery continue to have a higher risk of experiencing poor mental health outcomes. One study found that, compared to controls, sex-reassigned individuals were about 5 times more likely to attempt suicide and about 19 times more likely to die by suicide.
- Children are a special case when addressing transgender issues. Only a minority of children who experience cross-gender identification will continue to do so into adolescence or adulthood.
- There is little scientific evidence for the therapeutic value of interventions that delay puberty or modify the secondary sex characteristics of adolescents, although some children may have improved psychological well-being if they are encouraged and supported in their cross-gender identification. There is no evidence that all children who express gender-atypical thoughts or behavior should be encouraged to become transgender.

Sexuality and Gender

Findings from the Biological, Psychological, and Social Sciences

Lawrence S. Mayer, M.B., M.S., Ph.D. and Paul R. McHugh, M.D.

Introduction

Few topics are as complex and controversial as human sexual orientation and gender identity. These matters touch upon our most intimate thoughts and feelings, and help to define us as both individuals and social beings. Discussions of the ethical questions raised by sexual orientation and gender identity can become heated and personal, and the associated policy issues sometimes provoke intense controversies. The disputants, journalists, and lawmakers in these debates often invoke the authority of science, and in our news and social media and our broader popular culture we hear claims about what “science says” on these matters.

This report offers a careful summary and an up-to-date explanation of many of the most rigorous findings produced by the biological, psychological, and social sciences related to sexual orientation and gender identity. We examine a vast body of scientific literature from several disciplines. We try to acknowledge the limitations of the research and to avoid premature conclusions that would result in over-interpretation of scientific findings. Since the relevant literature is rife with inconsistent and ambiguous definitions, we not only examine the empirical evidence but also delve into underlying conceptual problems. This report does not, however, discuss matters of morality or policy; our focus is on the scientific evidence—what it shows and what it does not show.

We begin in Part One by critically examining whether concepts such as heterosexuality, homosexuality, and bisexuality represent distinct, fixed, and biologically determined properties of human beings. As part of this discussion, we look at the popular “born that way” hypothesis, which

posits that human sexual orientation is biologically innate; we examine the evidence for this claim across several subspecialties of the biological sciences. We explore the developmental origins of sexual attractions, the degree to which such attractions may change over time, and the complexities inherent in the incorporation of these attractions into one's sexual identity. Drawing on evidence from twin studies and other types of research, we explore genetic, environmental, and hormonal factors. We also explore some of the scientific evidence relating brain science to sexual orientation.

In Part Two we examine research on health outcomes as they relate to sexual orientation and gender identity. There is a consistently observed higher risk of poor physical and mental health outcomes for lesbian, gay, bisexual, and transgender subpopulations compared to the general population. These outcomes include depression, anxiety, substance abuse, and most alarmingly, suicide. For example, among the transgender subpopulation in the United States, the rate of attempted suicide is estimated to be as high as 41%, ten times higher than in the general population. As physicians, academics, and scientists, we believe all of the subsequent discussions in this report must be cast in the light of this public health issue.

We also examine some ideas proposed to explain these differential health outcomes, including the “social stress model.” This hypothesis—which holds that stressors like stigma and prejudice account for much of the additional suffering observed in these subpopulations—does not seem to offer a complete explanation for the disparities in the outcomes.

Much as Part One investigates the conjecture that sexual orientation is fixed with a causal biological basis, a portion of Part Three examines similar issues with respect to gender identity. Biological sex (the binary categories of male and female) is a fixed aspect of human nature, even though some individuals affected by disorders of sex development may exhibit ambiguous sex characteristics. By contrast, gender identity is a social and psychological concept that is not well defined, and there is little scientific evidence that it is an innate, fixed biological property.

Part Three also examines sex-reassignment procedures and the evidence for their effectiveness at alleviating the poor mental health outcomes experienced by many people who identify as transgender. Compared to the general population, postoperative transgender individuals continue to be at high risk of poor mental health outcomes.

An area of particular concern involves medical interventions for gender-nonconforming youth. They are increasingly receiving therapies that affirm their felt genders, and even hormone treatments or surgical

modifications at young ages. But the majority of children who identify as a gender that does not conform to their biological sex will no longer do so by the time they reach adulthood. We are disturbed and alarmed by the severity and irreversibility of some interventions being publicly discussed and employed for children.

Sexual orientation and gender identity resist explanation by simple theories. There is a large gap between the certainty with which beliefs are held about these matters and what a sober assessment of the science reveals. In the face of this complexity and uncertainty, we need to be humble about what we know and do not know. We readily acknowledge that this report is neither an exhaustive analysis of the subjects it addresses nor the last word on them. Science is by no means the only avenue for understanding these astoundingly complex, multifaceted topics; there are other sources of wisdom and knowledge—including art, religion, philosophy, and lived human experience. And much of our scientific knowledge in this area remains unsettled. However, we offer this overview of the scientific literature in the hope that it can provide a shared framework for intelligent, enlightened discourse in political, professional, and scientific exchanges—and may add to our capacity as concerned citizens to alleviate suffering and promote human health and flourishing.

Part One

Sexual Orientation

While some people are under the impression that sexual orientation is an innate, fixed, and biological trait of human beings—that, whether heterosexual, homosexual, or bisexual, we are “born that way”—there is insufficient scientific evidence to support that claim. In fact, the concept of sexual orientation itself is highly ambiguous; it can refer to a set of behaviors, to feelings of attraction, or to a sense of identity. Epidemiological studies show a rather modest association between genetic factors and sexual attractions or behaviors, but do not provide significant evidence pointing to particular genes. There is also evidence for other hypothesized biological causes of homosexual behaviors, attractions, or identity—such as the influence of hormones on prenatal development—but that evidence, too, is limited. Studies of the brains of homosexuals and heterosexuals have found some differences, but have not demonstrated that these differences are inborn rather than the result of environmental factors that influenced both psychological and neurobiological traits. One environmental factor that appears to be correlated with non-heterosexuality is childhood sexual abuse victimization, which may also contribute to the higher rates of poor mental health outcomes among non-heterosexual subpopulations, compared to the general population. Overall, the evidence suggests some measure of fluidity in patterns of sexual attraction and behavior—contrary to the “born that way” notion that oversimplifies the vast complexity of human sexuality.

The popular discussion of sexual orientation is characterized by two conflicting ideas about why some individuals are lesbian, gay, or bisexual. While some claim that sexual orientation is a choice, others say that sexual orientation is a fixed feature of one’s nature, that one is “born that way.” We hope to show here that, though sexual orientation is not a choice, neither is there scientific evidence for the view that sexual orientation is a fixed and innate biological property.

A prominent recent example of a person describing sexual orientation as a choice is Cynthia Nixon, a star of the popular television series *Sex and the City*, who in a January 2012 *New York Times* interview explained, “For me it’s a choice, and you don’t get to define my gayness for me,” and commented that she was “very annoyed” about the issue of whether or not gay people are born that way. “Why can’t it be a choice? Why is that any less legitimate?”¹ Similarly, Brandon Ambrosino wrote in *The New Republic* in

2014 that “It’s time for the LGBT community to stop fearing the word ‘choice,’ and to reclaim the dignity of sexual autonomy.”²

By contrast, proponents of the “born that way” hypothesis—expressed for instance in Lady Gaga’s 2011 song “Born This Way”—posit that there is a causal biological basis for sexual orientation and often try to bolster their claims with scientific findings. Citing three scientific studies³ and an article from *Science* magazine,⁴ Mark Joseph Stern, writing for *Slate* in 2014, claims that “homosexuality, at least in men, is clearly, undoubtedly, inarguably an inborn trait.”⁵ However, as neuroscientist Simon LeVay, whose work in 1991 showed brain differences in homosexual men compared to heterosexual men, explained some years after his study, “It’s important to stress what I didn’t find. I did not prove that homosexuality is genetic, or find a genetic cause for being gay. I didn’t show that gay men are ‘born that way,’ the most common mistake people make in interpreting my work. Nor did I locate a gay center in the brain.”⁶

Many recent books contain popular treatments of science that make claims about the innateness of sexual orientation. These books often exaggerate—or at least oversimplify—complex scientific findings. For example, in a 2005 book, psychologist and science writer Leonard Sax responds to a worried mother’s question as to whether her teenage son will outgrow his homosexual attractions: “Biologically, the difference between a gay man and a straight man is something like the difference between a left-handed person and a right-handed person. Being left-handed isn’t just a phase. A left-handed person won’t someday magically turn into a right-handed person.... Some children are destined at birth to be left-handed, and some boys are destined at birth to grow up to be gay.”⁷

As we argue in this part of the report, however, there is little scientific evidence to support the claim that sexual attraction is simply fixed by innate and deterministic factors such as genes. Popular understandings of scientific findings often presume deterministic causality when the findings do not warrant that presumption.

Another important limitation for research and for interpretation of scientific studies on this topic is that some central concepts—including “sexual orientation” itself—are often ambiguous, making reliable measurements difficult both within individual studies and when comparing results across studies. So before turning to the scientific evidence concerning the development of sexual orientation and sexual desire, we will examine at some length several of the most troublesome conceptual ambiguities in the study of human sexuality in order to arrive at a fuller picture of the relevant concepts.

Problems with Defining Key Concepts

A 2014 *New York Times Magazine* piece titled “The Scientific Quest to Prove Bisexuality Exists”⁸ provides an illustration of the themes explored in this Part—sexual desire, attraction, orientation, and identity—and of the difficulties with defining and studying these concepts. Specifically, the article shows how a scientific approach to studying human sexuality can conflict with culturally prevalent views of sexual orientation, or with the self-understanding that many people have of their own sexual desires and identities. Such conflicts raise important questions about whether sexual orientation and related concepts are as coherent and well-defined as is often assumed by researchers and the public alike.

The author of the article, Benoit Denizet-Lewis, an openly gay man, describes the work of scientists and others trying to demonstrate the existence of a stable bisexual orientation. He visited researchers at Cornell University and participated in tests used to measure sexual arousal, tests that include observing the way pupils dilate in response to sexually explicit imagery. To his surprise, he found that, according to this scientific measure, he was aroused when watching pornographic films of women masturbating:

Might I actually be bisexual? Have I been so wedded to my gay identity—one I adopted in college and announced with great fanfare to family and friends—that I haven’t allowed myself to experience another part of myself? In some ways, even asking those questions is anathema to many gays and lesbians. That kind of publicly shared uncertainty is catnip to the Christian Right and to the scientifically dubious, psychologically damaging ex-gay movement it helped spawn. As out gay men and lesbians, after all, we’re supposed to be sure—we’re supposed to be “born this way.”⁹

Despite the apparently scientific (though admittedly limited) evidence of his bisexual-typical patterns of arousal, Denizet-Lewis rejected the idea that he was actually bisexual, because “It doesn’t feel true as a sexual orientation, nor does it feel right as my identity.”¹⁰

Denizet-Lewis’s concerns here illustrate a number of the quandaries raised by the scientific study of human sexuality. The objective measures the researchers used seemed to be at odds with the more intuitive, subjective understanding of what it is to be sexually aroused; our own understanding of what we are sexually aroused by is tied up with the entirety of our lived experience of sexuality. Furthermore, Denizet-Lewis’s insistence

that he is gay, not bisexual, and his concern that uncertainty about his identity could have social and political implications, points to the fact that sexual orientation and identity are understood not only in scientific and personal terms, but in social, moral, and political terms as well.

But how do categories of sexual orientation—with labels such as “bisexual” or “gay” or “straight”—help scientists study the complex phenomenon of human sexuality? When we examine the concept of sexual orientation, it becomes apparent, as this part will show, that it is too vague and poorly defined to be very useful in science, and that in its place we need more clearly defined concepts. We strive in this report to use clear terms; when discussing scientific studies that rely on the concept of “sexual orientation,” we try as much as possible to specify how the scientists defined the term, or related terms.

One of the central difficulties in examining and researching sexual orientation is that the underlying concepts of “sexual desire,” “sexual attraction,” and “sexual arousal” can be ambiguous, and it is even less clear what it means that a person identifies as having a sexual orientation grounded in some pattern of desires, attractions, or states of arousal.

The word “desire” all by itself might be used to cover an aspect of volition more naturally expressed by “want”: I want to go out for dinner, or to take a road trip with my friends next summer, or to finish this project. When “desire” is used in this sense, the objects of desire are fairly determinate *goals*—some may be perfectly achievable, such as moving to a new city or finding a new job; others may be more ambitious and out of reach, like the dream of becoming a world-famous movie star. Often, however, the language of desire is meant to include things that are less clear: indefinite *longings* for a life that is, in some unspecified sense, different or better; an inchoate sense of something being missing or lacking in oneself or one’s world; or, in psychoanalytic literature, unconscious dynamic forces that shape one’s cognitive, emotional, and social behaviors, but that are separate from one’s ordinary, conscious sense of self.

This more full-blooded notion of desire is, itself, ambiguous. It might refer to a hoped-for state of affairs like finding a sense of meaning, fulfillment, and satisfaction with one’s life, a desire that, while not completely clear in its implications, is presumably not entirely out of reach, although such longings may also be forms of fantasizing about a radically altered or perhaps even unattainable state of affairs. If I want to take a road trip with my friends, the steps are clear: call up my friends, pick a date, map out a route, and so on. However, if I have an inchoate longing for change, a hope for sustainable intimacy, love, and belonging, or an unconscious conflict

that is disrupting my ability to move forward in the life I have tried to build for myself, I face a different sort of challenge. There is not necessarily a set of well-defined or conscious goals, much less established ways of achieving them. This is not to say that the satisfaction of these longings is impossible, but doing so often involves not only choosing concrete actions to achieve particular goals but the more complex shaping of one's own life through acting in and making sense of the world and one's place in it.

So the first thing to note when considering both popular discussions and scientific studies of sexuality is that the use of the term "desire" could refer to distinct aspects of human life and experience.

Just as the meanings that might be intended by the term "desire" are many, so also is each of these meanings varied, making clear delineations a challenge. For example, a commonsense understanding might suggest that the term "sexual desire" means wanting to engage in specific sexual acts with particular individuals (or categories of individuals). Psychiatrist Steven Levine articulated this common view in his definition of sexual desire as "the sum of the forces that incline us toward and away from sexual behavior."¹¹ But it is not obvious how one might study this "sum" in a rigorous way. Nor is it obvious why all the diverse factors that can potentially influence sexual behavior, such as material poverty—in the case of prostitution, for instance—alcohol consumption, and intimate affection, should all be grouped together as aspects of sexual desire. As Levine himself points out, "In anyone's hands, sexual desire can be a slippery concept."¹²

Consider a few of the ways that the term "sexual desire" has been employed in scientific contexts—designating one or more of the following distinct phenomena:

1. States of physical arousal that may or may not be linked to a specific physical activity and may or may not be objects of conscious awareness.
2. Conscious erotic interest in response to finding others attractive (in perception, memory, or fantasy), which may or may not involve any of the bodily processes associated with measurable states of physical arousal.
3. Strong interest in finding a companion or establishing a durable relationship.
4. The romantic aspirations and feelings associated with infatuation or falling in love with a specific individual.

5. Inclination towards attachment to specific individuals.
6. The general motivation to seek intimacy with a member of some specific group.
7. An aesthetic measure that latches onto perceived beauty in others.¹³

In a given social science study, the concepts mentioned above will often each have its own particular operational definition for the purposes of research. But they cannot all mean the *same* thing. Strong interest in finding a companion, for example, is clearly distinguishable from physical arousal. Looking at this list of experiential and psychological phenomena, one can easily envision what confusions might arise from using the term “sexual desire” without sufficient care.

The philosopher Alexander Pruss provides a helpful summary of some of the difficulties involved in characterizing the related concept of sexual attraction:

What does it mean to be “sexually attracted” to someone? Does it mean to have a tendency to be aroused in their presence? But surely it is possible to find someone sexually attractive without being aroused. Does it mean to form the belief that someone is sexually attractive to one? Surely not, since a belief about who is sexually attractive to one might be wrong—for instance, one might confuse admiration of form with sexual attraction. Does it mean to have a noninstrumental desire for a sexual or romantic relationship with the person? Probably not: we can imagine a person who has no sexual attraction to anybody, but who has a noninstrumental desire for a romantic relationship because of a belief, based on the testimony of others, that romantic relationships have noninstrumental value. These and similar questions suggest that there is a cluster of related concepts under the head of “sexual attraction,” and any precise definition is likely to be an undesirable shoehorning. But if the concept of sexual attraction is a cluster of concepts, neither are there simply univocal concepts of heterosexuality, homosexuality, and bisexuality.¹⁴

The ambiguity of the term “sexual desire” (and similar terms) should give us pause to consider the diverse aspects of human experience that are often associated with it. The problem is neither irresolvable nor unique to this subject matter. Other social science concepts—aggression and addiction, for example—may likewise be difficult to define and to

operationalize and for this reason admit of various usages.* Nevertheless, the ambiguity presents a significant challenge for both research design and interpretation, requiring that we take care in attending to the meanings, contexts, and findings specific to each study. It is also important to bracket any subjective associations with or uses of these terms that do not conform to well-defined scientific classifications and techniques.

It would be a mistake, at any rate, to ignore the varied uses of this and related terms or to try to reduce the many and distinct experiences to which they might refer to a single concept or experience. As we shall see, doing so could in some cases adversely affect the evaluation and treatment of patients.

The Context of Sexual Desire

We can further clarify the complex phenomenon of sexual desire if we examine what relationship it has to other aspects of our lives. To do so, we borrow some conceptual tools from a philosophical tradition known as phenomenology, which conceives of human experience as deriving its meaning from the whole context in which it appears.

The testimony of experience suggests that one's experience of sexual desire and sexual attraction is not voluntary, at least not in any immediate way. The whole set of inclinations that we generally associate with the experience of sexual desire—whether the impulse to engage in particular acts or to enjoy certain relationships—does not appear to be the sole product of any deliberate choice. Our sexual appetites (like other natural appetites) are experienced as given, even if their expression is shaped in subtle ways by many factors, which might very well include volition. Indeed, far from appearing as a product of our will, sexual desire—however we define it—is often experienced as a powerful force, akin to hunger, that many struggle (especially in adolescence) to bring under direction and control. Furthermore, sexual desire can impact one's attention involuntarily or color one's day-to-day perceptions, experiences, and encounters. What seems to be to some extent in our control is how we choose to live with this appetite, how we integrate it into the rest of our lives.

But the question remains: What *is* sexual desire? What is this part of our lives that we consider to be given, prior even to our capacity to

* "Operationalizing" refers to the way social scientists make a variable measurable. Homosexuality may be operationalized as the answers that survey respondents give to questions about their sexual orientation. Or it could be operationalized as answers to questions about their desires, attractions, and behavior. Operationalizing variables in ways that will reliably measure the trait or behavior being studied is a difficult but important part of any social science research.

deliberate and make rational choices about it? We know that some sort of sexual appetite is present in non-human animals, as is evident in the mammalian estrous cycle; in most mammalian species sexual arousal and receptivity are linked to the phase of the ovulation cycle during which the female is reproductively receptive.¹⁵ One of the relatively unique features of *Homo sapiens*, shared with only a few other primates, is that sexual desire is not exclusively linked to the woman's ovulatory cycle.¹⁶ Some biologists have argued that this means that sexual desire in humans has evolved to facilitate the formation of sustaining relationships between parents, in addition to the more basic biological purpose of reproduction. Whatever the explanation for the origins and biological functions of human sexuality, the lived experience of sexual desires is laden with significance that goes beyond the biological purposes that sexual desires and behaviors serve. This significance is not just a subjective add-on to the more basic physiological and functional realities, but something that pervades our lived experience of sexuality.

As philosophers who study the structure of conscious experience have observed, our way of experiencing the world is shaped by our “embodiment, bodily skills, cultural context, language and other social practices.”¹⁷ Long before most of us experience anything like what we typically associate with sexual desire, we are already enmeshed in a cultural and social context involving other persons, feelings, emotions, opportunities, deprivations, and so on. Perhaps sexuality, like other human phenomena that gradually become part of our psychological constitution, has roots in these early meaning-making experiences. If meaning-making is integral to human experience in general, it is likely to play a key role in sexual experience in particular. And given that volition is operative in these other aspects of our lives, it stands to reason that volition will be operative in our experience of sexuality too, if only as one of many other factors.

This is not to suggest that sexuality—including sexual desire, attraction, and identity—is the result of any deliberate, rational decision calculus. Even if volition plays an important role in sexuality, volition itself is quite complex: many, perhaps most, of our volitional choices do not seem to come in the form of discrete, conscious, or deliberate decisions; “volitional” does not necessarily mean “deliberate.” The life of a desiring, volitional agent involves many tacit patterns of behavior owing to habits, past experiences, memories, and subtle ways of adopting and abandoning different stances on one's life.

If something like this way of understanding the life of a desiring, volitional agent is true, then we do not deliberately “choose” the objects of our

sexual desires any more than we choose the objects of our other desires. It might be more accurate to say that we gradually guide and give ourselves over to them over the course of our growth and development. This process of forming and reforming ourselves as human beings is similar to what Abraham Maslow calls self-actualization.¹⁸ Why should sexuality be an exception to this process? In the picture we are offering, internal factors, such as our genetic make-up, and external environmental factors, such as past experiences, are only ingredients, however important, in the complex human experience of sexual desire.

Sexual Orientation

Just as the concept of “sexual desire” is complex and difficult to define, there are currently no agreed-upon definitions of “sexual orientation,” “homosexuality,” or “heterosexuality” for purposes of empirical research. Should homosexuality, for example, be characterized by reference to desires to engage in particular acts with individuals of the same sex, or to a patterned history of having engaged in such acts, or to particular features of one’s private wishes or fantasies, or to a consistent impulse to seek intimacy with members of the same sex, or to a social identity imposed by oneself or others, or to something else entirely?

As early as 1896, in a book on homosexuality, the French thinker Marc-André Raffalovich argued that there were more than ten different types of affective inclination or behavior captured by the term “homosexuality” (or what he called “unisexuality”).¹⁹ Raffalovich knew his subject matter up close: he chronicled the trial, imprisonment, and resulting social disgrace of the writer Oscar Wilde, who had been prosecuted for “gross indecency” with other men. Raffalovich himself maintained a prolonged and intimate relationship with John Gray, a man of letters thought to be the inspiration for Wilde’s classic *The Picture of Dorian Gray*.²⁰ We might also consider the vast psychoanalytic literature from the early twentieth century on the topic of sexual desire, in which the experiences of individual subjects and their clinical cases are catalogued in great detail. These historical examples bring into relief the complexity that researchers still face today when attempting to arrive at clean categorizations of the richly varied affective and behavioral phenomena associated with sexual desire, in both same-sex and opposite-sex attractions.

We may contrast such inherent complexity with a different phenomenon that can be delineated unambiguously, such as pregnancy. With very few exceptions, a woman is or is not pregnant, which makes classification

of research subjects for the purposes of study relatively easy: compare pregnant women with other, non-pregnant women. But how can researchers compare, say, “gay” men to “straight” men in a single study, or across a range of studies, without mutually exclusive and exhaustive definitions of the terms “gay” and “straight”?

To increase precision, some researchers categorize concepts associated with human sexuality along a continuum or scale according to variations in pervasiveness, prominence, or intensity. Some scales focus on both intensity and the objects of sexual desire. Among the most familiar and widely used is the Kinsey scale, developed in the 1940s to classify sexual desires and orientations using purportedly measurable criteria. People are asked to choose one of the following options:

- 0 - Exclusively heterosexual
- 1 - Predominantly heterosexual, only incidentally homosexual
- 2 - Predominantly heterosexual, but more than incidentally homosexual
- 3 - Equally heterosexual and homosexual
- 4 - Predominantly homosexual, but more than incidentally heterosexual
- 5 - Predominantly homosexual, only incidentally heterosexual
- 6 - Exclusively homosexual²¹

But there are considerable limitations to this approach. In principle, measurements of this sort are valuable for social science research. They can be used, for example, in empirical tests such as the classic “t-test,” which helps researchers measure statistically meaningful differences between data sets. Many measurements in social science, however, are “ordinal,” meaning that variables are rank-ordered along a single, one-dimensional continuum but are not intrinsically significant beyond that. In the case of the Kinsey scale, this situation is even worse, because it measures the self-identification of individuals, while leaving unclear whether the values they report all refer to the same aspect of sexuality—different people may understand the terms “heterosexual” and “homosexual” to refer to feelings of attraction, or to arousal, or to fantasies, or to behavior, or to any combination of these. The ambiguity of the terms severely limits the use of the Kinsey scale as an ordinal measurement that gives a rank order to variables along a single, one-dimensional continuum. So it is not clear that this scale helps researchers to make even rudimentary classifications among the relevant groups using qualitative criteria, much less to rank-order variables or conduct controlled experiments.

Perhaps, given the inherent complexity of the subject matter, attempts to devise “objective” scales of this sort are misguided. In a critique of such approaches to social science, philosopher and neuropsychologist Daniel N. Robinson points out that “statements that lend themselves to different interpretation do not become ‘objective’ merely by putting a numeral in front of them.”²² It may be that self-reported identifications with culturally fraught and inherently complex labels simply cannot provide an objective basis for quantitative measurements in individuals or across groups.

Another obstacle for research in this area may be the popular, but not well-supported, belief that romantic desires are sublimations of sexual desires. This idea, traceable to Freud’s theory of unconscious drives, has been challenged by research on “attachment theory,” developed by John Bowlby in the 1950s.²³ Very roughly, attachment theory holds that later affective experiences that are often grouped under the general rubric “romantic” are explained in part by early childhood attachment behaviors (associated with maternal figures or caregivers)—not by unconscious, sexual drives. Romantic desires, following this line of thought, might not be as strongly correlated with sexual desires as is commonly thought. All of this is to suggest that simple delineations of the concepts relating to human sexuality cannot be taken at face value and that ongoing empirical research sometimes changes or complicates the meanings of the concepts.

If we look at recent research, we find that scientists often use at least one of three categories when attempting to classify people as “homosexual” or “heterosexual”: sexual *behavior*; sexual *fantasies* (or related emotional or affective experiences); and *self-identification* (as “gay,” “lesbian,” “bisexual,” “asexual,” and so forth).²⁴ Some add a fourth: inclusion in a community defined by sexual orientation. Consider, for example, the American Psychological Association’s definition of sexual orientation in a 2008 document designed to educate the public:

Sexual orientation refers to an enduring pattern of emotional, romantic and/or sexual *attractions* to men, women or both sexes. Sexual orientation also refers to a person’s sense of *identity* based on those attractions, related *behaviors*, and membership in a *community* of others who share those attractions. Research over several decades has demonstrated that sexual orientation ranges along a *continuum*, from exclusive attraction to the other sex to exclusive attraction to the same sex.²⁵ [Emphases added.]

One difficulty with grouping these categories together under the same general rubric of “sexual orientation” is that research suggests they often

do not coincide in real life. Sociologist Edward O. Laumann and colleagues summarize this point clearly in a 1994 book:

While there is a core group (about 2.4 percent of the total men and about 1.3 percent of the total women) in our survey who *define themselves* as homosexual or bisexual, have same-gender *partners*, and express homosexual *desires*, there are also sizable groups who do not consider themselves to be either homosexual or bisexual but have had adult homosexual experiences or express some degree of desire.... [T]his preliminary analysis provides unambiguous evidence that no single number can be used to provide an accurate and valid characterization of the incidence and prevalence of homosexuality in the population at large. In sum, homosexuality is fundamentally a multidimensional phenomenon that has manifold meanings and interpretations, depending on context and purpose.²⁶ [Emphases added.]

More recently, in a 2002 study, psychologists Lisa M. Diamond and Ritch C. Savin-Williams make a similar point:

The more carefully researchers map these constellations—differentiating, for example, between *gender identity* and *sexual identity*, *desire* and *behavior*, *sexual* versus *affectionate* feelings, early-appearing versus late-appearing *attractions* and *fantasies*, or social *identifications* and sexual *profiles*—the more complicated the picture becomes because few individuals report uniform inter-correlations among these domains.²⁷ [Emphases added.]

Some researchers acknowledge the difficulties with grouping these various components under a single rubric. For example, researchers John C. Gonsiorek and James D. Weinrich write in a 1991 book: “It can be safely assumed that there is no necessary relationship between a person’s sexual behavior and self-identity unless both are individually assessed.”²⁸ Likewise, in a 1999 review of research on the development of sexual orientation in women, social psychologist Letitia Anne Peplau argues: “There is ample documentation that same-sex attractions and behaviors are not inevitably or inherently linked to one’s identity.”²⁹

In sum, the complexities surrounding the concept of “sexual orientation” present considerable challenges for empirical research on the subject. While the general public may be under the impression that there are widely accepted scientific definitions of terms such as “sexual orientation,” in fact, there are not. Diamond’s assessment of the situation in 2003 is still true today, that “there is currently no scientific or popular consensus on

the exact constellation of experiences that definitively ‘qualify’ an individual as lesbian, gay, or bisexual.”³⁰

It is owing to such complexities that some researchers, for instance Laumann, proceed by characterizing sexual orientation as a “multidimensional phenomenon.” But one might just as well wonder whether, in trying to shoehorn this “multidimensional phenomenon” into a single category, we are not reifying a concept that corresponds to something far too plastic and diffuse in reality to be of much value in scientific research. While labels such as “heterosexual” and “homosexual” are often taken to designate stable psychological or even biological traits, perhaps they do not. It may be that individuals’ affective, sexual, and behavioral experiences do not conform well to such categorical labels because these labels do not, in fact, refer to natural (psychological or biological) kinds. At the very least, we should recognize that we do not yet possess a clear and well-established framework for research on these topics. Rather than attempting to research sexual desire, attraction, identity, and behavior under the general rubric of “sexual orientation,” we might do better to examine empirically each domain separately and in its own specificity.

To that end, this part of our report considers research on sexual desire and sexual attraction, focusing on the empirical findings related to etiology and development, and highlighting the underlying complexities. We will continue to employ ambiguous terms like “sexual orientation” where they are used by the authors we discuss, but we will try to be attentive to the context of their use and the ambiguities attaching to them.

Challenging the “Born that Way” Hypothesis

Keeping in mind these reflections on the problems of definitions, we turn to the question of how sexual desires originate and develop. Consider the different patterns of attraction between individuals who report experiencing predominant sexual or romantic attraction toward members of the same sex and those who report experiencing predominant sexual or romantic attraction toward members of the opposite sex. What are the causes of these two patterns of attraction? Are such attractions or preferences innate traits, perhaps determined by our genes or prenatal hormones; are they acquired by experiential, environmental, or volitional factors; or do they develop out of some combination of both kinds of causes? What role, if any, does human agency play in the genesis of patterns of attraction? What role, if any, do cultural or social influences play?

Research suggests that while genetic or innate factors may influence the emergence of same-sex attractions, these biological factors cannot provide a complete explanation, and environmental and experiential factors may also play an important role.

The most commonly accepted view in popular discourse we mentioned above—the “born that way” notion that homosexuality and heterosexuality are biologically innate or the product of very early developmental factors—has led many non-specialists to think that homosexuality or heterosexuality is in any given person unchangeable and determined entirely apart from choices, behaviors, life experiences, and social contexts. However, as the following discussion of the relevant scientific literature shows, this is not a view that is well-supported by research.

Studies of Twins

One powerful research design for assessing whether biological or psychological traits have a genetic basis is the study of identical twins. If the probability is high that both members in a pair of identical twins, who share the same genome, exhibit a trait when one of them does—this is known as the concordance rate—then one can infer that genetic factors are likely to be involved in the trait. If, however, the concordance rate for identical twins is no higher than the concordance rate of the same trait in fraternal twins, who share (on average) only half their genes, this indicates that the shared environment may be a more important factor than shared genes.

One of the pioneers of behavioral genetics and one of the first researchers to use twins to study the effect of genes on traits, including sexual orientation, was psychiatrist Franz Josef Kallmann. In a landmark paper published in 1952, he reported that for all the pairs of identical twins he studied, if one of the twins was gay then both were gay, yielding an astonishing 100% concordance rate for homosexuality in identical twins.³¹ Were this result replicated and the study designed better, it would have given early support to the “born that way” hypothesis. But the study was heavily criticized. For example, philosopher and law professor Edward Stein notes that Kallmann did not present any evidence that the twins in his study were in fact genetically identical, and his sample was drawn from psychiatric patients, prisoners, and others through what Kallmann described as “direct contacts with the clandestine homosexual world,” leading Stein to argue that Kallmann’s sample “in no way constituted a reasonable cross-section of the homosexual population.”³²

(Samples such as Kallmann's are known as convenience samples, which involve selecting subjects from populations that are conveniently accessible to the researcher.)

Nevertheless, well-designed twin studies examining the genetics of homosexuality indicate that genetic factors likely play some role in determining sexual orientation. For example, in 2000, psychologist J. Michael Bailey and colleagues conducted a major study of sexual orientation using twins in the Australian National Health and Medical Research Council Twin Registry, a large probability sample, which was therefore more likely to be representative of the general population than Kallmann's.³³ The study employed the Kinsey scale to operationalize sexual orientation and estimated concordance rates for being homosexual of 20% for men and 24% for women in identical (maternal, monozygotic) twins, compared to 0% for men and 10% for women in non-identical (fraternal, dizygotic) twins.³⁴ The difference in the estimated concordance rates was statistically significant for men but not for women. On the basis of these findings, the researchers estimated that the heritability of homosexuality for men was 0.45 with a wide 95% confidence interval of 0.00–0.71; for women, it was 0.08 with a similarly wide confidence interval of 0.00–0.67. These estimates suggest that for males 45% of the differences between certain sexual orientations (homosexual versus heterosexuals as measured by the Kinsey scale) could be attributed to differences in genes.

The large confidence intervals in the study by Bailey and colleagues mean that we must be careful in assessing the substantive significance of these findings. The authors interpret their findings to suggest that “any major gene for strictly defined homosexuality has either low penetrance or low frequency,”³⁵ but their data did show (marginal) statistical significance. While the concordance estimates seem somewhat high in the models used, the confidence intervals are so wide that it is difficult to judge the reliability, including the replicability, of these estimates.

It is worth clarifying here what “heritability” means in these studies, since the technical meaning in population genetics is narrower and more precise than the everyday meaning of the word. Heritability is a measure of how much variation in a particular trait within a population can be attributed to variation in genes in that population. It is not, however, a measure of how much a trait is genetically determined.

Traits that are almost entirely genetically determined can have very low heritability values, while traits that have almost no genetic basis can be found to be highly heritable. For instance, the number of fingers human beings have is almost completely genetically determined. But there is little

variation in the number of fingers humans have, and most of the variation we do see is due to non-genetic factors such as accidents, which would lead to low heritability estimates for the trait. Conversely, cultural traits can sometimes be found to be highly heritable. For instance, whether a given individual in mid-twentieth century America wore earrings would have been found to be highly heritable, because it was highly associated with being male or female, which is in turn associated with possessing XX or XY sex chromosomes, making variability in earring-wearing behavior highly associated with genetic differences, despite the fact that wearing earrings is a cultural rather than biological phenomenon. Today, heritability estimates for earring-wearing behavior would be lower than they were in mid-twentieth century America, not because of any changes in the American gene pool, but because of the increased acceptance of men wearing earrings.³⁶

So, a heritability estimate of 0.45 does not mean that 45% of sexuality is determined by genes. Rather, it means that 45% of the variation between individuals in the population studied can be attributed in some way to genetic factors, as opposed to environmental factors.

In 2010, psychiatric epidemiologist Niklas Långström and colleagues conducted a large, sophisticated twin study of sexual orientation, analyzing data from 3,826 identical and fraternal same-sex twin pairs (2,320 identical and 1,506 fraternal pairs).³⁷ The researchers operationalized homosexuality in terms of lifetime same-sex sexual partners. The sample's concordance rates were somewhat lower than those found in the study by Bailey and colleagues. For having had at least one same-sex partner, the concordance for men was 18% in identical twins and 11% in fraternal twins; for women, 22% and 17%, respectively. For total number of sexual partners, concordance rates for men were 5% in identical twins and 0% in fraternal twins; for women, 11% and 7%, respectively.

For men, these rates suggest an estimated heritability rate of 0.39 for having had at least one lifetime same-sex partner (with a 95% confidence interval of 0.00–0.59), and 0.34 for total number of same-sex partners (with a 95% confidence interval of 0.00–0.53). Environmental factors experienced by one twin but not the other explained 61% and 66% of the variance, respectively, while environmental factors shared by the twins failed to explain any of the variance. For women, the heritability rate for having had at least one lifetime same-sex partner was 0.19 (95% confidence interval of 0.00–0.49); for total number of same-sex partners, it was 0.18 (95% confidence interval of 0.11–0.45). Unique environmental factors accounted for 64% and 66% of the variance, respectively, while

shared environmental factors accounted for 17% and 16%, respectively. These values indicate that, while the genetic component of homosexual behavior is far from negligible, non-shared environmental factors play a critical, perhaps preponderant, role. The authors conclude that sexual orientation arises from both heritable and environmental influences unique to the individual, stating that “the present results support the notion that the individual-specific environment does indeed influence sexual preference.”³⁸

Another large and nationally representative study of twins published by sociologists Peter S. Bearman and Hannah Brückner in 2002 used data from the National Longitudinal Study of Adolescent to Adult Health (commonly abbreviated as “Add Health”) of adolescents in grades 7–12.³⁹ They attempted to estimate the relative influence of social factors, genetic factors, and prenatal hormonal factors on the development of same-sex attractions. Overall, 8.7% of the 18,841 adolescents in their study reported same-sex attractions, 3.1% reported a same-sex romantic relationship, and 1.5% reported same-sex sexual behavior. The authors first analyzed the “social influence hypothesis,” according to which opposite-sex twins receive less gendered socialization from their families than same-sex twins or opposite-sex siblings, and found that this hypothesis was well-supported in the case of males. While female opposite-sex twins in the study were the least likely of all the groups to report same-sex attractions (5.3%), male opposite-sex twins were the likeliest to report same-sex attractions (16.8%)—more than twice as likely as males with a full, non-twin sister (16.8% vs. 7.3%). The authors concluded there was “substantial indirect evidence in support of a socialization model at the individual level.”⁴⁰

The authors also examined the “intrauterine hormone transfer hypothesis,” according to which prenatal hormone transfers between opposite-sex twin fetuses influences the sexual orientation of the twins. (Note that this is different from the more general hypothesis that prenatal hormones influence the development of sexual orientation.) In the study, the proportion of male opposite-sex twins reporting same-sex attraction was about twice as high for those without older brothers (18.7%) as for those with older brothers (8.8%). The authors argued that this finding was strong evidence against the hormone-transfer hypothesis, since the presence of older brothers should not decrease the likelihood of same-sex attraction if that attraction has a basis in prenatal hormonal transfers. However, that conclusion seems premature: the observations are consistent with the possibility of *both* hormonal factors *and* the presence of an older brother having an effect (especially if the latter influences the former). This study

also found no correlation between experiencing same-sex attraction and having multiple older brothers, which had been reported in some earlier studies.⁴¹

Finally, Bearman and Brückner did not find evidence of significant genetic influence on sexual attraction. Significant influence would require that identical twins have significantly higher concordance rates for same-sex attraction than fraternal twins or non-twin siblings. But in the study, the rates were statistically similar: identical twins were 6.7% concordant, dizygotic pairs 7.2% concordant, and full siblings 5.5% concordant. The authors concluded that “it is more likely that any genetic influence, if present, can only be expressed in specific and circumscribed social structures.”⁴² Based on their data, they suggested the one observed social structure that might enable this genetic expression is the more limited “gender socialization associated with firstborn OS [opposite-sex] twin pairs.”⁴³ Thus, they inferred that their results “support the hypothesis that less gendered socialization in early childhood and preadolescence shapes subsequent same-sex romantic preferences.”⁴⁴ While the findings here are suggestive, further research is needed to confirm this hypothesis. The authors also argued that the higher concordance rates for same-sex attraction reported in previous studies may be unreliable due to methodological problems such as non-representative samples and small sample sizes. (It should be noted, however, that these remarks were published prior to the study by Långström and colleagues discussed above, which uses a study design that does not appear to have these limitations.)

To reconcile the somewhat mixed data on heritability, we could hypothesize that attraction to the same sex may have a stronger heritable component as people age—that is, when researchers attempt to measure sexual orientation later in life (as in the 2010 study by Långström and colleagues) than when measured earlier in life. Heritability estimates can change depending on the age at which a trait is measured because changes in the environmental factors that might influence variation in the trait may vary for individuals at different ages, and because genetically influenced traits may become more fixed at a later stage in an individual’s development (height, for instance, becomes fixed in early adulthood). This hypothesis is also suggested by findings, discussed below, that same-sex attraction may be more fluid in adolescence than in later stages of adulthood.

In contrast to the studies just summarized, psychiatrist Kenneth S. Kendler and colleagues conducted a large twin study using a probability sample of 794 twin pairs and 1,380 non-twin siblings.⁴⁵ Based on concordance rates for sexual orientation (defined in this study as self-iden-

tification based on attraction), the authors state that their results “suggest that genetic factors may provide an important influence on sexual orientation.”⁴⁶ The study does not, however, appear to be sufficiently powerful to draw strong conclusions about the degree of genetic influence on sexuality: only 19 of 324 identical twin pairs had any non-heterosexual member, with 6 of the 19 pairs concordant; 15 of 240 same-sex fraternal twin pairs had any non-heterosexual member, with 2 of the 15 pairs concordant. Because only 8 twin pairs were concordant for non-heterosexuality, the study’s ability to draw substantively significant comparisons between identical and fraternal twins (or between twins and non-twin siblings) is limited.

Overall, these studies suggest that (depending on how homosexuality is defined) in anywhere from 6% to 32% of cases, both members of an identical twin pair would be homosexual if at least one member is. Since some twin studies found higher concordance rates in identical twins than in fraternal twins or non-twin siblings, there may be genetic influences on sexual desire and behavioral preferences. One needs to bear in mind that identical twins typically have even more similar environments—early attachment experiences, peer relationships, and the like—than fraternal twins or non-twin siblings. Because of their similar appearances and temperaments, for example, identical twins may be more likely than fraternal twins or other siblings to be treated similarly. So some of the higher concordance rates may be attributable to environmental factors rather than genetic factors. In any case, if genes do play a role in predisposing people toward certain sexual desires or behaviors, these studies make clear that genetic influences cannot be the whole story.

Summarizing the studies of twins, we can say that there is no reliable scientific evidence that sexual orientation is determined by a person’s genes. But there is evidence that genes play a role in influencing sexual orientation. So the question “Are gay people born that way?” requires clarification. There is virtually no evidence that anyone, gay or straight, is “born that way” if that means their sexual orientation was genetically determined. But there is some evidence from the twin studies that certain genetic profiles probably increase the likelihood the person later identifies as gay or engages in same-sex sexual behavior.

Future twin studies on the heritability of sexual orientation should include analyses of larger samples or meta-analyses or other systematic reviews to overcome the limited sample size and statistical power of some of the existing studies, and analyses of heritability rates across different dimensions of sexuality (such as attraction, behavior, and identity) to

overcome the imprecisions of the ambiguous concept of sexual orientation and the limits of studies that look at only one of these dimensions of sexuality.

Molecular Genetics

In examining the question whether, and perhaps to what extent, there may be genetic contributions to homosexuality, we have so far looked at studies that employ methods of classical genetics to estimate the heritability of a trait like sexual orientation but that do not identify particular genes that may be associated with the trait.⁴⁷ But genetics can also be studied using what are often called molecular methods that provide estimates of which particular genetic variations are associated with traits, whether physical or behavioral.

One early attempt to identify a more specific genetic basis for homosexuality was a 1993 study by geneticist Dean Hamer and colleagues of 40 pairs of homosexual brothers.⁴⁸ By examining the family history of homosexuality for these individuals, they identified a possible linkage between homosexuality in males and genetic markers on the Xq28 region of the X chromosome. Attempts to replicate this influential study's results have had mixed results: George Rice and colleagues attempted and failed to replicate Hamer's findings,⁴⁹ though in 2015 Alan R. Sanders and colleagues were able to replicate Hamer's original findings using a larger population size of 409 male twin pairs of homosexual brothers, and to find additional genetic linkage sites.⁵⁰ (Since the effect was small, however, the genetic marker would not be a good predictor of sexual orientation.)

Genetic linkage studies like the ones discussed above are able to identify particular regions of chromosomes that may be associated with a trait by looking at patterns of inheritance. Today, one of the chief methods for inferring which genetic variants are associated with a trait is the genome-wide association study, which uses DNA sequencing technologies to identify particular differences in DNA that may be associated with a trait. Scientists examine millions of genetic variants in large numbers of individuals who have a particular trait, as well as individuals who do not have the trait, and compare the frequency of genetic variants among those who do and do not have the trait. Specific genetic variants that occur more frequently among those who have than those who do not have the trait are inferred to have some association with that trait. Genome-wide association studies have become popular in recent years, yet few such scientific studies have found significant associations of genetic variants with sexual

orientation. The largest attempt to identify genetic variants associated with homosexuality, a study of over 23,000 individuals from the 23andMe database presented at the American Society of Human Genetics annual meeting in 2012, found no linkages reaching genome-wide significance for same-sex sexual identity for males or females.⁵¹

So, again, the evidence for a genetic basis for homosexuality is inconsistent and inconclusive, which suggests that, though genetic factors explain some of the variation in sexual orientation, the genetic contribution to this trait is not likely to be strong and even less likely to be decisive.

As is often true of human behavioral tendencies, there may be genetic contributions to the tendency toward homosexual inclinations or behaviors. Phenotypic expression of genes is usually influenced by environmental factors—different environments may lead to different phenotypes even for the same genes. So even if there are genetic factors that contribute to homosexuality, an individual's sexual attractions or preferences may also be influenced by a number of environmental factors, such as social stressors, including emotional, physical, or sexual abuse. Looking to developmental, environmental, experiential, social, or volitional factors will be necessary to arrive at a fuller picture of how sexual interests, attractions, and desires develop.

The Limited Role of Genetics

Lay readers might note at this point that even at the purely biological level of genetics, the shopworn “nature vs. nurture” debates regarding human psychology have been abandoned by scientists, who recognize that no credible hypothesis can be offered for any particular traits that would be determined either purely by genetics or the environment. The growing field of epigenetics, for example, demonstrates that even for relatively simple traits, gene expression itself can be influenced by innumerable other external factors that can shape the functioning of genes.⁵² This is even more relevant when it comes to the relationship between genes and complex traits like sexual attraction, drives, and behaviors.

These gene-environment relationships are complex and multidimensional. Non-genetic developmental factors and environmental experiences may be sculpted, in part, by genetic factors working in subtle ways. For example, social geneticists have documented the indirect role of genes in peer-aligned behaviors, such that an individual's physical appearance could influence whether a particular social group will include or exclude that individual.⁵³

Contemporary geneticists know that genes can influence a person's range of interests and motivations, therefore indirectly affecting behavior. While genes may in this way incline a person to certain behaviors, compelling behavior directly, independently of a wide range of other factors, seems less plausible. They may influence behavior in more subtle ways, depending on external environmental stimuli (for instance, peer pressure, suggestion, and behavioral rewards) in conjunction with psychological factors and physical makeup. Dean Hamer, whose work on the possible role of genetics in homosexuality was examined above, explained some of the limitations of behavioral genetics in a 2002 article in *Science*: "The real culprit [of lack of progress in behavioral genetics] is the assumption that the rich complexity of human thought and emotion can be reduced to a simple, linear relation between individual genes and behaviors.... This oversimplified model, which underlies most current research in behavior genetics, ignores the critical importance of the brain, the environment, and gene expression networks."⁵⁴

The genetic influences affecting any complex human behavior—whether sexual behaviors, or interpersonal interactions—depend in part on individuals' life experiences as they mature. Genes constitute only one of the many key influences on behavior in addition to environmental influences, personal choices, and interpersonal experiences. The weight of evidence to date strongly suggests that the contribution of genetic factors is modest. We can say with confidence that genes are not the sole, essential cause of sexual orientation; there is evidence that genes play a modest role in contributing to the development of sexual attractions and behaviors but little evidence to support a simplistic "born that way" narrative concerning the nature of sexual orientation.

The Influence of Hormones

Another area of research relevant to the hypothesis that people are born with dispositions toward different sexual orientations involves prenatal hormonal influences on physical development and subsequent male- or female-typical behaviors in early childhood. For ethical and practical reasons, the experimental work in this field is carried out in non-human mammals, which limits how this research can be generalized to human cases. However, children who are born with disorders of sexual development (DSD) serve as a population in which to examine the influence of genetic and hormonal abnormalities on the subsequent development of non-typical sexual identity and sexual orientation.

Hormones responsible for sexual differentiation are generally thought to exert on the developing fetus either *organizational* effects—which produce permanent changes in the wiring and sensitivity of the brain, and thus are considered largely irreversible—or *activating* effects, which occur later in an individual's life (at puberty, and into adulthood).⁵⁵ Organizational hormones may prime the fetal systems (including the brain) structurally, and set the stage for sensitivity to hormones presenting at puberty and beyond, when the hormone will then “activate” systems which were “organized” prenatally.

Periods of peak response to the hormonal environment are thought to occur during gestation. For example, testosterone is thought to influence the male fetus maximally between weeks 8 and 24, and then again at birth, until about three months of age.⁵⁶ Estrogens are provided throughout gestation by the placenta and the mother's blood system.⁵⁷ Studies in animals reveal there may even be multiple periods of sensitivity for a variety of hormones, that the presence of one hormone may influence the action of another hormone, and the sensitivity of the receptors for these hormones can influence their actions.⁵⁸ Sexual differentiation, alone, is a highly complex system.

Specific hormones of interest in this area of research are testosterone, dihydrotestosterone (a metabolite of testosterone, and more potent than testosterone), estradiol, progesterone, and cortisol. The generally accepted pathways of normal hormonal influence of development in utero are as follows. The typical pattern of sex differentiation in human fetuses begins with the differentiation of the sex organs into testes or ovaries, a process that is largely genetically controlled. Once these organs have differentiated, they produce specific hormones that determine development of external genitalia. This window of time in gestation is when hormones exert their phenotypic and neurological effects. Testosterone secreted by the testes contributes to the development of male external genitalia and affects neurological development in males;⁵⁹ it is the absence of testosterone in females which allows for the female pattern of external genitalia to develop.⁶⁰ Imbalances of testosterone or estrogen, as well as their presence or absence at specific critical periods of gestation, may cause disorders of sexual development. (Genetic or environmental effects can also lead to disorders of sexual development.)

Stress may also play some role in influencing the way hormones shape gonadal development, neurodevelopment, and subsequent sex-typical behaviors in early childhood.⁶¹ Cortisol is the main hormone associated

with stress responses. It may originate from the mother, if she experiences severe stressors during her pregnancy, or from the fetus under stress.⁶² Elevated levels of cortisol may also occur from genetic defects.⁶³ One of the most extensively studied disorders of sexual development is congenital adrenal hyperplasia (CAH), which in females can result in genital virilization.⁶⁴ Over 90% of cases of CAH result from a mutation in a gene that codes for an enzyme that helps synthesize cortisol.⁶⁵ This results in an overproduction of cortisol precursors, some of which are converted into androgens (hormones associated with male sex development).⁶⁶ As a result, girls are born with some degree of virilization of their genitalia, depending on the severity of the genetic defect.⁶⁷ For severe cases of genital virilization, surgical intervention is sometimes performed to normalize the genitalia. Hormone therapies are also often administered to mitigate the effects of excess androgen production.⁶⁸ Females with CAH, who as fetuses were exposed to above-average levels of androgens, are less likely to be exclusively heterosexual than females without CAH, and females with more severe forms of CAH are more likely to be non-heterosexual than females with milder forms of the condition.⁶⁹

Likewise, there are disorders of sexual development in genetic males affected by androgen insensitivity. In males with androgen insensitivity syndrome, the testes produce testosterone normally, but the receptors to testosterone are not functional.⁷⁰ The genitalia, at birth, appear to be female, and the child is usually raised as a female. The individual's endogenous testosterone is broken down into estrogen, such that the individual begins to develop female secondary sex characteristics.⁷¹ It does not become apparent that there is a problem until puberty, when the individual does not start menses appropriately.⁷² These patients generally prefer to continue life as females, and their sexual orientation does not differ from females having an XX genotype.⁷³ Studies have suggested that they are just as likely if not more likely to be exclusively interested in male partners than XX females.⁷⁴

There are other disorders of sexual development affecting some genetic males (i.e., with an XY genotype) in whom androgen deficiencies are a direct result of the lack of enzymes either to synthesize dihydrotestosterone from testosterone or to produce testosterone from its precursor hormone.⁷⁵ Individuals with these deficiencies are born with varied degrees of ambiguous genitalia, and are sometimes raised as girls. During puberty, however, these individuals often experience physical virilization, and must then decide whether to live as men or women. Peggy T. Cohen-Kettenis, a professor of gender development and psychopathology, found that 39 to

64% of individuals with these deficiencies who are raised as girls change to live as men in adolescence and early adulthood, and she also reported that “the degree of external genital masculinization at birth does not seem to be related to gender role changes in a systematic way.”⁷⁶

The twin studies reviewed earlier may shed light on the role of maternal hormonal influences, since both identical and fraternal twins are exposed to similar maternal hormonal influences in utero. The relatively weak concordance rates in the twin studies suggest that prenatal hormones, like genetic factors, do not play a strongly determinative role in sexual orientation. Other attempts at finding significant hormonal influences on sexual development have likewise been mixed, and the salience of the findings is not yet clear. Since direct studies of prenatal hormonal influences on sexual development are methodologically difficult, some studies have tried to develop models whereby differences in prenatal hormonal exposure can be inferred indirectly—by measuring subtle morphological changes or by examining hormonal disorders that are present later during development.

For example, one rough proxy of prenatal testosterone levels used by researchers is the ratio between the length of the second finger (index finger) and the fourth finger (ring finger), which is commonly called the “2D:4D ratio.” Some evidence suggests that the ratio may be influenced by prenatal exposure to testosterone, such that in males higher levels of exposure to testosterone cause shorter index fingers relative to the ring finger (or having a low 2D:4D ratio), and vice versa.⁷⁷ According to one hypothesis, homosexual men may have a higher 2D:4D ratio (closer to the ratio found in females than in heterosexual males), while another hypothesis suggests the opposite, that homosexual men may be hypermasculinized by prenatal testosterone, resulting in a lower ratio than in heterosexual men. For women, the hypothesis for homosexuality that they have been hypermasculinized (lower ratio, higher testosterone) has also been proposed. Several studies comparing this trait in homosexually versus heterosexually identified men and women have shown mixed results.

A study published in *Nature* in 2000 found that in a sample of 720 California adults, the right-hand 2D:4D ratio of homosexual women was significantly more masculine (that is, the ratio was smaller) than that of heterosexual women and did not differ significantly from that of heterosexual men.⁷⁸ This study also found no significant difference in mean 2D:4D ratio between heterosexual and homosexual men. Another study that year, which used a relatively small sample of homosexual and heterosexual men from the United Kingdom, reported a lower 2D:4D (that

is, more masculine) ratio in homosexual men.⁷⁹ A 2003 study using a London-based sample also found that homosexual men had a lower 2D:4D ratio than heterosexuals,⁸⁰ while two other studies with samples from California and Texas showed *higher* 2D:4D ratios for homosexual men.⁸¹

A 2003 twin study compared seven female monozygotic twin pairs discordant for homosexuality (one twin was lesbian) and five female monozygotic twin pairs concordant for homosexuality (both twins were lesbian).⁸² In the twin pairs discordant for sexual orientation, the individuals identifying as homosexual had significantly lower 2D:4D ratios than their twins, whereas the concordant twins showed no difference. The authors interpreted this result as suggesting that “low 2D:4D ratio is a result of differences in prenatal environment.”⁸³ Finally, a 2005 study of 2D:4D ratios in an Austrian sample of 95 homosexual and 79 heterosexual men found that the 2D:4D ratios of heterosexual men were not significantly different from those of homosexual men.⁸⁴ After reviewing the several studies on this trait, the authors conclude that “more data are essential before we can be sure whether there is a 2D:4D effect for sexual orientation in men when ethnic variation is controlled for.”⁸⁵

Much research has examined the effects of prenatal hormones on behavior and brain structure. Again, these results come primarily from studies of non-human primates, but the study of disorders of sexual development has provided helpful insights into the effects of hormones on sexual development in humans. Since hormonal influences typically occur during time-sensitive periods of development, when their effects manifest physically, it is reasonable to assume that organizational effects of these early, time-linked hormonal patterns are likely to direct aspects of neural development. Neuroanatomical connectivity and neurochemical sensitivities may be among such influences.

In 1983, Günter Dörner and colleagues performed a study investigating whether there is any relationship between maternal stress during pregnancy and later sexual identity of their children, interviewing two hundred men about stressful events that may have occurred to their mothers during their prenatal lives.⁸⁶ Many of these events occurred as a consequence of World War II. Of men who reported that their mothers had experienced moderately to severely stressful events during pregnancy, 65% were homosexual, 25% were bisexual, and 10% were heterosexual. (Sexual orientation was assessed using the Kinsey scale.) However, more recent studies have shown much smaller or no significant correlations.⁸⁷ In a 2002 prospective study on the relationship between sexual orientation and prenatal stress during the second and third trimesters, Hines

and colleagues found that stress reported by mothers during pregnancy showed “only a small relationship” to male-typical behaviors in their daughters at the age of 42 months, “and no relationship at all” to female-typical behaviors in their sons.⁸⁸

In summary, some forms of prenatal hormone exposure, particularly CAH in females, are associated with differences in sexual orientation, while other factors are often important in determining the physical and psychological effects of those exposures. Hormonal conditions that contribute to disorders of sex development may contribute to the development of non-heterosexual orientations in some individuals, but this does not demonstrate that such factors explain the development of sexual attractions, desires, and behaviors in the majority of cases.

Sexual Orientation and the Brain

There have been several studies examining neurobiological differences between individuals who identify as heterosexual and those who identify as homosexual. This work began with neuroscientist Simon LeVay’s 1991 study that reported biological differences in the brains of gay men as compared to straight men—specifically, a difference in volume in a particular cell group of the interstitial nuclei of the anterior hypothalamus (INAH3).⁸⁹ Later work by psychiatrist William Byne and colleagues showed more nuanced findings: “In agreement with two prior studies... we found INAH3 to be sexually dimorphic, occupying a significantly greater volume in males than females. In addition, we determined that the sex difference in volume was attributable to a sex difference in neuronal number and not in neuronal size or density.”⁹⁰ The authors noted that, “Although there was a trend for INAH3 to occupy a smaller volume in homosexual men than in heterosexual men, there was no difference in the number of neurons within the nucleus based on sexual orientation.” They speculated that “postnatal experience” may account for the differences in volume in this region between homosexual and heterosexual men, though this would require further research to confirm.⁹¹ They also noted that the functional significance of sexual dimorphism in INAH3 is unknown. The authors conclude: “Based on the results of the present study as well as those of LeVay (1991), sexual orientation cannot be reliably predicted on the basis of INAH3 volume alone.”⁹² In 2002, psychologist Mitchell S. Lasco and colleagues published a study examining a different part of the brain—the anterior commissure—and found that there were no significant differences in that area based either on sex or sexual orientation.⁹³

Other studies have since been conducted to ascertain structural or functional differences between the brains of heterosexual and homosexual individuals (using a variety of criteria to define these categories). Findings from several of these studies are summarized in a 2008 commentary published in the *Proceedings of the National Academy of Sciences*.⁹⁴ Research of this kind, however, does not seem to reveal much of relevance regarding the etiology or biological origins of sexual orientation. Due to inherent limitations, this research literature is fairly unremarkable. For example, in one study functional MRI was used to measure activity changes in the brain when pictures of men and women were shown to subjects, finding that viewing a female face produced stronger activity in the thalamus and orbitofrontal cortex of heterosexual men and homosexual women, whereas in homosexual men and heterosexual women these structures reacted more strongly to the face of a man.⁹⁵ That the brains of heterosexual women and homosexual men reacted distinctively to the faces of men, whereas the brains of heterosexual men and homosexual women reacted distinctively to the faces of women, is a finding that seems rather trivial with respect to understanding the etiology of homosexual attractions. In a similar vein, one study reported different responses to pheromones between homosexual and heterosexual men,⁹⁶ and a follow-up study showed a similar finding in homosexual compared to heterosexual women.⁹⁷ Another study showed differences in cerebral asymmetry and functional connectivity between homosexual and heterosexual subjects.⁹⁸

While findings of this kind may suggest avenues for future investigation, they do not move us much closer to an understanding of the biological or environmental determinants of sexual attractions, interests, preferences, or behaviors. We will say more about this below. For now, we will briefly illustrate a few of the inherent limitations in this area of research with the following hypothetical example. Suppose we were to study the brains of yoga teachers and compare them to the brains of bodybuilders. If we search long enough, we will eventually find statistically significant differences in some area of brain morphology or brain function between these two groups. But this would not imply that such differences determined the different life trajectories of the yoga teacher and the bodybuilder. The brain differences could have been the result, rather than the cause, of distinctive patterns of behavior or interests.⁹⁹ Consider another example. Suppose that gay men tend to have less body fat than straight men (as indicated by lower average scores on body mass indices). Even though body mass is, in part, determined by genetics, we could not claim based on this finding that there is some innate, genetic cause of both body

mass and homosexuality at work. It could be the case, for instance, that being gay is associated with a diet that lowers body mass. These examples illustrate one of the common problems encountered in the popular interpretation of such research: the suggestion that the neurobiological pattern determines a particular behavioral expression.

With this overview of studies on biological factors that might influence sexual attraction, preferences, or desires, we can understand the rather strong conclusion by social psychologist Letitia Anne Peplau and colleagues in a 1999 review article: “To recap, more than 50 years of research has failed to demonstrate that biological factors are a major influence in the development of women’s sexual orientation.... Contrary to popular belief, scientists have not convincingly demonstrated that biology determines women’s sexual orientation.”¹⁰⁰ In light of the studies we have summarized here, this statement could also be made for research on male sexual orientation, however this concept is defined.

Misreading the Research

There are some significant built-in limitations to what the kind of empirical research summarized in the preceding sections can show. Ignoring these limitations is one of the main reasons the research is routinely misinterpreted in the public sphere. It may be tempting to assume, as we just saw with the example of brain structure, that if a particular biological profile is associated with some behavioral or psychological trait, then that biological profile *causes* that trait. This reasoning relies on a fallacy, and in this section we explain why, using concepts from the field of epidemiology. While some of these issues are rather technical in detail, we will try to explain them in a general way that is accessible to the non-specialist reader.

Suppose for the sake of illustration that one or more differences in a biological trait are found between homosexual and heterosexual men. That difference could be a discrete measure (call this D) such as presence of a genetic marker, or it could be a continuous measure (call this C) such as the average volume of a particular part of the brain.

Showing that a risk factor significantly increases the chances of a particular health outcome or a behavior might give us a clue to development of that health outcome or that behavior, but it does not provide evidence of causation. Indeed, it may not provide evidence of anything but the weakest of correlations. The inference is sometimes made that if it can be shown that gay men and straight men differ significantly in the

probability that D is present (whether a gene, a hormonal factor, or something else), no matter how low that probability, then this finding suggests that being gay has a biological basis. But this inference is unwarranted. Doubling (or even tripling or quadrupling) the probability of a relatively rare trait can have little value in terms of predicting who will or will not identify as gay.

The same would be true for any continuous variable (C). Showing a significant difference at the mean or average for a given trait (such as the volume of a particular brain region) between men who identify as heterosexual and men who identify as homosexual does not suffice to show that this average difference contributes to the probability of identifying as heterosexual or homosexual. In addition to the reasons explained above, a significant difference at the means of two distributions can be consistent with a great deal of overlap between the distributions. That is, there may be virtually no separation in terms of distinguishing between some individual members of each group, and thus the measure would not provide much predictability for sexual orientation or preference.

Some of these issues could, in part, be addressed by additional methodological approaches, such as the use of a training sample or cross-validation procedures. A training sample is a small sample used to develop a model (or hypothesis); this model is then tested on a larger independent sample. This method avoids testing a hypothesis on the same data used to develop the hypothesis. Cross-validation includes procedures used to examine whether a statistically significant effect is really there or just due to chance. If one wants to show the result did not occur by chance (and if the sample is large), one can run the same tests on a random split of the relevant sample. After finding a difference in the prevalence of trait D or C between a gay sample and a straight sample, researchers could randomly split the gay sample into two groups and then show that these two groups do not differ regarding D or C. Suppose one finds five differences out of 100 comparing gay to straight men in the overall samples, then finds five differences out of 100 when comparing the split gay samples. This would cast additional doubt on the initial finding of a difference between the means of gay and straight individuals.

Sexual Abuse Victimization

Whereas the preceding discussion considered the part that biological factors might play in the development of sexual orientation, this section will summarize evidence that a particular environmental factor—childhood

sexual abuse—is reported significantly more often among those who later identify as homosexual. The results presented below raise the question whether there is an association between sexual abuse, particularly in childhood, and later expressions of sexual attraction, behavior, or identity. If so, might child abuse increase the probability of having a non-heterosexual orientation?

Correlations, at least, have been found, as we will summarize below. But we should note first that they might be accounted for by one or more of the following conjectures:

1. Abuse might contribute to the development of non-heterosexual orientation.
2. Children with (signs of future) non-heterosexual tendencies might attract abusers, placing them at elevated risk.
3. Certain factors might contribute to *both* childhood sexual abuse and non-heterosexual tendencies (for instance, a dysfunctional family or an alcoholic parent).

It should be kept in mind that these three hypotheses are not mutually exclusive; all three, and perhaps others, might be operative. As we summarize the studies on this issue, we will try to evaluate each of these hypotheses in light of current scientific research.

Behavioral and community health professor Mark S. Friedman and colleagues conducted a 2011 meta-analysis of 37 studies from the United States and Canada examining sexual abuse, physical abuse, and peer victimization in heterosexuals as compared to non-heterosexuals.¹⁰¹ Their results showed that non-heterosexuals were on average 2.9 times more likely to report having been abused as children (under 18 years of age). In particular, non-heterosexual males were 4.9 times likelier—and non-heterosexual females, 1.5 times likelier—than their heterosexual counterparts to report sexual abuse. Non-heterosexual adolescents as a whole were 1.3 times likelier to indicate physical abuse by parents than their heterosexual peers, but gay and lesbian adolescents were only 0.9 times as likely (bisexuals were 1.4 times as likely). As for peer victimization, non-heterosexuals were 1.7 times likelier to report being injured or threatened with a weapon or being attacked.

The authors note that although they hypothesized that the rates of abuse would decrease as social acceptance of homosexuality rose, “disparities in prevalence rates of sexual abuse, parental physical abuse, and peer

victimization between sexual minority and sexual nonminority youths did not change from the 1990s to the first decade of the 2000s.”¹⁰² While these authors cite authorities who claim that sexual abuse does not “cause individuals to become gay, lesbian, or bisexual,”¹⁰³ their data do not give evidence against the hypothesis that childhood sexual abuse might affect sexual orientation. On the other hand, the causal path could be in the opposite direction or bi-directional. The evidence does not refute or support this conjecture; the study’s design is not capable of shedding much light on the question of directionality.

The authors invoke a widely-cited hypothesis to explain the higher rates of sexual abuse among non-heterosexuals, the hypothesis that “sexual minority individuals are...more likely to be targeted for sexual abuse, as youths who are perceived to be gay, lesbian, or bisexual are more likely to be bullied by their peers.”¹⁰⁴ The two conjectures—that abuse is a cause and that it is a result of non-heterosexual tendencies—are not mutually exclusive: abuse may be a causal factor in the development of non-heterosexual attractions and desires, and at the same time non-heterosexual attractions, desires, and behaviors may increase the risk of being targeted for abuse.

Community health sciences professor Emily Faith Rothman and colleagues conducted a 2011 systematic review of the research investigating the prevalence of sexual assault against people who identify as gay, lesbian, or bisexual in the United States.¹⁰⁵ They examined 75 studies (25 of which used probability sampling) involving a total of 139,635 gay or bisexual (GB) men and lesbian or bisexual (LB) women, which measured the prevalence of victimization due to lifetime sexual assault (LSA), childhood sexual assault (CSA), adult sexual assault (ASA), intimate partner sexual assault (IPSA), and hate-crime-related sexual assault (HC). Although the study was limited by not having a heterosexual control group, it showed alarmingly high rates of sexual assault, including childhood sexual assault, for this population, as summarized in Table 1.

Using a multi-state probability-based sample in a 2013 study, psychologist Judith Anderson and colleagues compared differences in adverse childhood experiences—including dysfunctional households; physical, sexual, or emotional abuse; and parental discord—among self-identified homosexual, heterosexual, and bisexual adults.¹⁰⁶ They found that bisexuals had significantly higher proportions than heterosexuals of all adverse childhood experience factors, and that gays and lesbians had significantly higher proportions than heterosexuals of all these measures except parental separation or divorce. Overall, gays and lesbians had nearly 1.7 times,

Table 1. Sexual Assault among Gay/Bisexual Men and Lesbian/Bisexual Women

GB Men (%)	LB Women (%)
CSA: 4.1–59.2 (median 22.7)	CSA: 14.9–76.0 (median 34.5)
ASA: 10.8–44.7 (median 14.7)	ASA: 11.3–53.2 (median 23.2)
LSA: 11.8–54.0 (median 30.4)	LSA: 15.6–85.0 (median 43.4)
IPSA: 9.5–57.0 (median 12.1)	IPSA: 3.0–45.0 (median 13.3)
HC: 3.0–19.8 (median 14.0)	HC: 1.0–12.3 (median 5.0)

and bisexuals 1.6 times, the heterosexual rate of adverse childhood experiences. The data for abuse are summarized in Table 2.

While this study, like some others we have discussed, may be limited by recall bias—that is, inaccuracies introduced by errors of memory—it has the merit of having a control group of self-identified heterosexuals to compare with self-identified gay/lesbian and bisexual cohorts. In their discussion of findings, the authors critique the hypothesis that childhood trauma has a causal relationship to homosexual preferences. Among their reasons for skepticism, they note that the vast majority of individuals who suffer childhood trauma do not become gay or bisexual, and that gender-nonconforming behavior may help explain the elevated rates of abuse. However, it is plausible from these and related results to hypothesize

Table 2. Adverse Childhood Experiences among Gays/Lesbians, Bisexuals, and Heterosexuals

Sexual Abuse (%)		
GLs	Bisexuals	Heterosexuals

Physical Abuse (%)		
GLs	Bisexuals	Heterosexuals
29.3	30.3	16.7

that adverse childhood experiences may be a significant—but not a determinative—factor in developing homosexual preferences. Further studies are needed to see whether either or both hypotheses have merit.

A 2010 study by professor of social and behavioral sciences Andrea Roberts and colleagues examined sexual orientation and risk of post-traumatic stress disorder (PTSD) using data from a national epidemiological face-to-face survey of nearly 35,000 adults.¹⁰⁷ Individuals were placed into several categories: heterosexual with no same-sex attraction or partners (reference group); heterosexual with same-sex attraction but no same-sex partners; heterosexual with same-sex partners; self-identified gay/lesbian; and self-identified bisexual. Among those reporting exposure to traumatic events, gay and lesbian individuals as well as bisexuals had about twice the lifetime risk of PTSD compared to the heterosexual reference group. Differences were found in rates of childhood maltreatment and interpersonal violence: gays, lesbians, bisexuals, and heterosexuals with same-sex partners reported experiencing worse traumas during childhood and adolescence than the reference group. The findings are summarized in Table 3.

Similar patterns emerged in a 2012 study by psychologist Brendan Zietsch and colleagues that primarily focused on the distinct question of whether common causal factors could explain the association between sexual orientation—in this study defined as sexual preference—and depression.¹⁰⁸ In a community sample of 9,884 adult twins, the authors found that non-heterosexuals had significantly elevated prevalence of lifetime depression (odds ratio for males 2.8; odds ratio for females 2.7). As the authors point out, the data raised questions about whether higher rates of depression for non-heterosexuals could be explained, in their entirety, by the social stress hypothesis (the idea, discussed in depth in Part Two of this report, that social stress

**Table 3. Childhood Exposure to Maltreatment
or Interpersonal Violence (before Age 18)**

Women	Men
49.2% of lesbians	31.5% of gays
51.2% of bisexuals	Approximately 32% of bisexuals ¹⁰⁹
40.9% of heterosexuals with same-sex partners	27.9% of heterosexuals with same-sex partners
21.2% of heterosexuals	19.8% of heterosexuals

experienced by sexual minorities accounts for their elevated risks of poor mental health outcomes). Heterosexuals with a non-heterosexual twin had higher rates of depression (39%) than heterosexual twin pairs (31%), suggesting that genetic, familial, or other factors may play a role.

The authors note that “in both males and females, significantly higher rates of non-heterosexuality were found in participants who experienced childhood sexual abuse and in those with a risky childhood family environment.”¹¹⁰ Indeed, 41% of non-heterosexual males and 42% of non-heterosexual females reported childhood family dysfunction, compared to 24% and 30% of heterosexual males and females, respectively. And 12% of non-heterosexual males and 24% of non-heterosexual females reported sexual abuse before the age of 14, compared with 4% and 11% of heterosexual males and females, respectively. The authors are careful to emphasize that their findings should not be interpreted as disproving the social stress hypothesis, but suggest that there may be other factors at work. Their findings do, however, suggest there could be common etiological factors for depression and non-heterosexual preferences, as they found that genetic factors account for 60% of the correlation between sexual orientation and depression.¹¹¹

In a 2001 study, psychologist Marie E. Tomeo and colleagues noted that the previous literature had consistently found increased rates of reported childhood molestation in the homosexual population, with somewhere between 10% and 46% reporting that they had experienced childhood sexual abuse.¹¹² The authors found that 46% of homosexual men and 22% of homosexual women reported that they had been molested by a person of the same gender, as compared with 7% of heterosexual men and 1% of heterosexual women. Moreover, 38% of homosexual women interviewed did not identify as homosexual until after the abuse, while the authors report conflicting figures—68% in one part of the paper and (by inference) 32% in another—for the number of homosexual men who did not identify as homosexual until after the abuse. The sample for this study was relatively small, only 267 individuals; also, the “sexual contact” measure of abuse in the survey was somewhat vague, and the subjects were recruited from participants in gay pride events in California. But the authors state that “it is most unlikely that all the present findings apply only to homosexual persons who go to homosexual fairs and volunteer to participate in questionnaire research.”¹¹³

In 2010, psychologists Helen Wilson and Cathy S. Widom published a prospective 30-year follow-up study—one that looked at children who had experienced abuse or neglect between 1961 and 1971, and then followed up with those children after 30 years—to ascertain whether physical abuse, sexual abuse, or neglect in childhood increased the likelihood of same-sex

sexual relationships later in life.¹¹⁴ An original sample of 908 abused and/or neglected children was matched with a non-maltreated control group of 667 individuals (matched for age, sex, race or ethnicity, and approximate socioeconomic status). Homosexuality was operationalized as anyone who had cohabited with a same-sex romantic partner or had a same-sex sexual partner, which made up 8% of the sample. Among these 8%, most individuals also reported having had opposite-sex partners, suggesting high rates of bisexuality or fluidity in sexual attractions or behaviors. The study found that those who reported histories of childhood sexual abuse were 2.8 times more likely to report having had same-sex sexual relationships, though the “relationship between childhood sexual abuse and same-sex sexual orientation was significant only for men.”¹¹⁵ This finding suggested that boys who are sexually abused may be more likely to establish both heterosexual and homosexual relationships.

The authors advised caution in interpreting this result, because the sample size of sexually abused men was small, but the association remained statistically significant when they controlled for total lifetime number of sexual partners and for engaging in prostitution. The study was also limited by a definition of sexual orientation that was not sensitive to how participants identified themselves. It may have failed to capture people with same-sex attractions but no same-sex romantic relationship history. The study had two notable methodological strengths. The prospective design is better suited for evaluating causal relationships than the typical retrospective design. Also, the childhood abuse recorded was documented when it occurred, thus mitigating recall bias.

Having examined the statistical association between childhood sexual abuse and later homosexuality, we turn to the question of whether the association suggests causation.

A 2013 analysis by health researcher Andrea Roberts and colleagues attempted to provide an answer to this question.¹¹⁶ The authors noted that while studies show 1.6 to 4 times more reported childhood sexual and physical abuse among gay and lesbian individuals than among heterosexuals, conventional statistical methods cannot demonstrate a strong enough statistical relationship to support the argument of causation. They argued that a sophisticated statistical method called “instrumental variables,” imported from econometrics and economic analysis, could increase the level of association.¹¹⁷ (The method is somewhat similar to the method of “propensity scores,” which is more sophisticated and more familiar to public health researchers.) The authors applied the method of instrumental variables to data collected from a nationally representative sample.

They used three dichotomous measures of sexual orientation: any vs. no same-sex attraction; any vs. no lifetime same-sex sexual partners; and lesbian, gay, or bisexual vs. heterosexual self-identification. As in other studies, the data showed associations between childhood sexual abuse or maltreatment and all three dimensions of non-heterosexuality (attraction, partners, identity), with associations between sexual abuse and sexual identity being the strongest.

The authors' instrumental variable models suggested that early sexual abuse increased the predicted rate of same-sex attraction by 2.0 percentage points, same-sex partnering by 1.4 percentage points, and same-sex identity by 0.7 percentage points. The authors estimated the rate of homosexuality that might be attributable to sexual abuse "using effect estimates from conventional models" and found that on conventional effect estimates, "9% of same-sex attraction, 21% of any lifetime same-sex sexual partnering, and 23% of homosexual or bisexual identity was due to childhood sexual abuse."¹¹⁸ We should note that these correlations are cross-sectional: they compare groups of people to groups of people, rather than model the course of individuals over time. (A study design with a time-series analysis would give the strongest statistical support to the claim of causality.) Additionally, these results have been strongly criticized on methodological grounds for having made unjustified assumptions in the instrumental variables regression; a commentary by Drew H. Bailey and J. Michael Bailey claims, "Not only do Roberts et al.'s results fail to provide support for the idea that childhood maltreatment causes adult homosexuality, the pattern of differences between males and females is opposite what should be expected based on better evidence."¹¹⁹

Roberts and colleagues conclude their study with several conjectures to explain the epidemiological associations. They echo suggestions made elsewhere that sexual abuse perpetrated by men might cause boys to think they are gay or make girls averse to sexual contact with men. They also conjecture that sexual abuse might leave victims feeling stigmatized, which in turn might make them more likely to act in ways that are socially stigmatized (as by engaging in same-sex sexual relationships). The authors also point to the biological effects of maltreatment, citing studies that show that "quality of parenting" can affect chemical and hormonal receptors in children, and hypothesizing that this might influence sexuality "through epigenetic changes, particularly in the stria terminalis and the medial amygdala, brain regions that regulate social behavior."¹²⁰ They also mention the possibilities that emotional numbing caused by maltreatment may drive victims to seek out risky behaviors associated

with same-sex sexuality, or that same-sex attractions and partnering may result from “the drive for intimacy and sex to repair depressed, stressed, or angry moods,” or from borderline personality disorder, which is a risk factor in individuals who have been maltreated.¹²¹

In short, while this study suggests that sexual abuse may sometimes be a causal contributor to having a non-heterosexual orientation, more research is needed to elucidate the biological or psychological mechanisms. Without such research, the idea that sexual abuse may be a causal factor in sexual orientation remains speculative.

Distribution of Sexual Desires and Changes Over Time

However sexual desires and interests develop, there is a related issue that scientists debate: whether sexual desires and attractions tend to remain fixed and unalterable across the lifespan of a person—or are fluid and subject to change over time but tend to become fixed after a certain age or developmental period. Advocates of the “born that way” hypothesis, as mentioned earlier, sometimes argue that a person is not only born with a sexual orientation but that that orientation is immutable; it is fixed for life.

There is now considerable scientific evidence that sexual desires, attractions, behaviors, and even identities can, and sometimes do, change over time. For findings in this area we can turn to the most comprehensive study of sexuality to date, the 1992 National Health and Social Life Survey conducted by the National Opinion Research Center at the University of Chicago (NORC).¹²² Two important publications have appeared using data from NORC’s comprehensive survey: *The Social Organization of Sexuality: Sexual Practices in the United States*, a large tome of data intended for the research community, and *Sex in America: A Definitive Survey*, a smaller and more accessible book summarizing the findings for the general public.¹²³ These books present data from a reliable probability sample of the American population between ages 18 and 59.

According to data from the NORC survey, the estimated prevalence of non-heterosexuality, depending on how it was operationalized, and on whether the subjects were male or female, ranged between roughly 1% and 9%.¹²⁴ The NORC studies added scientific respectability to sexual surveys, and these findings have been largely replicated in the United States and abroad. For example, the British National Survey of Sexual Attitudes and Lifestyles (Natsal) is probably the most reliable source of information on sexual behavior in that country—a study conducted every ten years since 1990.¹²⁵

The NORC study also suggested ways in which sexual behaviors and identities can vary significantly under different social and environmental circumstances. The findings revealed, for example, a sizable difference in rates of male homosexual behavior among individuals who spent their adolescence in rural as compared to large metropolitan cities in America, suggesting the influence of social and cultural environments. Whereas only 1.2% of males who had spent their adolescence in a rural environment responded that they had had a male sexual partner in the year of the survey, those who had spent adolescence living in metropolitan areas were close to four times (4.4%) more likely to report that they had had such an encounter.¹²⁶ From these data one cannot infer differences between these environments in the prevalence of sexual interests or attractions, but the data do suggest differences in sexual behaviors. Also of note is that women who attended college were nine times more likely to identify as lesbians than women who did not.¹²⁷

Moreover, other population-based surveys suggest that sexual desire may be fluid for a considerable number of individuals, especially among adolescents as they mature through the early stages of adult development. In this regard, opposite-sex attraction and identity seem to be more stable than same-sex or bisexual attraction and identity. This is suggested by data from the National Longitudinal Study of Adolescent to Adult Health (the “Add Health” study discussed earlier). This prospective longitudinal study of a nationally representative sample of U.S. adolescents starting in grades 7–12 began during the 1994–1995 school year, and followed the cohort into young adulthood, with four follow-up interviews (referred to as Waves I, II, III, IV in the literature).¹²⁸ The most recent was in 2007–2008, when the sample was aged 24–32.

Same-sex or both-sex romantic attractions were quite prevalent in the study’s first wave, with rates of approximately 7% for the males and 5% for the females.¹²⁹ However, 80% of the adolescent males who had reported same-sex attractions at Wave I later identified themselves as exclusively heterosexual as young adults at Wave IV.¹³⁰ Similarly, for adolescent males who, at Wave I, reported romantic attraction to both sexes, over 80% of them reported no same-sex romantic attraction at Wave III.¹³¹ The data for the females surveyed were similar but less striking: for adolescent females who had both-sex attractions at Wave I, more than half reported exclusive attraction to males at Wave III.¹³²

J. Richard Udry, the director of Add Health for Waves I, II, and III,¹³³ was among the first to point out the fluidity and instability of romantic attraction between the first two waves. He reported that among boys who

reported romantic attraction *only* to boys and *never* to girls at Wave I, 48% did so during Wave II; 35% reported no attraction to either sex; 11% reported exclusively same-sex attraction; and 6% reported attraction to both sexes.¹³⁴

Ritch Savin-Williams and Geoffrey Ream published a 2007 analysis of the data from Waves I–III of Add Health.¹³⁵ Measures used included whether individuals ever had a romantic attraction for a given sex, sexual behavior, and sexual identity. (The categories for sexual identity were 100% heterosexual, mostly heterosexual but somewhat same-sex attracted, bisexual, mostly homosexual but somewhat attracted to opposite sex, and 100% homosexual.) While the authors noted the “stability of opposite-sex attraction and behavior” between Waves I and III, they found a “high proportion of participants with same- and both-sex attraction and behavior that migrated into opposite-sex categories between waves.”¹³⁶ A much smaller proportion of those in the heterosexual categories, and a similar proportion of those without attraction, moved to non-heterosexual categories. The authors summarize: “All attraction categories other than opposite-sex were associated with a lower likelihood of stability over time. That is, individuals reporting any same-sex attractions were more likely to report subsequent shifts in their attractions than were individuals without any same-sex attractions.”¹³⁷

The authors also note the difficulties these data present for trying to define sexual orientation and to classify individuals according to such categories: “the critical consideration is whether having ‘any’ same-sex sexuality qualifies as nonheterosexuality. How much of a dimension must be present to tip the scales from one sexual orientation to another was not resolved with the present data, only that such decisions matter in terms of prevalence rates.”¹³⁸ The authors suggested that researchers could “for-sake the general notion of sexual orientation altogether and assess only those components relevant for the research question.”¹³⁹

Another prospective study by biostatistician Miles Ott and colleagues of 10,515 youth (3,980 males; 6,535 females) in 2013 showed findings on sexual orientation change in adolescents consistent with the findings of the Add Health data, again suggesting fluidity and plasticity of same-sex attractions among many adolescents.¹⁴⁰

A few years after the Add Health data were originally published, the *Archives of Sexual Behavior* published an article by Savin-Williams and Joyner that critiqued the Add Health data on sexual attraction change.¹⁴¹ Before outlining their critique, Savin-Williams and Joyner summarize the key Add Health findings: “in the approximately 13 years between Waves

I and IV, regardless of whether the measure was identical across waves (romantic attraction) or discrepant in words but not in theory (romantic attraction and sexual orientation identity), approximately 80% of adolescent boys and half of adolescent girls who expressed either partial or exclusive same-sex romantic attraction at Wave I ‘turned’ heterosexual (opposite-sex attraction or exclusively heterosexual identity) as young adults.”¹⁴² The authors propose three hypotheses to explain these discrepancies:

- (1) gay adolescents going into the closet during their young adult years;
- (2) confusion regarding the use and meaning of romantic attraction as a proxy for sexual orientation; and (3) the existence of mischievous adolescents who played a ‘jokester’ role by reporting same-sex attraction when none was present.¹⁴³

Savin-Williams and Joyner reject the first hypothesis but find support for the second and the third. With respect to the second hypothesis, they question the use of romantic attraction to operationalize sexual identity:

To help us assess whether the construct/measurement issue (romantic attraction versus sexual orientation identity) was driving results, we compared the two constructs at Wave IV....Whereas over 99% of young adults with opposite-sex romantic attraction identified as heterosexual or mostly heterosexual and 94% of those with same-sex romantic attraction identified as homosexual or mostly homosexual, 33% of both-sex attracted men identified as heterosexual (just 6% of both-sex attracted women identified as heterosexual). These data indicated that young adult men and women generally understood the meaning of romantic attraction to the opposite- or same-sex to imply a particular (and consistent) sexual orientation identity, with one glaring exception—a substantial subset of young adult men who, despite their stated both-sex romantic attraction, identified as heterosexual.

Regarding the third hypothesis for explaining the Add Health data, Savin-Williams and Joyner note that surveys of adolescents sometimes yield unusual or distorted results due to adolescents who do not respond truthfully. The Add Health survey, they observe, had a significant number of unusual responders. For example, several hundred adolescents reported in the Wave I questionnaire that they had an artificial limb, whereas in later at-home interviews, only two of those adolescents reported having an artificial limb.¹⁴⁴ Adolescent boys who went from nonheterosexual in Wave I to heterosexual in Wave IV were significantly less likely to report

having filled out the Wave I questionnaire honestly; these boys also displayed other significant differences, such as lower grade point averages. Additionally, like consistently heterosexual boys, boys who were inconsistent between Waves I and IV were more popular in their school with boys than girls, whereas consistently nonheterosexual boys were more popular with girls. These and other data¹⁴⁵ led the authors to conclude that “boys who emerged from a gay or bisexual adolescence to become a heterosexual young adulthood were, by-and-large, heterosexual adolescents who were either confused and did not understand the measure of romantic attraction or jokesters who decided, for reasons we were not able to detect, to dishonestly report their sexuality.”¹⁴⁶ However, the authors were not able to estimate the proportion of inaccurate responders, which would have helped evaluate the explanatory power of the hypotheses.

Later in 2014, the *Archives of Sexual Behavior* published a critique of the Savin-Williams and Joyner explanation of Add Health data by psychologist Gu Li and colleagues.¹⁴⁷ Along with criticizing the methodology of Savin-Williams and Joyner, these authors argued that the data were consistent with a scenario in which some nonheterosexual adolescents went “back into the closet” in later years as a possible reaction to social stress. (We will examine the effects of social stress on mental health in LGBT populations in Part Two of this report.) They also claimed that “it makes little sense to use responses to Wave IV sexual identity to validate or invalidate responses to Waves I or IV romantic attractions when these aspects of sexual orientation may not align in the first place.”¹⁴⁸ Regarding the jokester hypothesis, these authors pose this difficulty: “Although some participants might be ‘jokesters,’ and we as researchers should be cautious of problems associated with self-report surveys whenever analyzing and interpreting data, it is unclear why the ‘jokesters’ would answer questions about delinquency honestly, but not questions about their sexual orientation.”¹⁴⁹

Savin-Williams and Joyner published a response to the critique in the same issue of the journal.¹⁵⁰ Responding to the criticism that their comparison of Wave IV self-reported sexual identity to Wave I self-reported romantic attractions was unsound, Savin-Williams and Joyner claimed that the results were quite similar if one used attraction as the Wave IV measure. They also deemed it highly unlikely that a large proportion of the respondents who were classified as nonheterosexuals in Wave I and heterosexuals in Wave IV went “back into the closet,” because the proportion of individuals in adolescence and young adulthood who are “out of the closet” usually increases over time.¹⁵¹

The following year, the *Archives of Sexual Behavior* published another response to Savin-Williams and Joyner by psychologist Sabra Katz-Wise and colleagues, which argued that Savin-Williams and Joyner's "approach to identifying 'dubious' sexual minority youth is inherently flawed."¹⁵² They wrote that "romantic attraction and sexual orientation identity are two distinct dimensions of sexual orientation that may not be concordant, even at a single time point."¹⁵³ They also claimed that "even if Add Health had assessed the same facets of sexual orientation at all waves, it would still be incorrect to infer 'dubious' sexual minorities from changes on the same dimension of sexual orientation, because these changes may reflect sexual fluidity."¹⁵⁴

Unfortunately, the Add Health study does not appear to contain the data that would allow an assessment to determine which, if any, of these interpretations is likely to be correct. It may well be the case that a combination of factors contributed to the differences between the Wave I and Wave IV data. For example, there may have been some adolescents who responded to the Wave I sexual attraction questions inaccurately, some openly nonheterosexual adolescents who later went "back into the closet," and some adolescents who experienced nonheterosexual attractions before Wave I that largely disappeared by Wave IV. Other prospective study designs that track specific individuals across adolescent and adult development may shed further light on these issues.

While ambiguities in defining and characterizing sexual desire and orientation make changes in sexual desire difficult to study, data from these large, population-based national studies of randomly sampled individuals do suggest that all three dimensions of sexuality—affect, behavior, and identity—may change over time for some people. It is unclear, and current research does not address, whether and to what extent factors subject to volitional control—choice of sexual partners or sexual behaviors, for example—may influence such changes through conditioning and other mechanisms that are characterized in the behavioral sciences.

Several researchers have suggested that sexual orientation and attractions may be especially plastic for women.¹⁵⁵ For example, Lisa Diamond argued in her 2008 book *Sexual Fluidity* that "women's sexuality is fundamentally more fluid than men's, permitting greater variability in its development and expression over the life course," based on research by her and many others.¹⁵⁶

Diamond's longitudinal five-year interviews of women in sexual relationships with other women also shed light on the problems with the concept of sexual orientation. In many cases, the women in her study

reported not so much setting out to form a lesbian sexual relationship but rather experiencing a gradual growth of affective intimacy with a woman that eventually led to sexual involvement. Some of these women rejected the labels of “lesbian,” “straight,” or “bisexual” as being inconsistent with their lived experience.¹⁵⁷ In another study, Diamond calls into question the utility of the concept of sexual orientation, especially as it applies to females.¹⁵⁸ She points out that if the neural basis of parent-child attachment—including attachment to one’s mother—forms at least part of the basis for romantic attachments in adulthood, then it would not be surprising for a woman to experience romantic feelings for another woman without necessarily wanting to be sexually intimate with her. Diamond’s research indicates that these kinds of relationships form more often than we typically recognize, especially among women.

Some researchers have also suggested that men’s sexuality is more fluid than it was previously thought. For example, Diamond presented a 2014 conference paper, based on initial results from a survey of 394 people, entitled “I Was Wrong! Men Are Pretty Darn Sexually Fluid, Too!”¹⁵⁹ Diamond based this conclusion on a survey of men and women between the ages of 18 and 35, which asked about their sexual attractions and self-described identities at different stages of their lives. The survey found that 35% of self-identified gay men reported experiencing opposite-sex attractions in the past year, and 10% of self-identified gay men reported opposite-sex sexual behavior during the same period. Additionally, nearly as many men transitioned at some time in their life from gay to bisexual, queer, or unlabeled identity as did men from bisexual to gay identity.

In a 2012 review article entitled “Can We Change Sexual Orientation?” published in the *Archives of Sexual Behavior*, psychologist Lee Beckstead wrote, “Although their sexual behavior, identity, and attractions may change throughout their lives, this may not indicate a change in sexual orientation...but a change in awareness and an expansion of sexuality.”¹⁶⁰ It is difficult to know how to interpret this claim—that sexual behavior, identity, and attractions may change but that this does not necessarily indicate a change in sexual orientation. We have already analyzed the inherent difficulties of defining sexual orientation, but however one chooses to define this construct, it seems that the definition would somehow be tied to sexual behavior, identity, or attraction. Perhaps we can take Beckstead’s claim here as one more reason to consider dispensing with the construct of sexual orientation in the context of social science research, as it seems that whatever it might represent, it is only loosely or inconsistently tied to empirically measurable phenomena.

Given the possibility of changes in sexual desire and attraction, which research suggests is not uncommon, any attempt to infer a stable, innate, and fixed identity from a complex and often shifting *mélange* of inner fantasies, desires, and attractions—sexual, romantic, aesthetic, or otherwise—is fraught with difficulties. We can imagine, for example, a sixteen-year-old boy who becomes infatuated with a young man in his twenties, developing fantasies centered around the other's body and build, or perhaps on some of his character traits or strengths. Perhaps one night at a party the two engage in physical intimacy, catalyzed by alcohol and by the general mood of the party. This young man then begins an anguished process of introspection and self-exploration aimed at finding the answer to the enigmatic question, "Does this mean I'm gay?"

Current research from the biological, psychological, and social sciences suggests that this question, at least as it is framed, makes little sense. As far as science can tell us, there is nothing "there" for this young man to discover—no fact of nature to uncover or to find buried within himself. What his fantasies, or his one-time liaison, "really mean" is subject to any number of interpretations: that he finds the male figure beautiful, that he was lonely and feeling rejected the night of the party and responded to his peer's attentions and affections, that he was intoxicated and influenced by the loud music and strobe lights, that he does have a deep-seated sexual or romantic attraction to other men, and so on. Indeed, psychodynamic interpretations of such behaviors citing unconscious motivational factors and inner conflicts, many of them interesting, most impossible to prove, can be spun endlessly.

What we can say with more confidence is that this young man had an experience encompassing complex feelings, or that he engaged in a sexual act conditioned by multiple complex factors, and that such fantasies, feelings, or associated behaviors may (or may not) be subject to change as he grows and develops. Such behaviors could become more habitual with repetition and thus more stable, or they may extinguish and recur rarely or never. The research on sexual behaviors, sexual desire, and sexual identity suggests that both trajectories are real possibilities.

Conclusion

The concept of sexual orientation is unusually ambiguous compared to other psychological traits. Typically, it refers to at least one of three things: attractions, behaviors, or identity. Additionally, we have seen that sexual orientation often refers to several other things as well: belonging

to a certain community, fantasies (as distinct in some respects from attractions), longings, strivings, felt needs for certain forms of companionship, and so on. It is important, then, that researchers are clear about which of these domains are being studied, and that we keep in mind the researchers' specified definitions when we interpret their findings.

Furthermore, not only can the term "sexual orientation" be understood in several different senses, most of the senses are themselves complex concepts. Attraction, for example, could refer to arousal patterns, or to romantic feelings, or to desires for company, or other things; and each of these things can be present either sporadically and temporarily or pervasively and long-term, either exclusively or not, either in a deep or shallow way, and so forth. For this reason, even specifying one of the basic senses of orientation (attraction, behavior, or identity) is insufficient for doing justice to the richly varied phenomenon of human sexuality.

In this part we have criticized the common assumption that sexual *desires*, *attractions*, or *longings* reveal some innate and fixed feature of our biological or psychological constitution, a fixed sexual *identity* or *orientation*. Furthermore, we may have some reasons to doubt the common assumption that in order to live happy and flourishing lives, we must somehow discover this innate fact about ourselves that we call *sexuality* or *sexual orientation*, and invariably express it through particular patterns of sexual behavior or a particular life trajectory. Perhaps we ought instead to consider what sorts of behaviors—whether in the sexual realm or elsewhere—tend to be conducive to health and flourishing, and what kinds of behaviors tend to undermine a healthy and flourishing life.

Part Two

Sexuality, Mental Health Outcomes, and Social Stress

Compared to the general population, non-heterosexual and transgender subpopulations have higher rates of mental health problems such as anxiety, depression, and suicide, as well as behavioral and social problems such as substance abuse and intimate partner violence. The prevailing explanation in the scientific literature is the social stress model, which posits that social stressors—such as stigmatization and discrimination—faced by members of these subpopulations account for the disparity in mental health outcomes. Studies show that while social stressors do contribute to the increased risk of poor mental health outcomes for these populations, they likely do not account for the entire disparity.

Many of the issues surrounding sexual orientation and gender identity remain controversial among researchers, but there is general agreement on the observation at the heart of Part Two: lesbian, gay, bisexual, and transgender (LGBT) subpopulations are at higher risk, compared to the general population, of numerous mental health problems. Less certain are the causes of that increased risk and thus the social and clinical approaches that may help to ameliorate it. In this part we review some of the research documenting the increased risk, focusing on papers that are data-based with sound methodology, and that are widely cited in the scientific literature.

A robust and growing body of research examines the relationships between sexuality or sexual behaviors and mental health status. The first half of this part discusses the associations of sexual identities or behaviors with psychiatric disorders (such as mood disorders, anxiety disorders, and adjustment disorders), suicide, and intimate partner violence. The second half explores the reasons for the elevated risks of these outcomes among non-heterosexual and transgender populations, and considers what social science research can tell us about one of the most prevalent ways of explaining these risks, the social stress model. As we will see, social stressors such as harassment and stigma likely explain some but not all of the elevated mental health risks for these populations. More research

is needed to understand the causes of and potential solutions for these important clinical and public health issues.

Some Preliminaries

We turn first to the evidence for the statistical links between sexual identities or behaviors and mental health outcomes. Before summarizing the relevant research, we should mention the criteria used in selecting the studies reviewed. In an attempt to distill overall findings of a large body of research, each section begins by summarizing the most extensive and reliable meta-analyses—papers that compile and analyze the statistical data from the published research literature. For some areas of research, no comprehensive meta-analyses have been conducted, and in these areas we rely on review articles that summarize the research literature without going into quantitative analyses of published data. In addition to reporting these summaries, we also discuss a few select studies that are of particular value because of their methodology, sample size, controls for confounding factors, or ways in which concepts such as heterosexuality or homosexuality are operationalized; and we discuss key studies published after the meta-analyses or review articles were published.

As we showed in Part One, explaining the exact biological and psychological origins of sexual desires and behaviors is a difficult scientific task, one that has not yet been and may never be satisfactorily completed. However, researchers can study the correlations between sexual behavior, attraction, or identity and mental health outcomes, though there may be—and often are found to be—differences between how sexual behavior, attraction, and identity relate to particular mental health outcomes. Understanding the scope of the health challenges faced by individuals who engage in particular sexual behaviors or experience certain sexual attractions is a necessary step in providing these individuals with the care they need.

Sexuality and Mental Health

In a 2008 meta-analysis of research on mental health outcomes for non-heterosexuals, University College London professor of psychiatry Michael King and colleagues concluded that gays, lesbians, and bisexuals face “higher risk of suicidal behaviour, mental disorder and substance misuse and dependence than heterosexual people.”¹ This survey of the literature examined papers published between January 1966 and April 2005 with data from 214,344 heterosexual and 11,971 non-heterosexual individuals.

The large sample size allowed the authors to generate estimates that are highly reliable, as indicated by the relatively small confidence intervals.²

Compiling the risk ratios found in these papers, the authors estimated that lesbian, gay, and bisexual individuals had a 2.47 times higher lifetime risk than heterosexuals for suicide attempts,³ that they were about twice as likely to experience depression over a twelve-month period,⁴ and approximately 1.5 times as likely to experience anxiety disorders.⁵ Both non-heterosexual men and women were found to be at an elevated risk for substance abuse problems (1.51 times as likely),⁶ with the risk for non-heterosexual women especially high—3.42 times higher than for heterosexual women.⁷ Non-heterosexual men, on the other hand, were at a particularly high risk for suicide attempts: while non-heterosexual men and women together were at a 2.47 times greater risk of suicide attempts over their lifetimes, non-heterosexual men were found to be at a 4.28 times greater risk.⁸

These findings have been replicated in other studies, both in the United States and internationally, confirming a consistent and alarming pattern. However, there is considerable variation in the estimates of the increased risks of various mental health problems, depending on how researchers define terms such as “homosexual” or “non-heterosexual.” The findings from a 2010 study by Northern Illinois University professor of nursing and health studies Wendy Bostwick and colleagues examined associations of sexual orientation with mood and anxiety disorders among men and women who either identified as gay, lesbian, or bisexual, or who reported engaging in same-sex sexual behavior, or who reported feeling same-sex attractions. The study employed a large, U.S.-based random population sample, using data collected from the 2004–2005 wave of the National Epidemiologic Survey on Alcohol and Related Conditions, which was based on 34,653 interviews.⁹ In its sample, 1.4% of respondents identified as lesbian, gay, or bisexual; 3.4% reported some lifetime same-sex sexual behavior; and 5.8% reported non-heterosexual attractions.¹⁰

Women who identified as lesbian, bisexual, or “not sure” reported higher rates of lifetime mood disorders than women who identified as heterosexual: the prevalence was 44.4% in lesbians, 58.7% in bisexuals, and 36.5% in women unsure of their sexual identity, as compared to 30.5% in heterosexuals. A similar pattern was found for anxiety disorders, with bisexual women experiencing the highest prevalence, followed by lesbians and those unsure, and heterosexual women experiencing the lowest prevalence. Examining the data for women with different sexual *behavior* or sexual *attraction* (rather than identity), those reporting sexual behavior

with or attractions to both men and women had a higher rate of lifetime disorders than women who reported exclusively heterosexual or homosexual behaviors or attractions, and women reporting exclusive same-sex sexual behavior or exclusive same-sex attraction in fact had the *lowest* rates of lifetime mood and anxiety disorders.¹¹

Men who identified as gay had more than double the prevalence of lifetime mood disorders compared to men who identified as heterosexual (42.3% vs. 19.8%), and more than double the rate of any lifetime anxiety disorder (41.2% vs. 18.6%), while those who identified as bisexual had a slightly lower prevalence of mood disorders (36.9%) and anxiety disorders (38.7%) than gay men. When looking at sexual attraction or behavior for men, those who reported sexual attraction to “mostly males” or sexual behavior with “both females and males” had the highest prevalence of lifetime mood disorders and anxiety disorders compared to other groups, while those reporting exclusively heterosexual attraction or behavior had the lowest prevalence of any group.

Other studies have found that non-heterosexual populations are at a higher risk of physical health problems in addition to mental health problems. A 2007 study by UCLA professor of epidemiology Susan Cochran and colleagues examined data from the California Quality of Life Survey of 2,272 adults to assess links between sexual orientation and self-reported physical health status, health conditions, and disability, as well as psychological distress among lesbians, gay men, bisexuals, and those they classified as “homosexually experienced heterosexual individuals.”¹² While the study, like most, was limited by the use of self-reporting of health conditions, it had several strengths: it studied a population-based sample; it separately measured identity and behavioral dimensions of sexual orientation; and it controlled for race (ethnicity), education, relationship status, and family income, among other factors.

While the authors of this study found a number of health conditions that appeared to have elevated prevalence among non-heterosexuals, after adjusting for demographic factors that are potential confounders the only group with significantly greater prevalence of non-HIV physical health conditions was bisexual women, who were more likely to have health problems than heterosexual women. Consistent with the 2010 study by Bostwick and colleagues, higher rates of psychological stress were reported by lesbians, bisexual women, gay men, and homosexually experienced heterosexual men, both before and after adjusting for demographic confounding. Among men, self-identified gay and homosexually experienced heterosexual respondents reported the highest rates of several health problems.

Using the same California Quality of Life Survey, a 2009 study by UCLA professor of psychiatry and biobehavioral sciences Christine Grella and colleagues (including Cochran) examined the relationship between sexual orientation and receiving treatment for substance use or mental disorders.¹³ They used a population-based sample, with sexual minorities oversampled to provide more statistical power to detect group differences. The usage of treatment was classified according to whether or not respondents reported receiving treatment in the preceding twelve months for “emotional, mental health, alcohol or other drug problems.” Sexual orientation was operationalized by a combination of behavioral history and self-identification. For example, they grouped together as “gay/bisexual” or “lesbian/bisexual” both those who identified as gay, lesbian, or bisexual, and those who had reported same-sex sexual behaviors. They found that women who were lesbian or bisexual were most likely to have received treatment, followed by men who were gay or bisexual, then heterosexual women, with heterosexual men being the least likely group to have reported receiving treatment. Overall, more than twice as many LGB individuals, compared to heterosexuals, had reported receiving treatment in the past twelve months (48.5% compared to 22.5%). The pattern was similar for men and women; 42.5% of homosexual men, compared to 17.1% of heterosexual men, had reported receiving treatment, while 55.3% of lesbian and bisexual women and 27.1% of heterosexual women reported receiving treatment. (Bostwick and colleagues had found that women with exclusively same-sex attractions and behaviors had a lower prevalence of mood and anxiety disorders compared to heterosexual women. The difference in results could be due to the fact that Grella and colleagues grouped those who identified as lesbians together with those who identified as bisexuals or who reported same-sex sexual behavior.)

A 2006 study by Columbia University psychiatry professor Theodorus Sandfort and colleagues examined a representative, population-based sample from the second Dutch National Survey of General Practice, carried out in 2001, to assess links between self-reported sexual orientation and health status among 9,511 participants, of whom 0.9% were classified as bisexual and 1.5% as gay or lesbian.¹⁴ To operationalize sexual orientation, the researchers asked respondents about their sexual preference on a 5-point scale: exclusively women, predominantly women, equally men and women, predominantly men, and exclusively men. Only those who reported an equal preference for men and women were classified as bisexual, while men reporting predominant preferences for women, or women reporting a predominant preference for men were classified as heterosexual. They

found that gay, lesbian, and bisexual respondents reported experiencing higher numbers of acute mental health problems and reported worse general mental health than heterosexuals. The results for physical health were mixed, however: lesbian and gay respondents reported experiencing more acute physical symptoms (such as headaches, back pain, or sore throats) over the past fourteen days, though they did not report experiencing two or more such symptoms any more than heterosexuals.

Lesbian and gay respondents were more likely to report chronic health problems, though bisexual men (that is, men who reported an equal sexual preference for men and women) were less likely to report chronic health problems and bisexual women were no more likely than heterosexual women to do so. The researchers did not find a statistically significant relationship between sexual orientation and overall physical health. After controlling for the possible confounding effects of mental health problems on the reporting of physical health problems, the researchers also found that the statistical effect of reporting a gay or lesbian sexual preference on chronic and acute physical conditions disappeared, though the effect of bisexual preference remained.

The Sandfort study defined sexual orientation in terms of preference or attraction without reference to behavior or self-identification, which makes it a challenge to compare its results to the results of studies that operationalize sexual orientation differently. For example, it is difficult to compare the findings of this study regarding bisexuals (defined as men or women who report an equal sexual preference for men and women) with the findings of other studies regarding “homosexually experienced heterosexual individuals” or those who are “unsure” of their sexual identity. As in most of these types of studies, the health assessments were self-reported, which may make the results somewhat unreliable. But this study also has several strengths: it used a large and representative sample of a country’s population, as opposed to the convenience samples that are sometimes used for these kinds of studies, and this sample included a sufficient number of gays and lesbians for their data to be treated in separate groups in the study’s statistical analyses. Only three people in the sample reported HIV infection, so this did not appear to be a potential confounding factor, though HIV could have been underreported.

In an effort to summarize findings in this area, we can cite the 2011 report from the Institute of Medicine (IOM), *The Health of Lesbian, Gay, Bisexual, and Transgender People*.¹⁵ This report is an extensive review of scientific literature citing hundreds of studies that examine the health status of LGBT populations. The authors are scientists who are well versed

in these issues (although we wish there had been more involvement of experts in psychiatry). The report reviews findings on physical and mental health in childhood, adolescence, early and middle adulthood, and late adulthood. Consistent with the studies cited above, this report reviews evidence showing that, compared with heterosexual youth, LGB youth are at a higher risk of depression, as well as suicide attempts and suicidal ideation. They are also more likely to experience violence and harassment and to be homeless. LGB individuals in early or middle adulthood are more prone to mood and anxiety disorders, depression, suicidal ideation, and suicide attempts.

The IOM report shows that, like LGB youth, LGB adults—and women in particular—appear to be likelier than heterosexuals to smoke, use or abuse alcohol, and abuse other drugs. The report cites a study¹⁶ that found that self-identified non-heterosexuals used mental health services more often than heterosexuals, and another¹⁷ that found that lesbians used mental health services at higher rates than heterosexuals.

The IOM report notes that “more research has focused on gay men and lesbians than on bisexual and transgender people.”¹⁸ The relatively few studies focusing on transgender populations show high rates of mental disorders, but the use of nonprobability samples and the lack of non-transgender controls call into question the validity of the studies.¹⁹ Although some studies have suggested that the use of hormone treatments may be associated with negative physical health outcomes among transgender populations, the report notes that the relevant research has been “limited” and that “no clinical trials on the subject have been conducted.”²⁰ (Health outcomes for transgender individuals will be further discussed below in this part and also in Part Three.)

The IOM report claims that the evidence that LGBT populations have worse mental and physical health outcomes is not fully conclusive. To support this claim, the IOM report cites a 2001 study²¹ of mental health in 184 sister pairs in which one sister was lesbian and the other heterosexual. The study found no significant differences in rates of mental health problems, and found significantly higher self-esteem in the lesbian sisters. The IOM report also cites a 2003 study²² that found no significant differences between heterosexual and gay or bisexual men in general happiness, perceived health, and job satisfaction. Acknowledging these caveats and the studies that do not support the general trend, the vast majority of studies cited in the report point to a generally higher risk of poor mental health status in LGBT populations compared to heterosexual populations.

Sexuality and Suicide

The association between sexual orientation and suicide has strong scientific support. This association merits particular attention, since among all the mental health risks, the increased risk of suicide is the most concerning, owing in part to the fact that the evidence is robust and consistent, and in part to the fact that suicide is so devastating and tragic for the person, family, and community. A better understanding of the risk factors for suicide could allow us, quite literally, to save lives.²³

Sociologist and suicide researcher Ann Haas and colleagues published an extensive review article in 2011 based on the results of a 2007 conference sponsored by the Gay and Lesbian Medical Association, the American Foundation for Suicide Prevention, and the Suicide Prevention Resource Center.²⁴ They also examined studies reported since the 2007 conference. For the purposes of their report, the authors defined sexual orientation as “sexual self-identification, sexual behavior, and sexual attraction or fantasy.”²⁵

Haas and colleagues found the association between homosexual or bisexual orientation and suicide attempts to be well supported by data. They noted that population-based surveys of U.S. adolescents since the 1990s indicate that suicide attempts are two to seven times more likely in high school students who identify as LGB, with sexual orientation being a stronger predictor in males than females. They reviewed data from New Zealand that suggested that LGB individuals were six times more likely to have attempted suicide. They cited health-related surveys of U.S. men and Dutch men and women showing same-sex behavior linked to higher risk of suicide attempts. Studies cited in the report show that lesbian or bisexual women are likelier, on average, to experience suicidal ideation, that gay or bisexual men are more likely, on average, to attempt suicide, and that lifetime suicide attempts among non-heterosexuals are greater in men than in women.

Examining studies that looked at rates of mental disorders in relation to suicidal behavior, Haas and colleagues discussed a New Zealand study²⁶ showing that gay people reporting suicide attempts had higher rates of depression, anxiety, and conduct disorder. Large-scale health surveys suggested that rates of substance abuse are up to one third higher for the LGB subpopulation. Combined worldwide studies showed up to 50% higher rates of mental disorders and substance abuse among persons self-identifying in surveys as lesbian, gay, or bisexual. Lesbian or bisexual women showed higher levels of substance abuse, while gay or bisexual men had higher rates of depression and panic disorder.

Haas and colleagues also examined transgender populations, noting that scant information is available about transgender suicides but that the existing studies indicate a dramatic increased risk of completed suicide. (These findings are noted here but examined in more detail in Part Three.) A 1997 clinical study²⁷ estimated elevated risks of suicide for Dutch male-to-female transsexual individuals on hormone therapy, but found no significant differences in overall mortality. A 1998 international review of 2,000 persons receiving sex-reassignment surgery identified 16 possible suicides, an “alarmingly high rate of 800 suicides for every 100,000 post-surgery transsexuals.”²⁸ In a 1984 study, a clinical sample of transgender individuals requesting sex-reassignment surgery showed suicide attempt rates between 19% and 25%.²⁹ And a large sample of 40,000 mostly U.S. volunteers completing an Internet survey in 2000 found transgender persons to report higher rates of suicide attempts than any group except lesbians.³⁰

Finally, the review by Haas and colleagues suggests that it is not clear which aspects of sexuality (identity, attraction, behavior) are most closely linked with the risk of suicidal behavior. The authors cite a 2010 study³¹ showing that adolescents identifying as heterosexual while reporting same-sex attraction or behavior did not have significantly higher suicide rates than other self-identified heterosexuals. They also cite the large national survey of U.S. adults conducted by Wendy Bostwick and colleagues (discussed earlier),³² which showed mood and anxiety disorders—key risk factors for suicidal behavior—more closely related to sexual self-identity than to behavior or attraction, especially for women.

A more recent critical review of existing studies of suicide risk and sexual orientation was presented by Austrian clinical psychologist Martin Plöderl and colleagues.³³ This review rejects several hypotheses developed to account for the increased suicide risk among non-heterosexuals, including biases in self-reporting and failures to measure suicide attempts accurately. The review argues that methodological improvements in studies since 1997 have provided control groups, better representativeness of study samples, and more clarity in defining both suicide attempts and sexual orientation.

The review mentions a 2001 study³⁴ by Ritch Savin-Williams, a Cornell University professor of developmental psychology, that reported no statistically significant difference between heterosexual and LGB youths after eliminating false-positive reports of suicide attempts and blaming a “‘suffering suicidal’ script” for leading to an over-reporting of suicidal behavior among gay youths. Plöderl and colleagues argue, however, that

the Savin-Williams study's finding that there was no statistically significant difference between the suicide rates of LGB and heterosexual youths might be attributable to the small sample size, which yielded low statistical power.³⁵ The later work has not replicated this finding. Subsequent questionnaire or interview-based studies with stricter definitions of suicide attempts have found significantly increased rates of suicide attempts among non-heterosexuals. Several large-scale surveys of young people have found that the elevated risk of reported suicidal behavior increased with the severity of the attempts.³⁶ Finally, according to Plöderl and colleagues, comparing results of questionnaires with clinical interviews indicates that homosexual youth are less likely to over-report suicide attempts in surveys than heterosexual youth.

Plöderl and colleagues concluded that among psychiatric patients, homosexual or bisexual populations are over-represented in "serious suicide attempts," and that sexual orientation is one of the strongest predictors of suicide. Similarly, in nonclinical population-based studies, non-heterosexual status is found to be one of the strongest predictors of suicide attempts. The authors note:

The most exhaustive collation of published and unpublished international studies on the association of suicide attempts and sexual orientation with different methodologies has produced a very consistent picture: nearly all studies found increased incidences of self-reported suicide attempts among sexual minorities.³⁷

In acknowledging the challenges of all such research, the authors suggest that "the major problem remains as to where one draws the line between a heterosexual or non-heterosexual orientation."³⁸

A 1999 study by Richard Herrell and colleagues analyzed 103 middle-aged male twin pairs from the Vietnam Era Twin Registry in Hines, Illinois, in which one twin, but not the other, reported having a male sex partner after the age of 18.³⁹ The study adopted several measures of suicidality and controlled for potential confounding factors such as substance abuse or depression. It found a "substantially increased lifetime prevalence of suicidal symptoms" in male twins who had sex with men compared with co-twins who did not, independent of the potential confounding effects of drug and alcohol abuse.⁴⁰ Though it is a relatively small study and relied on self-reporting for both same-sex behaviors and suicidal thoughts or behaviors, it is notable for using a probability sample (which eliminates selection bias), and for using the co-twin control method (which reduces the effects of genetics, age, race, and the like).

The study looked at middle-aged men; what the implications might be for adolescents is not clear.

In a 2011 study, Robin Mathy and colleagues analyzed the impact of sexual orientation on suicide rates in Denmark during the first twelve years after the legalization of same-sex registered domestic partnerships (RDPs) in that country, using data from death certificates issued between 1990 and 2001 as well as Danish census population estimates.⁴¹ The researchers found that the age-adjusted suicide rate for same-sex RDP men was nearly eight times the rate for men in heterosexual marriages, and nearly twice the rate for men who had never married. For women, RDP status had a small, statistically insignificant effect on suicide mortality risk, and the authors conjectured that the impact of HIV status on the health of gay men might have contributed to this difference between the results for men and women. The study is limited by the fact that RDP status is an indirect measure of sexual orientation or behavior, and does not include those gays and lesbians who are not in a registered domestic partnership; the study also excluded individuals under the age of 18. Finally, the absolute number of individuals with current or past RDP status was relatively small, which may limit the study's conclusions.

Professor of pediatrics Gary Remafedi and colleagues published a 1991 study that looked at 137 males age 14–21 who self-identified as gay (88%) or bisexual (12%). Remafedi and colleagues attempted, with a case-controlled approach, to examine which factors for this population were most predictive of suicide.⁴² Compared to those who did not attempt suicide, those who did were significantly more likely to label themselves and identify publicly as bisexual or homosexual at younger ages, report sexual abuse, and report illicit drug use. The authors noted that the likelihood of a suicide attempt “diminished with advancing age at the time of bisexual or homosexual self-labeling.” Specifically, “with each year’s delay in self-identification, the odds of a suicide attempt declined by more than 80%.”⁴³ This study is limited by using a relatively small nonprobability sample, though the authors note that its result comports with their previous finding⁴⁴ of an inverse relationship between psychosocial problems and the age at which one identifies as homosexual.

In a 2010 study, Plöderl and colleagues solicited self-reported suicide attempts among 1,382 Austrian adults to confirm existing evidence that homosexual and bisexual individuals are at higher risk.⁴⁵ To sharpen the results, the authors developed more rigorous definitions of “suicide attempts” and assessed multiple dimensions of sexual orientation, distinguishing among sexual fantasies, preferred partners, self-identification,

recent sexual behavior, and lifetime sexual behavior. This study found an increased risk for suicide attempts for sexual minorities along all dimensions of sexual orientation. For women, the risk increases were largest for those with homosexual behaviors; for men, they were largest for homosexual or bisexual behavior in the previous twelve months and self-identification as homosexual or bisexual. Those reporting being unsure of their identity reported the highest percentage of suicide attempts (44%), although this group was small, comprising less than 1% of participants.

A 2016 meta-analysis by University of Toronto graduate student Travis Salway Hottes and colleagues aggregated data from thirty cross-sectional studies on suicide attempts that together included 21,201 sexual minority adults.⁴⁶ These studies used either population-based sampling or community-based sampling. Since each sampling method has its own strengths and potential biases,⁴⁷ the researchers wanted to examine any differences in the rates of attempted suicide between the two sampling types. Of the LGB respondents to population-based surveys, 11% reported having attempted suicide at least once, compared to 4% of heterosexual respondents to these surveys.⁴⁸ Of the LGB respondents to community-based surveys, 20% reported having attempted suicide.⁴⁹ Statistical analysis showed that the difference in the sampling methods accounted for 33% of the variation in the suicide figures reported by the studies.

The research on sexuality and the risk of suicide suggests that those who identify as gay, lesbian, bisexual, or transgender, or those who experience same-sex attraction or engage in same-sex sexual behavior are at substantially increased risk of suicidal ideation, suicide attempts, and completed suicide. In the section later in Part Two on the social stress model, we will examine—and raise questions about—one set of arguments put forward to explain these findings. Given the tragic consequences of inadequate or incomplete information in these matters and its effect on public policy and clinical care, more research into the reasons for elevated suicide risk among sexual minorities is desperately needed.

Sexuality and Intimate Partner Violence

Several studies have examined the differences between rates of intimate partner violence (IPV) in same-sex couples and opposite-sex couples. The research literature examines rates of IPV *victimization* (being subjected to violence by a partner) and rates of IPV *perpetration* (committing violence against a partner). In addition to physical and sexual violence, some studies also examine psychological violence, which comprises verbal attacks,

threats, and similar forms of abuse. The weight of evidence indicates that the rate of intimate partner violence is significantly higher among same-sex couples.

In 2014, London School of Hygiene and Tropical Medicine researcher Ana Buller and colleagues conducted a systematic review of 19 studies (with a meta-analysis of 17 of these studies) examining associations between intimate partner violence and health among men who have sex with men.⁵⁰ Combining the available data, they found that the pooled lifetime prevalence of any IPV was 48% (estimates from the studies were quite heterogeneous, ranging from 32% to 82%). For IPV within the previous five years, pooled prevalence was 32% (estimates ranging from 16% to 51%). IPV victimization was associated with increased rates of substance use (pooled odds ratio of 1.9), positive HIV status (pooled odds ratio of 1.5), and increased rates of depressive symptoms (pooled odds ratio of 1.5). IPV perpetration was also associated with increased rates of substance use (pooled odds ratio of 2.0). An important limitation of this meta-analysis was that the number of studies it included was relatively small. Also, the heterogeneity of the studies' results may undermine the precision of the meta-analysis. Further, most of the reviewed studies used convenience samples rather than probabilistic samples, and they used the word "partner" without distinguishing long-term relationships from casual encounters.

English psychologists Sabrina Nowinski and Erica Bowen conducted a 2012 review of 54 studies on the prevalence and correlates of intimate partner violence victimization among heterosexual and gay men.⁵¹ The studies showed rates of IPV victimization for gay men ranging from 15% to 51%. Compared to heterosexual men, the review reports, "it appears that gay men experienced more total and sexual IPV, slightly less physical IPV, and similar levels of psychological IPV."⁵² The authors also report that according to estimates of IPV prevalence over the most recent twelve months, gay men "experienced less physical, psychological and sexual IPV" than heterosexual men, though the relative lack of twelve-month estimates may make this result unreliable. The authors note that "one of the most worrying findings is the prevalence of severe sexual coercion and abuse in male same-gender relationships,"⁵³ citing a 2005 study⁵⁴ on IPV in HIV-positive gay men. Nowinski and Bowen found positive HIV status to be associated with IPV in both gay and heterosexual relationships. An important limitation of their review is the fact that many of the same-sex IPV studies they examined were based on small convenience samples.

Catherine Finneran and Rob Stephenson of Emory University in 2012 conducted a systematic review of 28 studies examining IPV among men

who have sex with men.⁵⁵ Every study in the review estimated rates of IPV for gay men that were similar to or higher than those for all women regardless of sexual orientation. The authors conclude that “the emergent evidence reviewed here demonstrates that IPV—psychological, physical, and sexual—occurs in male-male partnerships at alarming rates.”⁵⁶ Physical IPV victimization was reported most frequently, with rates ranging from 12% to 45%.⁵⁷ The rate of sexual IPV victimization ranged from 5% to 31%, with 9 out of 19 studies reporting rates over 20%. Psychological IPV victimization was recorded in six studies, with rates ranging from 5% to 73%.⁵⁸ Perpetration of physical IPV was reported in eight studies, with rates ranging from 4% to 39%. Rates of perpetration of sexual IPV ranged from 0.7% to 28%; four of the five studies reviewed reported rates of 9% or more. Only one study measured perpetration of psychological violence, and the estimated prevalence was 78%. Lack of consistent research design among the studies examined (for example, some differences regarding the exact definition of IPV, the correlates of IPV examined, and the recall periods used to measure violence) makes it impossible to calculate a pooled prevalence estimate, which would be useful given the lack of a national probability-based sample.

A 2013 study by UCLA’s Naomi Goldberg and Ilan Meyer used a large probability sample of almost 32,000 individuals from the California Health Interview Survey to assess differences in intimate partner violence between various cohorts: heterosexual; self-identified gay, lesbian, and bisexual individuals; and men who have sex with men but did not identify as gay or bisexual, and women who have sex with women but did not identify as lesbian or bisexual.⁵⁹ All three LGB groups had greater lifetime and one-year prevalence of intimate partner violence than the heterosexual group, but this difference was only statistically significant for bisexual women and gay men. Bisexual women were more likely to have experienced lifetime IPV (52% of bisexual women vs. 22% of heterosexual women and 32% of lesbians) and to have experienced IPV in the preceding year (27% of bisexuals vs. 5% of heterosexuals and 10% of lesbians). For men, all three non-heterosexual groups had higher rates of lifetime and one-year IPV, but this was only statistically significant for gay men, who were more likely to have experienced IPV over a lifetime (27% of gay men vs. 11% of heterosexual men and 19.6% of bisexual men) and over the preceding year (12% of gay men vs. 5% of heterosexual men and 9% of bisexual men). The authors also tested whether binge drinking and psychological distress could explain the higher prevalence of IPV victimization in gay men and bisexual women; controlling for these

variables revealed that they did not. This study is limited by the fact that other potentially confounding psychological variables (besides drinking and distress) were not controlled for, statistically or otherwise, and may have accounted for the findings.

To estimate the prevalence of battering victimization among gay partners, AIDS-prevention researcher Gregory Greenwood and colleagues published a 2002 study based on telephone interviews with a probability-based sample of 2,881 men who have sex with men (MSM) in four cities from 1996 to 1998.⁶⁰ Of those interviewed, 34% reported experiencing psychological or symbolic abuse, 22% reported physical abuse, and 5% reported sexual abuse. Overall, 39% reported some type of battering victimization, and 18% reported more than one type of battering in the previous five years. Men younger than 40 were significantly more likely than men over 60 to report battering violence. The authors conclude that “the prevalence of battering within the context of intimate partner relationships was very high” among their sample of men who have sex with men, and that since lifetime rates are usually higher than those for a five-year recall, “it is likely that a substantially greater number of MSM than of heterosexual men have experienced lifetime victimization.”⁶¹ The five-year prevalence of physical battering among this sample of urban MSM was also “significantly higher” than the annual rate of severe violence (3%) or total violence (12%) experienced in a representative sample of heterosexual women living with men, suggesting that the estimates of battering victimization for MSM in this study “are higher than or comparable to those reported for heterosexual women.”⁶² This study was limited by its use of a sample from four cities, so it is not clear how well the results generalize to non-urban settings.

Transgender Health Outcomes

The research literature for mental health outcomes in transgender individuals is more limited than the research on mental health outcomes in LGB populations. Because people identifying as transgender make up a very small proportion of the population, large population-based surveys and studies of such individuals are difficult if not impossible to conduct. Nevertheless, the limited available research strongly suggests that transgender people have increased risks of poor mental health outcomes. It appears that the rates of co-occurring substance use disorders, anxiety disorders, depression, and suicide tend to be higher for transgender people than for LGB individuals.

In 2015, Harvard pediatrics professor and epidemiologist Sari Reisner and colleagues conducted a retrospective matched-pair cohort study of mental health outcomes for 180 transgender subjects aged 12–29 years (106 female-to-male and 74 male-to-female), matched to non-transgender controls based on gender identity.⁶³ Transgender youth had an elevated risk of depression (50.6% vs. 20.6%)⁶⁴ and anxiety (26.7% vs. 10.0%).⁶⁵ Transgender youth also had higher risk of suicidal ideation (31.1% vs. 11.1%),⁶⁶ suicide attempts (17.2% vs. 6.1%),⁶⁷ and self-harm without lethal intent (16.7% vs. 4.4%)⁶⁸ relative to the matched controls. A significantly greater proportion of transgender youth accessed inpatient mental health care (22.8% vs. 11.1%)⁶⁹ and outpatient mental health care (45.6% vs. 16.1%)⁷⁰ services. No statistically significant differences in mental health status were observed when comparing female-to-male transgender individuals to the male-to-female transgender individuals after adjusting for age, race/ethnicity, and hormone use.

This study had the merit of including individuals who presented to a community-based health clinic, and who thus were not identified solely as meeting the diagnostic criteria for gender identity disorder in the fourth edition of the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders (DSM-IV)*, and were not selected from a population of patients presenting to a clinic for treatment of gender identity issues. However, Reisner and colleagues note that their study has the limitations typically found in the retrospective chart review study design, such as incomplete documentation and variation in the quality of information recorded by medical professionals.

A report from the American Foundation for Suicide Prevention and the Williams Institute, a think tank for LGBT issues at the UCLA School of Law, summarized findings on suicide attempts among transgender and gender-nonconforming adults from a large national sample of over 6,000 individuals.⁷¹ This constitutes the largest study of transgender and gender-nonconforming adults to date, though it used a convenience sample rather than a population-based sample. (Large population-based samples are nearly impossible given the low overall prevalence in the general population of transgendered individuals.) Summarizing the major findings of this study, the authors write:

The prevalence of suicide attempts among respondents to the National Transgender Discrimination Survey (NTDS), conducted by the National Gay and Lesbian Task Force and National Center for Transgender Equality, is 41 percent, which vastly exceeds the 4.6

percent of the overall U.S. population who report a lifetime suicide attempt, and is also higher than the 10–20 percent of lesbian, gay and bisexual adults who report ever attempting suicide.⁷²

The authors note that “respondents who said they had received transition-related health care or wanted to have it someday were more likely to report having attempted suicide than those who said they did not want it,” however, “the survey did not provide information about the timing of reported suicide attempts in relation to receiving transition-related health care, which precluded investigation of transition-related explanations for these patterns.”⁷³ The survey data suggested associations between suicide attempts, co-occurring mental health disorders, and experiences of discrimination or mistreatment, although the authors note some limitations of these outcomes: “The survey data did not allow us to determine a direct causal relationship between experiencing rejection, discrimination, victimization, or violence, and lifetime suicide attempts,” although they did find evidence that stressors interacted with mental health factors “to produce a marked vulnerability to suicidal behavior in transgender and gender non-conforming individuals.”⁷⁴

A 2001 study by Kristen Clements-Nolle and colleagues of 392 male-to-female and 123 female-to-male transgender persons found that 62% of the male-to-female and 55% of the female-to-male transgender persons were depressed at the time of the study, and 32% of each population had attempted suicide.⁷⁵ The authors note: “The prevalence of suicide attempts among male-to-female and female-to-male transgender persons in our study was much higher than that found in US household probability samples and a population-based sample of adult men reporting same-sex partners.”⁷⁶

Explanations for the Poor Health Outcomes: The Social Stress Model

The greater prevalence of mental health problems in LGBT subpopulations is a cause for concern, and policymakers and clinicians should strive to reduce these risks. But to know what kinds of measures will help ameliorate them we must better understand their causes. At this time, the medical and social strategies for helping non-heterosexual populations in the United States are quite limited, and this may be due in part to the relatively limited explanations for the poor mental health outcomes offered by social scientists and psychologists.

Despite the limits of the scientific understanding of why non-heterosexual subpopulations are more likely to have such poor mental

health outcomes, much of the public effort to ameliorate these problems is motivated by a particular hypothesis called the *social stress model*. This model posits that discrimination, stigmatization, and other similar stresses contribute to poor mental health outcomes among sexual minorities. An implication of the social stress model is that reducing these stresses would ameliorate the mental health problems experienced by sexual minorities.

Sexual minorities face distinct social challenges such as stigma, overt discrimination and harassment, and, often, struggle with reconciling their sexual behaviors and identities with the norms of their families and communities. In addition, they tend to be subject to challenges similar to those of some other minority populations, arising from marginalization by or conflict with the larger part of society in ways that may adversely impact their health.⁷⁷ Many researchers classify these various challenges under the concept of *social stress* and believe that social stress contributes to the generally higher rates of mental health problems among LGBT subpopulations.⁷⁸

In attempting to account for the mental health disparities between heterosexuals and non-heterosexuals, researchers occasionally refer to a social or minority stress *hypothesis*.⁷⁹ However, it is more accurate to refer to a social or minority stress *model*, because the postulated connection between social stress and mental health is more complex and less precise than anything that could be stated as a single hypothesis.⁸⁰ The term *stress* can have a number of meanings, ranging from a description of a physiological condition to a mental or emotional state of anger or anxiety to a difficult social, economic, or interpersonal situation. More questions arise when one thinks about various kinds of *stressors* that may disproportionately affect mental health in minority populations. We will discuss some of these aspects of the social stress model after a concise overview of the model as it has been presented in recent literature on LGBT mental health.

The social stress model attempts to explain why non-heterosexual people have, on average, higher incidences of poor mental health outcomes than the rest of the population. It does not put forth a complete explanation for the disparities between non-heterosexuals and heterosexuals, and it does not explain the mental health problems of a particular patient. Rather, it describes social factors that might directly or indirectly influence the health risks for LGBT people, which may only become apparent at a population level. Some of these factors may also influence heterosexuals, but LGBT people are probably disproportionately exposed to them.

In an influential 2003 article on the social stress model, psychiatric epidemiologist and sexual orientation law expert Ilan Meyer distinguished between *distal* and *proximate* minority stressors. Distal stressors do not

depend on the individual's "perceptions or appraisals," and thus "can be seen as independent of personal identification with the assigned minority status."⁸¹ For instance, if a man who was perceived to be gay by an employer was fired on that basis, this would be a distal stressor, since the stressful event of discrimination would have had nothing to do with whether the man actually identified as gay, but only with someone else's attitude and perception. Distal stressors tend to reflect social circumstances rather than the individual's reaction to those circumstances. Proximate stressors, in contrast, are more subjective and are closely related to the individual's self-identity as lesbian, gay, bisexual, or transgender. An example of a proximate stressor would be when a young woman personally identifies as being a lesbian, and chooses to hide that identity from her family members out of fear of disapproval, or because of an internal sense of shame. The effects of proximate stressors such as this one are highly dependent on the individual's self-understanding and unique social circumstances. In this section we describe the types of stressors postulated in the social stress model, starting at the distal and proceeding to the most proximate stressors, and examine some of the empirical evidence that has been offered on the links between the stressors and mental health outcomes.

Discrimination and prejudice events. Overt acts of mistreatment, ranging from violence to harassment and discrimination, are categorized together by researchers as "prejudice events." These are thought to be significant stressors for non-heterosexual populations.⁸² Surveys of LGBT subpopulations have found that they tend to experience these kinds of prejudice events more frequently than the general population.⁸³

The available evidence indicates that prejudice events likely contribute to mental health problems. A 1999 study by UC Davis professor of psychology Gregory Herek and colleagues using survey data from 2,259 LGB individuals in Sacramento found that self-identified lesbians and gays who experienced a bias crime in the preceding five years—a crime, such as assault, theft, or vandalism, motivated by the actual or perceived sexual identity of the victim—reported significantly higher levels of depressive symptoms, traumatic stress symptoms, and anxiety than lesbians and gays who had not experienced a bias crime over that same period.⁸⁴ Additionally, lesbians and gays who reported being the victims of bias crimes in the last five years showed significantly higher levels of depressive and traumatic stress symptoms than individuals who experienced non-bias crimes in the same period (though the two groups did not display significant differences in anxiety). Comparable significant correlations were not found for

self-identified bisexuals, who constituted a much smaller portion of the survey respondents. The study also found that lesbians and gays subject to bias crimes were significantly more likely than other respondents to report feelings of vulnerability and a decreased sense of personal mastery or agency. Corroborating these findings on the harmful impact of bias crimes was a 2001 study by Northeastern University social scientist Jack McDevitt and colleagues that examined aggravated assaults using data from the Boston Police Department.⁸⁵ They found that bias crime victims tended to experience the effects of victimization more intensely and for a longer period of time than non-bias crime victims. (The study looked at bias-motivated assaults in general, rather than restricting its analysis to assaults motivated by LGBT bias, though a substantial portion of the subjects did experience assaults motivated by their non-heterosexual status.)

Similar patterns also appear among non-heterosexual adolescents, for whom maltreatment is particularly high.⁸⁶ In a 2011 study, University of Arizona social and behavioral scientist Stephen T. Russell and colleagues analyzed a survey of 245 young LGBT adults that retrospectively assessed school victimization due to actual or perceived LGBT status between the ages of 13 and 19. They found strong correlations between school victimization and poor mental health as young adults.⁸⁷ Victimization was assessed by asking yes-or-no questions, such as, “During my middle or high school years, while at school, I was pushed, shoved, slapped, hit, or kicked by someone who wasn’t just kidding around,” followed by a question of how often these events were related to the respondent’s sexual identity. Respondents who reported high levels of school victimization due to their sexual identity were 2.6 times more likely to report depression as young adults and 5.6 times more likely to report that they had attempted suicide, compared to those who reported low levels of victimization. These differences were highly statistically significant, though the study is potentially limited by its use of retrospective surveys to measure incidents of victimization. A study by professor of social work Joanna Almeida and colleagues, which relied on the 2006 Boston Youth Survey (a biennial survey of high school students in Boston public schools), found that perceptions of having been victimized due to LGBT status accounted for increased symptoms of depression among LGBT students. For male LGBT students, but not females, the study also found a positive correlation between victimization and suicidal thoughts and self-harm.⁸⁸

Differences in compensation suggest discrimination in the workplace, which can have both direct and indirect effects on mental health. M. V. Lee Badgett, a professor of economics at the University of Massachusetts,

Amherst, analyzed data collected between 1989 and 1991 in the General Social Survey and found that non-heterosexual male employees received significantly lower compensation (11% to 27%) than heterosexuals, even after controlling for experience, education, occupation, and other factors.⁸⁹ According to a 2009 review by Badgett,⁹⁰ nine studies from the 1990s and early 2000s “consistently show that gay and bisexual men earned 10% to 32% less than heterosexual men,” and that differences in occupation cannot account for much of the wage disparity. Researchers have also found that non-heterosexual women earn more than heterosexual women,⁹¹ which may suggest either that patterns of discrimination differ for men and women, or that there are other factors associated with non-heterosexual behavior and self-identification in men and women influencing their respective earnings, such as a lower rate of child-rearing or being the family primary wage earner.

There is evidence that suggests that wage disparities can help explain some population-level disparities in mental health outcomes,⁹² though it is difficult to tell if differences in mental health help explain the differences in wages. A 1999 study⁹³ by Craig Waldo on the relationship between workplace heterosexism—defined as negative social attitudes toward non-heterosexuals—and stress-related outcomes in 287 LGB individuals found that LGB individuals who experienced heterosexism in the workplace “exhibited higher levels of psychological distress and health-related problems, as well as decreased satisfaction with several aspects of their jobs.” The cross-sectional data used by many of these studies make it impossible to infer causality, though both prospective studies and qualitative analyses of the impact of unemployment on mental health suggest that at least some of the correlations are likely accounted for by the psychological and material effects of unemployment.⁹⁴

Stigma. Sociologists have for many years documented a range of adverse effects of stigma on individuals, ranging from issues with self-esteem to academic achievement.⁹⁵ Stigma is typically regarded as an attribute attaching to a person that reduces that person’s worth to others in a particular social context.⁹⁶ These negative evaluations are in many cases widely shared among a cultural group and become the basis for excluding or differentially treating stigmatized individuals. For example, mental illness can become stigmatized when it is regarded as a character flaw in mentally ill people. One reason why stigma serves an important role in the social stress model is that it can be invoked as an explanation even in the absence of particular events of discrimination or maltreatment. For

example, stigmatization of depression may take place when a depressed person conceals the depression on the expectation that friends and family members will regard it as a character flaw. Even when this concealment is successful, and there is therefore no actual discrimination or mistreatment by the individual's friends or family, anxiety over the attitudes others may have can affect the depressed person's emotional and mental well-being.

Researchers have found associations between the risk of poor mental health and stigma toward certain populations, though there has been little empirical research on the mental health effects of stigma on LGBT people in particular. Stigma is not easy to define or operationalize, making it a difficult and vague concept for empirical social scientists to study. Nevertheless, researchers have attempted to work with the concept using surveys of self-perceived devaluation by others and have found correlations between experiences of stigma and the risk of poor mental health status. One highly cited 1997 study by sociologist and epidemiologist Bruce Link and colleagues on the connection between stigma and mental health found a "strong and enduring" negative effect of stigma on the mental well-being of men who were suffering from a mental disorder and substance abuse.⁹⁷ In this study, the effects of stigma appeared to persist even after the men had received largely successful treatment for their original mental and substance abuse problems. The study found significant correlations between certain stigma variables—self-reported experiences of devaluation and rejection—and depressive symptoms before and after treatment, suggesting that the effects of stigma are relatively long-lasting. This might simply indicate that people with depressive symptoms tend to report more stigma, but if that were the case, one would have expected reports of stigma to decline over the course of the treatment program, as depression did. However, since stigma reports stayed constant, the authors concluded that stigma must have had a causal role in shaping depressive symptoms. It is worth noting that this study found stigma variables to account uniquely for around 10% or slightly more of the variance in depressive symptoms—in other words, stigma had a minor effect on depressive symptoms, though such an effect might manifest itself in significant ways on a population level. Some other researchers have suggested that the effects of stigma are usually minor and transitory; for example, Vanderbilt sociologist Walter Gove argued that for the "vast majority of cases the stigma [experienced by mental patients] appears to be transitory and does not appear to pose a severe problem."⁹⁸

Researchers have relatively recently begun pursuing both empirical and theoretical work⁹⁹ on how stigma affects the mental health of LGBT

people, though there has been some controversy over the magnitude and duration of effects due to stigma. Some of the controversy may stem from the difficulty of defining and quantifying stigma as well as the variations in stigma across different social contexts. A 2013 study by Columbia University medical psychologist Walter Bockting and colleagues on mental health in 1,093 transgender people found a positive correlation between psychological distress and both enacted and felt stigma, which were measured using survey questions.¹⁰⁰ A 2003 study¹⁰¹ by clinical psychologist Robin Lewis and colleagues of predictors of depressive symptoms in 201 LGB individuals found that stigma consciousness was significantly associated with depressive symptoms, where stigma consciousness was assessed using a ten-item questionnaire that assessed “the degree to which one expects to be judged on the basis of a stereotype.”¹⁰² However, depressive symptoms are often associated with negative cognition about the self, the world, and the future, and this may contribute to the subjective perception of stigmatization among individuals suffering from depression.¹⁰³ A 2011 study¹⁰⁴ by Bostwick that also used measures of stigma consciousness and depressive symptoms found a modest positive correlation between stigma scores and depressive symptoms in bisexual women, although the study was limited by having a relatively small sample size. However, a 2003 longitudinal study¹⁰⁵ of Norwegian adolescents by psychologist Lars Wichstrøm and colleague found that sexual orientation was associated with poor mental health status after accounting for a variety of psychological risk factors, including self-worth. While this study did not directly consider stigma as a risk factor, it suggests that psychological factors such as stigma consciousness alone likely cannot fully account for the disparities in mental health between heterosexuals and non-heterosexuals. Additionally, it is important to note that due to the cross-sectional design of these studies, causal inferences cannot be supported by the data—different kinds of data and more evidence would be needed to support conclusions about causal relationships. In particular, it is impossible to prove through these studies that stigma leads to poor mental health, as opposed to, for example, poor mental health leading people to report higher levels of stigma, or a third factor being responsible for both poor mental health and higher levels of stigma.

Concealment. Stigma may affect non-heterosexual individuals’ decisions about whether to disclose or conceal their sexual orientation. LGBT people may decide to conceal their sexual orientation to protect themselves against possible bias or discrimination, to avoid a sense of shame, or to

avoid a potential conflict between their social role and sexual desires or behaviors.¹⁰⁶ Particular contexts in which LGBT people may be more likely to conceal their sexual orientation include school, work, and other places in which they feel that disclosure could negatively affect the way that people regard them.

There is a large amount of evidence from psychological research indicating that concealment of an important aspect of one's identity may have adverse mental health consequences. In general, expressing one's emotions and sharing important aspects of one's life with others play large roles in maintaining mental health.¹⁰⁷ Recent decades have seen a growing body of research on the relationships between concealment and disclosure and mental health in LGBT subpopulations.¹⁰⁸ For example, a 2007 study¹⁰⁹ by Belle Rose Ragins and colleagues of workplace concealment and disclosure in 534 LGB individuals found that fear of disclosing was associated with psychological strain and other outcomes such as job satisfaction. However, the study also challenged the notion that disclosure leads to positive psychological and social outcomes, since employees' disclosure was not significantly associated with most of the outcome variables. The authors interpret this result by saying that "this study suggests that concealment may be a necessary and adaptive decision in an unsupportive or hostile environment, thus underscoring the importance of social context."¹¹⁰ Due to the relatively rapid changes in social acceptance of same-sex marriage and of same-sex relationships more broadly in recent decades,¹¹¹ it is possible that some of the research on the psychological effects of concealment and disclosure is outdated, because in general there may now be less pressure for those identifying as LGB to conceal their identities.

Testing the model. One of the implications of the social stress model is that reducing the amount of discrimination, prejudice, and stigmatization of sexual minorities would help reduce the rates of mental health problems for these populations. Some jurisdictions have sought to reduce these social stressors by passing anti-discrimination and hate-crime laws. If such policies are in fact successful at reducing these stressors then they could be expected to reduce the rates of mental health problems in LGB populations to the extent that the social stress model accurately accounts for the causes of these problems. So far, studies have not been designed in such a way that could allow them to test conclusively the hypothesis that social stress accounts for the high rates of poor mental health outcomes in non-heterosexual populations, but there is research that provides some data on a testable implication of the social stress model.

A 2009 study by sociomedical scientist Mark Hatzenbuehler and colleagues investigated the association between psychiatric morbidity in LGB populations and two state-level policies that pertained to these populations: hate-crime laws that did not include sexual orientation as a protected category, and laws prohibiting employment discrimination based on sexual orientation.¹¹² The study used data on mental health outcomes from Wave 2 of the National Epidemiologic Survey on Alcohol and Related Conditions (NESARC), a nationally representative sample of 34,653 civilian, non-institutionalized adults, and measuring psychiatric disorders according to *DSM-IV* criteria.¹¹³ Wave 2 of NESARC took place in 2004–2005. Of the sample, 577 respondents identified as lesbian, gay, or bisexual. The analysis of the data showed that LGB individuals living in states with no hate-crime laws and no non-discrimination laws tended to have higher odds of psychiatric morbidity (compared to LGB individuals in states with one or two protective laws), but the analysis found statistically significant correlations only for dysthymia (a less severe but more persistent form of depression), generalized anxiety disorder, and post-traumatic stress disorder, while the correlations between seven other psychiatric conditions investigated were not found to be statistically significant. No epidemiological inferences can be made due to the nature of the data, suggesting the need for more studies on this and similar topics.

Hatzenbuehler and colleagues attempted to improve on this cross-sectional study by doing a prospective study, published in 2010, this time examining changes in psychiatric morbidity over the period in which certain states passed constitutional amendments defining marriage as a union between one man and one woman—amendments that were described by the study’s authors as “bans on gay marriage.”¹¹⁴ The authors examined differences in psychiatric morbidity between Wave 1 of NESARC, which took place in 2001–2002, and Wave 2, which coincided with the 2004 and 2005 state-constitutional amendments. They observed that the prevalence in mood disorders in LGB respondents living in states that passed marriage amendments increased by 36.6% between Waves 1 and 2. Mood disorders for LGB respondents living in states that did not pass marriage amendments decreased by 23.6%, though this change was not statistically significant. The prevalence of certain disorders increased both in states that passed such amendments and in states that did not. Generalized anxiety disorder, for example, increased in both, but by a much larger and statistically significant magnitude in states that passed marriage amendments. Hatzenbuehler and colleagues found that drug-use disorders increased more in states that did *not* pass marriage amendments,

and the increase was statistically significant only for those states. (Total substance abuse disorders increased in both cases, by a roughly similar amount.) As with the earlier cross-sectional study, for the majority of the psychiatric conditions investigated there were no significant correlations between the conditions and the social policies that were hypothesized to have an influence on mental health outcomes.

Some of the limitations of the study's findings noted by the authors include the following: healthier LGB respondents may have moved out of the states that would eventually pass marriage amendments into the states that would not; sexual orientation was only assessed during Wave 2 of NESARC, and there is some fluidity to sexual identity that may have led to misclassification of some LGB respondents; and the sample size of LGB respondents living in states that passed marriage amendments was relatively small, limiting the statistical power of the study.

One hypothesized causal mechanism for the change in mental health variables associated with the marriage amendments is that the public debate surrounding the amendments may have elevated the stress experienced by non-heterosexuals—a hypothesis that was put forward by psychologist Sharon Scales Rostosky and colleagues in a study of the attitudes of LGB adults in states that passed marriage amendments in 2006.¹¹⁵ The survey data collected during this study showed that LGB respondents living in states that passed marriage amendments in 2006 had higher levels of various kinds of psychological distress, including stress and depressive symptoms. The study also found that participation in LGBT activism during the election season was associated with increased psychological distress. It may be that part of the psychological distress recorded by this survey, which included perceived stress, depressive symptoms (but not diagnoses of depressive disorders), and what the researchers called “amendment-related affect,” may have simply reflected the typical feelings of advocates when they experience political defeat on an issue that they care passionately about. Other key limitations of the study were its cross-sectional design and its reliance on volunteers for the survey (in contrast to the previous study by Hatzenbuehler and colleagues). The survey methodology may also have biased the results—the researchers advertised on websites and through listserv e-mail announcements that they were looking for survey respondents for a study on “attitudes and experiences of LGB...individuals regarding the debate” over gay marriage. As with many forms of convenience sampling, individuals with strong attitudes regarding the issues under investigation in the survey may have been more likely to respond.

As for the effects of particular policies, the evidence is equivocal at best. The 2009 study by Hatzenbuehler and colleagues demonstrated significant correlations between the risk of some (though not all) mental health problems in the LGB subpopulation and state policies on hate crime and employment protections. Even for the aspects of mental health that this study found to be correlated with hate-crime or employment-protection policies, the study was unable to show an epidemiological relationship between policies and health outcomes.

Conclusion

The social stress model probably accounts for some of the poor mental health outcomes experienced by sexual minorities, though the evidence supporting the model is limited, inconsistent and incomplete. Some of the central concepts of the model, such as stigmatization, are not easily operationalized. There is evidence linking some forms of mistreatment, stigmatization, and discrimination to some of the poor mental health outcomes experienced by non-heterosexuals, but it is far from clear that these factors account for all of the disparities between the heterosexual and non-heterosexual populations. Those poor mental health outcomes may be mitigated to some extent by reducing social stressors, but this strategy is unlikely to eliminate all of the disparities in mental health status between sexual minorities and the wider population. Other factors, such as the elevated rates of sexual abuse victimization among the LGBT population discussed in Part One, may also account for some of these mental health disparities, as research has consistently shown that “survivors of childhood sexual abuse are significantly at risk of a wide range of medical, psychological, behavioral, and sexual disorders.”¹¹⁶

Just as it does a disservice to non-heterosexual subpopulations to ignore or downplay the statistically higher risks of negative mental health outcomes they face, so it does them a disservice to misattribute the causes of these elevated risks, or to ignore other potential factors that may be at work. Assuming that a single model can explain all of the mental health risks faced by non-heterosexuals can mislead clinicians and therapists charged with helping this vulnerable subpopulation. The social stress model deserves further research, but should not be assumed to offer a complete explanation of the causes of mental health disparities if clinicians and policymakers want to adequately address the mental health challenges faced by the LGBT community. More research is needed to explore the causes of, and solutions to, these important public health challenges.

Part Three

Gender Identity

The concept of biological sex is well defined, based on the binary roles that males and females play in reproduction. By contrast, the concept of gender is not well defined. It is generally taken to refer to behaviors and psychological attributes that tend to be typical of a given sex. Some individuals identify as a gender that does not correspond to their biological sex. The causes of such cross-gender identification remain poorly understood. Research investigating whether these transgender individuals have certain physiological features or experiences in common with the opposite sex, such as brain structures or atypical prenatal hormone exposures, has so far been inconclusive. Gender dysphoria—a sense of incongruence between one’s biological sex and one’s gender, accompanied by clinically significant distress or impairment—is sometimes treated in adults by hormones or surgery, but there is little scientific evidence that these therapeutic interventions have psychological benefits. Science has shown that gender identity issues in children usually do not persist into adolescence or adulthood, and there is little scientific evidence for the therapeutic value of puberty-delaying treatments. We are concerned by the increasing tendency toward encouraging children with gender identity issues to transition to their preferred gender through medical and then surgical procedures. There is a clear need for more research in these areas.

As described in Part One, there is a widely held belief that *sexual orientation* is a well-defined concept, and that it is innate and fixed in each person—as it is often put, gay people are “born that way.” Another emerging and related view is that *gender identity*—the subjective, internal sense of being a man or a woman (or some other gender category)—is also fixed at birth or at a very early age and can diverge from a person’s biological sex. In the case of children, this is sometimes articulated by saying that a little boy may be trapped in a little girl’s body, or vice versa.

In Part One we argued that scientific research does not give much support to the hypothesis that sexual orientation is innate and fixed. We will argue here, similarly, that there is little scientific evidence that gender identity is fixed at birth or at an early age. Though biological sex is innate, and gender identity and biological sex are related in complex ways, they

are not identical; gender is sometimes defined or expressed in ways that have little or no biological basis.

Key Concepts and Their Origins

To clarify what is meant by “gender” and “sex,” we begin with a widely used definition, here quoted from a pamphlet published by the American Psychological Association (APA):

Sex is assigned at birth, refers to one’s biological status as either male or female, and is associated primarily with physical attributes such as chromosomes, hormone prevalence, and external and internal anatomy. *Gender* refers to the socially constructed roles, behaviors, activities, and attributes that a given society considers appropriate for boys and men or girls and women. These influence the ways that people act, interact, and feel about themselves. While aspects of biological sex are similar across different cultures, aspects of gender may differ.¹

This definition points to the obvious fact that there are social norms for men and women, norms that vary across different cultures and that are not simply determined by biology. But it goes further in holding that gender is wholly “socially constructed”—that it is detached from biological sex. This idea has been an important part of a feminist movement to reform or eliminate traditional gender roles. In the classic feminist book *The Second Sex* (1949), Simone de Beauvoir wrote that “one is not born, but becomes a woman.”² This notion is an early version of the now familiar distinction between sex as a biological designation and gender as a cultural construct: though one is born, as the APA explains, with the “chromosomes, hormone prevalence, and external and internal anatomy” of a female, one is socially conditioned to take on the “roles, behaviors, activities, and attributes” of a woman.

Developments in feminist theory in the second half of the twentieth century further solidified the position that gender is socially constructed. One of the first to use the term “gender” as distinct from sex in the social-science literature was Ann Oakley in her 1972 book, *Sex, Gender and Society*.³ In the 1978 book *Gender: An Ethnomethodological Approach*, psychology professors Suzanne Kessler and Wendy McKenna argued that “gender is a social construction, that a world of two ‘sexes’ is a result of the socially shared, taken for granted methods which members use to construct reality.”⁴

Anthropologist Gayle Rubin expresses a similar view, writing in 1975 that “Gender is a socially imposed division of the sexes. It is a product of

the social relations of sexuality.”⁵ According to her argument, if it were not for this social imposition, we would still have males and females but not “men” and “women.” Furthermore, Rubin argues, if traditional gender roles are socially constructed, then they can also be *d*econstructed, and we can eliminate “obligatory sexualities and sex roles” and create “an androgynous and genderless (though not sexless) society, in which one’s sexual anatomy is irrelevant to who one is, what one does, and with whom one makes love.”⁶

The relationship between gender theory and the deconstruction or overthrowing of traditional gender roles is made even clearer in the works of the influential feminist theorist Judith Butler. In works such as *Gender Trouble: Feminism and the Subversion of Identity* (1990)⁷ and *Undoing Gender* (2004)⁸ Butler advances what she describes as “performativity theory,” according to which being a woman or man is not something that one *is* but something that one *does*. “Gender is neither the causal result of sex nor as seemingly fixed as sex,” as she put it.⁹ Rather, gender is a constructed status radically independent from biology or bodily traits, “a free floating artifice, with the consequence that *man* and *masculine* might just as easily signify a female body as a male one, and *woman* and *feminine* a male body as easily as a female one.”¹⁰

This view, that gender and thus gender identity are fluid and plastic, and not necessarily binary, has recently become more prominent in popular culture. An example is Facebook’s move in 2014 to include 56 new ways for users to describe their gender, in addition to the options of male and female. As Facebook explains, the new options allow the user to “feel comfortable being your true, authentic self,” an important part of which is “the expression of gender.”¹¹ Options include *agender*, several *cis-* and *trans-* variants, *gender fluid*, *gender questioning*, *neither*, *other*, *pangender*, and *two-spirit*.¹²

Whether or not Judith Butler was correct in describing traditional gender roles of men and women as “performative,” her theory of gender as a “free-floating artifice” does seem to describe this new taxonomy of gender. As these terms multiply and their meanings become more individualized, we lose any common set of criteria for defining what gender distinctions mean. If gender is entirely detached from the binary of biological sex, gender could come to refer to any distinctions in behavior, biological attributes, or psychological traits, and each person could have a gender defined by the unique combination of characteristics the person possesses. This *reductio ad absurdum* is offered to present the possibility that defining gender too broadly could lead to a definition that has little meaning.

Alternatively, gender identity could be defined in terms of sex-typical traits and behaviors, so that being a boy means behaving in the ways boys typically behave—such as engaging in rough-and-tumble play and expressing an interest in sports and liking toy guns more than dolls. But this would imply that a boy who plays with dolls, hates guns, and refrains from sports or rough-and-tumble play might be considered to be a girl, rather than simply a boy who represents an exception to the typical patterns of male behavior. The ability to recognize exceptions to sex-typical behavior relies on an understanding of maleness and femaleness that is independent of these stereotypical sex-appropriate behaviors. The underlying basis of maleness and femaleness is the distinction between the reproductive roles of the sexes; in mammals such as humans, the female gestates offspring and the male impregnates the female. More universally, the male of the species fertilizes the egg cells provided by the female of the species. This conceptual basis for sex roles is binary and stable, and allows us to distinguish males from females on the grounds of their reproductive systems, even when these individuals exhibit behaviors that are not typical of males or females.

To illustrate how reproductive roles define the differences between the sexes even when behavior appears to be atypical for the particular sex, consider two examples, one from the diversity of the animal kingdom, and one from the diversity of human behavior. First, we look at the emperor penguin. Male emperor penguins provide more care for eggs than do females, and in this sense, the male emperor penguin could be described as more maternal than the female.¹³ However, we recognize that the male emperor penguin is not in fact female but rather that the species represents an exception to the general, but not universal, tendency among animals for females to provide more care than males for offspring. We recognize this because sex-typical behaviors like parental care do not define the sexes; the individual's role in sexual reproduction does.

Even other sex-typical biological traits, such as chromosomes, are not necessarily helpful for defining sex in a universal way, as the penguin example further illustrates. As with other birds, the genetics of sex determination in the emperor penguin is different than the genetics of sex determination in mammals and many other animals. In humans, males have XY chromosomes and females have XX chromosomes; that is, males have a unique sex-determining chromosome that they do not share with females, while females have two copies of a chromosome that they share with males. But in birds, it is females, not males, that have and pass on the sex-specific chromosome.¹⁴ Just as the observation that

male emperor penguins nurture their offspring more than their partners did not lead zoologists to conclude that the egg-laying member of the emperor penguin species was in fact the male, the discovery of the ZW sex-determination system in birds did not lead geneticists to challenge the age-old recognition that hens are females and roosters are males. The only variable that serves as the fundamental and reliable basis for biologists to distinguish the sexes of animals is their role in reproduction, not some other behavioral or biological trait.

Another example that, in this case, only appears to be non-sex-typical behavior is that of Thomas Beatie, who made headlines as a man who gave birth to three children between 2008 and 2010.¹⁵ Thomas Beatie was born a woman, Tracy Lehuanani LaGondino, and underwent a surgical and legal transition to living as a man before deciding to have children. Because the medical procedures he underwent did not involve the removal of his ovaries or uterus, Beatie was capable of bearing children. The state of Arizona recognizes Thomas Beatie as the father of his three children, even though, biologically, he is their mother. Unlike the case of the male emperor penguin's ostensibly maternal, "feminine" parenting behavior, Beatie's ability to have children does not represent an exception to the normal inability of males to bear children. The labeling of Beatie as a man despite his being biologically female is a personal, social, and legal decision that was made without any basis in biology; nothing whatsoever in biology suggests Thomas Beatie is a male.

In biology, an organism is male or female if it is structured to perform one of the respective roles in reproduction. This definition does not require any arbitrary measurable or quantifiable physical characteristics or behaviors; it requires understanding the reproductive system and the reproduction process. Different animals have different reproductive systems, but sexual reproduction occurs when the sex cells from the male and female of the species come together to form newly fertilized embryos. It is these reproductive roles that provide the conceptual basis for the differentiation of animals into the biological categories of male and female. There is no other widely accepted biological classification for the sexes.

But this definition of the biological category of sex is not universally accepted. For example, philosopher and legal scholar Edward Stein maintains that infertility poses a crucial problem for defining sex in terms of reproductive roles, writing that defining sex in terms of these roles would define "infertile males as females."¹⁶ Since an infertile male cannot play the reproductive role for which males are structured, and an infertile

female cannot play the reproductive role for which females are structured, according to this line of thinking, defining sex in terms of reproductive roles would not be appropriate, as infertile males would be classified as females, and infertile females as males. Nevertheless, while a reproductive system structured to serve a particular reproductive role may be impaired in such a way that it cannot perform its function, the system is still recognizably structured for that role, so that biological sex can still be defined strictly in terms of the structure of reproductive systems. A similar point can be made about heterosexual couples who choose not to reproduce for any of a variety of reasons. The male and female reproductive systems are generally clearly recognizable, regardless of whether or not they are being used for purposes of reproduction.

The following analogy illustrates how a system can be recognized as having a particular purpose, even when that system is dysfunctional in a way that renders it incapable of carrying out its purpose: Eyes are complex organs that function as processors of vision. However, there are numerous conditions affecting the eye that can impair vision, resulting in blindness. The eyes of the blind are still recognizably organs structured for the function of sight. Any impairments that result in blindness do not affect the purpose of the eye—any more than wearing a blindfold—but only its function. The same is true for the reproductive system. Infertility can be caused by many problems. However, the reproductive system continues to exist for the purpose of begetting children.

There are individuals, however, who are biologically “intersex,” meaning that their sexual anatomy is ambiguous, usually for reasons of genetic abnormalities. For example, the clitoris and penis are derived from the same embryonic structures. A baby may display an abnormally large clitoris or an abnormally small penis, causing its biological sex to be difficult to determine long after birth.

The first academic article to use the term “gender” appears to be the 1955 paper by the psychiatry professor John Money of Johns Hopkins on the treatment of “intersex” children (the term then used was “hermaphrodites”).¹⁷ Money posited that gender identity, at least for these children, was fluid and that it could be constructed. In his mind, making a child identify with a gender only required constructing sex-typical genitalia and creating a gender-appropriate environment for the child. The chosen gender for these children was often female—a decision that was not based on genetics or biology, nor on the belief that these children were “really” girls, but, in part, on the fact that at the time it was easier surgically to construct a vagina than it was to construct a penis.

The most widely known patient of Dr. Money was David Reimer, a boy who was not born with an intersex condition but whose penis was damaged during circumcision as an infant.¹⁸ David was raised by his parents as a girl named Brenda, and provided with both surgical and hormonal interventions to ensure that he would develop female-typical sex characteristics. However, the attempt to conceal from the child what had happened to him was not successful—he self-identified as a boy, and eventually, at the age of 14, his psychiatrist recommended to his parents that they tell him the truth. David then began the difficult process of reversing the hormonal and surgical interventions that had been performed to feminize his body. But he continued to be tormented by his childhood ordeal, and took his own life in 2004, at the age of 38.

David Reimer is just one example of the harm wrought by theories that gender identity can socially and medically be reassigned in children. In a 2004 paper, William G. Reiner, a pediatric urologist and child and adolescent psychiatrist, and John P. Gearhart, a professor of pediatric urology, followed up on the sexual identities of 16 genetic males affected by cloacal exstrophy—a condition involving a badly deformed bladder and genitals. Of the 16 subjects, 14 were assigned female sex at birth, receiving surgical interventions to construct female genitalia, and were raised as girls by their parents; 6 of these 14 later chose to identify as males, while 5 continued to identify as females and 2 declared themselves males at a young age but continued to be raised as females because their parents rejected the children's declarations. The remaining subject, who had been told at age 12 that he was born male, refused to discuss sexual identity.¹⁹ So the assignment of female sex persisted in only 5 of the 13 cases with known results.

This lack of persistence is some evidence that the assignment of sex through genital construction at birth with immersion into a “gender-appropriate” environment is not likely to be a successful option for managing the rare problem of genital ambiguity from birth defects. It is important to note that the ages of these individuals at last follow-up ranged from 9 to 19, so it is possible that some of them may have subsequently changed their gender identities.

Reiner and Gearhart's research indicates that gender is not arbitrary; it suggests that a biological male (or female) will probably not come to identify as the opposite gender after having been altered physically and immersed into the corresponding gender-typical environment. The plasticity of gender appears to have a limit.

What is clear is that biological sex is not a concept that can be reduced to, or artificially assigned on the basis of, the type of external genitalia

alone. Surgeons are becoming more capable of constructing artificial genitalia, but these “add-ons” do not change the biological sex of the recipients, who are no more capable of playing the reproductive roles of the opposite biological sex than they were without the surgery. Nor does biological sex change as a function of the environment provided for the child. No degree of supporting a little boy in converting to be considered, by himself and others, to be a little girl makes him biologically a little girl. The scientific definition of biological sex is, for almost all human beings, clear, binary, and stable, reflecting an underlying biological reality that is not contradicted by exceptions to sex-typical behavior, and cannot be altered by surgery or social conditioning.

In a 2004 article summarizing the results of research related to inter-sex conditions, Paul McHugh, the former chief of psychiatry at Johns Hopkins Hospital (and the coauthor of this report), suggested:

We in the Johns Hopkins Psychiatry Department eventually concluded that human sexual identity is mostly built into our constitution by the genes we inherit and the embryogenesis we undergo. Male hormones sexualize the brain and the mind. Sexual dysphoria—a sense of disquiet in one’s sexual role—naturally occurs amongst those rare males who are raised as females in an effort to correct an infantile genital structural problem.²⁰

We now turn our attention to transgender individuals—children and adults—who choose to identify as a gender different from their biological sex, and explore the meaning of gender identity in this context and what the scientific literature tells us about its development.

Gender Dysphoria

While biological sex is, with very few exceptions, a well-defined, binary trait (male versus female) corresponding to how the body is organized for reproduction, *gender identity* is a more subjective attribute. For most people, their own gender identity is probably not a significant concern; most biological males identify as boys or men, and most biological females identify as girls or women. But some individuals experience an incongruence between their biological sex and their gender identity. If this struggle causes them to seek professional help, then the problem is classified as “gender dysphoria.”

Some male children raised as females, as described in Reiner and colleagues’ 2004 study, came to experience problems with their gender

identity when their subjective sense of being boys conflicted with being identified and treated as girls by their parents and doctors. The biological sex of the boys was not in question (they had an XY genotype), and the cause of gender dysphoria lay in the fact that they were genetically male, came to identify as male, but had been assigned female gender identities. This suggests that gender identity can be a complex and burdensome issue for those who choose (or have others choose for them) a gender identity opposite their biological sex.

But the cases of gender dysphoria that are the subject of much public debate are those in which individuals come to identify as genders different from those based on their biological sex. These people are usually identified, and describe themselves, as “transgender.”*

According to the fifth edition of the American Psychiatric Association’s *Diagnostic and Statistical Manual of Mental Disorders (DSM-5)*, gender dysphoria is marked by “incongruence between one’s experienced/expressed gender and assigned gender,” as well as “clinically significant distress or impairment in social, occupational, or other important areas of functioning.”²¹

It is important to clarify that gender dysphoria is not the same as gender nonconformity or gender identity disorder. Gender nonconformity describes an individual who behaves in a manner contrary to the gender-specific norms of his or her biological sex. As the *DSM-5* notes, most transvestites, for instance, are not transgender—men who dress as women typically do not identify themselves as women.²² (However, certain forms of transvestitism can be associated with late-onset gender dysphoria.²³)

Gender identity disorder, an obsolete term from an earlier version of the *DSM* that was removed in its fifth edition, was used as a psychiatric diagnosis. If we compare the diagnostic criteria for gender dysphoria (the current term) and gender identity disorder (the former term), we see that both require the patient to display “a marked incongruence between one’s

* A note on terminology: In this report, we generally use the term *transgender* to refer to persons for whom there is an incongruity between the gender identity they understand themselves to possess and their biological sex. We use the term *transsexual* to refer to individuals who have undergone medical interventions to transform their appearance to better correspond with that of their preferred gender. The most familiar colloquial term used to describe the medical interventions that transform the appearance of transgender individuals may be “sex change” (or, in the case of surgery, “sex-change operation”), but this is not commonly used in the scientific and medical literature today. While no simple terms for these procedures are completely satisfactory, in this report we employ the commonly used terms *sex reassignment* and *sex-reassignment surgery*, except when quoting a source that uses “gender reassignment” or some other term.

experienced/expressed gender and assigned gender.”²⁴ The key difference is that a diagnosis of gender dysphoria requires the patient additionally to experience a “clinically significant distress or impairment in social, occupational, or other important areas of functioning” associated with these incongruent feelings.²⁵ Thus the major set of diagnostic criteria used in contemporary psychiatry does not designate all transgender individuals as having a psychiatric disorder. For example, a biological male who identifies himself as a female is not considered to have a psychiatric disorder unless the individual is experiencing significant psychosocial distress at the incongruence. A diagnosis of gender dysphoria may be part of the criteria used to justify sex-reassignment surgery or other clinical interventions. Furthermore, a patient who has had medical or surgical modifications to express his or her gender identity may still suffer from gender dysphoria. It is the nature of the struggle that defines the disorder, not the fact that the expressed gender differs from the biological sex.

There is no scientific evidence that all transgender people have gender dysphoria, or that they are all struggling with their gender identities. Some individuals who are not transgender—that is, who do not identify as a gender that does not correspond with their biological sex—might nonetheless struggle with their gender identity; for example, girls who behave in some male-typical ways might experience various forms of distress without ever coming to identify as boys. Conversely, individuals who do identify as a gender that does not correspond with their biological sex may not experience clinically significant distress related to their gender identity. Even if only, say, 40% of individuals who identify as a gender that does not correspond with their biological sex experience significant distress related to their gender identity, this would constitute a public health issue requiring clinicians and others to act to support those with gender dysphoria, and hopefully, to reduce the rate of gender dysphoria in the population. There is no evidence to suggest that the other 60% in this hypothetical—that is, the individuals who identify as a gender that does not correspond with their biological sex but who do not experience significant distress—would require clinical treatment.

The *DSM*’s concept of subjectively “experiencing” one’s gender as incongruent from one’s biological sex may require more critical scrutiny and possibly modification. The exact definition of gender dysphoria, however well-intentioned, is somewhat vague and confusing. It does not account for individuals who self-identify as transgender but do not experience dysphoria associated with their gender identity and who seek psychiatric care for functional impairment for problems unrelated to their

gender identity, such as anxiety or depression. They may then be mislabeled as having gender dysphoria simply because they have a desire to be identified as a member of the opposite gender, when they have come to a satisfactory resolution, subjectively, with this incongruence and may be depressed for reasons having nothing to do with their gender identity.

The *DSM-5* criteria for a diagnosis of gender dysphoria in children are defined in a “more concrete, behavioral manner than those for adolescents and adults.”²⁶ This is to say that some of the diagnostic criteria for gender dysphoria in children refer to behaviors that are stereotypically associated with the opposite gender. Clinically significant distress is still necessary for a diagnosis of gender dysphoria in children, but some of the other diagnostic criteria include, for instance, a “strong preference for the toys, games, or activities stereotypically used or engaged in by the other gender.”²⁷ What of girls who are “tomboys” or boys who are not oriented toward violence and guns, who prefer quieter play? Should parents worry that their tomboy daughter is really a boy stuck in a girl’s body? There is no scientific basis for believing that playing with toys typical of boys defines a child as a boy, or that playing with toys typical of girls defines a child as a girl. The *DSM-5* criterion for diagnosing gender dysphoria by reference to gender-typical toys is unsound; it appears to ignore the fact that a child could display an *expressed* gender—manifested by social or behavioral traits—incongruent with the child’s biological sex but without *identifying* as the opposite gender. Furthermore, even for children who do identify as a gender opposite their biological sex, diagnoses of gender dysphoria are simply unreliable. The reality is that they may have psychological difficulties in accepting their biological sex as their gender. Children can have difficulty with the expectations associated with those gender roles. Traumatic experiences can also cause a child to express distress with the gender associated with his or her biological sex.

Gender identity problems can also arise with intersex conditions (the presence of ambiguous genitalia due to genetic abnormalities), which we discussed earlier. These disorders of sex development, while rare, can contribute to gender dysphoria in some cases.²⁸ Some of these conditions include complete androgen insensitivity syndrome, where individuals with XY (male) chromosomes lack receptors for male sex hormones, leading them to develop the secondary sex characteristics of females, rather than males (though they lack ovaries, do not menstruate, and are consequently sterile).²⁹ Another hormonal disorder of sex development that can lead to individuals developing in ways that are not typical of their genetic sex include congenital adrenal hyperplasia, a condition that can

masculinize XX (female) fetuses.³⁰ Other rare phenomena such as genetic mosaicism³¹ or chimerism,³² where some cells in the individual's bodies contain XX chromosomes and others contain XY chromosomes, can lead to considerable ambiguity in sex characteristics, including individuals who possess both male and female gonads and sex organs.

While there are many cases of gender dysphoria that are not associated with these identifiable intersex conditions, gender dysphoria may still represent a different type of intersex condition in which the primary sex characteristics such as genitalia develop normally while secondary sex characteristics associated with the brain develop along the lines of the opposite sex. Controversy exists over influences determining the nature of neurological, psychological, and behavioral sex differences. The emerging consensus is that there may be some differences in patterns of neurological development in- and ex-utero for men and women.³³ Therefore, in theory, transgender individuals could be subject to conditions allowing a more female-type brain to develop within a genetic male (having the XY chromosomal patterns), and vice versa. However, as we will show in the next section, the research supporting this idea is quite minimal.

As a way of surveying the biological and social science research on gender dysphoria, we can list some of the important questions. Are there biological factors that influence the development of a gender identity that does not correspond with one's biological sex? Are some individuals born with a gender identity different from their biological sex? Is gender identity shaped by environmental or nurturing conditions? How stable are choices of gender identity? How common is gender dysphoria? Is it persistent across the lifespan? Can a little boy who thinks he is a little girl change over the course of his life to regard himself as male? If so, how often can such people change their gender identities? How would someone's gender identity be measured scientifically? Does self-understanding suffice? Does a biological girl become a gender boy by believing, or at least stating, she is a little boy? Do people's struggles with a sense of incongruity between their gender identity and biological sex persist over the life course? Does gender dysphoria respond to psychiatric interventions? Should those interventions focus on affirming the gender identity of the patient or take a more neutral stance? Do efforts to hormonally or surgically modify an individual's primary or secondary sex characteristics help resolve gender dysphoria? Does modification create further psychiatric problems for some of those diagnosed with gender dysphoria, or does it typically resolve existing psychiatric problems? We broach a few of these critical questions in the following sections.

Gender and Physiology

Robert Sapolsky, a Stanford professor of biology who has done extensive neuroimaging research, suggested a possible neurobiological explanation for cross-gender identification in a 2013 *Wall Street Journal* article, “Caught Between Male and Female.” He asserted that recent neuroimaging studies of the brains of transgender adults suggest that they may have brain structures more similar to their gender identity than to their biological sex.³⁴ Sapolsky bases this assertion on the fact that there are differences between male and female brains, and while the differences are “small and variable,” they “probably contribute to the sex differences in learning, emotion and socialization.”³⁵ He concludes: “The issue isn’t that sometimes people believe they are of a different gender than they actually are. Remarkably, instead, it’s that sometimes people are born with bodies whose gender is different from what they actually are.”³⁶ In other words, he claims that some people can have a female-type brain in a male body, or vice versa.

While this kind of neurobiological theory of cross-gender identification remains outside of the scientific mainstream, it has recently received scientific and popular attention. It provides a potentially attractive explanation for cross-gender identification, especially for individuals who are not affected by any known genetic, hormonal, or psychosocial abnormalities.³⁷ However, while Sapolsky may be right, there is fairly little support in the scientific literature for his contention. His neurological explanation for differences between male and female brains and those differences’ possible relevance to cross-gender identification warrant further scientific consideration.

There are many small studies that attempt to define causal factors of the experience of incongruence between one’s biological sex and felt gender. These studies are described in the following pages, each pointing to an influence that may contribute to the explanation for cross-gender identification.

Nancy Segal, a psychologist and geneticist, researched two case studies of identical twins discordant for female-to-male (FtM) transsexualism.³⁸ Segal notes that, according to another, earlier study that conducted nonclinical interviews with 45 FtM transsexuals, 60% suffered some form of childhood abuse, with 31% experiencing sexual abuse, 29% experiencing emotional abuse, and 38% physical abuse.³⁹ However, this earlier study did not include a control group and was limited by its small sample size, making it difficult to extract significant interactions, or generalizations, from the data.

Segal's own first case study was of a 34-year-old FtM twin, whose identical twin sister was married and the mother of seven children.⁴⁰ Several stressful events had occurred during the twins' mother's pregnancy, and they were born five weeks prematurely. When they were eight years old, their parents divorced. The FtM twin exhibited gender-nonconforming behavior early and it persisted throughout childhood. She became attracted to other girls in junior high school and as a teenager attempted suicide several times. She reported physical abuse and emotional abuse at the hand of her mother. The twins were raised in a Mormon household, in which transsexuality was not tolerated.⁴¹ The twin sister had never questioned her gender identity but did experience some depression. For Segal, the FtM twin's gender nonconformity and abuse in childhood were factors that contributed to gender dysphoria; the other twin was not subject to the same stressors in childhood, and did not develop issues around her gender identity. Segal's second case study also concerned identical twins with one twin transitioning from female to male.⁴² This FtM twin had early-onset nonconforming behaviors and attempted suicide as a young adult. At age 29 she underwent reassignment surgery, was well supported by family, met a woman, and married. As in the first case, the other twin was reportedly always secure in her female gender identity.

Segal speculates that each set of twins may have had uneven prenatal androgen exposures (though her study did not offer evidence to support this)⁴³ and concludes that "Transsexualism is unlikely to be associated with a major gene, but is likely to be associated with multiple genetic, epigenetic, developmental and experiential influences."⁴⁴ Segal is critical of the notion that the maternal abuse experienced by the FtM twin in her first case study may have played a causal role in the twin's "atypical gender identification" since the abuse "apparently *followed*" the twin's gender-atypical behaviors—though Segal acknowledges "it is possible that this abuse reinforced his already atypical gender identification."⁴⁵ These case studies, while informative, are not scientifically strong, and do not provide direct evidence for any causal hypotheses about the origins of atypical gender identification.

A source of more information—but also inadequate to make direct causal inferences—is a case analysis by Mayo Clinic psychiatrists J. Michael Bostwick and Kari A. Martin of an intersex individual born with ambiguous genitalia who was operated on and raised as a female.⁴⁶ By way of offering some background, the authors draw a distinction between gender identity disorder (an "inconsistency between perceived gender identity and phenotypic sex" that generally involves "no discernible neuroendocri-

nological abnormality”⁴⁷), and intersexuality (a condition in which biological features of both sexes are present). They also provide a summary and classification scheme of the various types of intersex disorders. After a thorough discussion of the various intersex developmental issues that can lead to a disjunction between the brain and body, the authors acknowledge that “Some adult patients with severe dysphoria—transsexuals—have neither history nor objective findings supporting a known biological cause of brain-body disjunction.”⁴⁸ These patients require thorough medical and psychiatric attention to avoid gender dysphoria.

After this helpful summary, the authors state that “Absent psychosis or severe character pathology, patients’ subjective assertions are presently the most reliable standards for delineating core gender identity.”⁴⁹ But it is not clear how we could consider subjective assertions more reliable in establishing gender identity, unless gender identity is defined as a completely subjective phenomenon. The bulk of the article is devoted to describing the various objectively discernible and identifiable ways in which one’s identity as a male or female is imprinted on the nervous and endocrine system. Even when something goes wrong with the development of external genitalia, individuals are more likely to act in accordance with their chromosomal and hormonal makeup.⁵⁰

In 2011, Giuseppina Rametti and colleagues from various research centers in Spain used MRI to study the brain structures of 18 FtM transsexuals who exhibited gender nonconformity early in life and experienced sexual attraction to females prior to hormone treatment.⁵¹ The goal was to learn whether their brain features corresponded more to their biological sex or to their sense of gender identity. The control group consisted of 24 male and 19 female heterosexuals with gender identities conforming to their biological sex. Differences were noted in the white matter microstructure of specific brain areas. In untreated FtM transsexuals, that structure was more similar to that of heterosexual males than to that of heterosexual females in three of four brain areas.⁵² In a complementary study, Rametti and colleagues compared 18 MtF transsexuals to 19 female and 19 male heterosexual controls.⁵³ These MtF transsexuals had white matter tract averages in several brain areas that fell between the averages of the control males and the control females. The values, however, were typically closer to the males (that is, to those that shared their biological sex) than to the females in most areas.⁵⁴ In controls the authors found that, as expected, the males had greater amounts of gray and white matter and higher volumes of cerebrospinal fluid than control females. The MtF transsexual brain volumes

were all similar to those of male controls and significantly different from those of females.⁵⁵

Overall, the findings of these studies by Rametti and colleagues do not sufficiently support the notion that transgender individuals have brains more similar to their preferred gender than to the gender corresponding with their biological sex. Both studies are limited by small sample sizes and lack of a prospective hypothesis—both analyzed the MRI data to find the gender differences and then looked to see where the data from transgender subjects fit.

Whereas both of these MRI studies looked at brain *structure*, a functional MRI study by Emiliano Santarnecchi and colleagues from the University of Siena and the University of Florence looked at brain *function*, examining gender-related differences in spontaneous brain activity during the resting state.⁵⁶ The researchers compared a single FtM individual (declared cross-gender since childhood), and control groups of 25 males and 25 females, with regard to spontaneous brain activity. The FtM individual demonstrated a “brain activity profile more close to his biological sex than to his desired one,” and based in part on this result the authors concluded that “untreated FtM transsexuals show a functional connectivity profile comparable to female control subjects.”⁵⁷ With a sample size of one, this study’s statistical power is virtually zero.

In 2013, Hsaio-Lun Ku and colleagues from various medical centers and research institutes in Taiwan also conducted functional brain imaging studies. They compared the brain activity of 41 transsexuals (21 FtMs, 20 MtFs) and 38 matched heterosexual controls (19 males and 19 females).⁵⁸ Arousal response of each cohort while viewing neutral as compared to erotic films was compared between groups. All of the transsexuals in the study reported sexual attractions to members of their natal, biological sex, and exhibited more sexual arousal than heterosexual controls when viewing erotic films that depicted sexual activity between subjects sharing their biological sex. A “selfness” score was also incorporated into the study, in which the researchers asked participants to “rate the degree to which you identify yourself as the male or female in the film.”⁵⁹ The transsexuals in the study identified with those of their preferred gender more than the controls identified with those of their biological gender, in both erotic films and neutral films. The heterosexual controls did not identify themselves with either males or females in either of the film types. Ku and colleagues claim to have demonstrated characteristic brain patterns for sexual attraction as related to biological sex but did not make meaningful neurobiological gender-identity comparisons among the three cohorts. In

addition, they reported findings that transsexuals demonstrated psychosocial maladaptive defensive styles.

A 2008 study by Hans Berglund and colleagues from Sweden's Karolinska Institute and Stockholm Brain Institute used PET and fMRI scans to compare brain-area activation patterns in 12 MtF transgendered individuals who were sexually attracted to women with those of 12 heterosexual women and 12 heterosexual men.⁶⁰ The first set of subjects took no hormones and had not undergone sex-reassignment surgery. The experiment involved smelling odorous steroids thought to be female pheromones, and other sexually neutral odors such as lavender oil, cedar oil, eugenol, butanol, and odorless air. The results were varied and mixed between the groups for the various odors, which should not be surprising, since *post hoc* analyses usually lead to contradictory findings.

In summary, the studies presented above show inconclusive evidence and mixed findings regarding the brains of transgender adults. Brain-activation patterns in these studies do not offer sufficient evidence for drawing sound conclusions about possible associations between brain activation and sexual identity or arousal. The results are conflicting and confusing. Since the data by Ku and colleagues on brain-activation patterns are not universally associated with a particular sex, it remains unclear whether and to what extent neurobiological findings say anything meaningful about gender identity. It is important to note that regardless of their findings, studies of this kind cannot support any conclusion that individuals come to identify as a gender that does not correspond to their biological sex because of an innate, biological condition of the brain.

The question is not simply whether there are differences between the brains of transgender individuals and people identifying with the gender corresponding to their biological sex, but whether gender identity is a fixed, innate, and biological trait, even when it does not correspond to biological sex, or whether environmental or psychological causes contribute to the development of a sense of gender identity in such cases. Neurological differences in transgender adults might be the consequence of biological factors such as genes or prenatal hormone exposure, or of psychological and environmental factors such as childhood abuse, or they could result from some combination of the two. There are no serial, longitudinal, or prospective studies looking at the brains of cross-gender identifying children who develop to later identify as transgender adults. Lack of this research severely limits our ability to understand causal relationships between brain morphology, or functional activity, and the later development of gender identity different from biological sex.

More generally, it is now widely recognized among psychiatrists and neuroscientists who engage in brain imaging research that there are inherent and ineradicable methodological limitations of *any* neuroimaging study that simply associates a particular trait, such as a certain behavior, with a particular brain morphology.⁶¹ (And when the trait in question is not a concrete behavior but something as elusive and vague as “gender identity,” these methodological problems are even more serious.) These studies cannot provide statistical evidence nor show a plausible biological mechanism strong enough to support *causal connections* between a brain feature and the trait, behavior, or symptom in question. To support a conclusion of causality, even epidemiological causality, we need to conduct prospective longitudinal panel studies of a fixed set of individuals across the course of sexual development if not their lifespan.

Studies like these would use serial brain images at birth, in childhood, and at other points along the developmental continuum, to see whether brain morphology findings were there from the beginning. Otherwise, we cannot establish whether certain brain features caused a trait, or whether the trait is innate and perhaps fixed. Studies like those discussed above of individuals who already exhibit the trait are incapable of distinguishing between *causes* and *consequences* of the trait. In most cases transgender individuals have been acting and thinking for years in ways that, through learned behavior and associated neuroplasticity, may have produced brain changes that could differentiate them from other members of their biological or natal sex. The only definitive way to establish epidemiological causality between a brain feature and a trait (especially one as complex as gender identity) is to conduct prospective, longitudinal, preferably randomly sampled and population-based studies.

In the absence of such prospective longitudinal studies, large representative population-based samples with adequate statistical controls for confounding factors may help narrow the possible causes of a behavioral trait and thereby increase the probability of identifying a neurological cause.⁶² However, because the studies conducted thus far use small convenience samples, none of them is especially helpful for narrowing down the options for causality. To obtain a better study sample, we would need to include neuroimaging in large-scale epidemiological studies. In fact, given the small number of transgender individuals in the general population,⁶³ the studies would need to be prohibitively large to attain findings that would reach statistical significance.

Moreover, if a study found significant differences between these groups—that is, a number of differences higher than what would be

expected by chance alone—these differences would refer to the average in a population of each group. Even if these two *groups* differed significantly for all 100 measurements, it would not necessarily indicate a biological difference among *individuals* at the extremes of the distribution. Thus, a randomly selected transgender individual and a randomly selected non-transgender individual might not differ on any of these 100 measurements. Additionally, since the probability that a randomly selected person from the general population will be transgender is quite small, statistically significant differences in the sample means are not sufficient evidence to conclude that a particular measurement is predictive of whether the person is transgender or not. If we measured the brain of an infant, toddler, or adolescent and found this individual to be closer to one cohort than another on these measures, it would not imply that this individual would grow up to identify as a member of that cohort. It may be helpful to keep this caveat in mind when interpreting research on transgender individuals.

In this context, it is important to note that there are no studies that demonstrate that any of the biological differences being examined have predictive power, and so all interpretations, usually in popular outlets, claiming or suggesting that a statistically significant difference between the brains of people who are transgender and those who are not is the cause of being transgendered or not—that is to say, that the biological differences determine the differences in gender identity—are unwarranted.

In short, the current studies on associations between brain structure and transgender identity are small, methodologically limited, inconclusive, and sometimes contradictory. Even if they were more methodologically reliable, they would be insufficient to demonstrate that brain structure is a cause, rather than an effect, of the gender-identity behavior. They would likewise lack predictive power, the real challenge for any theory in science.

For a simple example to illustrate this point, suppose we had a room with 100 people in it. Two of them are transgender and all others are not. I pick someone at random and ask you to guess the person's gender identity. If you know that 98 out of 100 of the individuals are not transgender, the safest bet would be to guess that the individual is not transgender, since that answer will be correct 98% of the time. Suppose, then, that you have the opportunity to ask questions about the neurobiology and about the natal sex of the person. Knowing the biology only helps in predicting whether the individual is transgender if it can improve on the original guess that the person is not transgender. So if knowing a characteristic of the individual's brain does not improve the ability to predict what group the patient belongs to, then the fact that the two groups differ at the mean is almost irrelevant.

Improving on the original prediction is very difficult for a rare trait such as being transgender, because the probability of that prediction being correct is already very high. If there really were a clear difference between the brains of transgender and non-transgender individuals, akin to the biological differences between the sexes, then improving on the original guess would be relatively easy. Unlike the differences between the sexes, however, there are no biological features that can reliably identify transgender individuals as different from others.

The consensus of scientific evidence overwhelmingly supports the proposition that a physically and developmentally normal boy or girl is indeed what he or she appears to be at birth. The available evidence from brain imaging and genetics does not demonstrate that the development of gender identity as different from biological sex is innate. Because scientists have not established a solid framework for understanding the causes of cross-gender identification, ongoing research should be open to psychological and social causes, as well as biological ones.

Transgender Identity in Children

In 2012, the *Washington Post* featured a story by Petula Dvorak, “Transgender at five,”⁶⁴ about a girl who at the age of 2 years began insisting that she was a boy. The story recounts her mother’s interpretation of this behavior: “Her little girl’s brain was different. Jean [her mother] could tell. She had heard about transgender people, those who are one gender physically but the other gender mentally.” The story recounts this mother’s distressed experiences as she began researching gender identity problems in children and came to understand other parents’ experiences:

Many talked about their painful decision to allow their children to publicly transition to the opposite gender—a much tougher process for boys who wanted to be girls. Some of what Jean heard was reassuring: Parents who took the plunge said their children’s behavior problems largely disappeared, schoolwork improved, happy kid smiles returned. But some of what she heard was scary: children taking puberty blockers in elementary school and teens embarking on hormone therapy before they’d even finished high school.⁶⁵

The story goes on to describe how the sister, Moyin, of the transgender child Tyler (formerly Kathryn) made sense of her sibling’s identity:

Tyler’s sister, who’s 8, was much more casual about describing her transgender sibling. “It’s just a boy mind in a girl body,” Moyin

explained matter-of-factly to her second-grade classmates at her private school, which will allow Tyler to start kindergarten as a boy, with no mention of Kathryn.⁶⁶

The remarks from the child's sister encapsulate the popular notion regarding gender identity: transgender individuals, or children who meet the diagnostic criteria for gender dysphoria, are simply "a boy mind in a girl body," or vice versa. This view implies that gender identity is a persistent and innate feature of human psychology, and it has inspired a gender-affirming approach to children who experience gender identity issues at an early age.

As we have seen above in the overview of the neurobiological and genetic research on the origins of gender identity, there is little evidence that the phenomenon of transgender identity has a biological basis. There is also little evidence that gender identity issues have a high rate of persistence in children. According to the *DSM-5*, "In natal [biological] males, persistence [of gender dysphoria] has ranged from 2.2% to 30%. In natal females, persistence has ranged from 12% to 50%."⁶⁷ Scientific data on persistence of gender dysphoria remains sparse due to the very low prevalence of the disorder in the general population, but the wide range of findings in the literature suggests that there is still much that we do not know about why gender dysphoria persists or desists in children. As the *DSM-5* entry goes on to note, "It is unclear if children 'encouraged' or supported to live socially in the desired gender will show higher rates of persistence, since such children have not yet been followed longitudinally in a systematic manner."⁶⁸ There is a clear need for more research in these areas, and for parents and therapists to acknowledge the great uncertainty regarding how to interpret the behavior of these children.

Therapeutic Interventions in Children

With the uncertainty surrounding the diagnosis of and prognosis for gender dysphoria in children, therapeutic decisions are particularly complex and difficult. Therapeutic interventions for children must take into account the probability that the children may outgrow cross-gender identification. University of Toronto researcher and therapist Kenneth Zucker believes that family and peer dynamics can play a significant role in the development and persistence of gender-nonconforming behavior, writing that

it is important to consider both predisposing and perpetuating factors that might inform a clinical formulation and the development of

a therapeutic plan: the role of temperament, parental reinforcement of cross-gender behavior during the sensitive period of gender identity formation, family dynamics, parental psychopathology, peer relationships and the multiple meanings that might underlie the child's fantasy of becoming a member of the opposite sex.⁶⁹

Zucker worked for years with children experiencing feelings of gender incongruence, offering psychosocial treatments to help them embrace the gender corresponding with their biological sex—for instance, talk therapy, parent-arranged play dates with same-sex peers, therapy for co-occurring psychopathological issues such as autism spectrum disorder, and parent counseling.⁷⁰

In a follow-up study by Zucker and colleagues of children treated by them over the course of thirty years at the Center for Mental Health and Addiction in Toronto, they found that gender identity disorder persisted in only 3 of the 25 girls they had treated.⁷¹ (Zucker's clinic was closed by the Canadian government in 2015.⁷²)

An alternative to Zucker's approach that emphasizes affirming the child's preferred gender identity has become more common among therapists.⁷³ This approach involves helping the children to self-identify even more with the gender label they prefer at the time. One component of the gender-affirming approach has been the use of hormone treatments for adolescents in order to delay the onset of sex-typical characteristics during puberty and alleviate the feelings of dysphoria the adolescents will experience as their bodies develop sex-typical characteristics that are at odds with the gender with which they identify. There is relatively little evidence for the therapeutic value of these kinds of puberty-delaying treatments, but they are currently the subject of a large clinical study sponsored by the National Institutes of Health.⁷⁴

While epidemiological data on the outcomes of medically delayed puberty is quite limited, referrals for sex-reassignment hormones and surgical procedures appear to be on the rise, and there is a push among many advocates to proceed with sex reassignment at younger ages. According to a 2013 article in *The Times* of London, the United Kingdom saw a 50% increase in the number of children referred to gender dysphoria clinics from 2011 to 2012, and a nearly 50% increase in referrals among adults from 2010 to 2012.⁷⁵ Whether this increase can be attributed to rising rates of gender confusion, rising sensitivity to gender issues, growing acceptance of therapy as an option, or other factors, the increase itself is concerning, and merits further scientific inquiry into the family dynamics

and other potential problems, such as social rejection or developmental issues, that may be taken as signs of childhood gender dysphoria.

A study of psychological outcomes following puberty suppression and sex-reassignment surgery, published in the journal *Pediatrics* in 2014 by child and adolescent psychiatrist Annelou L. C. de Vries and colleagues, suggested improved outcomes for individuals after receiving these interventions, with well-being improving to a level similar to that of young adults from the general population.⁷⁶ This study looked at 55 transgender adolescents and young adults (22 MtF and 33 FtM) from a Dutch clinic who were assessed three times: before the start of puberty suppression (mean age: 13.6 years), when cross-sex hormones were introduced (mean age: 16.7 years), and at least one year after sex-reassignment surgery (mean age: 20.7 years). The study did not provide a matched group for comparison—that is, a group of transgender adolescents who did not receive puberty-blocking hormones, cross-sex hormones, and/or sex-reassignment surgery—which makes comparisons of outcomes more difficult.

In the study cohort, gender dysphoria improved over time, body image improved on some measures, and overall functioning improved modestly. Due to the lack of a matched control group it is unclear whether these changes are attributable to the procedures or would have occurred in this cohort without the medical and surgical interventions. Measures of anxiety, depression, and anger showed some improvements over time, but these findings did not reach statistical significance. While this study suggested some improvements over time in this cohort, particularly the reported subjective satisfaction with the procedures, detecting significant differences would require the study to be replicated with a matched control group and a larger sample size. The interventions also included care from a multidisciplinary team of medical professionals, which could have had a beneficial effect. Future studies of this kind would ideally include long-term follow-ups that assess outcomes and functioning beyond the late teens or early twenties.

Therapeutic Interventions in Adults

The potential that patients undergoing medical and surgical sex reassignment may want to return to a gender identity consistent with their biological sex suggests that reassignment carries considerable psychological and physical risk, especially when performed in childhood, but also in adulthood. It suggests that the patients' pre-treatment beliefs about an ideal post-treatment life may sometimes go unrealized.

In 2004, Birmingham University's Aggressive Research Intelligence Facility (Arif) assessed the findings of more than one hundred follow-up studies of post-operative transsexuals.⁷⁷ An article in *The Guardian* summarized the findings:

Arif...concludes that none of the studies provides conclusive evidence that gender reassignment is beneficial for patients. It found that most research was poorly designed, which skewed the results in favour of physically changing sex. There was no evaluation of whether other treatments, such as long-term counselling, might help transsexuals, or whether their gender confusion might lessen over time. Arif says the findings of the few studies that have tracked significant numbers of patients over several years were flawed because the researchers lost track of at least half of the participants. The potential complications of hormones and genital surgery, which include deep vein thrombosis and incontinence respectively, have not been thoroughly investigated, either. "There is huge uncertainty over whether changing someone's sex is a good or a bad thing," says Dr Chris Hyde, director of Arif. "While no doubt great care is taken to ensure that appropriate patients undergo gender reassignment, there's still a large number of people who have the surgery but remain traumatized—often to the point of committing suicide."⁷⁸

The high level of uncertainty regarding various outcomes after sex-reassignment surgery makes it difficult to find clear answers about the effects on patients of reassignment surgery. Since 2004, there have been other studies on the efficacy of sex-reassignment surgery, using larger sample sizes and better methodologies. We will now examine some of the more informative and reliable studies on outcomes for individuals receiving sex-reassignment surgery.

As far back as 1979, Jon K. Meyer and Donna J. Reter published a longitudinal follow-up study on the overall well-being of adults who underwent sex-reassignment surgery.⁷⁹ The study compared the outcomes of 15 people who received surgery with those of 35 people who requested but did not receive surgery (14 of these individuals eventually received surgery later, resulting in three cohorts of comparison: operated, not-operated, and operated later). Well-being was quantified using a scoring system that assessed psychiatric, economic, legal, and relationship outcome variables. Scores were determined by the researchers after performing interviews with the subjects. Average follow-up time was approximately five years for subjects who had sex change surgery, and about two years for those subjects who did not.

Compared to their condition before surgery, the individuals who had undergone surgery appeared to show some improvement in well-being, though the results had a fairly low level of statistical significance. Individuals who had no surgical intervention did display a statistically significant improvement at follow-up. However, there was no statistically significant difference between the two groups' scores of well-being at follow-up. The authors concluded that "sex reassignment surgery confers no objective advantage in terms of social rehabilitation, although it remains subjectively satisfying to those who have rigorously pursued a trial period and who have undergone it."⁸⁰ This study led the psychiatry department at Johns Hopkins Medical Center (JHMC) to discontinue surgical interventions for sex changes for adults.⁸¹

However, the study has important limitations. Selection bias was introduced in the study population, because the subjects were drawn from those individuals who sought sex-reassignment surgery at JHMC. In addition, the sample size was small. Also, the individuals who did not undergo sex-reassignment surgery but presented to JHMC for it did not represent a true control group. Random assignment of the surgical procedure was not possible. Large differences in the average follow-up time between those who underwent surgery and those who did not further reduces any capacity to draw valid comparisons between the two groups. Additionally, the study's methodology was also criticized for the somewhat arbitrary and idiosyncratic way it measured the well-being of its subjects. Cohabitation or any form of contact with psychiatric services were scored as equally negative factors as having been arrested.⁸²

In 2011, Cecilia Dhejne and colleagues from the Karolinska Institute and Gothenburg University in Sweden published one of the more robust and well-designed studies to examine outcomes for persons who underwent sex-reassignment surgery. Focusing on mortality, morbidity, and criminality rates, the matched cohort study compared a total of 324 transsexual persons (191 MtFs, 133 FtMs) who underwent sex reassignment between 1973 and 2003 to two age-matched controls: people of the same sex as the transsexual person at birth, and people of the sex to which the individual had been reassigned.⁸³

Given the relatively low number of transsexual persons in the general population, the size of this study is impressive. Unlike Meyer and Reter, Dhejne and colleagues did not seek to evaluate the patient satisfaction after sex-reassignment surgery, which would have required a control group of transgender persons who desired to have sex-reassignment surgery but did not receive it. Also, the study did not compare outcome

variables before and after sex-reassignment surgery; only outcomes after surgery were evaluated. We need to keep these caveats in mind as we look at what this study found.

Dhejne and colleagues found statistically significant differences between the two cohorts on several of the studied rates. For example, the postoperative transsexual individuals had an approximately three times higher risk for psychiatric hospitalization than the control groups, even after adjusting for prior psychiatric treatment.⁸⁴ (However, the risk of being hospitalized for substance abuse was not significantly higher after adjusting for prior psychiatric treatment, as well as other covariates.) Sex-reassigned individuals had nearly a three times higher risk of all-cause mortality after adjusting for covariates, although the elevated risk was significant only for the time period of 1973–1988.⁸⁵ Those undergoing surgery during this period were also at increased risk of being convicted of a crime.⁸⁶ Most alarmingly, sex-reassigned individuals were 4.9 times more likely to attempt suicide and 19.1 times more likely to die by suicide compared to controls.⁸⁷ “Mortality from suicide was strikingly high among sex-reassigned persons, including after adjustment for prior psychiatric morbidity.”⁸⁸

The study design precludes drawing inferences “as to the effectiveness of sex reassignment as a treatment for transsexualism,” although Dhejne and colleagues state that it is possible that “things might have been even worse without sex reassignment.”⁸⁹ Overall, post-surgical mental health was quite poor, as indicated especially by the high rate of suicide attempts and all-cause mortality in the 1973–1988 group. (It is worth noting that for the transsexuals in the study who underwent sex reassignment from 1989 to 2003, there were of course fewer years of data available at the time the study was conducted than for those transsexuals from the earlier period. The rates of mortality, morbidity, and criminality in the later group may in time come to resemble the elevated risks of the earlier group.) In summary, this study suggests that sex-reassignment surgery may not rectify the comparatively poor health outcomes associated with transgender populations in general. Still, because of the limitations of this study mentioned above, the results also cannot establish that sex-reassignment surgery causes poor health outcomes.

In 2009, Annette Kuhn and colleagues from the University Hospital and University of Bern in Switzerland examined post-surgery quality of life in 52 MtF and 3 FtM transsexuals fifteen years after sex-reassignment surgery.⁹⁰ This study found considerably lower general life satisfaction in post-surgical transsexuals as compared with females who had at least one

pelvic surgery in the past. The postoperative transsexuals reported lower satisfaction with their general quality of health and with some of the personal, physical, and social limitations they experienced with incontinence that resulted as a side effect of the surgery. Again, inferences cannot be drawn from this study regarding the efficacy of sex-reassignment surgery due to the lack of a control group of transgender individuals who did not receive sex-reassignment surgery.

In 2010, Mohammad Hassan Murad and colleagues from the Mayo Clinic published a systematic review of studies on the outcomes of hormonal therapies used in sex-reassignment procedures, finding that there was “very low quality evidence” that sex reassignment via hormonal interventions “likely improves gender dysphoria, psychological functioning and comorbidities, sexual function and overall quality of life.”⁹¹ The authors identified 28 studies that together examined 1,833 patients who underwent sex-reassignment procedures that included hormonal interventions (1,093 male-to-female, 801 female-to-male).⁹² Pooling data across studies showed that, after receiving sex-reassignment procedures, 80% of patients reported improvement in gender dysphoria, 78% reported improvement in psychological symptoms, and 80% reported improvement in quality of life.⁹³ None of the studies included the bias-limiting measure of randomization (that is, in none of the studies were sex-reassignment procedures assigned randomly to some patients but not to others), and only three of the studies included control groups (that is, patients who were not provided the treatment to serve as comparison cases for those who did).⁹⁴ Most of the studies examined in Murad and colleagues’ review reported improvements in psychiatric comorbidities and quality of life, though notably suicide rates remained higher for individuals who had received hormone treatments than for the general population, despite reductions in suicide rates following the treatments.⁹⁵ The authors also found that there were some exceptions to reports of improvements in mental health and satisfaction with sex-reassignment procedures; in one study, 3 of 17 individuals regretted the procedure with 2 of these 3 seeking reversal procedures,⁹⁶ and four of the studies reviewed reported worsening quality of life, including continuing social isolation, lack of improvement in social relationships, and dependence on government welfare programs.⁹⁷

The scientific evidence summarized suggests we take a skeptical view toward the claim that sex-reassignment procedures provide the hoped-for benefits or resolve the underlying issues that contribute to elevated mental health risks among the transgender population. While we work to stop maltreatment and misunderstanding, we should also work to study

and understand whatever factors may contribute to the high rates of suicide and other psychological and behavioral health problems among the transgender population, and to think more clearly about the treatment options that are available.

Conclusion

Accurate, replicable scientific research results can and do influence our personal decisions and self-understanding, and can contribute to the public discourse, including cultural and political debates. When the research touches on controversial themes, it is particularly important to be clear about precisely what science has and has not shown. For complex, complicated questions concerning the nature of human sexuality, there exists at best provisional scientific consensus; much remains unknown, as sexuality is an immensely complex part of human life that defies our attempts at defining all its aspects and studying them with precision.

For questions that are easier to study empirically, however, such as those concerning the rates of mental health outcomes for identifiable subpopulations of sexual minorities, the research does offer some clear answers: these subpopulations show higher rates of depression, anxiety, substance abuse, and suicide compared to the general population. One hypothesis, the social stress model—which posits that stigma, prejudice, and discrimination are the primary causes of higher rates of poor mental health outcomes for these subpopulations—is frequently cited as a way to explain this disparity. While non-heterosexual and transgender individuals are often subject to social stressors and discrimination, science has not shown that these factors alone account for the entirety, or even a majority, of the health disparity between non-heterosexual and transgender subpopulations and the general population. There is a need for extensive research in this area to test the social stress hypothesis and other potential explanations for the health disparities, and to help identify ways of addressing the health concerns present in these subpopulations.

Some of the most widely held views about sexual orientation, such as the “born that way” hypothesis, simply are not supported by science. The literature in this area does describe a small ensemble of biological differences between non-heterosexuals and heterosexuals, but those biological differences are not sufficient to predict sexual orientation, the ultimate test of any scientific finding. The strongest statement that science offers to explain sexual orientation is that some biological factors appear, to an unknown extent, to predispose some individuals to a non-heterosexual orientation.

The suggestion that we are “born that way” is more complex in the case of gender identity. In one sense, the evidence that we are born with

a given gender seems well supported by direct observation: males overwhelmingly identify as men and females as women. The fact that children are (with a few exceptions of intersex individuals) born either biologically male or female is beyond debate. The biological sexes play complementary roles in reproduction, and there are a number of population-level average physiological and psychological differences between the sexes. However, while biological sex is an innate feature of human beings, gender identity is a more elusive concept.

In reviewing the scientific literature, we find that almost nothing is well understood when we seek biological explanations for what causes some individuals to state that their gender does not match their biological sex. The findings that do exist often have sample-selection problems, and they lack longitudinal perspective and explanatory power. Better research is needed, both to identify ways by which we can help to lower the rates of poor mental health outcomes and to make possible more informed discussion about some of the nuances present in this field.

Yet despite the scientific uncertainty, drastic interventions are prescribed and delivered to patients identifying, or identified, as transgender. This is especially troubling when the patients receiving these interventions are children. We read popular reports about plans for medical and surgical interventions for many prepubescent children, some as young as six, and other therapeutic approaches undertaken for children as young as two. We suggest that no one can determine the gender identity of a two-year-old. We have reservations about how well scientists understand what it even means for a child to have a developed sense of his or her gender, but notwithstanding that issue, we are deeply alarmed that these therapies, treatments, and surgeries seem disproportionate to the severity of the distress being experienced by these young people, and are at any rate premature since the majority of children who identify as the gender opposite their biological sex will not continue to do so as adults. Moreover, there is a lack of reliable studies on the long-term effects of these interventions. We strongly urge caution in this regard.

We have sought in this report to present a complex body of research in a way that will be intelligible to a wide audience of both experts and lay readers alike. Everyone—scientists and physicians, parents and teachers, lawmakers and activists—deserves access to accurate information about sexual orientation and gender identity. While there is much controversy surrounding how our society treats its LGBT members, no political

or cultural views should discourage us from understanding the related clinical and public health issues and helping people suffering from mental health problems that may be connected to their sexuality.

Our work suggests some avenues for future research in the biological, psychological, and social sciences. More research is needed to uncover the causes of the increased rates of mental health problems in the LGBT subpopulations. The social stress model that dominates research on this issue requires improvement, and most likely needs to be supplemented by other hypotheses. Additionally, the ways in which sexual desires develop and change across one's lifespan remain, for the most part, inadequately understood. Empirical research may help us to better understand relationships, sexual health, and mental health.

Critiquing and challenging both parts of the “born that way” paradigm—both the notion that sexual orientation is biologically determined and fixed, and the related notion that there is a fixed gender independent of biological sex—enables us to ask important questions about sexuality, sexual behaviors, gender, and individual and social goods in a different light. Some of these questions lie outside the scope of this work, but those that we have examined suggest that there is a great chasm between much of the public discourse and what science has shown.

Thoughtful scientific research and careful, circumspect interpretation of its results can advance our understanding of sexual orientation and gender identity. There is still much work to be done and many unanswered questions. We have attempted to synthesize and describe a complex body of scientific research related to some of these themes. We hope that this report contributes to the ongoing public conversation regarding human sexuality and identity. We anticipate that this report may elicit spirited responses, and we welcome them.

34. Bailey and colleagues calculated these concordance rates using a “strict” criterion for determining non-heterosexuality, which was a Kinsey score of 2 or greater. They also calculated concordance rates using a “lenient” criterion, a Kinsey score of 1 or greater. The concordance rates for this lenient criterion were 38% for men and 30% for women in identical twins, compared to 6% for men and 30% for women in fraternal twins. The differences between the identical and fraternal concordance rates using the lenient criterion were statistically significant for men but not for women.

46. *Ibid.*, 1845.
47. Quantitative genetic studies, including twin studies, rely on an abstract model based on many assumptions, rather than on the measurement of correlations between genes and phenotypes. This abstract model is used to infer the presence of a genetic contribution to a trait by means of correlation among relatives. Environmental effects can be controlled in experiments with laboratory animals, but in humans this is not possible, so it is likely that the best that can be done is to study identical twins raised apart. But it should be noted that even these studies can be somewhat misinterpreted because identical twins adopted separately tend to be adopted into similar socioeconomic environments. The twin studies on homosexuality do not include any separated twin studies, and the study designs report few effective controls for environmental effects (for instance, identical twins likely share a common rearing environment to a greater extent than ordinary siblings or even fraternal twins).

117. For those interested in the methodological details: this statistical method uses a two-step process where “instruments”—in this case, family characteristics that are known to be related to maltreatment (presence of a stepparent, parental alcohol abuse, or parental mental illness)—are used as the “instrumental variables” to predict the risk of maltreatment. In the second step, the predicted risk of maltreatment is employed as the independent variable and adult sexual orientation as the dependent variable; coefficients from this are the instrumental variable estimates. It should also be noted here that these instrumental variable estimation techniques rely on some important (and questionable) assumptions, in this case the assumption that the instruments (the stepparent, the alcohol abuse, the mental illness) do not affect the child’s sexual orientation measures except through child abuse. But this assumption is not demonstrated, and therefore may constitute a foundational limitation of the method. Causation is difficult to support statistically and continues to beguile research in the social sciences in spite of efforts to design studies capable of generating stronger associations that give stronger support to claims of causation.

Part Two: Sexuality, Mental Health Outcomes, and Social Stress

1. Michael King *et al.*, “A systematic review of mental disorder, suicide, and deliberate self harm in lesbian, gay and bisexual people,” *BMC Psychiatry* 8 (2008): 70, <http://dx.doi.org/10.1186/1471-244X-8-70>.

2. The researchers who performed this meta-analysis initially found 13,706 papers by searching academic and medical research databases, but after excluding duplicates and other spurious search results examined 476 papers. After further excluding uncontrolled studies, qualitative papers, reviews, and commentaries, the authors found 111 data-based papers, of which they excluded 87 that were not population-based studies, or that failed to employ psychiatric diagnoses, or that used poor sampling. The 28 remaining papers relied on 25 studies (some of the papers examined data from the same studies), which King and colleagues evaluated using four quality criteria: (1) whether or not random sampling was used; (2) the representativeness of the study (measured by survey response rates); (3) whether the sample was drawn from the general population or from some more limited subset, such as university students; and (4) sample size. However, only one study met all four criteria. Acknowledging the inherent limitations and inconsistencies of sexual orientation concepts, the authors included information on how those concepts were operationalized in the studies analyzed—whether in terms of same-sex attraction (four studies), same-sex behavior (thirteen studies), self-identification (fifteen studies), score above zero on the Kinsey scale (three studies), two different definitions of sexual orientation (nine studies), three different definitions (one study). Eighteen of the studies used a specific time frame for defining the sexuality of their subjects. The studies were also grouped into whether or not they focused on lifetime or twelve-month prevalence, and whether the authors analyzed outcomes for LGB populations separately or collectively.

Meyer, “Prejudice, Social Stress, and Mental Health in Lesbian, Gay, and Bisexual Populations: Conceptual Issues and Research Evidence,” *Psychological Bulletin* 129, no. 5 (2003): 674–697, <http://dx.doi.org/10.1037/0033-2909.129.5.674>; Robert Graham *et al.*, *The Health of Lesbian, Gay, Bisexual, and Transgender People*, *op. cit.*; Gregory M. Herek and Linda D. Garnets, “Sexual Orientation and Mental Health,” *Annual Review of Clinical Psychology* 3 (2007): 353–375, <http://dx.doi.org/10.1146/annurev.clinpsy.3.022806.091510>; Mark L. Hatzenbuehler, “How Does Sexual Minority Stigma ‘Get Under the Skin’? A Psychological Mediation Framework,” *Psychological Bulletin* 135, no. 5 (2009): 707–730, <http://dx.doi.org/10.1037/a0016441>.

79. See, for instance, Ilan H. Meyer, “The Right Comparisons in Testing the Minority Stress Hypothesis: Comment on Savin-Williams, Cohen, Joyner, and Rieger (2010),” *Archives of Sexual Behavior* 39, no. 6 (2010): 1217–1219.

80. This should not be taken to suggest that social stress is too vague a concept for empirical social science; the social stress model may certainly produce quantitative empirical hypotheses, such as hypotheses about correlations between stressors and specific mental health outcomes. In this context, the term “model” does not refer to a statistical model of the kind often used in social science research—the social stress model is a “model” in a metaphorical sense.

62. An additional clarification may be helpful with regard to research studies of this kind. Significant differences in the means of sample populations do not entail predictive power of any consequence. Suppose that we made 100 different types of brain measurements in cohorts of transgender and non-transgender individuals, and then calculated the means of each of those 100 variables for both cohorts. Statistical theory tells us that, due to mere chance, we can (on average) expect the two cohorts to differ significantly in the means of 5 of those 100 variables. This implies that if the significant differences are about 5 or fewer out of 100, these differences could easily be by chance and therefore we should not ignore the fact that 95 other measurements failed to find significant differences.

63. One recent paper estimates that 0.6% of the adult U.S. population is transgender. See Andrew R. Flores *et al.*, “How Many Adults Identify as Transgender in the United States?” (white paper), Williams Institute, UCLA School of Law, June 30, 2016, <http://williamsinstitute.law.ucla.edu/wp-content/uploads/How-Many-Adults-Identify-as-Transgender-in-the-United-States.pdf>.

To the FL Board of Medicine:

Thank you for taking public comments regarding the very serious issue of whether minors and youth should be subjected to life and health-altering medicalization in service of “gender affirmation.” I am an attorney and volunteer US Regional Coordinator with Genspect (www.Genspect.org). As a lawyer helping young people who have detransitioned and find themselves irreparably harmed medically and psychologically from being “affirmed” by mental health and medical professionals, I urge you to carefully consider the experiences like that of the young man who asked me to submit his statement (attached, and below), as well as an article he wrote (attached).

There is nothing unique or extraordinary about “gender identity” to justify allowing minors to sacrifice their health — specifically, their future fertility, sexual function, and normal healthy bodily growth & development — for something so nebulous and fluid as “internal identity.” Body dysmorphia, emotional distress over our bodies and/or over how we are treated socially due to being male or female, or a fantasy that being opposite sex or sexless would be “more authentic,” is not best treated by indulging in the fiction of “sex change” or “choosing a gender,” but by ordinary talk therapy to seek self acceptance, build confidence, and find resilience.

Sincerely,

Candice Jackson

I started seeking transition when I was fourteen years old after reading about it online. I had a difficult home life—divorced parents, dysfunctional stepparents—and at school I had no friends and was frequently bullied, struck, and sexually harassed. Transition seemed like an escape: I could become someone else, someone happier. I saw glowing testimonies online from happy transitioners and was urged by these people to transition as soon as possible, before “male puberty” had destroyed my chance to “pass” as female. These strangers coached me on what to say to doctors and therapists, but I wasn't very good at following their advice. Despite erratic behavior, frequent emotional outbursts, a refusal to even wear women's clothes before I'd started hormones, and comorbid symptoms of depression (diagnosed) and autism (as yet undiagnosed) I was put on puberty blockers at 15 and estrogen at 16.

I got an orchiectomy around the time I was 20. At that point, I was completely delusional and disconnected from reality. I suspect this was due to a combination of the cross-sex hormones I was taking, psychological pressure from the same online strangers who'd pushed me to transition in the first place, and a family tendency towards mental illness. I'd changed my name multiple times in the months leading up to the surgery and desired to escape my body entirely and turn into a liquid. I

needed to be psychologically assessed before insurance would cover the procedure, but I was sent to a psychiatrist at the same facility which prescribed me my hormones who asked me questions off a form for about an hour and a half and then rubber-stamped me for surgery. Anything else would have been considered "gatekeeping", which is anathema to much of the trans community and many trans healthcare providers.

Today, I still suffer complications from the surgery. I regularly experience painful cramping, and since my endocrine system is broken I'll need to take exogenous testosterone for the rest of my life. From the estrogen, I have a large amount of breast tissue which will require surgery to remove, surgery which will cause more scarring and nerve damage even if nothing goes wrong. I have no idea what the long-term effects of my years on the "puberty suppressor" Lupron—a notoriously harsh chemotherapy medication, prescribed off-label—and cross-sex hormones will be, as there's very little literature on the subject. What I have read suggests I'll be at significantly higher risk than normal of developing dementia or schizophrenia.

I was a kid, already on psychiatric medication for depression and anxiety which influenced my decision-making ability, who was incapable of understanding what the consequences of transition would be. Transition isn't a treatment for anything. It's a cosmetic procedure which causes serious permanent medical problems, which is sold as a miracle cure for all sorts of unhappiness by an ideologically captured medical industry and a cult of fanatics who push it to kids. It should not be covered by insurance and it should never be performed on children.

I started seeking transition when I was fourteen years old after reading about it online. How I was trapped by gender ideology

By [Steven A. Richards](#)

Publishing in the Washington Examiner, May 25, 2022 06:30 AM

I became a male-to-female transsexual when I was only 15 years old. Bullying at school, instability at home, and a lack of close friends had left me looking for somewhere to belong, and the transgender movement happily provided one — at the cost of my health and sanity. Living as a transgender woman left me delusional, paranoid, and sick. Despite this, I stayed transgender for eight years. The nature of the transgender movement makes it almost impossible to escape and pushes the people within it to adopt radical beliefs and irreversibly harm themselves.

My new identity brought me friends, mentors, and a purpose in life. I went from being a lonely, insecure teenager to a member of a loving community engaged in a heroic battle against an evil society that desired my destruction. Left-wing oppression narratives disseminated online and in local “queer youth” groups run by adult members of the movement cast “cis” people as villains. “Transitioning” was a baptismal ritual in which I was cleansed of my wicked nature as a “cis male” oppressor and reborn as a virtuous “marginalized” person with a new name and body.

Adult transsexuals online coached me on how to convince my parents, doctors, and therapists that I was suffering from gender dysphoria. The term supposedly refers to an incongruence between one’s sexed body and internal sense of gender but is used among transgender people as a catch-all term for any negative emotion. It’s an attractive narrative for vulnerable teenagers who are struggling with their developing bodies, sexualities, and the looming responsibilities of adulthood.

Not long after turning 15, I started Lupron, a chemotherapy medication that is used off-label to halt puberty in gender-dysphoric adolescents. At 16, I started taking synthetic estrogen.

When I expressed doubts, I was reassured that all transgender people sometimes feel like they aren’t really transgender and that contentment waited at the end of the line if I just stuck with it. Clinging to this fantasy of a happy future where my transition was “complete” let me ignore that the medication made me feel worse, not better. I couldn’t think clearly. I started missing school. I developed chronic migraines. My bones ached. I became suicidal. I barely scraped up enough credits to graduate from high school.

The community explained away these negative treatment outcomes as manifestations of gender dysphoria and minority stress. My worsening health had nothing to do with my rejection of my body and identity or the experimental medications I was taking — it was all the fault of the transphobic society that tyrannized me. With this narrative, the community cultivated fear of the outside world in its members. I viewed anyone who questioned my transition or expressed concern for me as a bigot and disregarded them on principle. My parents learned to choose their words carefully so they wouldn’t set me off. I developed a panic response to hearing anyone express opinions that were deemed “problematic.” I suspected that everyone I passed on the street wanted me dead for being transgender.

At 19, the delusion became untenable. I was miserable and getting worse. However, ending my transition would mean my body masculinizing, and that idea terrified me. I didn't want to become one of the monstrous "cis males" I feared so much, or to lose my friends and my purpose. Maybe, I rationalized, it wasn't that my transition wasn't working — I just hadn't gone far enough.

Hoping it would relieve my distress, I went to my doctor and said I wanted an orchiectomy — to have my testicles removed. I needed two letters from specialists to get the procedure covered by insurance. My doctor wrote one immediately. She then referred me to a psychiatrist associated with her clinic who wrote the other after a single meeting. Within a few months, I'd gotten myself castrated. But the euphoria I'd been promised didn't materialize. Mutilating myself hadn't made me whole — it had only made me mutilated. Two years after my orchiectomy, I found myself in the same situation I'd been in before: Either I could admit that transitioning was never going to fix me, or I could go in for another surgery and hope that *this time*, it would be enough. I couldn't make myself believe the lie again.

Coming to terms with what I lost has been the hardest thing I've ever done. Deciding to de-transition cost me many close friends and forced me to rebuild my whole life. For some members of the movement — those who have lost ties with their family, who rely on the community for food and housing — de-transitioning isn't an option. Many of them still live in the miserable world I escaped from, hoping that the next step in their transition — a new name, a new set of pronouns, another year of hormones, another surgery — will bring them the happiness they were promised. But, as I learned, it never can.

Steven A. Richards de-transitioned after living as a transgender woman for eight years. He writes about the transgender movement and the philosophy of gender identity at cutofftree.substack.com.

Dear Florida Board of Medicine,

We thank you for taking up the vital question of regulating the so-called "gender-affirming" hormones and surgeries for young people.

As parents of these children, we have seen some very well-meaning but misinformed doctors recommend these radical life-changing interventions sometimes on the first or second visit. The myth that our children are getting "assessments" is propagated widely, but no requirements have ever been clearly articulated about which child or young person distressed with their gender role will benefit vs will be harmed. This intervention sterilizes 100% of children if administered according to the Endocrine Society's recommendations.

Older adolescents can get hormones with no assessments at all, and have their healthy body parts amputated by eager surgeons on little more than self-declaration of "trans identity." Many of our children are gay and autistic and have come to believe their very real distress is explained by the fact that they are "transgender" and that hormones and surgeries will help. They do not. We have seen our children's mental and physical health plummet following "gender-affirmation."

We also encourage you to require exploratory psychotherapy and to issue a clear statement that psychotherapy for gender dysphoria is not conversion. Our children and families need safe non-invasive alternatives to radical experimentation known as "gender affirmation."

Thank you for doing what you can to regulate this experiment on our vulnerable children.

The gender affirming model of care should not be available to minors whose bodies, brains, and identities are still developing. The UK is a few years ahead of us on this and are now finding out what a huge mistake adopting this model for minors has been, and other European countries are backtracking as well. These gender clinics make a lot of money over long periods of time for every child they medically transition, in spite of alarmingly high rates of continued suicidal ideation and desistance (see subreddit r/detrans for stories from those who regret their transitions and feel betrayed by this system). The parents are led to believe that the only solution to their child's dysphoria is to alter their bodies, often resulting in permanent sterilization and even more suicidal ideation, after realizing that the magical cure they were sold did nothing to help their underlying/co-occurring mental health issues.

Proponents of gender affirming care claim "Puberty Blocker" drugs (like Lupron, which is used for chemical castration) have no harmful long term side effects, but no studies have corroborated this. Natural puberty hormones themselves may even gender dysphoria after time, as suggested by responsible endocrinologists. Use of these blockers pver time is linked to lower bone density, stunted growth, and sexual disfunction in adulthood, and they are about 99% of the time immediately followed with cross-sex hormones, the harms of which should be well known.

I think the most alarming part is the high rate of autistic patients who come to these clinics for help. This is effectively sterilizing them and other gender non-conforming children for life. This is not the way to help these kids.

Thank you,

Lesley Hill
Parent

Dear Mr Vazquez,

Gender transitioning by use of opposite gender hormones or surgical interventions is an unproven and potentially catastrophic intervention and should never be used on adolescents or anyone who has not reached the age of adulthood.

Dear Paul,

I am writing to express my deep concern about the consideration of the Florida Board of Medicines gender affirming care. This push to accept such care is clearly ideologically driven and not based in either reason or sound medical evidence.

There is excellent evidence coming from our European colleagues that such treatment fails to show improvement in youth experiencing gender dysphoria. In the UK an Independent systematic review of the data concluded that evidence was very low regarding hormonal interventions in gender dysphoric youth disorder. Finland, as a country, adopted a position of early transitioning of pediatric patients and they too showed a lack of improvement in mental health and have now moved to psychotherapy as first line therapy.

As a recent Medscape article pointed out by Dr William Malone Endocrinologist

- “Most cases of early childhood-onset gender dysphoria self-resolve. [Eleven out of 11 studies](#) that followed the trajectory of gender-variant youth show that the most common outcome is natural resolution of gender dysphoria [around or after puberty](#). Among those diagnosed as having gender identity disorder, 67% no longer met the diagnostic criteria as adults; among those subthreshold for diagnosis, [93% were not gender dysphoric](#) as adults. Gender dysphoria in childhood is a far better predictor of future homosexuality than of future trans identity.
- The future trajectory of people whose transgender identity emerged during or after puberty is entirely unknown. No one has studied future trajectories of patients whose transgender identity emerged for the first time after the onset of puberty — a previously rare but now increasingly common presentation. Growing numbers of young detransitioners and desisters are precisely from this demographic, suggesting that a transgender identity that emerges in adolescence may not be durable.
- Social transition does not improve mental health outcomes. Recent

studies show that while socially transitioned children can thrive in the short term, they [do not fare any better](#) than their non-socially transitioned dysphoric peers. It appears that [peer relations](#), not the social transition status, predict mental health in gender-dysphoric children. We don't yet know the long-term trajectories of socially transitioned minors, but [emerging evidence](#) suggests that they may [be more likely to persist](#) with gender-related distress rather than outgrow it, as previously observed. This in turn necessitates decades of invasive and risky medical interventions. In fact, the Dutch researchers who pioneered the protocol used to medically transition minors (see Box) [explicitly and strongly discouraged](#) social transition of children and early adolescents.

- Nearly 100% of children who begin puberty blockers will proceed to cross-sex hormones and surgeries. The two main studies that have [evaluated the effects of puberty blockers](#) on mental health found [no improvements](#) or [improvements of marginal clinical significance](#). Both studies are also at critical risk of bias due to the absence of control groups. [Four additional studies looking](#) at the mental health effects of puberty blockers were plagued by [design limitations](#) and also [failed](#) to show any convincing positive effects on psychological health. However, one effect of puberty blockers has been consistently replicated: [At least four studies show](#) that [virtually all of the children who start puberty blockers proceed to cross-sex hormones](#). This suggests that rather than being a pause button, puberty blockers may serve as the "gas pedal" for gender transition.

- Most of the long-term health risks are largely unknown. No long-term studies exist of patients who underwent medical transition as teens or young adults. Therefore, our ability to assess risks vs benefits is limited. Puberty blockers have been demonstrated to [significantly impair bone health](#), and it is not clear whether this will result in future [osteoporosis](#). Cross-sex hormones are associated with [roughly 3-5 times the risk](#) for [heart attacks and strokes](#), though long-term studies are of insufficient quality for accurate risk assessments. Other risks associated with these endocrine interventions will come to light as the practice continues to scale and as young people spend years and decades on these interventions. The risks to fertility are largely unknown, but it is almost

certain that if puberty blockers are given at the early stages of puberty and followed by cross-sex hormones, sterility will result.

- The medical pathway of "affirmative care" rests on a single Dutch study that is not applicable to the current populations of gender-dysphoric youth. Most of the youth presenting for care today would have been explicitly disqualified by the original Dutch protocol, as most have significant mental health comorbidities and post-puberty onset of trans identities. This fact has been recognized by the principal investigators of the Dutch protocol itself, who have [recently begun to sound the alarm](#) about the [potential misapplication of their protocol](#) and who suggest that psychotherapy — rather than gender reassignment — is more appropriate for many of the currently presenting cases.”

The fundamental principle in good medical practice is “do no harm”. The evidence clearly shows that harm is being done by these hormonal transitions and should not be encouraged or promoted. An individual is born either male or female and this accords with both reason and common sense. We as physicians should be working for the wholeness and well being of your patients and not contributing to further distress.

I appreciate your consideration of my comments in your deliberations.

Sincerely,

Margaret J. Hart, DO, FAAFP

Dear Sir,

My husband and I are both family physicians and parents of six children opposed to hormonal medications and genital altering surgeries for minor children. These treatments are potentially harmful and surgical procedures are irreversible. We have many patients who initially contemplate such treatments and then change their mind when they are older. Moreover the harms of hormones when started as adolescents (increased rates of cancer, thrombosis, etc) are well established. Finally, we believe that children and adolescents need a period of counseling and deep introspection to reflect on this kind of decision. It should not be rushed.

Children and adolescents are apt to change their minds frequently about a myriad of issues. Why would we not require them to be an adult to make this kind of permanent, altering life decision?

Dear Dr. Paul Vazquez and the FL BOM,

I am a Psychiatric APRN here in FL.

Please protect the children and adolescents in FL from the irreversible effects of puberty blockers, cross sex hormones and surgery.

As a Psych NP, I have had several encounters with transgender individuals. One adult wanted me to sign off on a hysterectomy that an OB/GYN surgeon would not do without psychiatry approval. She told me initially that the surgeon needed to do the surgery because of polycystic ovarian syndrome. When I questioned surgery as a treatment for Polycystic Ovarian surgery she said that she is transgender. I then asked if she was planning to have mastectomies and she said she was. However, prior to asking for approval from me as a Psych NP for a hysterectomy, she had never mentioned any of this is the few times I had seen her. When I mentioned that it would be difficult for me to agree to this as it would be a liability if she changes her mind at some point in time, she got angry and hung up. She did not schedule another appointment. Unfortunately, her insurance had lapsed and I was never paid for that appointment. This is an adult who did not tell me the truth initially. She did not tell me she had changed insurance or that it had lapsed. She did not in any way present as male. She had been in the psych hospital many, many, many times and was extremely mentally ill.

It is well known that adolescents brains do not fully develop until age 25. They are not allowed to drink until 21 or buy a gun. Should they be allowed to make a decision about something that has not been clearly researched and studied and is a trend among the youth causing irreversible damage to their young bodies? I do not think so. Twenty-five should be the minimum age to give such a consent. Until then, psychological care and living several years as the opposite sex should be required first as it was in the past for trans surgeries.

I had another trans young man in his early 20s. "He" had had a complete hysterectomy and mastectomies and had been in the hospital due to suicidal ideation after the surgeries. In spite of this psych hospitalization, his parents took him back to Texas to have a phalloplasty. After returning, "his" girlfriend broke up with him and he ended up in the psych hospital again. Thankfully, he did not return to my office which was a relief to me as it was very traumatic to me to care for this young girl who had had such body altering surgery at such a young age and was clearly not mentally stable when they did the phalloplasty. "He" had just been in a psych hospital the month before the surgery.

What I see is that no one is assessing the psychological problems these young people have. I only see adults so I have not had anyone younger than 18 but a psychologist colleague of mine is seeing many, many young transgender clients in the hospital for suicide attempts, etc.

Fund a huge research study. You will have more than enough young people willing to sign up. I don't know what the State of FL or BOM liability would be if you would do such a study. Can it pass a Do No Harm, Informed Consent process to ethically do such a study? Puberty blockers were never studied long term in transgender individuals. It is being used totally off label along with the cross sex hormones in adolescent young people who will never recover.

I do not believe any insurance that I might be paying for, including Medicaid which is funded by my taxes should be paying for these damaging, experimental treatments. If someone wants to pay cash, as has always been the case in the past, and they are 25 years old, then it can be up to them.

Please protect the consciences of those like myself, who are not comfortable with this experimental treatment. I have been a member of the Christian Medical and Dental Association since 1989 before I graduated as an NP in 1990. They have an ethics statement on transgender issues. See items D&E below

for the negative effects of hormone blockers, cross-sex hormones and surgery. I apologize the references did not copy clearly. The original is attached.

Thank you for your time in reading this.

CMDA Ethics Statement Transgender Identification

Preamble

A novel way of thinking about one's body has entered into popular culture. "Transgender" individuals refer to their "gender" as a sexual identity that may be male or female, something in between, or neither. This self-identification differs from, and takes priority over, their biological sex as recognized in their chromosomal DNA and innate physical sexual characteristics. The naming of gender as a category set apart from sex is an idea foreign to the holistic view of the person as understood within Christianity. Christians affirm the biblical understanding of humankind as having been created male and female, with the two sexes having equal dignity and a complementary relationship to each other.

At the heart of disagreement over transgenderism is a difference in worldviews. If the human body is nothing more than the product of mindless, random, purposeless physical forces, then one may do with it what one wishes, even to demand medical and surgical cooperation in projects to alter, amputate, or reconstruct normal tissue to conform to the patient's revised psychological sense of identity. If, on the other hand, our bodies are an inseparable aspect of our true selves and are a good gift from God, who has designed the sexes to be wonderfully paired, and who has a purpose for humanity, then respecting the gift of given sexual identity and the ensuing moral obligations to our neighbors is the surest path to human flourishing. Both worldviews share the recognition that humanity is broken and in need of renewal, but they look to different answers for healing. Christians seek not a reconfiguring of the body, but a spiritual transformation of the mind to become more like Christ; not rejecting the gifts of God, but welcoming God's purposes and demonstrating God's love by loving our neighbors. This love of neighbors includes loving our transgender neighbors as persons who, like all people, are created in God's image. However, loving them and validating them as people does not mean agreeing with their ideologies or use of language.

The Christian Medical & Dental Associations (CMDA) believes that healthcare professionals should not be forced to violate their conscientious commitment to their patients' health and welfare by being required to accept and participate in harmful gender-transition interventions, especially on the young and vulnerable. CMDA affirms the obligation of Christian healthcare professionals caring for patients struggling with gender identity to do so with sensitivity and

compassion, consistent with the humility and love that Jesus modeled and commanded us to show all people.

Introduction

CMDA affirms that all human beings are created in the image of, and beloved by, God. All human beings are our “neighbors”, and are to be loved by us as we love ourselves. All human beings possess intrinsic dignity and are worthy of equal respect and concern from Health Care Professionals.

CMDA considers “sex” (i.e., male or female) to be an objective biological fact (see section B.1. below). CMDA affirms the historic understanding of gender as referring to biological sex and the enduring biblical understanding of humankind as having been created male and female and that this is good. CMDA acknowledges the current cultural use of the word “gender” to refer to one’s sense of identity as male or female. CMDA cannot support the recent usage of the term “gender” to emphasize an identity other than one’s biological sex, that is, a subjective sense of self based on feelings or desires leading to identifying somewhere on a fluid continuum of gender identity.^{1,2,3,4} (See Glossary at the end of this document)

CMDA cannot support the prevailing culture’s acceptance of an ideology of unrestrained sexual self-definition that, in celebrating gender fluidity and gender transition efforts, is indifferent to biological reality and opposed to the biblical understanding of human sexuality. Further, CMDA is alarmed that some proponents of transgender ideology, through activism and intimidation, are insisting that healthcare professionals cooperate with and affirm their beliefs in gender fluidity, even if the healthcare professionals believe that such cooperation and affirmation would be doing harm to their patients. This violates the most fundamental core value of medicine since Hippocrates, that of caring only for the good and benefit of the patient while abstaining from all unnecessary harm. The evolving scientific and medical facts demonstrate that the mutilation of normal tissue and profound disruption of normal physiology that occur during gender transition procedures are very difficult to justify, as this constitutes deliberate harm.

CMDA affirms the obligation of Christian healthcare professionals caring for patients struggling with gender identity to do so with sensitivity and compassion. CMDA holds that attempts to radically reconstruct one’s body surgically or hormonally for psychological indications, however, are medically, ethically, and psychologically inappropriate. These measures alter healthy tissue and increasingly are not supported by scientific research evaluating behavioral, medical, and surgical outcomes.^{5,6,7,8,9,10,11}

Accordingly, CMDA opposes medical assistance with gender transition on the following grounds:

A. Biblical

1. God created humanity as male and female (Gen 1:27, 5:2; Matt 19:4; Mark 10:6). God's directives – to have dominion over the earth and to fulfill his goals of procreation, union, fellowship, and worship – are given to men and women together (Gen 1:26-28, 2:18-24).
2. Men and women are morally and spiritually equal (Gal 3:28) and are created to have roles that are in some respects alike and in other respects wonderfully complementary (Eph 5).
3. All people are loved by God (John 3:16-17). All struggle with moral failure and fall short of God’s standards (Rom 3:10-12) and, therefore, need the forgiveness that God provides through Christ alone (John 3:36; Rom 3:22-24; Col 1:15-22; 1 Tim 2:5-6).
4. For the Christian, all of ethics, grounded in God’s moral law, is based upon the first and

second greatest commandments: to love God with all our heart, soul, and mind, and to love our neighbors as ourselves (Matt 22: 37-40). If we encourage others to sin sexually, just as if we sin sexually ourselves, we are violating these two commandments. We violate the first greatest commandment by failing to love God in his holiness, wisdom, and rightful place as our Creator, and we violate the second greatest commandment as we fail to respect ourselves and each other by abetting lives of disobedience, deception and unholiness (1 Cor 6: 13b-20). Love may include a corrective component that should be applied in an appropriate and timely manner; affirmation can be enablement.

5. We live in a fallen world (Gen 3), and we all come into this world as fallen creatures with a sinful nature. (Rom 3:9-12). The fall is expressed in nature and in humanity in many ways, including sexuality. Confusion of gender identity is but one example of the fall, as are also marital breakdown and sexual immorality (Rom 1:24-32; Eph 5:3).
6. A lifestyle that is directed by pursuing sexual desires, or driven by personal sexual fulfillment, misses the divinely ordained purpose of sex, which is for procreation, bond creation, and re-creation¹² and for facilitating unity in the lifelong commitment of marriage, which is defined as being between one man and one woman. Heterosexual marriage fosters a secure and nurturing environment for children and it reflects the unity of Christ and the Church (Exod 20:1-18; Lev 20:10-21; Rom 1; Eph 5:23-33) (see also CMDA Statement on Homosexuality).
7. Believers in Christ, though having inherited the sinful nature common to all humanity, also receive a new nature in Christ. As the old nature, being crucified with Christ, dies, our new redeemed nature, sealed by Christ's bodily resurrection, is actively transforming our minds and hearts to be more and more like Christ. This transformation is spiritual, not sexual, and is God's work, not something of our own design (Psalm 100:3; Rom 12:2; Col 1:27).

B. Biological

1. Sex is an objective biological fact that is determined genetically at conception by the allocation of X and Y chromosomes to one's genome, is observable at birth, is found in every nucleated cell, and is immutable throughout one's lifetime. Sex is not a social construct arbitrarily assigned at birth and cannot be changed at will.^{2,3,13}
2. Human beings are sexually dimorphic. Male and female phenotypes are the outworking of sex gene expression, which shapes sex anatomy, determines patterns of sex hormone secretion, and influences sex differences in the development of the central nervous system and other organs.^{2,3,14}
3. Procreation requires genetic contributions from both one man and one woman.^{15,16}
4. CMDA recognizes that exceedingly rare congenital abnormalities exist in which phenotypic sex characteristics are not what is expected from the genotype.^{1,2} These disorders of sex development are of a diverse nature, but usually impair fertility.³ Treatment (including non-intervention) of these disorders differs categorically from transgender interventions, which are performed on persons with no inherent defect in sex organ development, function, or fertility. Anomalies of human biological sex are conditions rather than identities, something one has rather than who

one is. Disorders of sex development are not the fault of the patient, do not invalidate God's design in creation, and do not constitute a third sex.^{17,18,19,20}

5. Gender dysphoria²¹, the condition of experiencing discomfort or distress at one's sex and preferring a different "gender" identity, has not to date been linked to a genetic cause and

is a psychological disorder of unclear and complex origin.^{22,23,24} Gender dysphoria may cause profound distress. It should not be confused with transient gender-questioning that can occur in early childhood.^{25,26,27,28,29,30}

C. Social

1. CMDA recognizes that gender identity issues are complex. The inclination to identify with the opposite sex or as some other gender identity along a spectrum may have non-genetic biological,³¹ familial,^{32,33} and social^{27,28,34} causes that are not personally generated by particular individuals.²¹⁻³⁰
2. In our current social context, there is a prevailing view that removing traditional definitions and boundaries is a requirement for self-actualization. Thus, Christian healthcare professionals find themselves in the position of being at variance with evolving views of gender identity in which patients or their subcultures seek validation by medical professionals of their transgender desires and choices through medical or surgical solutions to gender dysphoria. Although such desires may be approved by society at large, they are contrary to a biblical worldview and to biological reality and thus are disordered.
3. In contrast to the current culture, CMDA believes that finding one's identity within God's design will result in genuine human flourishing. CMDA believes, moreover, that social movements which assert that gender is a choice are mistaken in defining gender as something independent of sex. Authentic personal identity consists in social gender expression that is congruent with one's natural biological sex but not limited to stereotypes. CMDA recognizes that this traditional view has become counter-cultural; however, CMDA affirms that God's design transcends culture.
4. CMDA opposes efforts to impose transgender ideology on all society by excluding, suppressing, marginalizing, intimidating, or portraying as hateful those individuals and organizations that disagree on scientific, medical, moral, or religious grounds. Such attacks are contrary to the freedoms of speech and religious liberty that lie at the very foundation of a just and democratic society.
5. There is a social contagion phenomenon luring young people into the transgender culture.^{32,33}
6. CMDA opposes efforts to compel healthcare professionals to grant medical legitimacy to transgender ideologies.^{35,36,37,38,39,40} Cooperation with requests for medical or surgical gender reassignment threatens professional integrity by undermining our respect for biological reality, evidence-based medical science, and our commitment to non-maleficence (see CMDA Statement on Healthcare Right of Conscience).
7. Promotion of transgender ideology by educational institutions and teachers to children

as young as 5 years of age is a danger to the health and safety of minor children (for medical reasons elaborated in the next section).^{41,42,43,44,45,46,47} Education should respect the value of every human being; in supporting and affirming the student, it need not affirm every desire.

8. No educational institution or teacher should ever block parents from supervising their child's education or withhold from them knowledge of the educational content.

D. Medical

1. Transient gender questioning can occur during childhood. Most children and adolescents who express transgender tendencies eventually come to identify with their biological sex during adolescence or early childhood.^{48,49,50,51,52,53} There is evidence that gender dysphoria is influenced by psychosocial experiences and can be exacerbated by promoters of transgender ideology.^{27,33} Early counseling for children expressing gender dysphoria is critical to treat any underlying psychological disorders, including depression, anxiety, or suicidal tendencies, and should be done without promoting attempts for gender transitioning.

2. Hormones prescribed to a previously biologically healthy child for the purpose of blocking puberty inhibit normal growth and fertility, cause sexual dysfunction, and may aggravate mental health issues. Continuation of cross-sex hormones, such as estrogen and testosterone, during adolescence and into adulthood, is associated with increased health risks including, but not limited to, high blood pressure, blood clots, stroke, heart attack, infertility, and some types of cancer.^{51,54,55,56,57,58,59,60}
3. Although some individuals report a sense of relief as they initiate the transitioning process, this is not always sustained or consistent over time. Some patients regret having undergone the transitioning attempt process and choose to detransition, which involves additional medical risk and cost.^{56,61,62,63,64}
4. Among individuals who identify as transgender, use cross-sex hormones, and undergo attempted gender reassignment surgery, there are well-documented increased incidences of depression, anxiety, suicidal ideation, substance abuse, and risky sexual behaviors in comparison to the general population.^{21,22,23,61,65,66,67} These health disparities are not prima facie evidence of healthcare system prejudice. These mental health co-morbidities have been shown to predate transgender identification.^{24,25,26,27,28,34,68} Patients' own gender- altering attempts and sexual encounter choices (or, in the case of children, their parents' choices on their behalf) are among the factors relevant to adverse outcomes in transgender-identified patients.
5. Although current medical evidence is incomplete and open to various interpretations, some studies suggest that surgical alteration of sex characteristics has uncertain and potentially harmful psychological effects and can mask or exacerbate deeper psychological problems.^{7,8,9,69} Evidence increasingly demonstrates that there is no reduction in depression, anxiety, suicidal ideation, or actual suicide attempts in patients who do undergo surgical transitioning compared to those who do not.^{7,70} The claim that sex-reassignment surgery leads to a reduction in suicide and severe psychological problems is not scientifically supported.^{64,71,72,73}
6. A patient has died because the medical records conveyed only the individual's gender

preference, and not their biological sex, leading to misdiagnosis and medical catastrophe.^{74,74}

E. Ethical

1. Restoring and preserving physical and mental health are goals of medicine, but assisting with or perpetuating psychosocial disorders are not. Accordingly, treatment of anomalous sexual anatomy is restorative.⁷⁵ Interventions to alter normal sexual anatomy and physiology to conform to identities arising from gender dysphoria are disruptive to health.^{9,76}
2. Medicine rests on science and should not be held captive to desires or demands that contradict biological reality. Sex reassignment operations are physically harmful because they disregard normal human anatomy and function. Normal anatomy is not a disease; dissatisfaction with natural anatomical and genetic sexual makeup is not a condition that
can be successfully remedied medically or surgically.
3. The medical status of gender identity disorder (currently termed gender dysphoria) as a mental or psychosocial disorder should not be discarded.
4. The inability of men, including men who identify as women, to bear children is not an illness to be remedied by medical or surgical means, such as uterine transplantation.⁷⁷ Uterine transplantation into biological men cannot be justified medically (See CMDA Statement on Enhancement and CMDA Statement on Transplantation).
5. Fundamentally, it is unrealistic to remove or mutilate normal organs and tissue and to disrupt normal physiology, and then to expect normal function. This illustrates the reality that complete gender transitioning is not medically possible.
6. Christian patients struggling with transgender inclinations face not only the psychological distress of a desire for a gender identity different from their biological sex, but may also face the spiritual distress that comes to anyone who follows a path in life that departs from God's design for humanity. Hormonal or surgical interventions cannot resolve spiritual distress but may lead to further spiritual turmoil. These, our neighbors, need and deserve the spiritual, psychological, and social support of the Christian community.
7. CMDA is especially concerned about the increasing phenomenon of parents enabling their gender-questioning children or adolescent minors to receive hormones to inhibit normal adolescent development. Children and adolescents lack the developmental cognitive capacity to assent or request such interventions, which have lifelong physical, psychological, and social consequences.⁵⁶ Facilitating hormonal or surgical transitioning interventions for those who have not reached the age of majority is a form of child endangerment and abuse.⁶⁴ Highly affirming parents have been shown to not improve the mental health statistics of transgender-identified children.⁷⁸
8. Many diseases affect men and women differently, according to biological sex

phenotype. Transgender designations may conceal biological sex differences relevant to medical risk factors, the recognition of which is important for effective healthcare and disease prevention. As accurate documentation is necessary for good patient care, healthcare professionals should document the patient's biological sex and any alterations of gender characteristics in the medical record.^{2,13,54,57,79,80,81} It is appropriate and should not be interpreted as disrespectful for healthcare professionals to discuss their patients' biological sex with them as part of their medical care.^{80,81}

9. For the overall health of the patient, the healthcare professional should be forthright with the patient that addressing the individual's sexual reality is necessary for appropriate medical care and should not be interpreted as disrespect.

CMDA Recommendations for the Christian Community

1. A person questioning or struggling with gender identity should evoke neither scorn nor enmity, but rather the Christian's concern, compassion, help, and understanding. Christians must respond to the complex issues surrounding gender identity with grace, civility, and love.
2. Christians should avail themselves of opportunities to help the larger society understand that male/female sexes are complementary and permanent. Both are good and part of the created order. For the reasons elaborated above, CMDA believes that attempting to define gender as fluid and changeable through technical means will have grave spiritual, emotional, cultural, and medical repercussions.
3. The Christian community, beginning with the Christian family, must resist stereotyping or rejecting individuals who do not fit the popular norms of masculinity and femininity. At the same time, parents should guide their children and adolescent minors in appropriate gender identity development. For children and adolescents experiencing gender dysphoria, the Christian community should provide appropriate role models and biblically informed guidance.
4. The Christian community must condemn hatred and violence directed against those struggling with questions of gender identity.
5. Since Christians are to love their neighbors as themselves, they are to love those struggling with gender dysphoria or incongruence of desired gender with biological sex. Love for the person does not condone or facilitate gender transitioning treatments.
6. In obedience to God who commands his followers to love one another, and for the sake of the common good, Christians should welcome inclusion of transgender-identified individuals into their communities, as we are all broken and sinners, not more or less valuable than each other. Transgender-identified individuals have the same rights shared by all other humans. We oppose granting special rights and privileges based on transgender identification. These special rights can negatively impact the rights of others (e.g., bathroom designations that allow biological males access to shared female restrooms or showers, female athletic competitions that give participating biological males an unfair physiologic advantage, affirmative actions, or claims for unnecessary

medical interventions).

7. The Christian community is to be a refuge of love for all who are broken – including the sexually broken – not to affirm their sin, nor to condemn, but to shepherd them to Jesus, who alone can forgive, heal, restore, and redirect to a godly, honorable, and virtuous way of life. God provides the remedy for all moral failure through repentance and faith in Jesus Christ and the life-changing power of the Holy Spirit. Though healing may be incomplete on earth, the promise of complete healing for those who are in Christ will ultimately be fulfilled in heaven.

CMDA Recommendations for Christian Healthcare Professionals

1. CMDA advocates that all Christian healthcare professionals provide ethically and medically competent care to all patients, including those who identify as transgender. Such care requires compassion, an open and trusting dialogue, a genuine effort to understand and respond to the patient's psychological distress when present, and acceptance of the person without agreeing with the person's ideology or providing a requested sex-altering intervention.
2. CMDA believes that the appropriate medical response to patients with gender dysphoria is to help them understand that they are people God loves and who are made in his image, even when their choices cannot be validated. Christian healthcare professionals should validate their right as individuals in a free society to make decisions for themselves. This right, however, does not extend to obligating Christian and other healthcare professionals to prescribe medication or perform surgical procedures that are harmful (see CMDA Statement on Healthcare Right of Conscience).
3. CMDA believes that Christian healthcare professionals should not initiate hormonal and surgical interventions that alter natural sex phenotypes. Such interventions contradict one of the basic principles of medical ethics, which is that medical treatment is intended to restore and preserve health, and not to harm.
4. CMDA believes that prescribing hormonal treatments to children or adolescents to disrupt normal sexual development for the purpose of attempting gender reassignment is ethically impermissible, whether requested by the child, the adolescent, or the parent (See CMDA Statement on Limits to Parental Authority in Medical Decision-Making, and CMDA Statement on Abuse of Human Life).
5. Supporting a patient's pursuit of gender transitioning procedures is neither loving nor the best means to help that individual who is experiencing gender dysphoria.

CMDA Recommendations Regarding Nondiscrimination

1. Mutual respect and civil discourse are cornerstones of a free society, and so is truthfulness. In the context of health care, identification of sex and gender has both interpersonal and medical implications. In regard to medical documentation, the medical record should document the sex observed at birth even when the patient expresses a different gender preference or has obtained a legal change in gender status.
2. Christian healthcare professionals, in particular, must care for their patients with gender identity disorders in a non-judgmental and compassionate manner, consistent with the

humility and love that Jesus modeled and commanded us to show all people. When questioning transgender ideology, Christian healthcare professionals should do so with an attitude of humility and love.

3. Those who hold to a biblical or traditional biological view of human sexuality, including CMDA members, should be permitted to question transgender ideology free from exclusion, oppression, or unjust discrimination. Healthcare professionals who hold the position that transgender identification is harmful and inconsistent with the will of God should not be stigmatized or accused of being bigoted, phobic, unprofessional, or discriminatory because of their desire to adhere to biological and medical reality as a sincerely held (and widely shared) belief.
4. To decline to provide a requested gender-altering treatment that is harmful, or is not medically indicated, does not constitute unjust discrimination against persons. CMDA affirms that Christian and other healthcare professionals should not be coerced or mandated to provide or refer for services they believe to be morally wrong or medically harmful to patients (See CMDA Statement on Healthcare Right of Conscience).
5. Healthcare professionals must not be prevented from providing counseling and support to patients with gender dysphoria and who request assistance with accepting and maintaining their biologic sex and gender identity.

GLOSSARY

Person and Image of God

According to the Bible, human persons (as opposed to divine and angelic persons) are embodied from conception onward. At conception, at least one genetically unique human person is formed (twinning may occur during the first two weeks of pregnancy). So the psalmist offers a hymn to God in Psalm 139, “you created my inmost being, you knit me together in my mother’s womb. I praise you because I am fearfully and wonderfully made; your works are wonderful, I know that full well. My frame was not hidden from you when I was made in the secret place, when I was woven together in the depth of the earth, Your eyes saw my unformed body; all the days ordained for me were written in your book before one of them came to be” (13-16 NIV). Human persons are, however, the only persons who are made in the *imago Dei* (image of God). Thus,

Jesus—fully God and fully human—is “image of the invisible God, the firstborn over all creation” (Colossians 1:15). Likewise, according to Genesis, “God created mankind in his own image, in the image of God he created them, male and female he created them” (Genesis 1:27).

Sex

Human sex and sexuality are aspects of God’s good, well-ordered creation. From the beginning he made humans sexual beings (Genesis 2:15-25). Humans are sexual beings who procreate through sexual reproduction. Sex is objective, identifiable, immutable, determined at conception, stamped on every nucleated cell, and highly consequential.^{82,83,84,85}

There are 2 sex cells or gametes, sperm and ova. There is no third. Human fallenness incurred pervasive distortions in humanity, including disorders of sexual biology, none of which limits either God’s love for each of us, or the inestimable value of creation in His image.

Sexuality

Human sexuality is a “very good” component of God’s well-ordered creation (Genesis 2:15-25). Sexuality is a broad and easily confusing term usually requiring contextualization for clear communication. As noted by McHugh and Mayer, sexuality incorporates desires,

attractions, behaviors, and/or identity.¹⁶ Furthermore, sexuality may vary regarding timing, intensity, consistency, and exclusivity. Its elements may be sporadic, temporary, pervasive, or long-term. Sexual expression may be healthful or unhealthful.

Because of human fallenness, sexuality has become disordered. The goods of sexuality are often distorted by pathologies in biology, psychology (e.g., sexual addiction or adultery), and society (e.g., sexual revolution and polyamory). Redeeming sex requires the reordering of human desires and practice. Celibacy outside of marriage, sexual fidelity within heterosexual marriage between one man and one woman, and the presumption in favor of procreation are ways human sex and sexuality may be redeemed.

Christian Worldview

A worldview is a way of seeing and understanding the phenomenon of the world around us. Like lenses of eyeglasses, one's worldview provides a set of interpretive assumptions that enable us to make sense of our experience. One's worldview is how one answers the big questions of life, such as: Is the world real? What is the nature of reality? Is there a God? What can we know about God? How do I know anything at all? Is matter all there is? Is there a supernatural? The orthodox Christian worldview is grounded on certain theological affirmations found in the Bible, which Christians believe to be the revealed word of God, and summarized in the great confessions in the history of Christianity, for instance, in the Nicene (325 AD) and Apostles (390 AD) Creeds.

The Fall and Human Fallenness

Rather than remaining faithful to God's will and purposes, Adam and Eve fell from their original righteous state through disobedience (i.e., sin). Their sin brought with it not only immediate deleterious consequences for them (Genesis 3), but for the entire created order thereafter. Those well-ordered desires to love God and love another have become disordered by human depravity. Love for God and others was replaced with hatred, envy, and murder (as in the case of Cain and Abel). The goods of honest labor were turned into toil and struggle in a creation that is now filled with corruption, death, disease, pain, and hardship. After the fall, human beings are born with a propensity to disobedience, selfishness, and sin.

Intrinsic Dignity

Because human beings are made in God's image, they possess an intrinsic dignity. They should never be used as a means to an end, but as ends in themselves. Their lives have sacred value and they should not be harmed without just cause. This dignity is intrinsic and equal for all human beings, not varied and dependent on level of function, cognitive or physical, presence or absence of injury or disability, age, or other traits or features for which human beings tend to impute upon others value or worth. Human dignity has been the foundation of Western ethics and jurisprudence and has been enshrined in secular language in the Nuremberg Code and global treaties in science, medicine, and public policy since that time.

Love

Christians are called to love God with all their hearts, souls, minds, and body and to love their neighbors as themselves (Deut 6:5; Lev 19:18; Mark 12:29-31). Love is a disposition of heart and life that impels one person to treat another person with respect and dignity quite apart from ethnicity, economic, social status, or what the individual can exploit or receive from the other. Furthermore, love seeks the best for another individual without the expectation any kind of recompense or remuneration.

Holiness

With respect to God, holiness is the supreme attribute of all of God's attributes, setting the God of the Bible apart from all other deities. The Triune God is holy in his love, righteousness, justice, wrath, and mercy (among other attributes). With respect to human beings and objects, holiness is being set apart for sacred use (as with the Old Testament

Temple). Christian holiness is the aspiration to live a life “set apart” from the corruptions of the world, and instead committed to fidelity, trust, and dependence on God, patterning ourselves after Jesus Christ.

Repentance

Repentance is a response to the recognition of harm done, either by commission or omission. The word used in the New Testament (metanoia) means to “turn and go in the other direction.” To repent, then, is to acknowledge one’s sin and turn back toward God. Turning back toward God may include ceasing to perform or pursue sinful acts, reconciling with those who have been harmed, or restoring items or relationships that have been damaged through one’s behavior. Repentance is not a one-time event, but a disposition of character.

Faith

Faith is the virtue of trust and dependence on God and his promises, believing and acting in ways consistent with that confidence (Hebrews 11).

Sexual Orientation

Orientation essentialism – the belief that a person has a given sexual orientation, be it innate or resulting from various combinations of biology and environment -- is an ideological position that has gained strong purchase in modern culture.

Per academics McHugh and Diamond, polar opposites in many ways:

Psychiatry professor Paul McHugh states, “Sexual orientation is a complex and amorphous phenomenon There is no scientific consensus on how to define sexual orientation, and the various definitions proposed by experts produce substantially different classes.”⁸³

Psychology professor Lisa Diamond, “There is currently no scientific or popular consensus . . . that definitively ‘qualify’ an individual as lesbian, gay, or bisexual.”⁸⁵

Genetic essentialism, like its orientation counterpart, is similarly ideological.

- • In a 2011 *Psychological Bulletin* Dar-Nimrod and Heine define genetic essentialism as,
“The tendency to infer a person's characteristics and behaviors from his or her perceived genetic makeup” (p. 801).⁸⁴ “Much of the ways that genes relate to human conditions can be described as weak genetic explanations” (p. 802).
- • Eric Turkheimer of UVA states, “...the amount of influence that genes have on behaviors is considerably smaller than one might think.”⁸⁴ And, “...genetic essentialists were wrong about gay genes and similar nonsense.”⁸³ Diamond and Rosky: “In essence, the current scientific revolution in our understanding of the human epigenome challenges the very notion of being “born gay,” along with the “born” with *any* complex trait. Rather, our genetic legacy is dynamic, developmental, and environmentally embedded.”⁸⁵

Same-sex attraction

Sexual attraction to members of the same sex. The propensity and degree may vary from near exclusive to occasional attraction, and is shown to potentially change over time. It does not preclude the same individual from experiencing varying degrees of attraction to members of the opposite sex.

Fornication

Per theologian Robert Gagnon “fornication,” likewise *porneia* in Greek, is frequently an overarching reference to sexual sin as defined in Torah. In more common usage, fornication is sexual intercourse between two people not married to each other. Sex between male and female is implied in the term’s reference to anatomy, fornix being

the curved vaginal recess created by the cervix and the term also being Latin for “arch.”

Fornication is separate from adultery or rape.

Temptation

A trial, being put to the test.

It is not yet sin, but an invitation to it.

Jesus “was in all *points* tempted as *we are, yet* without sin.” Hebrews 4:15. It is inherent to the fallen human condition.

“No temptation has overtaken you except such as is common to man; ...” I Corinthians 10:13.

God tests individuals.

Abraham (Genesis 22:1), Job (Job 23:10), I Corinthians 11:32, Hebrews 12:4-11, etc.

Satan tempts individual to sin.

Matthew 4:3, I Thessalonians 3:5. God provides means of rescue.

“*then* the Lord knows how to deliver the godly out of temptations...” 2 Peter 2:9. “...but God *is* faithful, who will not allow you to be tempted beyond what you are able, but with the temptation will also make the way of escape, that you may be able to bear *it*.” I Corinthians 10:13.

Scripture describes temptation as something to be avoided if possible: “And do not lead us into temptation...” Matthew 6:13.

“Watch and pray, lest you enter into temptation.” Mark 14:38.

Sexual Fantasy - when does it cross into sin?

Temptation is not yet sin. Everyone has a sex drive and the duty to manage it.

Experiencing sexual thoughts is not yet fantasy, or lust, unless willingly pursued. Some have compared the appearance of sexual thoughts to a bird flying over one’s head, thus out of our control; and fantasy or lust is compared to the equivalent of allowing that bird to build a nest on our head, something clearly in our power to resist.

Same-sex attraction chaste life - does it include avoidance of kissing? Is this equal to homosexual celibacy?

This is a multi-faceted question.

1. Scripture speaks of greeting each other with “a holy kiss” (Romans 16:16, I Corinthians 16:20), which is a salutation, something non-sexual.

Greeting with a kiss is a pervasive practice in the general cultures of several nations to this day. 2. The kissing implicit in the stated question is sexual, romantic.

There is no part of homosexual practice that is endorsed in scripture; it is condemned without exception.

3. Though we mean abstinence from homosexual practices when we say, “homosexual celibacy,” the application of the term “celibate” to same-sex sexual practice is Biblically problematic. Lifetime celibacy is referred to as a “gift” by the Apostle Paul in I Corinthians 7:7-9.

A Celibate person is giving up the God-ordained institution of marriage (exclusively between one man and one woman in scriptural standards) along with its God-ordained sexual practice. God gifts, or graces, that person with something else God-ordained in its place. But a person setting aside same-sex sexual practice is abstaining from or repenting of a sinful practice, which is both commanded and its own benefit. We wish to avoid canonizing homosexual temptation.

Same-sex lifestyle

The willing practice of same-sex sexuality.

Gay culture

Any assemblage of like-minded people creates a culture. Culture itself is a neutral term that gains a moral dimension in its practice. Gay culture endorses the ideological concept of gay identity along with its practices.

Scripturally and scientifically, we hold that sexuality is a verb and not just a noun. Gay and straight are category errors and false identities. Homosexuality by any name is a practice and not an identity, what one does and not who one is.

Likewise, “gay Christian” language canonizes temptation behind a false identity. Any name preceding “Christian” is an implicit priority, contravening Paul’s instruction to the Galatian church (Gal. 3:28).

Homophobia, -ic

Homophobia is an ideological and pejorative term that has gained common usage. It is often an accusation made against an individual failing to sufficiently celebrate same-sex sexuality, practices and politics.

But per MayoClinic.org: “A phobia is an overwhelming and unreasonable fear of an object or situation . . . a phobia is long lasting, causes intense physical and psychological reactions, and can affect your ability to function normally at work or in social settings.”

Disagreement is clearly not a phobia.

Linguistically, “homophobia” is somewhat nonsensical, meaning “fear of the same thing.”

Gender vs Sex

Sex is biological and stamped on every nucleated cell in a person’s body from conception onward. It is immutable down to the level of brain cells, so it is impossible to have “a man’s brain in a woman’s body,” for example.

Gender, in its common current usage, is an engineered term leveraging linguistics against biology; it is ideological and self-declared.

Historically, however, per theologian Christopher West:

“The root “gen”—from which we get words such as generous, generate, genesis, genetics, genealogy, progeny, gender, and genitals—means “to produce” or “give birth to.” A person’s gen-der, therefore, is based on the manner in which that person is designed to gen-erate new life. Contrary to widespread secular insistence, a person’s gender is not a malleable social construct. Rather, a person’s gender is determined by the kind of genitals he or she has.”⁸⁶

But ideology does not bow to history. Sex is biology, and gender is ideology.

Gender Identity

Gender identity is a feeling, a self-perception, of how one identifies with their biological sex or not, and it is often a sex stereotype. It is subjective, self-declared and fluid. Psychologist Dr. John Money of Johns Hopkins initiated its use in professional journals in 1955, referring to “the identity of the inner sexed self.”⁸⁷

Gender Confusion/Dysphoria

Gender identity confusion/dysphoria is a feeling/self-perception that one’s biology is not as one

wishes it to be or not as one identifies most comfortably as. Sechner notes, “A gender-dysphoric youth experiences a sense of incongruity between the gender expectations linked to her or his biological sex and her or his biological sex itself.”⁸⁸

The greater the discomfort/dissonance, the greater the dysphoria. Gender dysphoria is not synonymous with transgenderism, the latter being an umbrella term within which gender dysphoria fits, but to which transgenderism is not limited.

Gender - Should we be using that term or is there a better term? If so, how is it best defined?

The answer to that depends on the application and one must be careful.

Gender is an engineered term leveraging linguistics against biology; it is ideological and self-

declared. Sex is biological, right down to each human cell containing a nucleus. Though gender is sometimes used synonymously with sex (e.g., in forms asking if someone is male or female), ideologically it is considered separate and distinct from sex (e.g., “your sex is irrelevant to your gender identity”) in a manner that is quite Gnostic (i.e., the “higher knowledge” that transcends lowly biology).

Therefore, it is best to mean what you say and say what you mean in context. Using phrases like “identified gender,” “identifies as,” “gender incongruence,” “gender dysphoria,” “transgender identified,” etc. work well, don’t surrender reality to a claim, and do not imply agreement.

Best terminology for gender transition?

That depends on the intended usage.

“Transition efforts” or “transition-affirming treatments/procedures” are both quite clear and do not surrender to ideology as compared to terms like “gender-affirming” or “gender confirming” treatments and procedures.

Best terminology for transgender identity?

“Transgender-identified” or “transgender identification” are well understood and non-capitulating.

A final comment on language

Terms should be as descriptively accurate as possible while avoiding ideological programming. For instance, because an individual’s intrinsic sex cannot be changed, and gender is essentially a biologically meaningless term or concept aside from biological sex, terms such as “transgender identity,” as if it were an objective reality, should be replaced by “transgender-identified, - identifying, or -identification,” which are descriptively accurate. Similarly, because “gender transition” is not ontologically or biologically possible, more descriptively accurate terms, such as, “attempted transition efforts,” or “attempted transition-affirming treatments or procedures,” are more accurate and preferred.

CMDA Ethics Statement

Transgender Identification

Preamble

A novel way of thinking about one's body has entered into popular culture. "Transgender" individuals refer to their "gender" as a sexual identity that may be male or female, something in between, or neither. This self-identification differs from, and takes priority over, their biological sex as recognized in their chromosomal DNA and innate physical sexual characteristics. The naming of gender as a category set apart from sex is an idea foreign to the holistic view of the person as understood within Christianity. Christians affirm the biblical understanding of humankind as having been created male and female, with the two sexes having equal dignity and a complementary relationship to each other.

At the heart of disagreement over transgenderism is a difference in worldviews. If the human body is nothing more than the product of mindless, random, purposeless physical forces, then one may do with it what one wishes, even to demand medical and surgical cooperation in projects to alter, amputate, or reconstruct normal tissue to conform to the patient's revised psychological sense of identity. If, on the other hand, our bodies are an inseparable aspect of our true selves and are a good gift from God, who has designed the sexes to be wonderfully paired, and who has a purpose for humanity, then respecting the gift of given sexual identity and the ensuing moral obligations to our neighbors is the surest path to human flourishing.

Both worldviews share the recognition that humanity is broken and in need of renewal, but they look to different answers for healing. Christians seek not a reconfiguring of the body, but a spiritual transformation of the mind to become more like Christ; not rejecting the gifts of God, but welcoming God's purposes and demonstrating God's love by loving our neighbors. This love of neighbors includes loving our transgender neighbors as persons who, like all people, are created in God's image. However, loving them and validating them as people does not mean agreeing with their ideologies or use of language.

The Christian Medical & Dental Associations (CMDA) believes that healthcare professionals should not be forced to violate their conscientious commitment to their patients' health and welfare by being required to accept and participate in harmful gender-transition interventions, especially on the young and vulnerable. CMDA affirms the obligation of Christian healthcare professionals caring for patients struggling with gender identity to do so with sensitivity and compassion, consistent with the humility and love that Jesus modeled and commanded us to show all people.

Introduction

CMDA affirms that all human beings are created in the image of, and beloved by, God. All human beings are our “neighbors”, and are to be loved by us as we love ourselves. All human beings possess intrinsic dignity and are worthy of equal respect and concern from Health Care Professionals.

CMDA considers “sex” (i.e., male or female) to be an objective biological fact (see section B.1. below). CMDA affirms the historic understanding of gender as referring to biological sex and the enduring biblical understanding of humankind as having been created male and female and that this is good. CMDA acknowledges the current cultural use of the word “gender” to refer to one’s sense of identity as male or female. CMDA cannot support the recent usage of the term “gender” to emphasize an identity other than one’s biological sex, that is, a subjective sense of self based on feelings or desires leading to identifying somewhere on a fluid continuum of gender identity.^{1,2,3,4} (See Glossary at the end of this document)

CMDA cannot support the prevailing culture’s acceptance of an ideology of unrestrained sexual self-definition that, in celebrating gender fluidity and gender transition efforts, is indifferent to biological reality and opposed to the biblical understanding of human sexuality. Further, CMDA is alarmed that some proponents of transgender ideology, through activism and intimidation, are insisting that healthcare professionals cooperate with and affirm their beliefs in gender fluidity, even if the healthcare professionals believe that such cooperation and affirmation would be doing harm to their patients. This violates the most fundamental core value of medicine since Hippocrates, that of caring only for the good and benefit of the patient while abstaining from all unnecessary harm. The evolving scientific and medical facts demonstrate that the mutilation of normal tissue and profound disruption of normal physiology that occur during gender transition procedures are very difficult to justify, as this constitutes deliberate harm.

CMDA affirms the obligation of Christian healthcare professionals caring for patients struggling with gender identity to do so with sensitivity and compassion. CMDA holds that attempts to radically reconstruct one’s body surgically or hormonally for psychological indications, however, are medically, ethically, and psychologically inappropriate. These measures alter healthy tissue and increasingly are not supported by scientific research evaluating behavioral, medical, and surgical outcomes.^{5,6,7,8,9,10,11}

Accordingly, CMDA opposes medical assistance with gender transition on the following grounds:

A. Biblical

1. God created humanity as male and female (Gen 1:27, 5:2; Matt 19:4; Mark 10:6). God’s directives – to have dominion over the earth and to fulfill his goals of procreation, union, fellowship, and worship – are given to men and women together (Gen 1:26-28, 2:18-24).
2. Men and women are morally and spiritually equal (Gal 3:28) and are created to have roles that are in some respects alike and in other respects wonderfully complementary (Eph 5).
3. All people are loved by God (John 3:16-17). All struggle with moral failure and fall short of God’s standards (Rom 3:10-12) and, therefore, need the forgiveness that God provides through Christ alone (John 3:36; Rom 3:22-24; Col 1:15-22; 1 Tim 2:5-6).
4. For the Christian, all of ethics, grounded in God’s moral law, is based upon the first and

second greatest commandments: to love God with all our heart, soul, and mind, and to love our neighbors as ourselves (Matt 22: 37-40). If we encourage others to sin sexually, just as if we sin sexually ourselves, we are violating these two commandments. We violate the first greatest commandment by failing to love God in his holiness, wisdom, and rightful place as our Creator, and we violate the second greatest commandment as we fail to respect ourselves and each other by abetting lives of disobedience, deception and unholiness (1 Cor 6: 13b-20). Love may include a corrective component that should be applied in an appropriate and timely manner; affirmation can be enablement.

5. We live in a fallen world (Gen 3), and we all come into this world as fallen creatures with a sinful nature. (Rom 3:9-12). The fall is expressed in nature and in humanity in many ways, including sexuality. Confusion of gender identity is but one example of the fall, as are also marital breakdown and sexual immorality (Rom 1:24-32; Eph 5:3).
6. A lifestyle that is directed by pursuing sexual desires, or driven by personal sexual fulfillment, misses the divinely ordained purpose of sex, which is for procreation, bond creation, and re-creation¹² and for facilitating unity in the lifelong commitment of marriage, which is defined as being between one man and one woman. Heterosexual marriage fosters a secure and nurturing environment for children and it reflects the unity of Christ and the Church (Exod 20:1-18; Lev 20:10-21; Rom 1; Eph 5:23-33) (see also CMDA Statement on Homosexuality).
7. Believers in Christ, though having inherited the sinful nature common to all humanity, also receive a new nature in Christ. As the old nature, being crucified with Christ, dies, our new redeemed nature, sealed by Christ's bodily resurrection, is actively transforming our minds and hearts to be more and more like Christ. This transformation is spiritual, not sexual, and is God's work, not something of our own design (Psalm 100:3; Rom 12:2; Col 1:27).

B. Biological

1. Sex is an objective biological fact that is determined genetically at conception by the allocation of X and Y chromosomes to one's genome, is observable at birth, is found in every nucleated cell, and is immutable throughout one's lifetime. Sex is not a social construct arbitrarily assigned at birth and cannot be changed at will.^{2,3,13}
2. Human beings are sexually dimorphic. Male and female phenotypes are the outworking of sex gene expression, which shapes sex anatomy, determines patterns of sex hormone secretion, and influences sex differences in the development of the central nervous system and other organs.^{2,3,14}
3. Procreation requires genetic contributions from both one man and one woman.^{15,16}
4. CMDA recognizes that exceedingly rare congenital abnormalities exist in which phenotypic sex characteristics are not what is expected from the genotype.^{1,2} These disorders of sex development are of a diverse nature, but usually impair fertility.³ Treatment (including non-intervention) of these disorders differs categorically from transgender interventions, which are performed on persons with no inherent defect in sex organ development, function, or fertility. Anomalies of human biological sex are conditions rather than identities, something one has rather than who one is.⁴ Disorders of sex development are not the fault of the patient, do not invalidate God's design in creation, and do not constitute a third sex.^{17,18,19,20}
5. Gender dysphoria²¹, the condition of experiencing discomfort or distress at one's sex and preferring a different "gender" identity, has not to date been linked to a genetic cause and

is a psychological disorder of unclear and complex origin.^{22,23,24} Gender dysphoria may cause profound distress. It should not be confused with transient gender-questioning that can occur in early childhood.^{25,26,27,28,29,30}

C. Social

1. CMDA recognizes that gender identity issues are complex. The inclination to identify with the opposite sex or as some other gender identity along a spectrum may have non-genetic biological,³¹ familial,^{32,33} and social ^{27,28,34} causes that are not personally generated by particular individuals.²¹⁻³⁰
2. In our current social context, there is a prevailing view that removing traditional definitions and boundaries is a requirement for self-actualization. Thus, Christian healthcare professionals find themselves in the position of being at variance with evolving views of gender identity in which patients or their subcultures seek validation by medical professionals of their transgender desires and choices through medical or surgical solutions to gender dysphoria. Although such desires may be approved by society at large, they are contrary to a biblical worldview and to biological reality and thus are disordered.
3. In contrast to the current culture, CMDA believes that finding one's identity within God's design will result in genuine human flourishing. CMDA believes, moreover, that social movements which assert that gender is a choice are mistaken in defining gender as something independent of sex. Authentic personal identity consists in social gender expression that is congruent with one's natural biological sex but not limited to stereotypes. CMDA recognizes that this traditional view has become counter-cultural; however, CMDA affirms that God's design transcends culture.
4. CMDA opposes efforts to impose transgender ideology on all society by excluding, suppressing, marginalizing, intimidating, or portraying as hateful those individuals and organizations that disagree on scientific, medical, moral, or religious grounds. Such attacks are contrary to the freedoms of speech and religious liberty that lie at the very foundation of a just and democratic society.
5. There is a social contagion phenomenon luring young people into the transgender culture.^{32,33}
6. CMDA opposes efforts to compel healthcare professionals to grant medical legitimacy to transgender ideologies.^{35,36,37,38,39,40} Cooperation with requests for medical or surgical gender reassignment threatens professional integrity by undermining our respect for biological reality, evidence-based medical science, and our commitment to non-maleficence (see CMDA Statement on Healthcare Right of Conscience).
7. Promotion of transgender ideology by educational institutions and teachers to children as young as 5 years of age is a danger to the health and safety of minor children (for medical reasons elaborated in the next section).^{41,42,43,44,45,46,47} Education should respect the value of every human being; in supporting and affirming the student, it need not affirm every desire.
8. No educational institution or teacher should ever block parents from supervising their child's education or withhold from them knowledge of the educational content.

D. Medical

1. Transient gender questioning can occur during childhood. Most children and adolescents who express transgender tendencies eventually come to identify with their biological sex

during adolescence or early childhood.^{48,49,50,51,52,53} There is evidence that gender dysphoria is influenced by psychosocial experiences and can be exacerbated by promoters of transgender ideology.^{27,33} Early counseling for children expressing gender dysphoria is critical to treat any underlying psychological disorders, including depression, anxiety, or suicidal tendencies, and should be done without promoting attempts for gender transitioning.

2. Hormones prescribed to a previously biologically healthy child for the purpose of blocking puberty inhibit normal growth and fertility, cause sexual dysfunction, and may aggravate mental health issues. Continuation of cross-sex hormones, such as estrogen and testosterone, during adolescence and into adulthood, is associated with increased health risks including, but not limited to, high blood pressure, blood clots, stroke, heart attack, infertility, and some types of cancer.^{51,54,55,56,57,58,59,60}
3. Although some individuals report a sense of relief as they initiate the transitioning process, this is not always sustained or consistent over time. Some patients regret having undergone the transitioning attempt process and choose to detransition, which involves additional medical risk and cost.^{56,61,62,63,64}
4. Among individuals who identify as transgender, use cross-sex hormones, and undergo attempted gender reassignment surgery, there are well-documented increased incidences of depression, anxiety, suicidal ideation, substance abuse, and risky sexual behaviors in comparison to the general population.^{21,22,23,61,65,66,67} These health disparities are not prima facie evidence of healthcare system prejudice. These mental health co-morbidities have been shown to predate transgender identification.^{24,25,26,27,28,34,68} Patients' own gender-altering attempts and sexual encounter choices (or, in the case of children, their parents' choices on their behalf) are among the factors relevant to adverse outcomes in transgender-identified patients.
5. Although current medical evidence is incomplete and open to various interpretations, some studies suggest that surgical alteration of sex characteristics has uncertain and potentially harmful psychological effects and can mask or exacerbate deeper psychological problems.^{7,8,9,69} Evidence increasingly demonstrates that there is no reduction in depression, anxiety, suicidal ideation, or actual suicide attempts in patients who do undergo surgical transitioning compared to those who do not.^{7,70} The claim that sex-reassignment surgery leads to a reduction in suicide and severe psychological problems is not scientifically supported.^{64,71,72,73}
6. A patient has died because the medical records conveyed only the individual's gender preference, and not their biological sex, leading to misdiagnosis and medical catastrophe.^{74,74}

E. Ethical

1. Restoring and preserving physical and mental health are goals of medicine, but assisting with or perpetuating psychosocial disorders are not. Accordingly, treatment of anomalous sexual anatomy is restorative.⁷⁵ Interventions to alter normal sexual anatomy and physiology to conform to identities arising from gender dysphoria are disruptive to health.^{9,76}
2. Medicine rests on science and should not be held captive to desires or demands that contradict biological reality. Sex reassignment operations are physically harmful because they disregard normal human anatomy and function. Normal anatomy is not a disease; dissatisfaction with natural anatomical and genetic sexual makeup is not a condition that

- can be successfully remedied medically or surgically.
3. The medical status of gender identity disorder (currently termed gender dysphoria) as a mental or psychosocial disorder should not be discarded.
 4. The inability of men, including men who identify as women, to bear children is not an illness to be remedied by medical or surgical means, such as uterine transplantation.⁷⁷ Uterine transplantation into biological men cannot be justified medically (See CMDA Statement on Enhancement and CMDA Statement on Transplantation).
 5. Fundamentally, it is unrealistic to remove or mutilate normal organs and tissue and to disrupt normal physiology, and then to expect normal function. This illustrates the reality that complete gender transitioning is not medically possible.
 6. Christian patients struggling with transgender inclinations face not only the psychological distress of a desire for a gender identity different from their biological sex, but may also face the spiritual distress that comes to anyone who follows a path in life that departs from God's design for humanity. Hormonal or surgical interventions cannot resolve spiritual distress but may lead to further spiritual turmoil. These, our neighbors, need and deserve the spiritual, psychological, and social support of the Christian community.
 7. CMDA is especially concerned about the increasing phenomenon of parents enabling their gender-questioning children or adolescent minors to receive hormones to inhibit normal adolescent development. Children and adolescents lack the developmental cognitive capacity to assent or request such interventions, which have lifelong physical, psychological, and social consequences.⁵⁶ Facilitating hormonal or surgical transitioning interventions for those who have not reached the age of majority is a form of child endangerment and abuse.⁶⁴ Highly affirming parents have been shown to not improve the mental health statistics of transgender-identified children.⁷⁸
 8. Many diseases affect men and women differently, according to biological sex phenotype. Transgender designations may conceal biological sex differences relevant to medical risk factors, the recognition of which is important for effective healthcare and disease prevention. As accurate documentation is necessary for good patient care, healthcare professionals should document the patient's biological sex and any alterations of gender characteristics in the medical record.^{2,13,54,57,79,80,81} It is appropriate and should not be interpreted as disrespectful for healthcare professionals to discuss their patients' biological sex with them as part of their medical care.^{80,81}
 9. For the overall health of the patient, the healthcare professional should be forthright with the patient that addressing the individual's sexual reality is necessary for appropriate medical care and should not be interpreted as disrespect.

CMDA Recommendations for the Christian Community

1. A person questioning or struggling with gender identity should evoke neither scorn nor enmity, but rather the Christian's concern, compassion, help, and understanding. Christians must respond to the complex issues surrounding gender identity with grace, civility, and love.
2. Christians should avail themselves of opportunities to help the larger society understand that male/female sexes are complementary and permanent. Both are good and part of the created order. For the reasons elaborated above, CMDA believes that attempting to define gender as fluid and changeable through technical means will have grave spiritual, emotional, cultural, and medical repercussions.
3. The Christian community, beginning with the Christian family, must resist stereotyping or

rejecting individuals who do not fit the popular norms of masculinity and femininity. At the same time, parents should guide their children and adolescent minors in appropriate gender identity development. For children and adolescents experiencing gender dysphoria, the Christian community should provide appropriate role models and biblically informed guidance.

4. The Christian community must condemn hatred and violence directed against those struggling with questions of gender identity.
5. Since Christians are to love their neighbors as themselves, they are to love those struggling with gender dysphoria or incongruence of desired gender with biological sex. Love for the person does not condone or facilitate gender transitioning treatments.
6. In obedience to God who commands his followers to love one another, and for the sake of the common good, Christians should welcome inclusion of transgender-identified individuals into their communities, as we are all broken and sinners, not more or less valuable than each other. Transgender-identified individuals have the same rights shared by all other humans. We oppose granting special rights and privileges based on transgender identification. These special rights can negatively impact the rights of others (e.g., bathroom designations that allow biological males access to shared female restrooms or showers, female athletic competitions that give participating biological males an unfair physiologic advantage, affirmative actions, or claims for unnecessary medical interventions).
7. The Christian community is to be a refuge of love for all who are broken – including the sexually broken – not to affirm their sin, nor to condemn, but to shepherd them to Jesus, who alone can forgive, heal, restore, and redirect to a godly, honorable, and virtuous way of life. God provides the remedy for all moral failure through repentance and faith in Jesus Christ and the life-changing power of the Holy Spirit. Though healing may be incomplete on earth, the promise of complete healing for those who are in Christ will ultimately be fulfilled in heaven.

CMDA Recommendations for Christian Healthcare Professionals

1. CMDA advocates that all Christian healthcare professionals provide ethically and medically competent care to all patients, including those who identify as transgender. Such care requires compassion, an open and trusting dialogue, a genuine effort to understand and respond to the patient's psychological distress when present, and acceptance of the person without agreeing with the person's ideology or providing a requested sex-altering intervention.
2. CMDA believes that the appropriate medical response to patients with gender dysphoria is to help them understand that they are people God loves and who are made in his image, even when their choices cannot be validated. Christian healthcare professionals should validate their right as individuals in a free society to make decisions for themselves. This right, however, does not extend to obligating Christian and other healthcare professionals to prescribe medication or perform surgical procedures that are harmful (see CMDA Statement on Healthcare Right of Conscience).
3. CMDA believes that Christian healthcare professionals should not initiate hormonal and surgical interventions that alter natural sex phenotypes. Such interventions contradict one of the basic principles of medical ethics, which is that medical treatment is intended to restore and preserve health, and not to harm.
4. CMDA believes that prescribing hormonal treatments to children or adolescents to

disrupt normal sexual development for the purpose of attempting gender reassignment is ethically impermissible, whether requested by the child, the adolescent, or the parent (See CMDA Statement on Limits to Parental Authority in Medical Decision-Making, and CMDA Statement on Abuse of Human Life).

5. Supporting a patient's pursuit of gender transitioning procedures is neither loving nor the best means to help that individual who is experiencing gender dysphoria.

CMDA Recommendations Regarding Nondiscrimination

1. Mutual respect and civil discourse are cornerstones of a free society, and so is truthfulness. In the context of health care, identification of sex and gender has both interpersonal and medical implications. In regard to medical documentation, the medical record should document the sex observed at birth even when the patient expresses a different gender preference or has obtained a legal change in gender status.
2. Christian healthcare professionals, in particular, must care for their patients with gender identity disorders in a non-judgmental and compassionate manner, consistent with the humility and love that Jesus modeled and commanded us to show all people. When questioning transgender ideology, Christian healthcare professionals should do so with an attitude of humility and love.
3. Those who hold to a biblical or traditional biological view of human sexuality, including CMDA members, should be permitted to question transgender ideology free from exclusion, oppression, or unjust discrimination. Healthcare professionals who hold the position that transgender identification is harmful and inconsistent with the will of God should not be stigmatized or accused of being bigoted, phobic, unprofessional, or discriminatory because of their desire to adhere to biological and medical reality as a sincerely held (and widely shared) belief.
4. To decline to provide a requested gender-altering treatment that is harmful, or is not medically indicated, does not constitute unjust discrimination against persons. CMDA affirms that Christian and other healthcare professionals should not be coerced or mandated to provide or refer for services they believe to be morally wrong or medically harmful to patients (See CMDA Statement on Healthcare Right of Conscience).
5. Healthcare professionals must not be prevented from providing counseling and support to patients with gender dysphoria and who request assistance with accepting and maintaining their biologic sex and gender identity.

GLOSSARY

Person and Image of God

According to the Bible, human persons (as opposed to divine and angelic persons) are embodied from conception onward. At conception, at least one genetically unique human person is formed (twinning may occur during the first two weeks of pregnancy). So the psalmist offers a hymn to God in Psalm 139, "you created my inmost being, you knit me together in my mother's womb. I praise you because I am fearfully and wonderfully made; your works are wonderful, I know that full well. My frame was not hidden from you when I was made in the secret place, when I was woven together in the depth of the earth, Your eyes saw my unformed body; all the days ordained for me were written in your book before one of them came to be" (13-16 NIV). Human persons are, however, the only persons who are made in the *imago Dei* (image of God). Thus,

Jesus—fully God and fully human—is “image of the invisible God, the firstborn over all creation” (Colossians 1:15). Likewise, according to Genesis, “God created mankind in his own image, in the image of God he created them, male and female he created them” (Genesis 1:27).

Sex

Human sex and sexuality are aspects of God’s good, well-ordered creation. From the beginning he made humans sexual beings (Genesis 2:15-25). Humans are sexual beings who procreate through sexual reproduction. Sex is objective, identifiable, immutable, determined at conception, stamped on every nucleated cell, and highly consequential.^{82,83,84,85}

There are 2 sex cells or gametes, sperm and ova. There is no third. Human fallenness incurred pervasive distortions in humanity, including disorders of sexual biology, none of which limits either God’s love for each of us, or the inestimable value of creation in His image.

Sexuality

Human sexuality is a “very good” component of God’s well-ordered creation (Genesis 2:15-25). Sexuality is a broad and easily confusing term usually requiring contextualization for clear communication. As noted by McHugh and Mayer, sexuality incorporates desires, attractions, behaviors, and/or identity.¹⁶ Furthermore, sexuality may vary regarding timing, intensity, consistency, and exclusivity. Its elements may be sporadic, temporary, pervasive, or long-term. Sexual expression may be healthful or unhealthful.

Because of human fallenness, sexuality has become disordered. The goods of sexuality are often distorted by pathologies in biology, psychology (e.g., sexual addiction or adultery), and society (e.g., sexual revolution and polyamory). Redeeming sex requires the reordering of human desires and practice. Celibacy outside of marriage, sexual fidelity within heterosexual marriage between one man and one woman, and the presumption in favor of procreation are ways human sex and sexuality may be redeemed.

Christian Worldview

A worldview is a way of seeing and understanding the phenomenon of the world around us. Like lenses of eyeglasses, one’s worldview provides a set of interpretive assumptions that enable us to make sense of our experience. One’s worldview is how one answers the big questions of life, such as: Is the world real? What is the nature of reality? Is there a God? What can we know about God? How do I know anything at all? Is matter all there is? Is there a supernatural? The orthodox Christian worldview is grounded on certain theological affirmations found in the Bible, which Christians believe to be the revealed word of God, and summarized in the great confessions in the history of Christianity, for instance, in the Nicene (325 AD) and Apostles (390 AD) Creeds.

The Fall and Human Fallenness

Rather than remaining faithful to God’s will and purposes, Adam and Eve fell from their original righteous state through disobedience (i.e., sin). Their sin brought with it not only immediate deleterious consequences for them (Genesis 3), but for the entire created order thereafter. Those well-ordered desires to love God and love another have become disordered by human depravity. Love for God and others was replaced with hatred, envy, and murder (as in the case of Cain and Abel). The goods of honest labor were turned into toil and struggle in a creation that is now filled with corruption, death, disease, pain, and hardship. After the fall, human beings are born with a propensity to disobedience, selfishness, and sin.

Intrinsic Dignity

Because human beings are made in God's image, they possess an intrinsic dignity. They should never be used as a means to an end, but as ends in themselves. Their lives have sacred value and they should not be harmed without just cause. This dignity is intrinsic and equal for all human beings, not varied and dependent on level of function, cognitive or physical, presence of absence of injury or disability, age, or other traits or features for which human beings tend to impute upon others value or worth. Human dignity has been the foundation of Western ethics and jurisprudence and has been enshrined in secular language in the Nuremberg Code and global treaties in science, medicine, and public policy since that time.

Love

Christians are called to love God with all their hearts, souls, minds, and body and to love their neighbors as themselves (Deut 6:5; Lev 19:18; Mark 12:29-31). Love is a disposition of heart and life that impels one person to treat another person with respect and dignity quite apart from ethnicity, economic, social status, or what the individual can exploit or receive from the other. Furthermore, love seeks the best for another individual without the expectation any kind of recompense or remuneration.

Holiness

With respect to God, holiness is the supreme attribute of all of God's attributes, setting the God of the Bible apart from all other deities. The Triune God is holy in his love, righteousness, justice, wrath, and mercy (among other attributes). With respect to human beings and objects, holiness is being set apart for sacred use (as with the Old Testament Temple). Christian holiness is the aspiration to live a life "set apart" from the corruptions of the world, and instead committed to fidelity, trust, and dependence on God, patterning ourselves after Jesus Christ.

Repentance

Repentance is a response to the recognition of harm done, either by commission or omission. The word used in the New Testament (metanoia) means to "turn and go in the other direction." To repent, then, is to acknowledge one's sin and turn back toward God. Turning back toward God may include ceasing to perform or pursue sinful acts, reconciling with those who have been harmed, or restoring items or relationships that have been damaged through one's behavior. Repentance is not a one-time event, but a disposition of character.

Faith

Faith is the virtue of trust and dependence on God and his promises, believing and acting in ways consistent with that confidence (Hebrews 11).

Sexual Orientation

Orientation essentialism – the belief that a person has a given sexual orientation, be it innate or resulting from various combinations of biology and environment -- is an ideological position that has gained strong purchase in modern culture.

Per academics McHugh and Diamond, polar opposites in many ways:

Psychiatry professor Paul McHugh states, "Sexual orientation is a complex and amorphous phenomenon There is no scientific consensus on how to define sexual orientation, and the various definitions proposed by experts produce substantially different classes."⁸³

Psychology professor Lisa Diamond, “There is currently no scientific or popular consensus . . . that definitively ‘qualify’ an individual as lesbian, gay, or bisexual.”⁸⁵

Genetic essentialism, like its orientation counterpart, is similarly ideological.

- In a 2011 *Psychological Bulletin* Dar-Nimrod and Heine define genetic essentialism as, “The tendency to infer a person's characteristics and behaviors from his or her perceived genetic makeup” (p. 801).⁸⁴ “Much of the ways that genes relate to human conditions can be described as weak genetic explanations” (p. 802).
- Eric Turkheimer of UVA states, “...the amount of influence that genes have on behaviors is considerably smaller than one might think.”⁸⁴ And, “...genetic essentialists were wrong about gay genes and similar nonsense.”⁸³ Diamond and Rosky: “In essence, the current scientific revolution in our understanding of the human epigenome challenges the very notion of being “born gay,” along with the “born” with *any* complex trait. Rather, our genetic legacy is dynamic, developmental, and environmentally embedded.”⁸⁵

Same-sex attraction

Sexual attraction to members of the same sex. The propensity and degree may vary from near exclusive to occasional attraction, and is shown to potentially change over time. It does not preclude the same individual from experiencing varying degrees of attraction to members of the opposite sex.

Fornication

Per theologian Robert Gagnon “fornication,” likewise *porneia* in Greek, is frequently an overarching reference to sexual sin as defined in Torah. In more common usage, fornication is sexual intercourse between two people not married to each other. Sex between male and female is implied in the term’s reference to anatomy, fornix being the curved vaginal recess created by the cervix and the term also being Latin for “arch.”

Fornication is separate from adultery or rape.

Temptation

A trial, being put to the test.

It is not yet sin, but an invitation to it.

Jesus “was in all *points* tempted as *we are*, yet without sin.” Hebrews 4:15.

It is inherent to the fallen human condition.

“No temptation has overtaken you except such as is common to man; ...” I Corinthians 10:13.

God tests individuals.

Abraham (Genesis 22:1), Job (Job 23:10), I Corinthians 11:32, Hebrews 12:4-11, etc.

Satan tempts individual to sin.

Matthew 4:3, I Thessalonians 3:5.

God provides means of rescue.

“*then* the Lord knows how to deliver the godly out of temptations...” 2 Peter 2:9.

“...but God *is* faithful, who will not allow you to be tempted beyond what you are able, but with the temptation will also make the way of escape, that you may be able to bear *it*.” I Corinthians 10:13.

Scripture describes temptation as something to be avoided if possible:

“And do not lead us into temptation...” Matthew 6:13.

“Watch and pray, lest you enter into temptation.” Mark 14:38.

Sexual Fantasy - when does it cross into sin?

Temptation is not yet sin. Everyone has a sex drive and the duty to manage it.

Experiencing sexual thoughts is not yet fantasy, or lust, unless willingly pursued. Some have compared the appearance of sexual thoughts to a bird flying over one's head, thus out of our control; and fantasy or lust is compared to the equivalent of allowing that bird to build a nest on our head, something clearly in our power to resist.

Same-sex attraction chaste life - does it include avoidance of kissing? Is this equal to homosexual celibacy?

This is a multi-faceted question.

1. Scripture speaks of greeting each other with “a holy kiss” (Romans 16:16, I Corinthians 16:20), which is a salutation, something non-sexual.

Greeting with a kiss is a pervasive practice in the general cultures of several nations to this day.

2. The kissing implicit in the stated question is sexual, romantic.

There is no part of homosexual practice that is endorsed in scripture; it is condemned without exception.

3. Though we mean abstinence from homosexual practices when we say, “homosexual celibacy,” the application of the term “celibate” to same-sex sexual practice is Biblically problematic.

Lifetime celibacy is referred to as a “gift” by the Apostle Paul in I Corinthians 7:7-9.

A Celibate person is giving up the God-ordained institution of marriage (exclusively between one man and one woman in scriptural standards) along with its God-ordained sexual practice.

God gifts, or graces, that person with something else God-ordained in its place. But a person setting aside same-sex sexual practice is abstaining from or repenting of a sinful practice, which is both commanded and its own benefit. We wish to avoid canonizing homosexual temptation.

Same-sex lifestyle

The willing practice of same-sex sexuality.

Gay culture

Any assemblage of like-minded people creates a culture. Culture itself is a neutral term that gains a moral dimension in its practice. Gay culture endorses the ideological concept of gay identity along with its practices.

Scripturally and scientifically, we hold that sexuality is a verb and not just a noun. Gay and straight are category errors and false identities. Homosexuality by any name is a practice and not an identity, what one does and not who one is.

Likewise, “gay Christian” language canonizes temptation behind a false identity. Any name preceding “Christian” is an implicit priority, contravening Paul's instruction to the Galatian church (Gal. 3:28).

Homophobia, -ic

Homophobia is an ideological and pejorative term that has gained common usage. It is often an accusation made against an individual failing to sufficiently celebrate same-sex sexuality, practices and politics.

But per MayoClinic.org: “A phobia is an overwhelming and unreasonable fear of an object or situation . . . a phobia is long lasting, causes intense physical and psychological reactions, and can affect your ability to function normally at work or in social settings.”

Disagreement is clearly not a phobia.

Linguistically, “homophobia” is somewhat nonsensical, meaning “fear of the same thing.”

Gender vs Sex

Sex is biological and stamped on every nucleated cell in a person’s body from conception onward. It is immutable down to the level of brain cells, so it is impossible to have “a man’s brain in a woman’s body,” for example.

Gender, in its common current usage, is an engineered term leveraging linguistics against biology; it is ideological and self-declared.

Historically, however, per theologian Christopher West:

“The root “gen”—from which we get words such as generous, generate, genesis, genetics, genealogy, progeny, gender, and genitals—means “to produce” or “give birth to.” A person’s gen-der, therefore, is based on the manner in which that person is designed to gen-erate new life. Contrary to widespread secular insistence, a person’s gender is not a malleable social construct. Rather, a person’s gender is determined by the kind of genitals he or she has.”⁸⁶

But ideology does not bow to history. Sex is biology, and gender is ideology.

Gender Identity

Gender identity is a feeling, a self-perception, of how one identifies with their biological sex or not, and it is often a sex stereotype. It is subjective, self-declared and fluid. Psychologist Dr. John Money of Johns Hopkins initiated its use in professional journals in 1955, referring to “the identity of the inner sexed self.”⁸⁷

Gender Confusion/Dysphoria

Gender identity confusion/dysphoria is a feeling/self-perception that one’s biology is not as one wishes it to be or not as one identifies most comfortably as. Sechner notes, “A gender-dysphoric youth experiences a sense of incongruity between the gender expectations linked to her or his biological sex and her or his biological sex itself.”⁸⁸

The greater the discomfort/dissonance, the greater the dysphoria. Gender dysphoria is not synonymous with transgenderism, the latter being an umbrella term within which gender dysphoria fits, but to which transgenderism is not limited.

Gender - Should we be using that term or is there a better term? If so, how is it best defined?

The answer to that depends on the application and one must be careful.

Gender is an engineered term leveraging linguistics against biology; it is ideological and self-declared. Sex is biological, right down to each human cell containing a nucleus.

Though gender is sometimes used synonymously with sex (e.g., in forms asking if someone is male or female), ideologically it is considered separate and distinct from sex (e.g., “your sex is irrelevant to your gender identity”) in a manner that is quite Gnostic (i.e., the “higher knowledge” that transcends lowly biology).

Therefore, it is best to mean what you say and say what you mean in context. Using phrases like “identified gender,” “identifies as,” “gender incongruence,” “gender dysphoria,” “transgender identified,” etc. work well, don’t surrender reality to a claim, and do not imply agreement.

Best terminology for gender transition?

That depends on the intended usage.

“Transition efforts” or “transition-affirming treatments/procedures” are both quite clear and do not surrender to ideology as compared to terms like “gender-affirming” or “gender confirming” treatments and procedures.

Best terminology for transgender identity?

“Transgender-identified” or “transgender identification” are well understood and non-capitulating.

A final comment on language

Terms should be as descriptively accurate as possible while avoiding ideological programming. For instance, because an individual’s intrinsic sex cannot be changed, and gender is essentially a biologically meaningless term or concept aside from biological sex, terms such as “transgender identity,” as if it were an objective reality, should be replaced by “transgender-identified, -identifying, or -identification,” which are descriptively accurate. Similarly, because “gender transition” is not ontologically or biologically possible, more descriptively accurate terms, such as, “attempted transition efforts,” or “attempted transition-affirming treatments or procedures,” are more accurate and preferred.

Florida Board of Medicine

Dear Mr. Vazquez and the Florida Board of Medicine Members,

I am writing as the parent of a trans-identified child in order to give my input as a person who has been navigating the system of gender affirming care for many years. First, I would like to state that I am politically center left- a Democrat, and I am not writing with a political agenda. I want you to know that I am very grateful that this medical board has turned its attention to this matter, and I truly thank you from the bottom of my heart, for making this a priority since all other American institutions have decided to turn a blind eye to a system that is clearly corrupt and ideologically captured.

The idea that any medical model should be 'client driven' is radical, but it becomes absurd when it is applied to children. My child began identifying as non-binary around her 13th birthday, following a difficult puberty, a diagnosis of Asperger's, and a long period of self-harming and depression that was brought on when she identified as EMO (a culture she described as "hating yourself" and which she discovered online). Prior to this, she was a happy, energetic, curious, interested and self-loving child who never displayed any discomfort with her physical self.

It cannot be a coincidence that most teenage girls who identify as transgender seem to have a similar trajectory. At the time of the trans identification, my child was being treated by a group of doctors at NYU Children's Hospital, and had outside DBT and ASD specialist. I was unable at the time to comprehend how these doctors, who were treating her for self harm and social communications disorder, just accepted my child's sudden and inexplicable change of name and pronouns, asserting that though they were recommending an in-patient therapeutic program, that this one thing about herself- that she was non-binary- was the only one true thing my child knew about herself. Leaving it at that, my child was affirmed

and no further cause or issue regarding identity was further investigated or challenged.

At the time, I was naive and I thought she would explore this identity and move on, but then by the interventions of staff at the above mentioned program, the identity changed to gay boy. It was not long after that that my child's mental and physical health got worse and did not seem to recover until many years later when I started pushing back on the ideology by asking questions. This trajectory also appears to be common amongst this cohort, as I've found out from talking to a lot of parents.

This is a long story to say that in my experience with affirmation, including allowing children to decide their sex, names, pronouns and to socially transition- especially in a medical setting, triggers an unspooling of mental health disorders, achieving the opposite of what it purports to do. Moreover, as I realized in horror after doing some research, none of those interventions are neutral, and in actuality seem to forfeit a child's ability to feel comfortable with themselves.

Doctors, teachers, neighbors, do-gooders, and even family members who 'affirm' a person's transgender identity before said person has had a chance to investigate and question the origins of the identification, are doing great harm. It is my experience that they tend to do so for their own good, as it makes them feel progressive and supportive of someone under the LGBT banner, without understanding any of the harms they cause. I have many friends whose intrusive family members or friends have been instrumental in turning their kids against them.

Doctors, allies, and teachers who affirm other people's children without parent consent have no understanding of all the unhealthy and negative cultural and ideological forces that belie the identification. While gender ideologues and affirmation proponents like to paint a picture of self-acceptance, healthy development, and everything that is rosy with rainbows and glitter, the reality is that most of us at home who look into what our children are doing online, in school GSA and LGBT groups, and in that culture, come to understand that the identity is often tied to pornography, sexual fetishes, inappropriate contact with adults who pose

as a 'glitter family,' and a lot of coaching inner self-talk about being 'born in the wrong body.'

To many of us, it is obvious that the trans identification triggers an iatrogenic development of gender dysphoric feelings that cause our children to reject their body and their past selves. This must be studied and researched carefully by a set of neutral scientists interested in really helping this cohort. In the case of my child, after 4 years of refusing to move lest she 'feels' herself, she now suffers from obesity, pre-diabetes, and metabolic disorder. Someone who was average weight all her life, was a dancer, a swimmer, a lover of movement and of herself, is now an unhealthy young adult who is immobile, obese, and who needs a plethora of medications that make her feel ill all the time.

The various pediatricians, psychiatrists, psychologists, therapists, endocrinologists, and other doctors that are entrusted with our children's care don't understand or don't want to see that affirmation is problematic. For example, not one of my child's many doctors ever questioned fallacies in her recollections of when this disorder set in, or her false memories that we knew had not occurred. Though I made them aware of the horrendous materials she had accessed online, they never bothered to question or help her explore what all of that meant, and to this day, most people and professionals will dismiss the possibility that online content can influence our children.

Affirmation appears to function as the imposition of an ideology or outside personal beliefs onto the developing minds of innocent and vulnerable children and adolescents. It must be studied: what effect does it actually have? especially when used by doctors or therapists who have an outsize influence on their patients. There is NO evidence that social transition, cross-dressing, using affirmative drugs and medical treatments, actually heal or help these children in any way. Considering the lack of evidence base to support it, is actually mind-boggling that this practice has been unfurled and is so widely practiced.

It is my opinion that the Florida Board of Medicine should look closely at the following issues and phenomena in order to fully understand what is appropriate medical care and what is simply activist directive designed to

provide cover for a lot of unhealthy and predatory actors (including unethical doctors, charities, private citizens, paraphilic men, misguided parents, and mentally ill persons):

1. WPATH and USPATH- Why is an organization made up of activists and the very doctors who work in the field allowed to dictate the standards by which the treat patients? My insurance booklet states that WPATH is an activist, not a medical organization- so why are we allowing activists who will benefit financially and socially to determine treatment protocols? especially because they tend to do poor science and seem to have an agenda? How is this legal?

They are so unfettered by reality and feel so untouchable that they had the gaul to add the identity of eunuch to the SoC8, released last week. How can a child even identify as a eunuch when the condition requires that one has already become an adult This really makes me wonder about the mental capacity and judgment of this group of people.

2. Informed consent clinics, including Planned Parenthood, Community LGBT+ service centers, and virtual providers such as Plume and Folx Health. These businesses have had a great influx of investor money and NGO funding and they are sending out hormones with very little medical case management, proper blood testing, or proper informed consent. Often times they do not even adhere to the WPATH's laughable SoC.

1. Regarding PP: When my child turned 18, she insisted that she wanted hormones. Though I opposed this, I did support her and took her to see her psychiatrist and endocrinologist. Both doctors explained to her that hormone therapy is still experimental, and that especially for people on the autism spectrum, it is better to wait until the brain is fully developed and the person has tried other ways to find relief. The endocrinologist aded that her metabolic panel and current weight anyways disqualified her for hormones because it is contraindicated for obese people who have high cholesterol due to chances of stroke. About 6 months later, on the urging of some friends, my child made a virtual appointment at Planned Parenthood, where she was seen by a midwife! My daughter was affirmed, but luckily, she did not chose to go on hormones. A month later, my child received a bill for \$370, though she had originally been told that the consultation was only

\$40. If Planned Parenthood is unable to clearly explain their pay structure to a young person on the spectrum, how can they possibly ever hope to give proper medical care and get informed consent correctly? If my child had decided to go ahead with taking hormones as prescribed by PP, she may have suffered a stroke or other consequences.

I have heard many such stories for mothers about Planned Parenthood, and I think they are going to destroy their brand with these shenanigans. I am adding below some more information about PP's practices, including some stories by detransitioners about the bad care they received there. I believe that their practices need to be considered carefully by the medical board:

2. <https://lacroicsz.substack.com/p/limerence>
3. <https://littmanresearch.com/publications/>
4. https://pitt.substack.com/p/detransitioner-perspective-how-trans?utm_source=email
5. <https://hormonehangover.substack.com/p/thinspo-and-gender-goals>

5. Direct advertising of gender treatments and surgeries by providers to children on social media: start with Florida's own-
<https://www.tiktok.com/@gendersurgeon>

6. Link to porn and fetishes such as BDSM, hypno-sissy porn, and Autogynophilia:

1. <https://grahamlinehan.substack.com/p/sissy-porn-the-gender-movements-dirty>
2. <https://www.feministcurrent.com/2020/11/29/why-isnt-anyone-talking-about-the-influence-of-porn-on-the-trans-trend/>
3. <https://pitt.substack.com/p/transgenders-connection-with-pornography>
4. <https://www.gendermapper.org/post/3-part-series-on-what-your-dysphoric-child-is-watching-online>
5. <https://link.springer.com/article/10.1007/BF01541769>
6. <https://link.springer.com/article/10.1007/s10508-005-4343-8>
7. <https://4thwavenow.com/2019/08/13/how-mental-illnesses-become-identities-tumblr-a-callout-post-part-2/>

7. Illegal services that send hormones to kids without prescription and the adults who enable it. One example is from a friend of mine whose kid ordered elicit hormones from this website: <https://steroidify.com>

The child is a minor and they paid via crypto following instructions from an online forum. The drugs were shipped to the home of an adult 'aly' who deemed herself this child's savior. This parent's rights were completely undermined by not only strangers online, but also a porous US customs process that allowed these drugs in from the eastern Europe to be delivered to a third person. This must be stopped.

8. There should also be in investigation into record keeping practices at all informed consent clinics as well as hospitals that provide surgery. Data reporting in this field should be mandated in the same way that the CDC mandates reporting from fertility clinics. The government should initiate an audit of clinic outcomes thus far, and require future reporting on all intakes and outcomes. Currently, there seems to be no record keeping or follow up, and when patients come with problems and complications the doctors ignore them, pass them over to other doctors, or mistreat them, as per the testimony of many detransitioners. Vaginoplasty and phalloplasty have horrifically high rates of complications and negative outcome rates. This data needs to be reported, and these procedures need to be kept to the SAME standards as any other surgical procedure:

<https://www.statsforgender.org/surgery/>

9. Researching detransition. The input from patients who were medically harmed by current practices, including affirmative care and informed consent models, are a good way to inform what has gone wrong and what needs to change.

10. Debunk the suicide myth of trans people:

<https://www.statsforgender.org/suicide/>

11. Investigate the large NGOs and charities that put out an incredible amount of disinformation that is unhealthy for LGBT+ individuals because they are based on propaganda and lies:

- <https://www.aclu.org/issues/lgbtq-rights/transgender-rights>
- <https://www.glaad.org>
- <https://www.thetrevorproject.org>
- <https://www.hrc.org>
- <https://pflag.org>
- <https://www.lambdalegal.org>

This form of medical practice is so broken and so dysfunctional, that I can go on forever. There is so much more to say and look at, but I will leave you with the thought that having done a preliminary review of the medical literature, you are well aware that this medicine is not sound. The USA as a world leader, must join other progressive countries such as Sweden, the UK, France and Denmark in putting science before activism and going back to the drawing board to figure out what really IS the best way to help these people. I don't think I am advocating for the end of transgenderism by asking that any surgery or medical intervention performed on anyone in this group be based on safe and sound practices that have been developed with purpose, discipline, and rigor. What is transphobic, homophobic, and misogynist is the current practice of experimenting on this vulnerable and often desperate population without care or respect for the patient.

Thank you again for your interest, your time, and your hard work in this matter.

Sincerely,

Rosita Weissberg

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

My name is Dr. Richard Florentine, MD.

I am a licensed board certified physician of Internal Medicine in Massachusetts. I am writing to you about my strong concerns about the attempt in your state to advance the practice of "gender affirming care" for vulnerable patients with gender dysphoria despite the lack of good quality evidence on the benefits of this method of treatment and it's highly likely life- long and irreversible harm to vulnerable, young children and adolescents who do not have adequate brain maturation to be able to give fully informed consent.

The impetus for this push for "gender affirming care" seems to be mostly motivated by ideology and politics rather than medical facts and supportive evidence based proposals. This is very DANGEROUS for the practice of medicine and for some of the most vulnerable patients in our society. This practice needs to be halted until further study and adequate and well designed studies can protect these vulnerable children from a profit driven, ideologically dominated medical complex which is NOT founded on a sufficiently sound high quality evidence base to support it's claims. High quality evidence is required of every other kind of medical practice. The even more vulnerable children with gender dysphoria should not be subjected to irreversible harm to their bodies and brains without the usual medical practice of extensive study of new treatment possibilities.

The ideological foundations of this type of proposed medical care was proposed by Dr. John Money at Johns Hopkins University in Baltimore, whose experiment on an unfortunate male patient, David Reimer, who was not intersex but had a damaged penis from a botched circumcision, and was raised by his parents, at the recommendation of Dr. Money, as a girl. His treatment included both surgical and hormonal interventions to ensure that he would develop female-typical sex characteristics. This conformed with Money's theory that gender was a social construct that could be altered by the conditions under which a child was raised. However, the attempt to conceal from the child what had happened to him was not successful—the child self identified as a boy. Eventually, with the guidance from his psychiatrist, his parents informed him of what had happened to him at birth and he decided to reverse the hormonal and surgical interventions that had been performed to feminize his body. He continued to be tormented by his childhood ordeal and took his on wife at the age of 38.

David's life story is an example of the harm wrought by theories that gender identity can socially and medically be reassigned in children.

Previous medical literature had shown that in young male patients (the majority of the cases of GD) (in the past) with prepubescent gender dysphoria showed a high rate of natural resolution with 61-98% of the children reidentifying with their biological sex during the experience of their own puberty with psychological support. (work of Zucker).

Currently there has been a complete reversal of this pattern of gender dysphoria with a NEW (?Epidemic) form of non childhood initiated gender dysphoria in genetic adolescent girls, which has increased by 5000%. In addition, many of these patients have comorbid conditions such as autism/ASD and Attention Deficit/ Hyperactivity Disorder. The reasons for this new phenomena has not been fully explained. But since the recent introduction of "gender affirming treatment" on this subgroup of patients, has lead to 100 % of these patients have pursuing "gender transition" treatments.

In the US, the thrust for this kind of "gender affirming care" has been ideologically motivated, with an effort to

“silence’ all debate or oppositional voices.

In Europe, however, there has been a movement at reassessment after the leading Gender Identity Development Service, called Tavistock and Portman Trust’s Gender Identity Development Service clinic in London were closed after a “damning report on ideological malpractice”. On July 29,2022, the World’s Largest Pediatric Gender Clinic was shut down due to Poor Evidence , Risk of Harm and Operational Failures. These concerns have also been recognized increasingly in Western Europe, where more thorough medical records are kept, Thus Sweden has made the decision to no longer offer gender transition to minors outside of clinical trials. Finland has also now sharply restricted eligibility for gender transition to minors with a classic, early childhood onset gender dysphoria and no mental health comorbidities, and has stated that “psychotherapy” should be the first line of treatment.

At the Federal level of the USA, the US continues to assert that “gender-affirming” care is safe and effective, despite the findings of multiple systemic reviews of evidence that found that the benefits of gender transition are highly uncertain while the risks may be significant. Specifically, the Endocrine Society’s treatment guidelines for gender-dysphoric youth are followed, a minor’s future sterility is likely. Other health risks include compromised bone health, brain development, cardiovascular complications and a number of other, as yet unknown risks.

For these and other reasons, I strongly urge you to oppose supporting medical treatments that are not sufficiently evidence based, especially when irreversible harms is great and informed consent is not possible.

Sincerely yours,

Richard Florentine, MD
Massachusetts

To whom it may concern,

I am writing regarding the proposed regulations on “gender-affirming” care currently under review in Florida. I am the parent of a gender-diverse son. We are currently living in Europe.

My son is 22 and is somewhat autistic. He is studying to be a software engineer but failed his end-of-term exams last year because he has an addiction to gaming, pornography and the internet that takes up most of his time and energy. On top of all of this, thanks to the undue influence of the online culture, he suddenly began to perceive his gender non-conforming style to mean that he is a ‘girl’. It should not need to be said, as it is very obvious to me, but this biology-defying claim is another manifestation of the mass psychosis through which we are currently living.

I am deeply concerned that adolescents like my son are being rushed into medicalization without us really understanding where all this gender confusion is suddenly coming from and, more importantly, with little or no serious clinical data about the long-term risks to health.

I would like to draw your attention to Dr Cass’ interim report in the UK in which she raises many concerns about the medicalization of gender non-conforming youth, such as the alarming fact that puberty blockers may cause “brain maturation” to be “temporarily or permanently disrupted”. I urge you to read her report for further information <https://cass.independent-review.uk/publications/interim-report/>

I believe that there are many routes that may lead to the development of distress over a young person’s gender and that there are just as many routes out of such distress.

I believe we should be looking at more **evidence-based approaches** to gender-questioning adolescents such as my son. We should be looking more **holistically** at young people to understand what is going on and we should not be centering treatment around untested medical options that pose such a danger to health, especially given the absolute lack of knowledge about the outcomes.

I support a **slow and cautious** approach that avoids medicalization and affirmation in favour of **watchful waiting**, comprehensive mental health support and evidence-based talking therapies.

Thank you for your time and consideration.

Your sincerely,

Rozy Wells

Dear Paul A. Vazquez, J.D. Executive Director Florida Board of Medicine,

I am a mom of a 24 year old young woman identifying as a man. My concern for my daughter's physical and mental health led me to research this movement. I am deeply shocked at the level of "knowledgeable" danger being exercised on and in children's bodies by professionals who have taken the Hippocratic Oath. The phenomenon we are witnessing right now is not just a case of social contagion influencing our children, but a social contagion affecting our adult population of governing entities.

There is a palpable fear of being shamed and/or losing jobs and reputation that has cowed medical and educational experts who know deep down something is amiss.

Meanwhile, this blind eye and fear of standing up for true health standards are exposing an entire generation to experimental damage. Irreversible procedures are currently being performed on an incalculable amount of innocent children whose moods, desires, and self-perceptions change from year to year.

The Puberty Blocker is being portrayed by media and information outlets as a harmless viable solution for children to consume while waiting for identity to emerge—yet it is nothing but harmful. It is a treatment destructive to human health—creating a myriad of serious lifelong complications such as sterility, stunted penis growth, vaginal atrophy and prolapse, stress on the endocrine system, etc.—not to mention hormone dependency (which affects brain function).

All this is being lauded and steamrolled under political advancement and medical profitability which is disconnected from the health care practice promised under the Hippocratic oath "to do no harm".

Please, as a mom, I beg you—help stop this crisis.

Paula Masters

Paul.Vazquez@flhealth.gov

Dear Mr. Vazquez,

As physicians we are committed to the statement, “First, Do No Harm”. I completely concur with the Florida Department of Health’s finding that “Gender Affirming Therapies” are experimental. This is reaffirmed in an article by Dr. Paul Hruz, *Deficiencies in Scientific Evidence for Medical Management of Gender Dysphoria* published in the 2020 issue of the Linacre Quarterly¹. In commenting on his extensive research, Dr. Paul Hruz sums up his overview with this convicting exhortation for all physicians:²

“The care of people with gender dysphoria must be held to the same ethical and evidence-based standards demanded in other areas of medical practice. Despite claims to the contrary, there is so much that we do not yet know about sex-gender discordance. This makes it difficult if not impossible to adequately assess the long-term risks versus benefits of gender affirming medical interventions”

These treatments for our children must be guided by long term scientific and medical studies not by political whims.

I thank you for your commitment to protecting our children.

September 18, 2022

Paul A. Vazquez, J.D.
Executive Director Florida Board of Medicine

Dear Dr. Vazquez,

I am the mother of a young adult male. I am just one of many mothers going through the unimaginable. I raised my son with love, respect, values and I taught him to love himself and to accept who God created him to be. He was growing up as a young man who was happy, loved his family, created many memories with his family and never showed any signs of distress over his sex or gender confusion of any kind.

Suddenly, he started spending more and more time on-line watching videos of other "trans-identifying" kids and getting brainwashed to believe that he was also "trans" and this would solve his "pain and suffering". He didn't talk to his parents about it, he didn't try to talk to his pediatrician whose care he had been under for 20 years, he just wanted to medically transition and there was an urgency to start immediately. He made an appointment with an endocrinologist at a Planned Parenthood clinic, met for a quick 15-minute session, and left with a prescription for cross-sex hormones on that first visit. That was three years ago.

The young adults who are identifying as "trans" suffer from depression, anxiety, eating disorders, body dysmorphia, ADHD, autism, some were sexually molested earlier in life and some are simply deeply hurting from a broken relationship where they ended up feeling rejected by someone they loved. Yet when they went to the medical professional, they were not referred to a mental health specialist. No one sat and talked with them to see why they think they need to change their perfectly healthy bodies. Instead, these "doctors" prescribed the hormones and continue to refill these harmful drugs. Further, they are being lied to and told they can actually become the opposite sex. This is not biologically possible.

Where is the evidence proving that these drugs will heal them of their gender dysphoria? There is no evidence that medically transitioning children actually improves mental health outcomes of these children. Every cell in our body is marked XX or XY and there is no way of changing that. Those doctors are encouraging vulnerable kids to think that "transitioning" is the way to solve all their normal teenage angst. My son has been prescribed estradiol,

spironolactone, and progesterone even though he has Crohn's disease and family history of heart and liver disease. These drugs are shaving years off of his life, will make him sterile, cause blood clots, cancer, brain issues, and basically cause non-reversible side effects. These doctors took the Hippocratic Oath. They promised to uphold ethical standards. Why are they doing this to our children? Are these drugs even safe for my son to take?

These young men and women who are identifying as "trans" were growing up as healthy young men and women. Yes, many are uncomfortable with their bodies, but weren't we all during our teenage years? Would you prescribe diet pills to a child with anorexia because they "believe they are fat" or would you recommend that the anorexic patient see a psychologist? Why are these medical professionals medicalizing these young kids instead of referring them to mental health professionals? Our daughters and sons don't need cross sex hormones, they need mental health care. They hate their bodies, they have succumbed to the Internet with its videos and websites portraying happiness if you only transition. They are experiencing normal discomfort with their body, but are being convinced that any amount of discomfort with their body is an indication that they are "transgender." Isn't it surprising to our medical professionals that they are seeing more and more young patients seeking hormones? Where is the medical curiosity as to why we are seeing this increase? Isn't it alarming that just a few years ago you there were but a few patients identifying as transexual and how the number of young kids who identity as "trans" has increased by 500%?

It seems like a cookie-cutter story due to a social contagion that has all these kids wanting to transition as if being "trans" would make them popular or accepted by their peers. I am part of a support group of 500+ parents and every single one of us has a similar story to tell. Our sons or daughters, all of a sudden, announced they were "trans". It came out of nowhere. Virtually all of them were vulnerable in some way and many have co-occurring mental health issues. Some waited until they were away at college to make the announcement and they all went to a Planned Parenthood clinic (or even had a virtual visit) and walked away with a prescription for cross-sex hormones on the first visit. No consultation, no mental health screening, nothing. There is zero safe-guarding in place. Isn't this alarming? Can these medical professionals just continue to look the other way and continue prescribing the hormones without regard for the mental health of these children and the harm this is doing to their bodies?

Young girls are having double mastectomy surgeries!!!! This was a procedure reserved for cancer patients and now young girls, with perfectly healthy body parts, are CHOOSING to have a double mastectomy because they hate their body. Some are creating GoFundMe pages to raise money for these harmful surgeries!!!! They are being told by these "so-called" professionals that if you hate your body, you must be "trans", and removing your perfectly healthy body parts is the right thing to do. Do you really believe that? Would you want your own daughter, son, niece, nephew, grandchild to be part of this "trans" cult and undergo these dangerous procedures because they "feel" that they were born in the wrong body? Feelings are not facts and feelings change constantly during adolescence.

I am begging you to rethink the medical guidelines that are in place today in Florida for these “gender-confused” young kids. I am begging you to stand up and say “no” to this social contagion disguised as “transgenderism”. Please get these kids mental health care, which is what they need, not harmful and experimental drugs! All of us concerned parents are hoping for the same thing: that Florida and this board will put legislation in place that will prevent doctors from being able to prescribe experimental drugs such as puberty blockers and cross sex hormones and will prevent doctors from performing any type of gender affirming surgeries such as double mastectomies, breast augmentation, vaginoplasty or phalloplasty on minors. Even young adults who are under 25 should not be allowed to receive these experimental drugs or surgeries as there is real evidence that the brain is not fully developed until age 25 and therefore these young adults cannot give informed consent because they don’t have the ability to fully understand the consequences of these treatments.

Things are changing in parts of Europe and in the UK. In the US, a growing movement of parents and ETHICAL clinicians, most of whom are lifelong progressives and active supporters of LGBTQ people and causes, are organizing and becoming vocal about their outrage and rejection of gender ideology. They are speaking out about the unsupported diagnostic claims and harmful treatment practices it has given rise to. When the lawsuits start coming this will be exposed as one of the biggest medical scandals in history. It’s only a matter of time. Please also keep in mind that we are also now seeing the number of de-transitioners increase every day because they are realizing that medical transitioning did not fix their discomfort and many are saying that the source of their discomfort was a mental health issue all along and that was ignored and never explored by the medical professionals.

PLEASE STOP ALLOWING THE GENDER MEDICALIZATION OF OUR SONS AND DAUGHTERS!

Sincerely,

Maria Purvis

Dear Mr. Vazquez and Members of the Florida Board of Medicine:

As a practicing family physician in the State of Florida, I write to implore that the Florida Board of Medicine restrict the practice of “gender-affirming care”—including social gender transition, hormone therapy, and gender-reassignment surgery—for children and adolescents. The short- and long-term harms as a result of such “gender-reassignment” practices on children are severely damaging and irreparable, and medical and evidence-based studies do not support their use.

Additionally, given that over 80% of children affected by gender dysphoria will eventually lose their desire to identify with their non-birth sex, it is a professional dereliction of duty for the medical community to allow such procedures—which result in disfigurement, sterility, and other lifelong damage to bodily and mental health-- with the professional sanction of the Board of Medicine.

It is my sincere hope that the Florida Board of Medicine will restrict the use of such “gender-reassignment” practices for children and adolescents, in the interest of preserving the health and well-being of Florida’s children and families.

Sincerely,

James O. Breen, M.D.

Dear Dr. Vazquez and fellow board members,

I am a mother of a teen daughter who suddenly started experiencing distress over her sex at age 13. I am also a licensed mental health counselor in Florida. My daughter expressed no previous signs of gender confusion in her childhood and the confusion only started after three other friends at school also started identifying as transgender. She was diagnosed with ADHD in the 4th grade, which makes her emotionally behind her peers. She also has difficulty making and maintaining meaningful, long-lasting friendships.

As we struggled to understand the sudden announcement from our daughter, we elicited the help of a mental health professional. Shortly after, we found out her middle school socially transitioned her without our knowledge or consent. Her mental health deteriorated. She became more angry, withdrawn and depressed. What the school had done was create a huge wedge between our daughter and us, which was a strain on all of us.

We chose a path of watchful waiting after doing months of research, along with the advice of her counselor. I looked into what gender affirming care truly was and I was shocked to discover that children and teenagers were being given experimental drugs in the form of puberty blockers and cross sex hormones that cause irreversible changes to their young bodies that include loss of future fertility and sexual function. There was also no high-quality evidence that medical transitioning produced positive outcomes in the patients. Why would we risk our daughter's future whole self and fertility on such low quality, flimsy research?

I also learned that surgeries like double mastectomies were being performed on minors here in Florida. I couldn't understand why parents would consent to these irreversible changes for their child or why doctors who understand the nature of adolescent brain development would be making these recommendations and treatments for children and teens. Children and teens certainly cannot give informed consent because their brains are not fully developed until approximately age 25. They don't have the ability to weigh the consequences of these choices and how they will feel about them in 5, 10, or 20 years. There used to be safeguarding in place for medical transitioning. Now, that safeguarding no longer exists. Children are being only affirmed at gender clinics, private physician offices and by mental health clinicians and are fast tracked along a medical pathway.

We also discovered that most of the major medical and psychological associations were blindly supporting these radical treatments without ever actually looking at the evidence and research being used to justify them. Many of the parents that do consent to their child being medically transitioned are coerced into believing that their child would commit suicide if they did not affirm. These parents could never truly have given informed consent because they were not offered any

alternate treatment pathways such as psychotherapy or watchful waiting. Further, how can they give informed consent when the long-term consequences are not fully known about these medications which are not FDA approved for gender dysphoria?

Now, we are seeing teens and young adults that were put on these medical pathways regret their transition because it did not fix their dysphoria or resolve the root cause of their distress. Many of these individuals have co-occurring mental health issues such as previous sexual trauma, eating disorders, anxiety, depression and autism. Some of the detransitioners are sterilized from the hormones, but many have no idea of the state of their fertility. There are detransitioners experiencing medical issues that doctors don't even fully know how to treat or fix, especially those with complications from gender surgeries such as phalloplasty.

We are literally allowing doctors to experiment on children based on a feeling the child has, a self-diagnosis, that could very well change over time as the child matures in a loving, neutral environment. Please stop allowing doctors to experiment on children. If we had affirmed my daughter, she would have absolutely gone down this path thinking medical transitioning would fix her pain. She was convinced that her pain would only be solved by hormones and surgeries, yet she had no idea what the short-term or long-term consequences of these treatments would be. If we had affirmed her in the false identity, what it really would have done is affirmed her self-loathing, encouraged body disassociation and put her along a path to be a medical patient for life that may have led to her suicide, given the suicide rate 7-10 years post transition is 19 times that of the normal population.

My daughter has desisted after two years and is on a path of self-love in the body she was created in. Please protect future children from the harm of medical experimental transition medications and surgeries. Please restore integrity to the medical community by creating a rule grounded in science and robust evidence-based research instead of ideology. There is no longer even a coherent, shared definition of the word "transgender" among the medical community. There is also no test to tell which child will desist and which child will persist in their desire to transition. There is no test that will tell us which child will regret these irreversible and experimental medical treatments and which will not. Our children deserve ethical and compassionate care for gender dysphoria, which is a mental health issue that needs to be treated by mental health professionals, not hormones and surgeries that will mutilate and disfigure their bodies. Thank you for your time and consideration.

Sincerely,

January Littlejohn

Dear Florida Board of Medicine,

Thank you for questioning the regulation of so-called "gender-affirming" hormones and surgeries for young people. I can guarantee that this is one of the most important issues of our lifetime.

As a parent of one of these children, I have seen some very well-meaning but misinformed doctors recommend these radical life-changing interventions sometimes on the first or second visit. The myth that our children are getting "assessments" is propagated widely, but no requirements have ever been clearly articulated about which child or young person distressed with their gender role will benefit vs will be harmed. This intervention sterilizes 100% of children if administered according to the Endocrine Society's recommendations. Even with an older child, there is often social dysmorphia and extreme OCD that should be addressed before anything having to do with gender is even talked about. My son is one of those older youth who was coerced into going on hormones and eventually ending up with an orchiectomy. The physicians and mental health "experts" did not fix his social anxiety or his TOCD. He is in a much worse place than he has ever been in. We are really struggling right now and worry every day about his mental state.

Older adolescents can get hormones with no assessments at all, and have their healthy body parts amputated by eager surgeons on little more than self-declaration of "trans identity." I suspect that my child may be gay with autistic traits and has come to believe his very real distress is explained by the fact that he is "transgender" and that hormones and surgeries will help. They will not. I have seen my child's mental and physical health plummet following "gender-affirmation."

I also encourage you to require exploratory psychotherapy and to issue a clear statement that psychotherapy for gender dysphoria is not conversion. Our children and families need safe non-invasive alternatives to radical experimentation known as "gender affirmation."

Thank you for doing what you can to regulate this social experiment on our vulnerable children. I believe that this is going to go down as the largest medical scandal ever in the history of bad medicine. It's time to pick a side. I hope you pick the side of children.

Thank you,

Connie Hahn

Hello- I understand the Florida BOM will be meeting to consider implementing regulations regarding sex based medicine. I am writing to state my strong opposition to this so-called gender affirming care, especially when it is directed at youth.

I am a physician and am very concerned that youth are being manipulated by adults for financial gain. This includes youth with intellectual disabilities and autism. It is especially troubling that parents may be removed from the process of consent.

I strongly encourage the Florida BOM to maintain its integrity and reject any regulations that would permit sex based medicine directed at youth.

Thank-you,

OPINION

How Do Gender Transitions Impact Children? Here's What The Science Says

By **Miriam Grossman, MD**

DailyWire.com

▀ PART 6 OF 8

What Is A Woman?

President Joe Biden has advised parents that early surgeries, hormone treatments, and affirmations are crucial for the health of their gender-confused children. According to the president, these are some of the most powerful things a parent can do. As a child and adolescent psychiatrist who treats some of the families facing these issues, his statements are surprising and, due to their medical and societal implications, warrant thorough fact-checking.

To clarify, “affirmation” means unquestioning acceptance of a child’s chosen gender identity – be it the opposite sex, a combination of male and female, neither male nor female, or one of the multitudes of other possibilities presented to children by the media, online, and at school. This means abandoning the use of a child’s given name and the pronouns consistent with their biology and replacing them with the name and pronouns they’ve picked; permitting them the clothing and hairstyle

of their choice; allowing girls to bind and boys to tuck; and facilitating their use of opposite sex restrooms, participation in opposite sex sports teams, and so on.

“Hormone treatment” refers to both puberty blocking agents (PBAs), which halt the critical process by which children mature into adults and cross-sex hormones, which are given a few years after PBAs to chemically simulate the puberty of the opposite sex.

“Surgeries” refer to bilateral mastectomies, the removal of ovaries and the uterus, and the construction of a faux penis in girls and breast implants, the removal of the penis and testes, and the construction of a faux vagina in boys. In the U.S., mastectomies are performed on girls as young as thirteen, and minor boys are being castrated. There is also a surgery that removes all genitalia, marketed by surgeons to individuals who identify as neither male nor female, or “non-binary.”

Perhaps Joe Biden believes there is strong evidence that these life-altering social and medical interventions lead to positive outcomes. If so, he couldn’t be more mistaken.

The severe lack of scientific knowledge of gender dysphoria is acknowledged by experts in the field. The American Psychological Association has stated, “...because no approach to working with [transgender and gender nonconforming] children has been adequately, empirically validated, consensus does not exist regarding best practice with pre-pubertal children.” The lack of knowledge is even more pronounced for gender dysphoria with onset in adolescence who constitute a new, unstudied cohort.

In 2020 the UK's National Institute for Health and Care Excellence (NICE) did a systematic review of puberty blockers and cross-sex hormones and found evidence that the medications' "potential benefits are of very low certainty."

Similarly, Dr. Stephen Levine, a pioneer in the study and treatment of sexuality and gender problems since 1974 and arguably the most highly credentialed and respected voice in the field, wrote in an expert affidavit: "The knowledge-base concerning the causes and treatment of gender dysphoria has low scientific quality."

Professor Carl Heneghan, Editor in Chief of the *British Medical Journal* and director of the Centre of Evidence Based Medicine at Oxford, along with Professor Tom Jefferson, a clinical epidemiologist, completed an independent analysis of research on transgender medical interventions. Concerning puberty blockers, Prof Heneghan stated, "The quality of evidence in this area is terrible."

For these and other reasons, the science regarding the treatment of children and teens with gender dysphoria is far from settled, and there is no consensus whatsoever among doctors and therapists.

The stakes are high: the consequences of hormones and surgeries include: infertility, sexual dysfunction, osteoporosis, cardiovascular disease, and, for some, crippling emotional pain.

Yet the president is calling for early treatment; it's one of the most powerful things a parent can do, he says. Jazz Jennings' parents made sure their child was treated early for gender dysphoria. Jazz, the poster

child for the transgender industry, started PBAs at the age of eleven and went on estrogen in high school. Before castration and the construction of a faux vagina at age seventeen, Jazz reported to surgeon Marci Bowers that sexual sensations and orgasm were unknown experiences. Now twenty-one, Jazz has gained a hundred pounds and is “struggling severely with mental health issues.”

For the White House to state that early affirmation of children with gender issues is “crucial” is a dangerous falsehood, one that misleads parents and places children at risk for serious harm and lifelong suffering.

Instead, parents must be aware of the following:

Regarding children who develop gender dysphoria before puberty, the great majority, on average about 80% but ranging between 50 and 96% depending on the study, become comfortable with their bodies. This improvement occurs if they go through normal puberty and is called “desistance.” There is no way to know if a particular child will desist, but Jazz could have been one.

One clinician with expertise in the field explains, “Gender dysphoria in pre-adolescent children is a condition that ameliorates by itself in most cases if you are just patient.”

Changing names, pronouns, and presentations can decrease desistance. Puberty blockers are controversial and have a history of lawsuits. Their off-label use in healthy children is experimental, and they have serious adverse effects that are irreversible, such as osteoporosis and early

menopause. There is no country in which PBAs are licensed for the treatment of gender dysphoria.

Once on puberty blockers, desistance is very rare. Nearly all children placed on blockers go on to take opposite sex hormones, which must be taken forever.

Until very recently, gender dysphoria was a very rare diagnosis, with a prevalence of 1:30,000 to 1:110,000 and a male to female ratio of 6:1. A massive explosion of gender dysphoria cases began in the past decade or so. A 2017 study noted a prevalence of self-reported transgender identity in children, adolescents, and adults ranging from 5:1000 to 13:1000. A 2021 study suggested that the rate of transgender identification among urban youth in the US may be as high as nine in 100. It is not definitively known what is causing so many young people to reject their biology.

The new form of gender dysphoria develops during adolescence, predominantly in girls with no earlier discomfort with their sex. It appears suddenly and is therefore known as Rapid Onset Gender Dysphoria (ROGD). The girls' discomfort with being female typically follows increased use of the internet and social media and is associated with comorbid mental health disorders and neurodevelopmental disability.

The social influence aspect of ROGD is striking, with one study showing that 86.7% of young people with ROGD had one or more friends who came out as transgender at the same time and/or had an increase in their use of social media. The spreading of behaviors and beliefs amongst friends, especially between girls, is a well-documented phenomenon.

Every adolescent goes through some degree of difficulty accepting the physical and emotional changes of puberty. That difficulty is magnified for children with emotional and neurodiverse conditions such as ADHD and autism spectrum disorder. They struggle with their changing bodies, nascent sexuality, individuation from parents, and acceptance by peers. Many are lonely; this was exacerbated during COVID lockdowns. These vulnerable kids search for relief, and they find it on the internet.

Transgenderism is promoted by online activists as a solution to nearly every psychosocial problem. Youth are led to believe their social awkwardness, lack of friends, sadness, eating issues, discomfort with their bodies – all of it – is because they might be “trans”: their gender does not “align” with the sex “assigned” to them at birth.

Upon announcing a “trans” identity, a new name, and new pronouns, a child is welcomed by an enthusiastic community, both online and in real life, and showered with attention, praise, and – most importantly – acceptance. It’s what he or she has always yearned for: to be admired and appreciated – to belong.

The significance to an unhappy, anxious, socially awkward child of being embraced and celebrated by peers cannot be overestimated. Parents and clinicians caring for trans-identified young people must look at the secondary gain of adopting new identity.

Recognizing that the nature of adolescence is to explore identity and that the brain – and therefore many cognitive processes related to identity and decision-making – is not fully developed until the mid-20’s, Arkansas and Tennessee passed bills outlawing hormonal and surgical treatments

for gender dysphoria in minors. Similar bills have been introduced in the state legislatures of Idaho, Utah, Missouri, and Alabama. President Biden calls these bills “hateful,” but they protect children who lack the capacity to grasp the long term consequences and risks of life-altering medical interventions.

Parents tempted to give the president’s words credibility should also know that treating their child’s distress with hormones and surgeries greatly reduces the size of their dating pool and their chance of marriage. Studies from different countries indicate more anxiety, depression, substance abuse, domestic violence, eating disorders, suicidal ideation, and suicide in the transgendered. A thirty year study from Denmark showed shortened life expectancy and a high incidence of suicide. A Swedish study found that sex-reassigned, transsexual persons – both male and female – had approximately a three times higher risk of all-cause mortality than non-transsexuals. Elevated causes of mortality included cancer, cardiovascular disease, and violent crime. A Dutch study over five decades showed an increased mortality risk in transgender people using hormone treatment.

There is a risk of suicide in gender-questioning teens, but there is no evidence that transition lowers that risk. One study showed that following genital surgery, transgender patients were 4.9 times more likely to attempt suicide and 19.1 times more likely to have died from suicide, after adjusting for the presence of psychiatric comorbidities.

President Biden failed to mention the possibility that a gender-confused child who is automatically affirmed and given hormones and operations

before he or she has a chance to grow up, experience the pleasure their healthy body can provide, or carefully consider parenthood, may one day deeply regret the entire process. Those people advising the president on this issue probably claim regret is rare, but it's not. This detransitioners' site alone has 28,000 members.

One of the major complaints of people who regret their transition is directed at the medical professionals who immediately affirmed their new identities without fully considering the possibility of other underlying emotional causes. Years later, these people realize they had serious mental health problems that led them to flee from their masculinity or femininity. If those problems had been addressed at the time, they claim they would not have transitioned.

It's deeply troubling that the president did not mention the role of psychotherapy in the treatment of gender-questioning children. Anyone who is following this topic knows that in contrast to U.S. practitioners who pressure parents to affirm and medicalize, several socially progressive and LGBT friendly countries, following systematic review of the literature, made dramatic U-turns in their treatment approach to minors: Finland and Sweden have banned hormones and surgeries for patients under 16 or 18 in regular clinical settings. England sharply curtailed medical treatment of minors. Holland examines each child closely and makes decisions on a case-by-case basis. France has urged "great caution." A position statement by psychiatrists in Australia and New Zealand does not specifically endorse affirmation. The preferred treatment in all those countries is now psychotherapy.

What this means is that a gender-questioning girl in Stockholm or Amsterdam will explore her struggles with a mental health professional. Whereas the same girl in Boston or Seattle can access Testosterone and mastectomies with ease, and within months, she'll have a flat chest and a permanently lowered voice.

Understand this: other countries have applied the brakes on affirmation, hormones, and surgery, but our president has instructed parents to accelerate. . But Biden's advice is scientifically baseless. Available data does not support the argument that any type of "affirmation" of transgender identity results in improved emotional health in the long term. To the contrary, there is evidence of serious harm. The White House is promoting nothing less than a reckless experiment on children. For this man-made catastrophe, young Americans and their families are paying and will continue to pay a terrible price.

Please lead the USA, adopt a cautious, slower and safer approach to treating children with gender questioning.

My 14 year old daughter is in extreme mental pain. Sexual trauma, suicide attempts, selfharm, eating disorders, 6 months in and out of psych hospitals. She says she is a boy. This is her solution to protect herself from more harm. Therapist, doctors, teachers, her peers all say "yes, of course you're a boy", and send her to the Gender Clinic. Where there is no exploratory therapy, no treatment except surgery and drugs.

Brain development is not solidified until the mid 20's. Adolescents can not comprehend "informed consent" - most can't drive, buy tobacco, alcohol etc. Is not reasonable to think they can understand the consequences of cutting off their breast, or hormones.

Youth Transition should be stopped. It's feeding the illusion that medicalizing will lead them to a new identity and stop their pain. Take away this option, let families focus on what is underneath the pain.

Please protect our children.

To whom it may concern,

I recently attended a conference in partnership with the Christian Medical & Dental Associations entitled "Critical Conversations on Identity & Gender". During the course of that event I had the opportunity to hear from Dr. Paul Hruz, whose credentials (taken from the event description) I have listed below:

"Paul Hruz, MD, PhD, is an Associate Professor of Pediatrics, and Associate Professor of Cellular Biology and Physiology in the Division of Pediatric Endocrinology and Diabetes within the Department of Pediatrics at Washington University School of Medicine, St Louis, Missouri. He is a member of the Endocrine Society, the Pediatric Endocrine Society, the American College of Pediatricians, and the American Diabetes Association. Hruz received his BS Degree from Marquette University and his MD and PhD degrees from the Medical College of Wisconsin. Dr. Hruz has over 20 years of clinical experience in caring for children with disorders of sexual development. He also has formal certification in Healthcare Ethics and is a regular contributor to his University's course of Research Ethics for graduate students. He has authored over 60 peer-reviewed manuscripts, scientific reviews and book chapters."

As can be manifestly seen, Dr. Hruz is an expert in his field, the field of pediatric endocrinology. As a doctor who has spent over 20 years working with children with disorders of sexual development, he is well positioned to speak about the evidence in the current literature which is used as the basis by proponents of medical gender transitioning for the advancement of such procedures.

Dr. Hruz' professional opinion is that on almost every point of issue, the evidence and research advocating for transitioning is either minimal or not up to sufficient standards.

As an MD candidate currently rotating in Miami area hospitals, and as someone who may practice medicine in the state of Florida in the very near future, I am strongly recommending that the Florida Medical Board consider a moratorium on this issue: there is simply not enough quality evidence to be able to support potentially psychologically, socially, and medically detrimental legislation which would allow for medical and/or surgical changes to alter secondary sexual characteristics in minors.

I also question if it is possible for a child under 18 to have the capacity to offer informed consent for

such things. When you were 18, my esteemed members of the board, were you as emotionally stable and mentally balanced as you are today? Or were you, like many of the children that we personally know (and counted ourselves as, at one time), emotionally and socially labile, and easily swayed by the popular opinions of those around us of the same age, and the same temperaments; a condition which has been exponentially magnified over the last decades by the institutions of social media and media streaming services.

As adults now in positions of authority, you all have the ability to rise above the hype and the uncontrolled and rapidly accelerating madness our culture is experiencing. As a plane which fly's through a cloud and experiences turbulence must rise above the cloud to be in a position to fly through smoother airs, so too can you all in this moment fly above the cultural turmoil which we are facing and be in a position to steer our states medical and legislative concourse back to a place where reason and due diligence of time and process mark the discussion and discourse in these respective bodies.

Thank you very much for your time and candid considerations on this matter.

Sincerely,

John-Mark Unsworth M.Sc, Medical Science

Dear Board Members,

I am a family medicine physician in Charlotte, North Carolina. I need a local group of physicians who are dedicated to practicing with well-formed bioethical principles in mind.

I am very concerned that there is a significant amount of data showing that gender affirming care leads to irreparable harm for the patient. The data is particularly clear that gender transition surgery does not resolve the underlying issues and particularly does not help with gender dysphoria and depression. Regret and irreparable infertility are often the result.

Solid bioethics are grounded in nonmaleficence, beneficence, and patient autonomy. Unfortunately, at this time, patient autonomy incorrectly holds sway with many medical decisions. I urge you and the others with the board of medicine to act with solid bioethical backing and predominant evolving opinion around the world in opposing most "gender affirming care" while focusing on the care for the patient and encouraging support for gender dysphoria without hormones and surgery.

Dear Mr. Vazquez, dear Members of Florida Board of Medicine,

The filmmakers who created a feature-length documentary-in-progress on **six detransitioners** harmed for life by the "gender-affirming care" are honored to make the documentary available for you, for your proceedings.

As of 09/20, the documentary is in the "Beta" phase -- **a complete cut**, but the dialogue audio is not edited, there is no musical score, no color correction, no Main title or End Credits crawl, etc. Nevertheless, I trust the testimonies made by six detransitioners and ten medical and mental health experts deeply familiar with the medical transitioning and detransitioning will make a worthwhile addition to your body of evidence. The running time of the doc is 90 minutes. Peer-reviewed medical articles are cited throughout the documentary.

Respectfully submitted,

Vera Lindner

Executive Producer

Dear Florida Board of Medicine,

I am a pediatrician in private practice for the past 13 years. I went to medical school at Northwestern University Feinberg School of Medicine and did my pediatrics residency at The University of Arizona. I currently have 5 patients who identify as transgender. My first patient with transgender tendencies was a 5 year old boy whose mother identified him as a girl. This was in 2007 during residency in Arizona. Interestingly, not one of my attendings suggested any sort of intervention like might be suggested today. The path followed was the one currently suggested by both Finland and Sweden that focuses on finding and treating both individual and familial trauma and psychopathology. This path does not include medication or surgery.

I did not see a patient with transgender tendencies again until 2018 when a long established 14 year old female patient with autism, ADHD, anxiety, depression, paranoia and at times psychosis all in the setting of significant parental psychopathology with attachment disorders decided to use male pronouns. She has since used they pronouns and sometimes presents as a male and sometimes as a female while having sexual desire for males and not being bothered by menstruation but desiring testosterone injections. She had felt that she didn't fit in since middle school but did not present with gender dysphoria until high school that quickly changed to gender identity disorder. Internet influence was definitely part of the process. Two other female patients presented with rapid onset gender dysphoria in high school with one currently being given testosterone by adolescent medicine as a gender identity disorder. Another patient is male and presented as female starting in high school after many years of enduring a difficult parental divorce due to the father abusing the mother. The last patient with male to female gender dysphoria starting at 5 years of age has been lost to follow up due to serious drug problems in the mother in the setting of verbal and emotional abuse by the father and brother.

I have used many resources to familiarize myself with diagnosis and treatment for gender dysphoria and gender identity disorder. The two I would point out to you are The Society for Evidence Based Gender Medicine, SEGM, segm.org, and Transgender Issues in Catholic Healthcare by the National Catholic Bioethics Center, NCBC, nbccenter.org. These two represent a wide variety of physicians and mental health professionals in contrast to WPATH. It seems to me from both my clinical experience and research that there are different groups of children with higher rates of gender dysphoria and gender identity disorder. The common factors are psychopathology and trauma. It is emotionally difficult and time consuming to take care of these patients of mine. I sit in the room and absorb all of the fear, sadness, paranoia. I am concerned with the psychosis and disconnect with reality and how that obviously makes them unable to give informed consent. I cannot believe that a patient could actually understand what will happen if they tell me that they hear voices and think people are knocking on their front door one second but then declare that they completely understand what will happen to them if they take hormones from the opposite sex. I am very concerned that these patients and families are being taken advantage of for the very reason that they seek care. They are in emotional despair and are offered a quick fix that they don't/can't understand and their parents often have similar problems or are inflicting problems on the patient. The groups effected tend to be autistic spectrum children trying to find a place to fit, parents with psychopathology that is manifesting itself in an attachment disorder in the child who then identifies with the opposite parent, children who just succumb to a fad because they are easily influenced, children with anxiety and depression who are trying to escape. It is not good medicine to lump all of these different patients into one group with the same treatment plan, especially a surgical treatment plan that permanently removes healthy organs or causes sterility. I see adolescents that act completely different from one check up to the next year after year. Trying to find yourself is the hallmark of adolescence and the struggle should not be treated with surgery or stopping the physiology of adolescence. It is not

possible for children and adolescents who have not completed puberty and/or who have not have sexual experiences within long term, exclusive, committed relationships to use their sexual organs as they are meant to function. And it is directly contradictory to say that the sexual organs don't matter but then make the whole treatment plan focused on mutilating or blocking the function of the sexual organs. What shocked me in 2019 and still does today is an American Academy of Pediatrics Pediatrics in Review article recommending treatments for people with gender dysphoria based on D and X grade evidence using a comic book as the main information resource. I had never before read a Pediatrics in Review article that I was asked to take seriously based on D and X grade evidence. Those are opinion grades, experimental grades. I am a serious scientist and a serious clinician. I am not about to make extraordinary claims of fixing all of the trauma and mental health problems I see in my struggling patients based on D and X grade evidence. I ask that you please take me seriously and call me if you would like to discuss my experience as a front line physician giving compassionate care to my patients with whom I have respectful and long term relationships. We, physicians in the US, should not disregard what has already been done in Finland and Sweden and England. We should follow their lead, admit our past failures, ignore overly emotional or sentimental diatribes, stop trying to do something to make us doctors feel like we fixed a problem only by oversimplifying complex problems and return to first do no harm while offering needed psychological and social support.

Dear Florida Board of Medicine, September 20, 2022

The Hippocratic oath requires physicians "to first do no harm". This is an axiom that most urgent when dealing with children. I'm a licensed physician and surgeon, board-certified psychiatrist, forensic psychiatrist, child and adolescent psychiatrist, marriage counselor, behavioral therapist with decades of experience. I have patients who are in multiple phases of dealing with gender identity disorder.

I have patients to have begun to wonder if they wish to be a different sex, have had hormone replacement therapy, have had gender transforming surgery and are dealing with transgender issues. I understand the difficulty that people have in dealing with these issues. As of now there is NO proof that any of these gender transitioning chemical, surgical or social treatments lead to any real long lasting benefit. There are many who once they have made chemical hormonal or surgical transitions and once transitioned regret what they have done and return or try to return to their original natural biologic gender.

Children do not have the mental or legal capacity to act as adults, they lack the ability to form a proper informed consent. Generally children are not permitted to consent to taking an aspirin without their parents informed consent. The issue of gender transitioning treatments for an adults totally different psychological and legal matter than for children. If a competent adult after due consideration and proper informed consent wishes to have a safe medical procedure than it may be there right to do so.

All children normally have doubts about themselves, their lives, their families and their bodies. Our role is to assist them in growing up in a natural and healthy manner so that they can be healthy adults and make healthy adult choices. Just because someone "feels or hopes" that something might give a desired result does not mean that it will help- and as history has shown us often medical fads are shown to be errors or even scams that actually harm people or prevent them from getting proper helpful proven treatments that actually work.

Gender transitioning chemical and surgical treatments are done with the expectation of making a permanent and reparable change in the natural process of human growth and development. Such permanent change, modification or mutilation of the human body and disruption of the normal chemical process should NEVER be made by a child or by anyone else until it has been PROVEN to be safe and effective and appropriate- which has NOT yet occurred.

Medical practice can be faddish, moving from one extreme to the other depending upon the political and social climate. It was not long ago that frontal lobotomies were recommended by institutions and family members for a perceived benefit -that was never proven-but became a common treatment nonetheless.

Please protect our innocent children from unproven and potentially permanently harmful treatments Please oppose unproven treatments under the euphemistic title headings of "youth transition" and "gender affirming care" until there is real PROOF that these are not harmful to children and actually helpful. Please wait for the science to show us the truth because it is your duty -to first do NO harm.

Respectfully submitted,

Dr. James E Kelly, D.O.

Licensed physician and surgeon, Diplomate of the American Board of psychiatry and neurology

Dear Members of the Florida Board of Medicine,

I'm a 55-year old mother, lifelong Liberal Democrat, business owner and an industry leader. Resident of Los Angeles (1999-2021). Our daughter (currently 16) is a gifted Autistic with severe ADD who was undiagnosed till age 14.

In the summer of 2020 (she was 14 at the time) she and her 4 neurodivergent friends began to persuade each other to make up male names and use male pronouns. As a hands-on mom running a tight ship, I interacted with the friends group often, driving them to the mall, restaurants, parks, sleepovers. During the entire 7th grade, these girls were OBSESSED with discussions about gender and queerness which they learned in the 6th grade GSA Club (Gay-Straight Alliance then, Gender-Sexuality Alliance now - the "ground-zero" of trans indoctrination!).

In June 2020 my daughter (saying she was a lesbian at the time) started weekly sessions with a seasoned talk therapist, a Lesbian in her mid-70's. In August 2020, my daughter declared a trans identity and quickly descended into a mental breakdown until she was catatonic, holed up in her room with the phone in her hand 14+ hours daily. **The therapist affirmed her trans delusion - even though my daughter said she was a Lesbian upon starting sessions - and never asked exploratory questions.** Full diagnostic clarity, following extensive psych evaluations and getting a psychiatrist, was available in late October 2020 and we immediately sent it to the therapist (ASD, ADHD-Inattentive, depression, anxiety, eating disorders, PCOS, liver problems). None of her neurodevelopmental conditions were ever addressed. The fact and truth that autistic people do not conform to society's arbitrary expectations of gender were never addressed. The fact and truth that autistic people have felt like aliens in their own bodies, living inside their heads, being bullied viciously and called "weirdos" since childhood was never addressed.

Throughout the fall of 2020, and especially starting in 2021, the therapist suggested to my daughter to call our insurance behind our backs and ask if she is eligible for Testosterone - at the depth of her mental breakdown. The therapist kept saying to her that *"Testosterone will bring her gender congruency."* (I have material evidence of what the therapist said exactly.) In May 2021 we discontinued therapy and left Los Angeles, moving to a small mountain community and home-schooling her.

Two years later, our daughter is flourishing, has a part-time job, and still takes Lexapro, Vyvanse and Metformin for pre-diabetes. She has friends, social circles, zero behavior problems and is thriving. The "trans" conversations have subsided. She thinks of herself as bisexual or gay. I attribute this healing to taking her out of the "ground-zero" of trans indoctrination and LIES -- the Los Angeles public school and the therapist who was actively "tranzing" our daughter, ignoring her co-morbidities which she NEVER ONCE addressed. I consider our lived experience to be a prime example of **medical malpractice, dereliction of duty and "lazy therapy"** as my husband called it (to the tune of \$250/session, out of pocket, weekly). The only reason I never

pursued legal action against the therapist is because California is extremely pro-trans and I'm afraid of Child Protection Services coming and taking our beautiful, brilliant daughter away.

I saved my child because I read studies on autism non-stop for 2 years (our entire extended family is gifted overachievers – Aspies, some with ADD, others with OCD, all with depression and anxiety), and read the statistics on ASD people being gender non-conforming. I saved my child also because I have the financial means to uproot my family and move just 3 months after we witnessed how our teen was being proactively shoved down a path of LIES and transgender medicalization. She is our only child. But what about any other parents? What about families with many kids? **This mass-scale recruitment of vulnerable patients for an uncontrolled medical experiment MUST BE STOPPED. This is a medical scandal of astronomical proportions and eugenics of the vulnerable youth.** The vulnerable youth includes: autistic, traumatized, LGB, or kids with mental illnesses or disability.

Thank you very much for your time.

Here is an excerpt of our story published in Dec. 2021 on PITT.substack.com:

To the unholy list of medical providers who failed to see the big picture of these interconnected diagnoses, I must also add her affirming therapist. The therapist was a lesbian in her 70s who, in hindsight, caused profound damage by affirming my child's trans delusion. The therapist casually discussed nonsensical terms such as "gender congruity", without delving deeply into past traumas. I trusted her experience, wisdom and depth of understanding of lesbians which I thought my daughter was, at the time. To be honest though, now, I am not positive my daughter is a lesbian. Maybe she will be a very late bloomer, like me and her dad, due to autism. The pressure for kids and teens to label themselves very early is ruinous. Autistics mature emotionally much later.

The therapist knew full well that my daughter had pre-diabetes. At the time, she was 100 lbs overweight (this has been successfully managed since), and her liver enzymes and cholesterol were abnormal. The therapist also knew all her mental diagnoses. The therapist suggested things such as, and I quote, *"Try calling your parents' insurance to see if you are eligible for Testosterone."* (T causes liver cancer and liver failure in women, alongside uterine atrophy.) *"Yes, T will bring you gender congruity."* I am still trying to understand, was the therapist trying to provoke my daughter, to see her reaction, or was she serious? The level of unprofessionalism to the tune of \$250/session was staggering. **In hindsight, I believe the**

therapist was a RECRUITER for the trans cult and was trying to enroll my daughter to become a patient for medicalization.

I was emphatic with the therapist about the fact that my daughter never before exhibited interest in being the opposite sex. None of my questions were answered, such as, *"Is it no longer OK to be a lesbian? And if so, why?"*, *"The 9th grade art teacher told me that 25% of her female art students use male names and pronouns – what is the explosion in trans all about?"* When I asked the therapist, *"Please discuss with my child curtailing the hours on Social Media,"* she replied, *"She is using Social Media to nurse her broken heart and to distract herself. It's OK to be on her phone all day..."* As though she wanted my teen to consume more and more trans propaganda online.

I did ask her in writing this question, which she never answered: *"Could this epidemic of girls self-identifying as 'trans' be a revolt by teen girls towards the extreme sexualization and victimization of women? Towards the total fetishization of the 'Barbie doll look' and elevating it as the only possible model for femininity? Towards the constant bullying and degrading attitudes towards teen girls who don't look like Barbie dolls? Towards the pervasive, profound and unchanging misogyny that girls experience at every step, personally, professionally, spiritually?"*

"Could this be a teenage rebellion against over-protective parents? Teenage revenge against a neurotic, controlling father and overwhelmed with work stress and deadlines mother? Because, sure as hell, our daughter does not have the first idea of what a transsexual person is, and this is all imitation and parroting."

The therapist never gave me answers to these questions. She called my daughter "he."

We discontinued with this therapist in May 2021.

As the parent of a child that suffers from Rapid On-Set Gender Dysphoria, I implore you to ban "Affirmative Care" for minors. Personally, I believe it should be banned for all ages. Afterall, the only long-term study that followed all participants showed that those who medically transition are 19.1 times more likely to commit suicide than the general public. There is also a recent study that, through the efforts of SEGM, had to correct their conclusions to accurately reflect that data showed there is no evidence that puberty blockers, cross-sex hormones, or gender affirming surgeries improve mental health.

We desperately need professionals to stand up and stop this insanity. The brain doesn't complete the maturation process until a person is at least 25 years old. Yet children are being allowed to make decisions that will affect them for the rest of their lives.

All of the procedures considered "Affirming Care" are experimental. Since none are being tracked or any long-term research following any of these procedures is being conducted, we will never know the depth of how devastating the outcomes are. At this point, we can only rely on the testimony of the tens of thousands of detransitioners. The common theme among detransitioners is they were led/coerced down the path of medical transitioning. Once they realized they had made a mistake transitioning, the same people who encouraged them, viscusly turned their backs on them, including the doctors and mental health professionals.

Once again, I ask that you ban "Affirmative Care" for gender-confused minors.

Thank you,
Michelle Faulk

Dear. Dr. Vazquez and board members,

When I heard that the Florida Board of Medicine would be meeting to consider implementing regulations regarding youth gender medicine and the informed consent process, I felt compelled to share my family's story. My pre-teen daughter has been identifying as trans for nearly three years, ever since 4th grade. She had not expressed any signs of gender confusion during her childhood until her best friend began identifying as transgender. My child's best friend resided part-time with a female teenage cousin who identified as transgender before she did. I am unaware of how the ideology reached my daughter's friend's cousin, but I'm sure it can be "contact traced" to a friend, other family member, or a personality the child followed on social media. The social contagion aspect is real.

In Kindergarten, my daughter had a circle of four girlfriends - none of whom indicated gender identity distress or questioning at the time. At the end of 1st grade, one child moved to a different school, and we were unable to stay in touch with her. The friend circle went from having four kids to three. By the time they reached fourth grade, three out of the three remaining friends began identifying as trans. While I recognize that after coming out, a trans youth may seek out other trans friends, and thus friend groups comprised of 100% trans kids would be observed, it is a different scenario entirely to have children who were exhibiting no confusion in Kindergarten "evolve" 100% into trans identification. The other friend who had changed schools, later reappeared in my daughter's life once they started attending the same middle school; this child is not identifying as trans. The child who had been removed from the friend group never "evolved" into trans self identification, while the three remaining friends did. This is an example of the social contagion at play. One may say that people feel more comfortable coming out as trans now, and that is the reason for the sharp increase. But if that is the case, in accordance with the statistic of 75% (three out of the four original friends), then shouldn't my mother be coming out now that there is less stigma, and claim to be my other father? Shouldn't I be reconsidering my own gender identity, or my grandmother reconsidering hers? One may scoff at my simplistic, and small sample size "statistic", but this anecdotal case is not mine alone. This is happening all over the country.

I feel that my daughter's childhood ended abruptly on the day that she came out as trans. Instead of playing with stuffed animals like she used to love doing, she was having phone conversations with her friends about wearing binders. I was shocked that newly-turned ten year olds were having conversations about changing their bodies in this way. I suspect that this was brought on, in large part, by discomfort associated with puberty - particularly developing breasts and menstruation. To this distress, I can relate. It is a natural part of the human experience to feel ashamed of and uncomfortable about these changes. It does not mean that children are in the wrong bodies. It does not mean that any medical

intervention should pause, turn off, or alter this part of one's life cycle. It is unfortunate that the voices promising "the cure" - gender transition - reach children during vulnerable times in their lives. I think back on my own childhood and am convinced that I would have been susceptible to this message. I challenge you to reflect on your own childhood, and the childhoods of those you hold dear, and ask yourself if you or your loved ones may have been susceptible as well.

Shortly after coming out to family, my daughter boldly came out to her 5th grade teacher (I think she would have come out to her 4th grade teacher had COVID not sent children home for the remainder of the school year). She requested that an announcement about her trans status be made to the class - not just her classroom - but the entire Graduating Class of 2028. I am not sure if our experience is unique in this way, but my daughter has a voracious appetite for attention. And she has always identified with and been a friend to the downtrodden. I think these personality traits greatly impacted her coming out publicly as trans. The trans movement has been displayed as a virtuous one, and I think my child considers it a badge of honor to be a part of the community. It was very distressing to receive a phone call from the school about this, but little did I know, I was lucky to receive any call at all informing me. While on the phone with the principal, I was forewarned that once my daughter moved on to middle school, per the LGBTQ+ school district policies, I would no longer be notified of these types of occurrences. I would not have a say in which pronouns or names would be used in the school, nor would I be informed of any social transitioning such as this taking place. It is a hurtful notion that our society would have ever considered that parents did not have a right to this sensitive information about their own children. At what point did considering a parent's role as adversarial become the blanket approach to all children? I hoped and prayed that by the time my child moved on to middle school that her fascination with the trans self-identification, ideology, and entire movement would be over.

We are now in the middle school years and my daughter still carries on with her trans belief system. Thankfully the laws of today require more transparency in the schools with regard to gender affirmation. I am still highly skeptical of her feelings – I believe it is the community camaraderie and her rebellious spirit that are the true reasons for her identification. We struggle constantly, and I am afraid to get her the help she needs for fear that I will make a mistake and unknowingly bring her to a therapist who follows the prevailing extremist viewpoint: that affirmation is the only treatment. I am concerned that I isolate her too much – I don't want her to hang out with kids who encourage her to feel badly about her body, and I don't want her to become the 'gateway friend' into this ideology for another child like her best friend in 4th grade was to her.

As medical professionals, I ask you the following:

In what other specialty of medicine are patients' opinions taken as proof that they suffer from the disorder or disease for which they have given themselves their own self-diagnosis? I cannot very well go to a psychiatrist and say that I suffer from bipolar disorder because sometimes I have "extreme ups and downs" and walk out with a prescription for lithium after a handful of visits. Please note that the trans activists have organized well in this regard - literal scripts are provided for appointments with medical providers which contain key words to help minors get their hands on puberty blockers and cross-sex hormones as quickly as possible.

How is gender dysphoria different from Body Integrity Dysphoria? I think these disorders can be viewed in parallel. What if there was an explosion of people - children especially - suffering with Body Integrity Dysphoria? Would those children be affirmed? After all, they

are experiencing a similar disconnect between the body and the mind, except instead of rejecting their biological sex, sufferers reject their physical ableness. They want to be their "true self," which often comes with a desire for amputation or disability to help them feel "complete" inside. Would children suffering from this be given experimental regional anesthesia treatments as an intermediary step (much like hormone blockers or cross-sex hormones are given to transgender individuals) before more drastic measures take place - such as limb amputation?

Families are engaged in a power struggle over our children with extreme trans activists, and it is in crisis mode. Radical trans activism has infiltrated government, schools, and most dangerously of all medicine. Activism is polluting science. The one-size fits all affirmation approach is not proper treatment for the majority of patients. This is evidenced by the droves of detransitioners who state that they had other underlying issues that were not sufficiently explored before the affirmation treatment route was taken. These individuals commonly state that they did not feel better in the years following their surgeries, and that the procedures did not resolve their anxieties as they were led to believe it would. They were sold gender affirmation snake oil. It is our communal duty, as medical professionals and caregivers of minors, to explore all other avenues before considering drastic affirmation treatments. Support should be given to medical professionals who suggest other evidence-based treatment options be implemented first. The current climate calls for these people to be silenced and ridiculed - which is extremist trans activism at work. Medical affirmation should be the final option after all other avenues have been explored, and never the first. Please consider that your peers in other western countries like the UK, Sweden, France, and Finland are re-evaluating these medical treatments for children and moving toward mental health treatment as the first line of defense. These countries have either stopped medical transitioning minors or are advocating for great caution when medically treating children.

Your Hippocratic Oath says to "do no harm" - by affirming, it seems that the medical community is agreeing with a child that they *should* dislike themselves as they were born and that the self-loathing of their body is appropriate. They *should* have these negative feelings about themselves - there *is* a problem with the child. Such a great problem, in fact, that the child should permanently and irreversibly disfigure and damage their own body. The medical community should instead be trying to improve the individual's self-perception to promote healing and overcome their dysphoria. I respectfully request that the Board create rules to prevent doctors from being able to prescribe experimental puberty blockers, cross sex hormones and perform any type of gender affirming surgeries on minors. There is a lack of high-quality rigorous evidence surrounding these treatment procedures, which make them experimental in nature since the long-term consequences of these drugs being used on children/teens are relatively unknown.

Thank you for taking the time to read my letter and for your consideration of what I and other concerned citizens have said on the matter.

Sincerely,
Nicole Linero

Dear Dr. Vazquez,

As a practicing physician, I appreciate the opportunity to testify about these matters. Many young people clearly suffer in their experience of sexuality. And, of course, well-meaning people want to help.

But regardless of how one conceives of gender, that person IS male or female, as defined by genotype, a biological reality.

Therefore, both common sense and scientific data tell us that infusing non-physiological hormones or surgically altering the body is NOT a solution for distress.

No pre-adult could possibly give proper informed consent to permanent sterilization or to the permanent alteration in body image, giving rise to a shocking rate of suicide and depression.

It is no wonder that Europe has put the brakes on all of this.

Please do whatever you can to exercise prudence in limiting such irreversible medical practice on our vulnerable young people.

Thank you so much.

Sincerely yours,

N. Joseph Schrandt, M.D.

Paul A. Vazquez, J.D.
Executive Director
Florida Medical Board

Dear Mr. Vazquez,

I am attaching a detailed report for the Florida Medical Board as you discuss the safety and efficacy of medical interventions for those who experience sex-discordant gender identity, particularly adolescents with gender dysphoria. As you know, much of the public discussion on this issue is filled with unjustified ideological assertions and emotive arguments. The medical profession is called to base care decisions on objective scientific evidence for both safety and efficacy. In many areas of medicine, there is insufficient evidence to make definitive conclusions. In such circumstances, a cautious approach is deemed most prudent. When new experimental treatments are attempted, our profession has established standards for mitigating risk to study subjects. Unfortunately, in the field of gender medicine, ideology and politics have usurped these standard practices. I applaud the Medical Board of the State of Florida for their efforts to consider relative merits and concerns of the affirmative model of care to individuals suffering from gender dysphoria. As needed, I am happy to provide additional information to the board.

Sincerely,

Paul W Hruz MD PhD
Associate Professor of Pediatrics
Associate Professor of Cellular Biology and Physiology

**Expert Physician Report for the
State of Florida's Medical Board Meeting on September 30, 2022**

**PAUL W. HRUZ, M.D., Ph.D.
September 20, 2022**

This report provides information that is essential for the Medical Board of the State of Florida as it considers the best approach for the care of individuals who experience sex-discordant gender identity. For each of my opinions detailed below, I provide relevant published scientific literature and other publicly available information. Copies of cited sources can be provided on request.

- 1. In my opinion, there is a serious lack of quality scientific evidence regarding the safety and efficacy of gender affirming medical interventions for individuals who experience sex discordant gender identity. Use of such medical interventions remains a highly controversial and experimental approach.**

Pediatric patients referred to our practice for the evaluation and treatment of gender dysphoria are cared for by an interdisciplinary team of providers that includes a psychologist and pediatric endocrinologist who have been specifically chosen for this role based upon a special interest and professional knowledge and training in this previously rare patient population. Due to the documented, important, ethical concerns regarding the safety, efficacy, and scientific validity of controversial, unproven, and experimental treatment paradigms, I have not personally engaged in the delivery of gender affirming medical interventions to children with gender dysphoria. Given the unproven long-term benefits and the well-documented risks and harms of “transitioning” children, I decline to participate in such experimental treatments until the science has proven that the relative risks and benefits of this approach warrant such procedures.

My decision is strengthened by the knowledge that the vast majority of children who report gender dysphoria will, if left untreated, grow out of the problem — a natural coping-developmental process — and willingly accept their biological sex. Despite differences in country, culture, decade, follow-up length and method, multiple studies have come to a remarkably similar conclusion: very few gender dysphoric children still want to transition by the time they reach adulthood. Many turn out to have been struggling with sexual orientation issues rather than sex discordant “transgender” identity. The exact number of children who experience realignment of gender identity with biological sex by early adult life varies by study.

Estimates within the peer reviewed published literature range from 50-98%, with most reporting desistance in approximately 85% of children prior to the widespread adoption of the “gender affirmation only” approach. Thus, desistance (*i.e.*, the child accepting their natal, biological sex identity and declining “transitioning” treatments) is the outcome for the vast majority of affected children who are not actively encouraged to proceed with sex-discordant gender affirmation.

Since there are no reliable assessment methods for identifying the small percentage of children with persisting sex-gender identity discordance from the vast majority who will accept their biological sex, and since puberty blocking treatments, hormone transition treatments, and surgical transition treatments are all known to have potentially life-long devastating, negative effects on patients, I and many colleagues view it as unethical to treat children with an unknown future by using experimental, aggressive, and intrusive gender affirming medical interventions.¹

2. Peer-reviewed, published research in credible science-medical journals.

My opinions as detailed in this report are based upon my knowledge and direct professional experience in the subject matters discussed. The materials that I have relied upon are the same types of materials that other experts in my field of clinical practice rely upon when forming opinions on the subject including hundreds of published, peer reviewed scientific research (and professional) articles.

As discussed in detail in this report, the extant published literature on the use of puberty blockers, cross-sex hormones and gender affirming surgeries are based, almost entirely, upon studies with major methodological limitations.²

This includes:

- Significant recruitment biases including internet-based convenience sampling;

¹ See Cantor, *Do Trans-Kids stay Trans- When The Group Up?*, Sexology Today, available at http://www.sexologytoday.org/2016/01/do-trans-kids-stay-trans-when-they-grow_99.html (providing summary of multiple research studies); *see also infra*, publications reviewed in detail below.

² See Hruz, *Deficiencies in Scientific Evidence for Medical Management of Gender Dysphoria*, Linacre Q 87(1): 34-42, doi: 10.1177/0024363919873762 (2020).

- Relatively small sample sizes for addressing a condition that is likely to be multifactorial;
- Short term follow-up;
- Lack of randomization to different treatment arms;
- Failure to even consider alternate hypotheses;
- Failure to include proper control groups and, in many studies *no* control group at all;
- Reliance on cross sectional sampling that may identify associations, but *cannot* establish causal relationships between intervention and outcome;
- A high rate of patients lost to follow up in longitudinal analyses which is relevant to questions of regret, desistance and completed suicide;
- Biased interpretation of study findings with a goal of validating *a priori* conclusions rather than seeking evidence to disprove the null hypothesis;
- Ignoring starkly contradictory research documenting the lack of effectiveness of “transitioning” procedures, the low quality of research in this area, and the ongoing contentions and disagreements over this highly controversial, experimental medical field.

3. Basis for my opinions.

My opinions documented in this report are based on my:

- (1) knowledge, training, and clinical experience in caring for thousands of patients over many years;
- (2) detailed methodological reviews of hundreds of relevant peer-reviewed science publications;
- (3) consults, discussions, and team analyses with colleagues and other experts in the field, including attendance and participation in various professional conferences;
- (4) publications in peer reviewed scientific journals;
- (5) editorial work for peer reviewed scientific journals; and
- (6) peer reviewed research grant receipt and review work.

The materials I have relied upon in preparing this report are the same types of materials that experts in my field of study typically and regularly rely upon when forming opinions on these subjects.

In addition to peer reviewed published research articles related to gender affirming medical interventions (see specific citations below), I also cite a wide variety of peer reviewed, published, scientific journal evidence documenting the recent, very public, disclosures of the multiple and serious methodological errors, failures, and defects of “transitioning treatment” research. Specific examples include:

- *The Branstrom Long-Term Treatment Outcome Study*. The historic Branstrom report is a peer reviewed, published, scientific journal article that documents a long-term treatment (10+ years) outcome research investigation testing the effects of hormonal and surgical “transitioning” treatments on patients. This historic research found no reliable benefits from these disfiguring-sterilizing “treatments,” as well as evidence suggesting *increased* suicide attempts and anxiety disorders following the “gender transitioning” treatments. In addition, detailed methodological critiques discovered significant research errors by the authors that appear to support the investigative theory that the authors had initially attempted to manipulate and misreport the findings of the study.³ The authors ultimately recanted their initial misreporting and agreed that their study produced no reliable evidence of benefits for gender reassignment hormone and surgical treatments. This historic investigation has helped to generate a profound collapse of support for these experimental procedures across Europe.⁴

³ See, *infra* for detailed notes and review with multiple citations.

⁴ See SEGM, *Correction of a Key Study: No Evidence of “Gender-Affirming” Surgeries Improving Mental Health*, available at https://segm.org/ajp_correction_2020 (Aug. 30, 2020; last accessed June 29, 2021); Van Mol et al., *Gender-Affirmation Surgery Conclusion Lacks Evidence*. *Am. J. Psych.* 177(8): 765-66 (2020).

- *The National Finland Review Recommending Suspension of Transitioning Treatments for Children as they Remain Experimental and of Uncertain Benefit.* A National Science Review in Finland carefully examined all relevant science and suspended transition treatments for minors under age 16.⁵ This official peer review recommends that psychotherapy should be the first line of treatment for gender dysphoric youth.⁶ “Cross-sex identification in childhood, even in extreme cases, generally disappears during puberty . . . The first-line treatment for gender dysphoria is psychosocial support and, as necessary, psychotherapy and treatment of possible comorbid psychiatric disorders . . . No gender confirmation surgeries are performed on minors . . . Potential risks of GnRH therapy include disruption in bone mineralization and the as yet unknown effects on the central nervous system . . . there are no medical treatments [for transitioning] that can be considered evidence-based . . . In cases of children and adolescents, ethical issues are concerned with the natural process of adolescent identity development, and the possibility that medical interventions may interfere with this process. It has been suggested that hormone therapy (e.g., pubertal suppression) alters the course of gender identity development; i.e., it may consolidate a gender identity that would have otherwise changed in some of the treated adolescents. The reliability of the existing studies with no control groups is highly uncertain, and because of this uncertainty, no decisions should be made that can permanently alter a still-maturing minor’s mental and physical development . . . A lack of recognition of co-morbid psychiatric disorders common among gender-dysphoric adolescents can also be detrimental. Since reduction of psychiatric symptoms

⁵ See SEGM, *One Year Since Finland Broke with WPATH “Standards of Care”* available at: https://segm.org/Finland_deviates_from_WPATH_prioritizing_psychotherapy_no_surgery_for_minors (July 2, 2021).

⁶ See Palveluvalikoima, *Recommendation of the Council for Choices in Health Care in Finland (PALKO/COHERE Finland): Medical Treatment Methods for Dysphoria Related to Gender Variance In Minors* (2020).

cannot be achieved with hormonal and surgical interventions, it is not a valid justification for gender reassignment. A young person's identity and personality development must be stable so that they can genuinely face and discuss their gender dysphoria, the significance of their own feelings, and the need for various treatment options. For children and adolescents, these factors are key reasons for postponing any interventions until adulthood... In light of available evidence, gender reassignment of minors is an experimental practice.”⁷

- *Sweden's Flagship Karolinska Hospital Suspends Transitioning Treatments for Children Under 16 and Requires Research Oversight for Patients Under 18.*

In Sweden, the world-renowned Karolinska Hospital reviewed the current research and suspended pediatric gender transitions for patients under 16 outside of experimental, monitored clinical trials settings as of May 2021. Treatment will focus on psychotherapy and assessment.⁸ The “Dutch protocol” for treating gender dysphoric minors has been discontinued over concerns of medical harm and uncertain benefits. This new Swedish policy is consistent with Finland's recently revised guidelines and changes in England's policies as well as the Arkansas legislation in the U.S. All have been changed to prioritize psychological interventions and social support in contrast to medical interventions, particularly for youth with no young childhood history of gender dysphoria (presently the most common patient presentation).⁹

- *A Sweden National Review Documents “Low Quality Research” in this Experimental and Controversial Field.*¹⁰ “This report was commissioned by the Swedish government and is a scoping review of the literature on gender dysphoria in children and adolescents. The report can be a basis for further evaluation of risk of bias and evidence.” The Swedish national review reported: “No relevant randomized controlled (treatment outcome) trials in children and adolescents were found.” The review also reported “Conclusions:”
 - We have not found any scientific studies which explains the increase in incidence in children and adolescents who seek the health care because of gender dysphoria.
 - We have not found any studies on changes in prevalence of gender dysphoria over calendar time, nor any studies on factors that can affect the societal acceptance of seeking for gender dysphoria.
 - There are few studies on gender affirming surgery in general in children and adolescents and only single studies on gender affirming genital surgery.
 - Studies on long-term effects of gender affirming treatment in children and adolescents are few, especially for the groups that have appeared during the recent decennium . . .
 - Almost all identified studies are observational, some with controls and some with evaluation before and after gender affirming treatment. No relevant randomized controlled trials in children and adolescents were found.
 - We have not found any composed national information from Sweden on: [] the proportion of those who seek health care for gender dysphoria that get a formal diagnosis [, nor] the proportion starting endocrine treatment to delay puberty [, nor] the proportion starting gender affirming hormonal treatment [, nor] the proportion subjected to different gender affirming surgery.
- *UK Researchers, Courts, and Other Reviewers Highlighted the Paucity of Quality Research, Limitations, Defects, and Risks in the Still Experimental, Controversial “Gender Transitioning” Treatment Field.* The British official

medical review office (the National Institute of Health and Care Excellence, or “NICE”) published reports on transitioning science.¹¹ An official review found, “[t]he evidence for using puberty blocking drugs to treat young people struggling with their gender identity is ‘very low.’” NICE said existing studies of the drugs were small and “subject to bias and confounding.” The assessment of the evidence into the drugs was commissioned by NHS England. It is part of a review into gender identity services for children and young people.¹² The NICE review noted it was difficult to draw conclusions from existing studies because of the way they had been designed. They were “all small” and did not have control groups, which are used to directly compare the effect of different treatments. There were other issues with the studies too, such as not describing what other physical and mental health problems a young person may have alongside gender dysphoria.

The British NICE service also reviewed the evidence base for cross-sex hormones.¹³ The review found the evidence of clinical effectiveness and safety of cross-sex hormones was also of “very low” quality, explaining “[a]ny potential benefits of gender-affirming hormones must be weighed against the largely unknown long-term safety profile of these treatments in children and adolescents with gender dysphoria.” Both documents were prepared by NICE in October 2020 and will now help inform Dr. Hilary Cass's independent review into NHS gender identity services for children and young people.¹⁴

This British study conclusion noted: “We found no evidence of change (no

improvement) in psychological function with GnRHa treatment as indicated by parent report (CBCL) or self-report (YSR) of overall problems, internalizing or externalizing problems or self-harm....”

Puberty blockers used to treat children aged 12 to 15 who have severe and persistent gender dysphoria had no significant effect on their psychological function, thoughts of self-harm, or body image, a study has found. However, as expected, the children experienced reduced growth in height and bone strength by the time they finished their treatment at age 16.¹⁵ Regarding the UK’s Tavistock and Portman NHS Trust’s Gender Identity Development Service’s experimental trial of puberty blockers for early teenagers with gender dysphoria, Oxford’s Professor Michael Biggs wrote, “To summarize, GIDS launched a study to administer experimental drugs to children suffering from gender dysphoria . . . After a year on GnRHa [puberty blockers] children reported greater self-harm, and girls experienced more behavioral and emotional problems and expressed greater dissatisfaction with their body—so puberty blockers actually exacerbated gender dysphoria.”¹⁶

As Griffin et al. discussed, “[a]s there is evidence that many psychiatric disorders persist despite positive affirmation and medical transition, it is puzzling why transition would come to be seen as a key goal rather than other outcomes, such as improved quality of life and reduced morbidity. When the phenomena related to identity disorders and the evidence base are uncertain, it might be wiser for the profession to admit the uncertainties.” In addition,

¹⁵ See Dyer, *Puberty Blockers: Children Under 16 Should Not be Referred Without Court Order, Says NHS England*, BMJ 371:m4717, doi: 10.1136/bmj.m4717 (2020); Dyer, *Puberty Blockers Do Not Alleviate Negative Thoughts in Children with Gender Dysphoria, Finds Study*, BMJ 372:n356, doi: 10.1136/bmj.n356 (2021); Carmichael et al., *Short-Term Outcomes of Pubertal Suppression in a Selected Cohort to 12 to 15 Year Old Young People with Persistent Gender Dysphoria in the UK*, medRxiv, doi: 10.1101/2020.12.01.20241653 (2020); BBC Summary, available at: <https://www.bbc.com/news/uk-55282113journal.pone.0243894>; see also Transgender Trend, *Tavistock’s Experimentation with Puberty Blockers: Scrutinizing the Evidence*, available at: <https://www.transgendertrend.com/tavistock-experiment-puberty-blockers/> (Mar. 5, 2019).

¹⁶ See also Griffin et al., *Sex, Gender and Gender Identity: A Re-Evaluation of the Evidence*, BJPsych Bulletin 45(5):291-99, doi:10.1192/bjb.2020.73 (2021).

Griffin et al. wrote: “Transgender support groups have emphasized the risk of suicide. After controlling for coexisting mental health problems, studies show an increased risk of suicidal behaviour and self-harm in the transgender population, although underlying causality has not been convincingly demonstrated.”¹⁷ In sum, political activists and too many providers have used a fear of suicide to push experimental unproven, hazardous treatments.

- *Review of the World Professional Association for Transgender Health’s (WPATH) Controversial and Outdated Treatment “Standards”*. A 2021 review found WPATH standards “incoherent.”¹⁸ Both WPATH and Endocrine Society guidelines have recently been assessed for quality by a systematic review, which found them to be of low quality. Specific to WPATH, the reviewers noted the difficulty of even extracting clear recommendations, describing the WPATH guidelines as “incoherent.” Standards of care should provide practitioners with evidence-based standards by which they may reliably inform the patient of projected outcomes and do so with a known error rate. Such data is the starting point for obtaining informed consent, which is not provided by either of these guidelines. The WPATH current version 7 standards violate minimal ethical and quality standards set by national organizations that review and post medical treatment standards including the National Academy of Medicine. WPATH board members suffer from serious financial conflicts of interest (e.g., virtually all WPATH BD members obtain most of their personal income from performing the very same “treatments” they are supposed to evaluate objectively). In addition, the minimal length of time treatment standards must be refreshed is every five years and WPATH version 7 is now nearly *ten* years old and thus far past its useful “shelf life.”

¹⁷ See Marshall et al., *Non-Suicidal Self-Injury and Suicidality in Trans People: A Systematic Review of the Literature*, Int. Rev. Psychiatry 28(1):58–69, doi: 10.3109/09540261.2015.1073143 (2016).

¹⁸ See Dahlen et al., *International Clinical Practice Guidelines for Gender Minority/Trans People: Systematic Review and Quality Assessment*, BMJ Open, 11(4):e048943, doi: 10.1136/bmjopen-2021-048943 (2021).

Given that the most current research¹⁹ are sharply critical of the ongoing failure of random control trials and the generally very low-quality evidence in this controversial field (the 10 year old WPATH version 7 standards have aged very poorly indeed and should be viewed as hazardous to patients.)

- *The UK High Court in the Bell Litigation – after hearing from multiple international expert witnesses – found transitioning treatments to be “experimental”*. In an internationally reported case, the High Court of London ruled these “gender transitioning” treatments were “experimental,” ordering protections for children who could not consent to such hazardous treatments given the lack of evidence of benefits and clear evidence of risks (*e.g.*, sterilization).

The court’s order that judges should oversee the consent of minors on a case-by-case basis was overturned on appeal — as the appeals court returned consent duties to medical providers — but left intact the trial court’s opinion that the evidence produced during the hearing demonstrated “gender transitioning treatments” remain controversial with serious risks of irreversible harm (including sterilization of the patient) and of unproven benefit.²⁰

“Children under 16 with gender dysphoria are unlikely to be able to give informed consent to undergo treatment with puberty-blocking drugs, three High Court judges have ruled . . . Given the long-term consequences of the clinical interventions at issue in this case, and given that the treatment is as yet innovative and experimental, we recognize that clinicians may well regard these as cases where the authorization of the court should be sought prior to commencing the clinical treatment . . . The judges also pointed to the lack of evidence about the long-term effects of puberty blockers.”²¹

¹⁹ Including, *e.g.*, the long-term Branstrom and Hisle-Gorman treatment outcome studies, the British NICE review, the Sweden review, the Finland review, the British Dr. Cass national review and others.

²⁰ See BBC, *Puberty Blockers: Under-16s 'Unlikely to be Able to Give Informed Consent'*, available at: <https://www.bbc.com/news/uk-england-cambridgeshire-55144148> (Dec. 1, 2020).

²¹ *Id.*

- *The British Independent Review of Gender Identity Services for Children and Young People: Interim Report by National Expert, Dr. Hilary Cass, M.D., was Published in February 2022.* The Dr Cass interim review concluded that “Evidence on the appropriate management of children and young people with gender incongruence and dysphoria is inconclusive both nationally and internationally.” Dr. Cass notes that “There is lack of consensus and open discussion about the nature of gender dysphoria and therefore about the appropriate clinical response.”²²
- *The Society for Evidence Based Gender Medicine (SEGM) Review Summarizes the Health Risks of Transitioning.* Consistent with changes in policy in Sweden, Finland, England, and Arkansas — due to much negative research findings over recent years — SEGM, a collection of national and international experts in the field, published a research summary documenting the serious health risks of “transitioning treatments” compared to the well-known lack of evidence of reliable benefits for such treatments.²³
- *The Cochrane Review Found Insufficient Evidence of Benefits.* The widely respected Cochrane Review examined hormonal treatment outcomes for male-to-female transitioners over 16 years. They found “insufficient evidence to determine the efficacy or safety of hormonal treatment approaches for transgender women in transition.” It is remarkable that decades after the first transitioned male-to-female patient, quality evidence for the benefit of transitioning is still lacking.²⁴

²² See The Cass Review, *Interim Report*, available at: <https://cass.independent-review.uk/publications/interim-report/>).

²³ See SEGM, *Science Studies – Health Risks of Medical and Surgical Gender Reassignment*, available at <https://www.segm.org/studies>.

²⁴ See Haupt et al., *Antiandrogen or Estradiol Treatment or Both During Hormone Therapy in Transitioning Transgender Women*, Cochrane Database Sys. Rev. (Review – Intervention), doi: 10.1002/14651858.CD013138.pub2 (2020).

4. **A March 2021 study – with the largest sample yet – is consistent with the new direction for Finland, Sweden, the UK, and France – show that most young gender dysphoric children, if left alone, grow out of the problem with no medical intervention.²⁵**

“Watchful waiting” is the recommended treatment: in the past, 67% of children meeting the diagnostic criteria for gender dysphoria no longer had the diagnosis as adults, with an even higher 93% rate of natural resolution of gender-related distress for the less significantly impacted cases.²⁶

5. **Experts are uniformly concerned with, and baffled by, the unexplained rapid and extreme demographic shifts in patient age and sex. Such shifts produce serious concerns about whether decades of previous research—done on a very different population group—even apply to the current patient cohort.**

For decades, transgender patients were mostly older adults or very young boys. Over the last few years, a tsunami of teenaged girls has flipped the demographics of transgender patients—now up to 7 to 1 teen girls. Many experts have noted that the previous research on trans patients cannot be relied upon when the patient group has so rapidly and mysteriously been transformed. In sum, the newly presenting cases are vastly overrepresented by adolescent females, the majority of whom also have significant mental health problems and neurocognitive comorbidities such as autism-spectrum disorder or ADHD.²⁷ The most recent evidence supports the emerging theory of social

²⁵ See Devita et al., *A Follow-Up Study of Boys with Gender Identity Disorder*, *Frontiers in Psychiatry* doi: 10.3389/fpsy.2021.632784 (March 2021).

²⁶ See also, e.g., Zucker, *The Myth of Persistence: Response to “A Critical Commentary on Follow-Up Studies and ‘Desistance’ Theories About Transgender and Gender Non-Conforming Children”* by Temple Newhook et al. (2018), *Int. J. Transgenderism* 19(2):231–24 (2018).

²⁷ See de Graaf & Carmichael, *Reflections on Emerging Trends in Clinical Work with Gender Diverse Children and Adolescents*, *Clin. Child Psychology & Psychiatry*, 24(2): 353-64 (2018).

contagion as estimates of sex-discordant gender identity are rocketing upwards from 1 in 10,000 to “the number of U.S. transgender-identified youth may be as high as 9%.”²⁸

This unexplained, radical transformations of demographics does not happen in actual illnesses (cancer, heart disease, anxiety disorders, etc.), but is tragically consistent with previous mental health system disasters such as the once very rare “multiple personality disorder” and “recovered repressed memory” patients that radically increased in the 1990s.

Dr. Thomas Steensma, a prominent investigator of the Dutch protocol—the original model for transitioning treatments—has recently noted, “[w]e don’t know whether studies we have done in the past can still be applied to this time,” specifically because of the unexplained surge in female adolescents reporting gender dysphoria. “Many more children are registering, but also of a different type . . . Suddenly there are many more girls applying who feel like a boy . . . now there are three times as many females as males.” He concluded with the warning that “[w]e conduct structural research in the Netherlands. But the rest of the world is blindly adopting our research.”²⁹

6. Examples of limited, low quality, and defective research.

The hazards of making treatment recommendations based on studies with major methodological weaknesses can be readily seen by considering representative studies used by advocates of medical gender affirmation to justify this approach. For example:

- The study by De Vries and colleagues³⁰ is often cited to support longitudinal evidence of benefit from pubertal blockade. Although improvements in mood were observed and changes in the risk of behavioral disorders with pubertal

²⁸ See Kidd et al., *Prevalence of Gender-Diverse Youth in an Urban School District*, *Pediatrics* 147(6):e2020049823, doi: 10.1542/peds.2020-049823 (2021).

²⁹ See Tetelepta, *More Research is Urgently Needed into Transgender Care for Young People*: “Where Does the Large Increase of Children Come From?” AD, translation available at: <https://www.voorzij.nl/more-research-is-urgently-needed-into-transgender-care-for-young-people-where-does-the-large-increase-of-children-come-from/> (Feb. 27, 2021).

³⁰ de Vries et al., *Puberty Suppression in Adolescents with Gender Identity Disorder: A Prospective Follow-Up Study*, *J. Sex, Med.* 8(8):2276-83, doi: 10.1111/j.1743-6109.2010.01943.x (2011).

blockade were found over baseline, this study had no control group. Thus, the authors were unable to determine the basis of this improvement. The authors acknowledge that psychological support or other reasons may have contributed to (or wholly caused) this observation. It is also important to note that gender dysphoria itself *did not diminish* in study subjects, and there were *no changes* in body image-related distress.

- The study by Turban and colleagues³¹ is often cited as proof that pubertal blockade prevents suicide in transgender youth. However, this study used an unreliable, biased sampling methodology. As stated in the paper, the authors considered “a cross-sectional online survey of 20,619 transgender adults aged 18 to 36 years” from the 2015 U.S. Transgender Survey. This was an online survey of transgender and “genderqueer” adults recruited from trans-friendly websites. Among the many problems with this sampling methodology, there is *no* evidence of study subject identities, *no* way to assess for potential false subjects, and *no* medical diagnosis for entry. *No causation can be determined from this retrospective, cross-sectional design.* Furthermore, the study failed to even assess desisters and regretters. Turban claimed that desisters and regretters would “not be likely” in this study group, which also only included adults. Thus, the study “does not include outcomes for people who may have initiated pubertal suppression and subsequently no longer identify as transgender.”

Turban’s misleading claim of lower suicidal ideation for treated patients excluded the most seriously mentally ill patients that would have been *denied* affirmation treatment. Those who received treatment with pubertal suppression, when compared with those who wanted pubertal suppression but did not receive it, had lower odds of lifetime suicidal ideation (adjusted odds ratio = 0.3; 95% confidence interval = 0.2– 0.6). In Table 3 of the paper, under

³¹ Turban et al., *Pubertal Suppression for Transgender Youth and Risk of Suicidal Ideation*, Pediatrics 145(2):e20191724, doi: 10.1542/peds.2019-1725 (2020).

“Suicidality (past 12 months)” reductions for suppressed group vs. non-suppressed were seen for ideation (50.6% vs. 64.8%) and “ideation with plan” (55.6% vs. 58.2%). However, it is essential to note that suicidal “ideation with plan and suicide attempt” for the hormone suppressed group, in raw numbers, *increased* after treatment to 24.4% vs. 21.5% for the “non-treatment group.”

The most clinically significant result in this study — that Affirmation Treatments *did not prevent serious suicide attempts* — was *improperly and/or unethically ignored by the authors*. “Suicide attempts resulting in inpatient care” = 45.5% for suppression groups vs. 22.8% for those who did not receive pubertal suppression. Although the result of increased suicide attempts did not reach “statistical significance”, the clinical significance of this finding cannot be ignored. It would be most reasonable to conclude from an observation of 45% attempted suicide requiring hospitalization in the treated arm that the intervention was unsuccessful in improving health. Turban et al. ignored their own findings that a history of puberty suppression was associated with a persistence of serious suicide attempts. In sum, the Turban 2020 Pediatrics study, based on an unverified U.S. Transgender Online Survey, tells us little about the effects of puberty suppression on children with gender dysphoria.³²

- The 2021 study of Bustos et al.³³ attempts to provide a systematic review of 27 observational or interventional studies that report on regret or detransition following gender-transition surgeries. A total of 7,928 subjects were included in their meta-analysis. The authors concluded that only 1% or less of those who had gender-transition surgeries expressed regret. It is important to

³² See Biggs, *Puberty Blockers and Suicidality in Adolescents Suffering from Gender Dysphoria*, Arch. Sex. Behav. 49:2227-29, doi: 10.1007/s10508-020-01743-6 (2020); and the multiple Letters to the Editor that criticized the multiple methodological errors in this study, available at: <https://pediatrics.aappublications.org/content/145/2/e20191725/tab-e-letters#re-pubertal-suppression-for-transgender-youth-and-risk-of-suicidal-ideation>.

³³ See Bustos et al., *Regret After Gender-affirmation Surgery: A Systematic Review and Meta-analysis of Prevalence*, Plast. Reconstr. Surg. Global Open 9(3):e3477, doi: 10.1097/GOX.0000000000003477 (2021).

understand the serious methodological limitations and high risk of bias contained within the analysis in the 2021 Bustos et al. study.³⁴ This includes failure to include major relevant studies addressing this question,³⁵ inaccurate analysis within one of the studies considered,³⁶ and the general lack of controlled studies (thus no causal conclusions are possible), incomplete and generally short-term follow-up, large numbers of lost subjects, and lack of valid assessment measures in the published literature addressing this question. As noted by Expósito-Campos & D'Angelo (2021),³⁷ moderate to high risk of bias was present in 23 of the 27 studies included in the analysis. Furthermore, 97% of subjects analyzed were found within studies deemed to be of fair to poor scientific quality. Thus, this study cannot be used as strong support for the contention that regret is rare.

- The 2018 paper by Wiepjes et al.³⁸ is a retrospective review of records from all patients of the Center of Expertise on Gender Dysphoria gender clinic in Amsterdam from 1972-2015. While the study appears to report on the regret rates among a large cohort of adolescents (812) and children (548), regret is only reported for children and adolescents who had undergone gonadectomy once over 18 years of age. Of the adolescents, 41% started puberty suppression. Of those who started GnRH agonists, only 2% stopped this intervention (meaning that 98% of those who started puberty suppression progressed to cross-sex hormone therapy). An additional 32%, having already completed puberty, started cross-sex hormone therapy without use of a GnRH agonist. Classification of regret was oddly restricted, requiring physician

³⁴ See Expósito-Campos & D'Angelo, *Letter to the Editor: Regret after Gender-Affirmation Surgery: A Systematic Review and Meta-analysis of Prevalence*, *Plast. Reconstr. Surg. Global Open* 9(11): e3951, doi: 10.1097/GOX.0000000000003951 (2021).

³⁵ See Dhejne et al., *An Analysis of All Applications for Sex Reassignment Surgery in Sweden, 1960-2010: Prevalence, Incidence, and Regrets*, *Arch. Sex. Behav.* 43(8):1535-45 (2014).

³⁶ Wiepjes et al., *The Amsterdam Cohort of Gender Dysphoria Study (1972-2015): Trends in Prevalence, Treatment, and Regrets*, *J. Sex. Med.* 15(4):582-90, doi: 10.1016/j.jsxm.2018.01.016 (2018).

³⁷ *Supra*, note 31.

³⁸ *Supra*, note 33.

documentation of patient verbalized regret after gonadectomy and start of sex-concordant hormones to treat the iatrogenic hypogonadism. This means there are significant limitations to the conclusions that can be drawn from 2018 paper by Wiepjes et al. There is no discussion in this paper regarding adolescent regret of use of puberty blockers, cross-sex hormones, or mastectomies. Importantly, 36% of patients were lost to follow-up. This is notable given that gonadectomy iatrogenically induces the pathologic state of primary hypogonadism. Affected patients have a lifelong dependency for exogenously administered sex-steroid hormones, and thus an acute need for ongoing follow-up. The number of lost subjects who experienced regret or completed suicides is simply unknown, a serious defect as most patients with “regret” are expected to just walk away and thus rarely come back to the clinic and express regrets to anyone much less the physician who “transitioned” them. It is also significant that the average time to regret was 130 months — far longer than virtually all transitioning studies followed patients. The authors themselves acknowledge that it may be too early to predict regret in patients who started hormone therapy in the past 10 years.

- The 2021 study by Narayan et al.³⁹ examines anonymous survey results from 154 surgeons affiliated with WPATH. The response rate for this survey was 30%. Of the respondents, 57% had encountered patients with surgical regret. It is important to recognize that this study was specifically directed toward patients who had undergone surgical transition. Acknowledged biases of this study included selection bias, recall bias, and response bias. This type of study cannot accurately identify the prevalence in the transgender population as a whole and is particularly limited in the ability to assess potential for regret in the pediatric population.

³⁹ Narayan et al., *Guiding the Conversation-Types of Regret After Gender-Affirming Surgery and Their Associated Etiologies*, Ann. Translational Med. 9(7):605, doi: 10.21037/atm-20-6204 (2021).

- The 2018 Olson-Kennedy paper⁴⁰ presents the results of a survey of biologically female patients with male gender identity at the lead author's institution using a novel rating system for "chest dysphoria" created by the study authors. There were an equal number (68) of nonsurgical and post-surgical subjects surveyed. Those who had undergone bilateral mastectomies were reported to have less chest dysphoria than those who did not receive this intervention. Limitations of this study include convenience sampling of nonsurgical study subjects with high potential for selection bias, cross-sectional design (*e.g.*, thus no causal conclusions are possible), and lack of validation of the primary outcome measure. Test validation is particularly relevant in assessing adolescent questionnaires due to a variety of cognitive and situational factors in this population.⁴¹ Rigorous validation methods have been previously used in several other established questionnaires addressing adolescent self-perception.⁴² As previously noted, this study cannot provide information about a causal relationship between the intervention and outcome observed.
- The 2021 Almazan study⁴³ attempts to address mental health outcomes in relation to gender-transition surgery. As previously noted, this study relies upon data from the highly unreliable 2015 U.S. Transgender Survey. Limitations and weaknesses of this survey tool include convenience sampling, recruitment of patients through transgender advocacy organizations, demand

⁴¹ See Brener et al., *Assessment of Factors Affecting the Validity of Self-Reported Health-Risk Behavior among Adolescents: Evidence from the Scientific Literature*, J. Adolesc. Health 33(6):436–57, doi: 10.1016/s1054-139x(03)00052-1 (2003).

⁴² See Palenzuela-Luis et al., *Questionnaires Assessing Adolescents' Self-Concept, Self-Perception, Physical Activity and Lifestyle: A Systematic Review*, Children (Basel) 9(1):91, doi: 10.3390/children9010091 (2022).

⁴³ Almazan & Keuroghlian, *Association Between Gender-Affirming Surgeries and Mental Health Outcomes*, JAMA Surgery 156(7):611–18, doi: 10.1001/jamasurg.2021.0952 (2021).

bias (a.k.a. the good subject effect), a high number of respondents who reported having not transitioned medically or surgically (and reported no desire to do so in the future), and several other serious data irregularities. One notable data irregularity was that a high number of respondents reported that their age was exactly 18 years — a highly unlikely result indicting fraudulent responses on the anonymous “survey” where no actual, living respondent was ever seen, heard, or evaluated. As noted by D’Angelo and colleagues, these irregularities raise serious questions about the reliability of all USTS data⁴⁴ and therefore, the reliability of conclusions based on that data.

- The paper by Mehringer⁴⁵ provides a summary of qualitative interviews with 30 transmasculine youth (biological females who identify as men) with comparison between those who underwent bilateral mastectomy (n=14) and those who did not receive this intervention (n=16). Mean time from surgery was only 19 months. No validated objective measures were used to assess mental health. There are numerous potential confounding variables (*e.g.*, psychological co-morbidities, testosterone exposure, family dynamics) that could be responsible for the subjective perceptions of the study subjects. As a cross-sectional survey at a single center, the study methodology cannot establish a causal relationship between intervention and outcome. At best, the study can be used for hypothesis generation. It does not establish the efficacy of this approach, nor does it consider whether alternate approaches could achieve the desired outcome.

⁴⁴ D’Angelo et al., *One Size Does Not Fit All: In Support of Psychotherapy for Gender Dysphoria*, Arch. Sex. Behav., 50(1):7–16, doi: 10.1007/s10508-020-01844-2 (2021).

⁴⁵ Mehringer et al., *Experience of Chest Dysphoria and Masculinizing Chest Surgery in Transmasculine Youth*, Pediatrics 147(3):e2020013300, doi: 10.1542/peds.2020-013300 (2021).

- The study by Julian et al.⁴⁶ is also often used as evidence of the efficacy of gender affirming surgery. This study is an internet based cross sectional survey of 684 transgender youth (mean age 16 years) who reported having "chest dysphoria" with 89% (n=608) reporting use of chest binding and 11% (n=76) who did not engage in this practice. The study utilized the non-validated chest dysphoria scale described above for the 2018 Olson -Kennedy study. This study methodology has high potential for recruitment bias. Furthermore, as a cross-sectional study, it cannot establish causal relationships in study parameters. Since it addressed breast binding and not surgery, it does not provide data on the safety and efficacy of bilateral mastectomies in gender dysphoric youth.
- The study by Sood et al.⁴⁷ is yet another study that is used to support treatment efficacy. This is a single cite cross-sectional survey of 156 adolescent female subjects who completed the unvalidated chest dysphoria rating scale of Olsen-Kennedy described above. The study reports an association between report of chest dysphoria and the presence of anxiety and depression. As noted above, this study cannot establish a causal relationship between these study parameters. Furthermore, it does not address whether or not gender-affirming surgery (specifically bilateral mastectomy) is safe or effective in resolving associated psychological distress.

7. There are major and highly significant differences between male and female responses to many drugs, including sex hormones.⁴⁸

⁴⁶ Julian et al., *The Impact of Chest Binding in Transgender and Gender Diverse Youth and Young Adults*, J. Adolesc. Health 68(6):1129-34, doi: 10.1016/j.jadohealth.2020.09.029 (2021).

⁴⁷ Sood et al., *Association of Chest Dysphoria with Anxiety and Depression in Transmasculine and Nonbinary Adolescents Seeking Gender-Affirming Care*, J. Adolesc. Health 68(6):1135-41, doi: 10.1016/j.jadohealth.2021.02.024 (2021).

⁴⁸ See, e.g., Madla et al., *Let's Talk About Sex: Differences in Drug Therapy in Males and Females*, Adv. Drug Deliv. Rev. 175:113804, doi: 10.1016/j.addr.2021.05.014 (2021).

Giving estrogen to a biological male is not equivalent to giving the same hormone to a biological female. Likewise, giving testosterone to a biological female is not equivalent to giving the same hormone to a biological male.⁴⁹ Differences are not limited to pharmacokinetic effects but are present even at the cellular level.⁵⁰ Failure to acknowledge these differences can have tragic consequences. For example, in addition to the inherent sterilizing effect of cross-sex hormone administration, non-physiological levels of estrogen in males has been shown to increase the risk of thromboembolic stroke above the incidence observed in females.⁵¹

8. Biological basis of sex.

Reliance upon external phenotypic expression of primary sexual traits is a highly accurate, reliable, and valid means to assign biologic sex. In over 99.9% of cases, this designation will correlate with internal sexual traits and capacity for normal biologic sexual function. Sex is therefore not “assigned at birth” but is rather recognized at birth. In my opinion, this view is generally accepted by the relevant scientific communities in endocrinology, psychiatry, neonatology, biology, genetics, gynecology, and other fields.

9. Disorders of sexual development are very rare.

Due to the complexity of the biological processes that are involved in normal sexual development, it is not surprising that a very small number of individuals are born with defects in this process (1 in 5,000 births). Defects can occur through either inherited or *de novo* mutations in genes that are involved in sexual determination or through environmental insults during critical states of sexual development. Persons who are born

⁴⁹ See, e.g., Soldin & Mattison, *Sex Differences in Pharmacokinetics and Pharmacodynamics*, Clin. Pharmacokinetics 48(3):143–57, doi: 10.2165/00003088-200948030-00001 (2009); Pogun & Yazarbas, *Sex Differences in Drug Effects*, Encyclop. Psychopharmacology (Springer, Stolerma, ed.), doi: 10.1007/978-3-540-68706-1_209 (2010).

⁵⁰ See, e.g., Walker et al., *Matters of the Heart: Cellular Sex Differences*, J. Mol. & Cell. Cardiology 160:42–55, doi: 10.1016/j.yjmcc.2021.04.010 (2021).

⁵¹ See, e.g., Getahun et al., *Cross-Sex Hormones and Acute Cardiovascular Events in Transgender Persons: A Cohort Study*, Ann. Inter. Med. 169(4): 205–13, doi: 10.7326/M17-2785 (2018).

with such abnormalities are considered to have a disorder of sexual development (DSD). Most often, this is first detected as ambiguity in the appearance of the external genitalia. Such detection measurements are reliable and valid and accepted by the relevant scientific community. In my opinion, this view is generally accepted by the relevant scientific communities in endocrinology, neonatology, gynecology, psychiatry, biology, genetics, and other fields.⁵²

10. The ethical foundations of medicine – “first do not harm.”

The fundamental purpose of the practice of medicine is to treat disease and alleviate suffering. An essential tenet of medical practice is to avoid doing harm in the process. Efforts to rely upon clear, valid, reliable, and definitive evidence on how to best accomplish treatment goals is the essential ethical, professional, scientific, and clinical goals of physicians. Proponents of gender reassignment surgery for adolescents violate this essential principle by using experimental treatments on vulnerable populations without properly informing them of the actual risks and limitations of the treatments.⁵³

11. The Endocrine Society recognizes that the quality of evidence for “affirmative” treatments is currently “low or very low” (“estimate of effect is very uncertain”).

There is no general acceptance of these treatments in the relevant scientific community. The error rate is unknown and could be very high. The Endocrine Society published 2009 clinical guidelines for the treatment of patients with persistent gender dysphoria.⁵⁴ The recommendations include temporary suppression of pubertal development of children with GnRH agonists (hormone blockers normally used for

⁵² See Sax, *How Common is Intersex? A Response to Anne Fausto-Sterling*, J. Sex Research 39(3);174-78, doi: 10.1080/00224490209552139 (2002).

⁵³ See Jonsen, *Clinical Ethics*, New York: McGraw Hill (9th ed., 2022).

⁵⁴ See Hembree et al., *Endocrine Treatment of Gender-Dysphoric/Gender-Incongruent Persons: An Endocrine Society Clinical Practice Guideline*, J. Clin. Endocrinology Metab. 102(11):3869-3902, doi:10.1210/jc.2017-01658 (2017).

children experiencing precocious puberty) followed by hormonal treatments to induce the development of secondary sexual traits consistent with one's gender identity. In developing these guidelines, the authors assessed the quality of evidence supporting the recommendations made with use of the GRADE (Recommendations, Assessment, Development, and Evaluation) system for rating clinical guidelines. As directly stated in the Endocrine Society publication, "the strength of recommendations and the quality of evidence was low or very low." According to the GRADE system, low recommendations indicate that "[f]urther research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate." Very low recommendations mean that "any estimate of effect is very uncertain."⁵⁵ An updated set of guidelines was published in September of 2017.⁵⁶ The low quality of evidence presented in this document persists to the current day, as the controversy over these "treatments" is accelerating in recent years.

12. Administering hormones to a child whose gender dysphoria highly likely (80%+) to resolve is risky, unscientific, and unethical.

Iatrogenic damages, including life-long sterility, stunted growth, increased heart attack risk, etc., are often irreversible. Treatment of gender dysphoric children who experience persistence of symptoms with hormones (pubertal suppression and cross-hormone therapy) carries significant risk. It is generally accepted, even by advocates of transgender hormone therapy, that hormonal treatment impairs fertility and often result in sterility, which in many cases is irreversible.⁵⁷

⁵⁵ See Guyatt et al., *GRADE: An Emerging Consensus on Rating Quality of Evidence and Strength of Recommendations*, BMJ 2008(336):924, doi:10.1136/bmj.39489.470347.AD (2008).

⁵⁶ See *supra*, note 52.

⁵⁷ See Nahata et al., *Low Fertility Preservation Utilization Among Transgender Youth*, J. Adolescent Health 61(1):40-44, doi:10.1016/j.jadohealth.2016.12.012 (2017).

Emerging data also show that treated patients have lower bone density which may lead to increased fracture risk later in life.⁵⁸ Other potential adverse effects include disfiguring acne, high blood pressure, weight gain, abnormal glucose tolerance, breast cancer, liver disease, thrombosis, and cardiovascular disease.⁵⁹

13. Long term effects are unknown.

Such treatments are not generally accepted by the relevant scientific community and have no known nor published error rate. Since strategies for the treatment of transgender children as summarized by the Endocrine Society guidelines are relatively new, long-term outcomes are unknown. Evidence presented as support for short-term reductions in psychological distress following social transition in a “gender affirming” environment remains inconclusive. When considered apart from advocacy-based agendas, multiple potential confounders are evident. The most notable deficiencies of existing research are the absence of proper control subjects and lack of randomization in study design.⁶⁰

Although appropriate caution is warranted in extrapolating the outcomes observed from prior studies with current treatments, adults who have undergone social transition with or without surgical modification of external genitalia continue to have *rates of depression, anxiety, substance abuse and suicide far above the background population*.⁶¹

Endocrinology & Metabolism 102(11):3914–23, doi: 10.1210/jc.2017-01643 (2017).

⁶⁰ See Hruz, *Deficiencies in Scientific Evidence for Medical Management of Gender Dysphoria*, Linacre Q 87:34-42, doi:10.1177/0024363919873762 (2020).

⁶¹ See Adams et al., *Varied Reports of Adult Transgender Suicidality: Synthesizing and Describing the Peer-Reviewed and Gray Literature*, Transgender Health 2(1):60-75, doi:10.1089/trgh.2016.0036 (2017);

14. Medical treatments contrary to the science could result in irreversible harms to many patients who would otherwise have recovered naturally from gender dysphoria.

Of particular concern is the likelihood that naively requested gender transition “treatments” and social changes could interfere with known very high rates of natural-untreated resolution of sex-gender discordance. Any activity that encourages or perpetuates transgender persistence for those who would otherwise desist could cause significant harm, particularly in light of the current treatment paradigm for persisting individuals. As noted, sterility can often be expected with hormonal or surgical disruption of normal gonadal function.⁶²

15. “Gender affirmative” treatments damage or destroy healthy bodily organs, leading to loss of essential bodily functions (e.g., medically induced sterilization).

Despite the fact that gender dysphoria represents a psychological condition (as catalogued in the DSM since the third edition of this publication), some conceptualize the condition as a medical illness similar to cancer. When considered from this viewpoint, the goal of “treatment” is to alter the appearance of the body to conform to a patient’s perceived sexual identity, including the physical removal of unwanted “diseased” sexual organs. Since undesired body parts are fully formed and functional prior to hormonal or surgical intervention, the result of these “therapies” is injury to innate sexual ability. In particular, loss or alteration of primary sexual organs leads directly to impairment of reproductive potential. Recognition of this obvious consequence is the basis for the

see also Dhejne et al., *Long-Term Follow-Up of Transsexual Persons Undergoing Sex Reassignment Surgery: Cohort Study in Sweden*, PLoS One 6:e16885, doi:10.1371/journal.pone.0016885 (2011).

⁶² See Cheng et al., *Fertility Concerns of the Transgender Patient*. Translational Andrology & Urology 8(5):209-218. doi: 10.21037/tau.2019.05.09 (2019).

development of new arenas of medical practice where there is an attempt to restore what has been intentionally destroyed.⁶³

16. No competent, scientifically valid, and reliable cost-benefit analysis has been done on “gender affirmative” treatments.

When the FDA tests a drug, the safety analysis looks at all related risks. Specifically, the drug must not only be effective, but it must not cause side effects that are more damaging than the proposed treatment. This is a key weaknesses in the affirmation model of care. Not only have the “treatments” *not* been proven reliably effective compared to *no* treatment, they are proposed against the existing knowledge of well-documented, long-term health problems and damages (e.g., testosterone use by transgender men increases the risk of fatal heart disease, estrogen use by transgender women increases risk of blood clots and strokes, gender transition treatments—if completed—can cause life-long sterility, etc.).

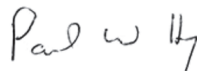

17. Summary opinions.

- There are no long-term, peer-reviewed published, reliable and valid, research studies documenting the number or percentage of patients receiving gender affirming medical interventions, including surgery, who are helped by such procedures.
- There are no long-term, peer-reviewed published, reliable and valid, research studies documenting the number or percentage of patients receiving gender affirming medical interventions, including surgery, who are injured or harmed by such procedures.
- Patients suffering from gender dysphoria or related issues have a right to be protected from experimental, potentially harmful treatments lacking reliable

⁶³ See, e.g., Ainsworth et al., *Fertility Preservation for Transgender Individuals: A Review*, Mayo Clin. Procs. 95(4):784-792, doi:10.1016/j.mayocp.2019.10.040 (2020).

and valid, peer reviewed, published, long-term scientific evidence of safety and effectiveness.

- Gender transition “affirmation” medical treatments, including surgery, for gender dysphoria and “transitioning” have no known, peer reviewed and published error rates—the treatments and assessment methods lack demonstrated, reliable and valid error rates.

To the Florida Board of Medicine:

I have been a physician for nearly forty years, and have witnessed the limitations of medicine's wisdom on many occasions. There have been some "advances", such as thalidomide and frontal lobotomy, that were hailed as breakthroughs in modern health care. Obviously, history has negated those predictions. However, while methods such as those had some scientific basis, albeit misguided, the bigger issue relating to transgender intervention is not based on evidence-based data. Rather, for the first time in my career, I am witnessing the support of a medical standard that is based solely on ideology, and not on science. This is a trap that you must recognize and avoid.

Although the American media and medical establishments do not want to recognize it, the experience of our European colleagues with these methods is critically important and instructive. The harm of these methods clearly and consistently overwhelms their "benefits", which are blatantly absent in objective longitudinal studies. It does not lessen the risk of suicide. If more than 80% of children desist and accept their biologic sex, with or without counseling, it is reprehensible that surgical mutilation should be promoted.

You have an opportunity to stop this politically and culturally motivated effort in Florida. The standard of care for gender dysphoric children and their parents is to "first do no harm". Do not allow political intimidation of medicine to advance further than it already has. Our patients and Florida's residents deserve that.

Dear Mr. Vazquez,

I hope that Florida will follow the example of Britain and other European countries in restricting gender affirming care to adults who can make their own health choices. These therapies formerly were available to adolescents and that policy was reversed when the frequency of significant complications and side effects became clear.

Dear Florida Board of Medicine,

Transgender ideology does not belong in pediatric healthcare as it is dangerous to impose this on our youth.

Gender dysphoria in pre-pubertal children resolves spontaneously (in 80-90%) after they develop through natural puberty. " Gender-affirming " practices have adverse consequences which affect children in mental, physical and spiritual ways. There are no long-term studies that have found beneficial effects from ' gender changing ' interventions that include but not limited to, puberty blockers or GNRH analogues , cross sex hormones and mutilating surgeries.

As we know, children are not small adults; they lack the developmental capacity to make these kind of decisions and they also need and deserve our protection from these harmful, life-altering interventions.

Let's let children be children !
Please help to keep gender transforming practices out of childhood.

Sincerely,

Dr. Angeli Maun Akey

I seriously question the rapidity and extent of the current trend in US transgender change.

Dr Cass's review with the associated pulling back to a more conservative approach in Finland, Sweden, and the UK should give us pause until longer term and more extensive studies confirm the better criteria for screening, management, and outcomes.

Hello,

Since this subject was discussed during the recent FMA annual meeting, I would like to provide input into the rules being discussed in the workshop 30-Sep-2022.

I believe that any rules need to include limits in the treatment of minors. Research shows that most (over 80%) minors with gender dysphoria see that condition resolve as a part of going through puberty. Also, many young adults express regret that they transitioned. Therefore, we are doing a great disservice to many young people by transitioning them too young. Likely there need to be other therapies required for minors before puberty blockers or other transition actions are taken.

Also, it is imperative that proper informed consent be required. This should include acknowledgement that the process is largely irreversible and that some others have had regrets of having gone through the procedure, and that this regret begins after it is too late.

And finally, I do not believe that public funds should be used to provide transition. We need to be very careful to ensure that the voices in medicine which actively support transition as treatment for gender dysphoria are not profiting from the process as that creates an obvious conflict of interest. These profit motives should also be part of the informed consent.

Thank you.

Sincerely,
Liudmila Buell, MD

To Whom It May Concern,

Thank you for taking the time to read my email.

Perhaps it is too late to save my son from the transgender ideology, but I feel compelled to do something to help save any other children from falling prey to this cult. Being a compassionate mother who dearly loves my son, the mama bear instinct naturally kicked in gear. I want to save my son and others from this evil ideology.

My family was dragged into this nightmare 7 years ago when my son was still in college.

My son is gifted, a loner and was diagnosed with what is now considered being on the Autism spectrum. He never showed any signs of identifying as transgender or having gender dysphoria when he was younger. While he was sensitive and empathetic, he was also a rough and tumble, energetic boy. We are still perplexed since he never showed signs of homosexuality, cross dressing or any paraphilia attributed to auto gynephilia.

He made a self-diagnosis after being heavily influenced by on-line sites such as Deviant Art and Reddit where he was made to feel like he belonged.

Doctors and therapists ignored several important details including his previous bouts of depression, that he suffered multiple concussions and that he was molested by a peer. In the first therapy session, he was told he needed to transition medically in order to prevent being suicidal. He is currently taking an antidepressant. Without having a mental health assessment, he was prescribed high dose female hormones after he signed an informed consent form. The therapist and physician's assistant should have seen red flags since cross-sex hormones and antidepressants do not mix.

Potential irreversible harms were never discussed by the doctor, physician's assistant, therapist or clinic. His mental illness has never been appropriately addressed. He was fast-tracked into becoming a patient for life, a cash cow for the therapists, the surgeons, the gender clinics and the pharmaceutical companies.

Today he is in his late twenties. In addition to taking cross-sex hormones, he had facial feminization surgery and laser hair removal. He has been castrated and he is being encouraged to have a vaginoplasty. He will need to be on some sort of hormones for the rest of his life as well as needing continuous therapy. He will never be able to have children and he has lost his sexual function. His life-expectancy is now shortened. He is at more risk for recurrent infections from surgeries, heart disease, stroke, mental illness and bone loss.

He needs to address the cause of his depression instead of making any further cosmetic changes to his body as he will never be a woman.

He has been told that he is better off without having his family in his life. We haven't seen him in almost 3 years. Our relationship with our son has been destroyed. My heart aches for him.

We have been called transphobic, angry and hateful since we do not affirm him as being female. We have been made to feel guilty by being asked "Wouldn't you rather have a live daughter than a dead son?" We will not participate in this lie.

How many more bodies will be harmed before this is stopped? My question for anyone who doubts this is happening, is "What if your son was told he needed to mutilate his body in order to become

mentally healthy or happy?"

The system has failed our son.

Mae Lyle

We are totally against any transitioning of minors in Florida as regards the medical community. We ask for a ban of gender-affirming care for minors - this is child abuse at the highest level.

Please record my comments as against any gender-affirming surgeries or "health-care" for minors.

Jeff Gerwitz

Dear Florida Medical Board,

My name is Joe Zalot, a Staff Ethicist at the National Catholic Bioethics Center (NCBC) in Philadelphia. I am writing to ask the medical board to take a very, very cautious approach to the issue of medical interventions for people, particularly children, who experience gender incongruence. My own and the NCBC's position is that so-called gender-affirming care (including puberty-blocking and cross-sex hormones, as well as surgical procedures) care violates the good of the human person and should not occur in any situation. Along with the American College of Pediatricians and Catholic Medical Association (among others), maintain that the most ethically appropriate treatment is psychotherapy that (1) seeks to discover and resolve the underlying issues giving rise to patients' sense of gender incongruence, and (2) supports patients as they learn to accept and align their sense of self with their biological sex.¹ This approach is wholly in accord with Catholic anthropology, Church teaching, and sound medical practice.² It is also in accord with the entirety of the Catholic health care tradition, including the *Ethical and Religious Directives for Catholic Health Care Services*.³

We maintain this approach for a number of reasons, here I will mention just two. The first is informed consent. As you well know, informed consent is moral principle that is foundational to the practice of medicine. It requires that one receive all relevant information about a proposed intervention (its nature, benefits, risks, consequences, and reasonable alternatives) in order to make a proper judgement about it. In addition, one must possess the capacity to understand this information, as well as the ability to critically evaluate it, in order to validly consent. Can children do this with regard to puberty-blocking hormones? Neuroscience demonstrates that the adolescent brain is cognitively immature and lacks capacity for risk assessment. It is not sufficiently mature to make significant medical decisions, particularly decisions that may have life-long, irreversible consequences.⁴ The NCBC agrees with the American College of Pediatricians that "treating" adolescent gender dysphoria with puberty-blocking (and later cross-sex) hormones constitutes mass experimentation on children who are incapable of providing proper informed consent. This is a form of child abuse.⁵

Second, if the Florida Medical Board allows so-called gender affirming care to continue (or upholds the latest HHS "guidance" on the issue), it constitutes a violation of my faith and my first

¹ ACPeds et al., "ACPedS, APPS, CMDA, and CMA Support Minors' Right to Therapy," accessed December 29, 2020, <https://static1.squarespace.com/static/55efa8b5e4b0c21dd4f4d8ee/t/58b85ab0197aea3090547486/1488476909245/2.22.17+Joint+Therapy+Ban+Letter.pdf>. Perceptions of gender incongruence are of the mind, not of the body. Thus, medical interventions should focus on the mind not on physically altering the body.

² Hruz, "Medical Approaches," 8–9. For perspectives on how Catholic physicians can treat patients experiencing gender incongruence, see Thomas Heyne et al., "A Catholic Approach to Adolescent Medicine," *National Catholic Bioethics Quarterly* 19.1 (Spring 2019): 75–82, doi: 10.5840/ncbq20191917.

³ To date, neither the Vatican nor the United States Conference of Catholic Bishops have issued definitive guidance on providing care to people suffering from gender incongruence. Some within Catholic health care exploit this lack of guidance to argue that directives 29, 33, and 53 of the *Ethical and Religious Directives for Catholic Health Care Services* (ERDs) can be used to justify hormonal, and even surgical, transitioning interventions. Both I and the NCBC disagree. While outside the purview of this essay to develop fully, the ERDs do not in any way offer justification for gender transitioning.

⁴ ACP, "Gender Dysphoria in Children," 10–11. See also Hruz, "Experimental Approaches to Gender Dysphoria," 99–100.

Amendment rights. Below is a brief explanation of how my faith tradition, Roman Catholicism, views gender ideology and so-called transitioning.

Essential points of Catholic anthropology, and how it contrasts with gender ideology, include the following:

1. Human beings are created male and female from conception (Gen. 1:27). Our dignity is grounded in part in this special creation as male and female.⁶ Gender ideology, in contrast, maintains that sex is assigned at birth, a notion that is demonstrably false (see below).
2. The human person is a body–soul union, and the body is a constitutive aspect of the person (*Catechism*, nn. 364, 365). As such, Catholicism rejects any dualistic conception of the human person that proposes a “self” separate from the body, which gender ideology necessarily entails. Gender ideology is founded in the perception that “I am not my body.” Its anthropological premise is that the body is unnecessary, even irrelevant, for understanding “who I am.”⁷
3. The body is a gift from God and is a constitutive dimension of our nature and being. As such, humans may not treat the body as a “piece of property” or “manipulate it as a thing or an instrument over which one is the master and arbiter”⁸—precisely what gender ideology does in its effort to reassign sex.
4. Sexual difference is willed by God as part of the divine plan. The complementarity that results from sexual differentiation is ordered to human good and flourishing, and in particular to marriage and family life (*Catechism*, nn. 369, 2333).⁹ As a result, humans are called to accept their sexual identity, manifested through the body, as a fixed and unchanging element of self (*Catechism*, n. 2393).¹⁰ Gender ideology, conversely, is not concerned with either sexual complementarity or the purpose and proper ordering of human sexuality. It is based in subjective perceptions of self and is focused solely on the perceived good of the individual person.

The Catholic understanding of the human person, and of human sexuality, has important moral consequences. Human persons act against their flourishing—and thus their good—when they directly intend what is contrary to their nature and God-given identity. Directly intending to transition one’s sex does exactly this. It seeks to alter what is biologically unalterable, establish a false identity, and both deny and contradict the individual’s authentic human existence as a male or female body–soul unity. Stated differently, transitioning undermines true human flourishing, and as a result, it runs contrary to the human good. It is never morally permissible.¹¹

Church teaching

In light of its anthropology and the seriousness of the realities involved, the Catholic Church in recent years has addressed gender ideology directly. Pope Benedict XVI warned in 2012 that *gender* has become the “new philosophy” of sexuality, one where biological sex is no longer regarded as a “given” of one’s nature. He then demonstrated the “obvious” and “profound” falsehood of this philosophy: “People dispute the idea that they have a nature, given by their bodily identity, that serves as a defining element of the human being. They deny their nature and decide that it is not something previously given to them, but that they make it for themselves.”¹² Seven years later, the Congregation for Catholic Education expanded on this theme by stating gender theory denotes a “process of denaturalization” whereby society moves away from the objective truth of nature and into the realm of pure subjectivism. It concluded that gender theory’s view of sexual identity is “often founded on nothing more than a confused concept of freedom in the realm of feelings and wants . . . as opposed to anything based on the truths of existence.”¹³

Pope Francis spoke to gender ideology in two well-known encyclicals of his early pontificate. In *Laudato si’*, he linked human sexual identity with care for the created order by stating, “Acceptance of our bodies as God’s gift is vital for welcoming and accepting the entire world as a gift from the Father and our common home.” He then warned that thinking that we enjoy absolute power over our own bodies turns, often subtly, into thinking that we enjoy absolute power over creation. Accepting and respecting the “fullest meaning” of our body is “an essential element of any genuine human ecology.”¹⁴

In *Amoris Laetitia*, Francis echoed Benedict XVI by warning that gender ideology “denies the difference and reciprocity in nature of a man and a woman,” which in turn leads to laws and educational curricula that “promote a personal identity and emotional intimacy radically separated from the biological difference between male and female.” This ideology then asserts itself as “absolute and unquestionable,” even usurping the proper role of parents in raising their children.¹⁵ In response, Francis emphasized that while biological sex and gender (understood as the sociocultural role of sex) can be distinguished, they can never be separated. He concludes, “It is one thing to be understanding of human weakness and the complexities of life, and another to accept ideologies that attempt to sunder what are inseparable aspects of reality. Let us not fall into the sin of trying to replace the Creator.”¹⁶

If you have any questions or need further clarification, please feel free to contact me at the email below. Thank you for your time and effort on this crucially important topic.

Paul A. Vazquez, J.D.
Executive Director
Florida Board of Medicine

Dear Mr. Vasquez,

Attached is a PDF of my testimony for Florida Board of Medicine. A copy of the transcript is below my signature as well.

Please let me know if you need anything more from me.

Sincerely,
Camille Kiefel

My name is Camille Kiefel. I stand here before you today, Florida Board of Medicine, in hopes that you make the right decision regarding transitioning children and take greater consideration for adults. I know you want the best for the citizens of Florida, to improve their health and become productive members of society.

I am the definition of treatment-resistant, can't take medications, approximately 20 years of talk therapy, hypnotherapy, EMDR (eye movement desensitization and reprocessing), DBT (dialectical behavior therapy), and two rounds of TMS (transcranial magnetic stimulation therapy). I had done everything conventional medicine had to offer. I was the perfect patient: diligent and wanting to heal, but nothing my doctors offered had healed me.

I was 30 when I transitioned and at the end of my rope. At the time I believed I was nonbinary. I struggled with CPTSD (complex post-traumatic stress disorder), MDD (major depressive disorder), ADHD (attention deficit hyperactivity disorder), GAD (generalized anxiety disorder), and suicidal ideation. When I was in 6th grade, my best friend had been raped by her brother. Being a girl meant I was vulnerable. I started to present more masculine. This should have been a red flag. Yet within a few months of requesting top surgery, it was performed on me. I developed complications after my surgery. There were many times I didn't know if I would make it through the night.

If I made this mistake as an adult, a young girl could, too. My top surgery not only exacerbated my mental health issues. I now struggle with physical complications as well. The reality is that young girls are struggling with overlooked mental and physical health issues. Presenting and taking on another gender was a form of escapism around womanhood. This is not a valid way of dealing with trauma. You will have to deal with it eventually.

I was able to work through these difficult emotions and improve my mental health through a

holistic approach. My physical health issues had been overlooked. Had that been managed, I would have never gotten the surgery. We need better options for treatment-resistant girls and women. This surgery was an abhorrent misdiagnosis. The goal of healthcare should always be to get to the root cause of the problem.

I am more grounded than I have been my entire life, but, I am mutilated. Between my carved-up body and the physical complications, I often question if there's anything on the other side. Where my breasts were are hollow. I can never get them back. I can never fit a dress the same way again. I can never breastfeed. Who will love me?

You know what keeps me going. It's stopping this from happening to someone else.

Thank you for your time. You all have a lot to consider, and I know you will make the right decision.

Dear Florida Board of Medicine members,

As you consider policies about gender dysphoria especially in children I exhort you to weigh the evidence for conservative and supportive treatment given the frequency of self-resolution. It seems apparent to me that the harms of sex change therapies likely outweigh the benefits especially in children.

Sincerely,
Nicholas A Stephanoff, MD

Dear Board Members,

I would like to tell you about why I believe a slower approach should be taken in regards to gender transition versus affirmative care.

My 21 year old son, "B" went to Planned Parenthood and was prescribed male to female hormones on his first visit.

B has a genetic mutation; SDHB which is called c.287-1g>c. This type of SDHB mutation can cause renal and papillary thyroid cancers, pituitary adenomas and also, an increased risk of developing paragangliomas or pheochromocytomas. These types of tumors are more likely to be malignant. Studies have shown that there is a **77-100% chance of B developing cancer** between 30-50 years of age. *See attached for additional information in regards to this mutation.*

Given that Estradiol is a hormone that is known for causing cancers, and with my sons predisposition of developing cancer/s (*in organs, that produce and regulate hormones!*), it seems like common sense that taking Estradiol and/or other similar hormones could be very dangerous to him. Yet, **he was prescribed Estradiol** on his very first visit **without any consultation** of his **Endocrinologist, Oncologist, Primary Care Physician nor his Genetic Counselor.**

Here is a bit of our family health history:

- B's father was diagnosed with **kidney cancer at age 32!** One of B's cousins was diagnosed with **kidney cancer and paraganglioma tumors, also at age 32**, and he **passed away within four years** of diagnosis! A second cousin developed **cancer at the age of 21 and died by the age 24!!** There have been many other family members with cancer and it is assumed they also had/have the genetic mutation. ****Estradiol can cause cancer!***
- There is a **very strong history** of heart disease in our family! B's father had a **heart attack at 47** years old, his maternal grandfather had a **heart attack at 34** and died on the fourth heart attack at 38 years old. Also, a second cousin died of a **heart attack at 31** years old! ****Estradiol can cause cardiovascular disease!***
- **Blood clots** (which can be hereditary) are also common in **both sides of our family!** Uncle's on from each side have had more than one blood clot at young ages. ****Estradiol can cause blood clots!***
- **Brain aneurysms** run in his family too! B's **grandmother had a brain aneurysm** that ruptured causing a hemorrhagic stroke. Her aneurysm lead to other family members being checked for aneurysms. **Myself and B's aunt also have/had brain aneurysms.** ****Estradiol can cause strokes!***
- Many family members have Diabetes. ***Estradiol can cause Type 2 Diabetes!***

**Link to estradiol side effects according to Mayo clinic: <https://www.mayoclinic.org/tests-procedures/feminizing-hormone-therapy/about/pac-20385096>*

B suffers from **depression** and has been diagnosed with **ADHD** too. I do not believe that B was of sound mind and psychology stable when he went to Planned Parenthood but a Psychiatrist, nor Therapist, nor any mental health professional did an evaluation of him before prescribing hormones to him. Perhaps if B worked with professionals for his depression and ADHD he might feel differently about transitioning but this was not offered as a solution. Wouldn't it be smarter to first try a non-invasive treatment, especially with B's medical history?!

There needs to be more time for these doctors to thoroughly determine whether the patient should proceed down the path of medicalization. Synthetic hormones can have many detrimental side effects and everything should to be taken into consideration before patients are prescribed hormones.

Patients should be required to submit medical records, have family and friends testify that they are mentally stable and have a proper psychological evaluation done. Additionally, the doctor should provided proper statistics about people that have detransitioned and patients should be **fully** taken through the **risks of hormones, surgeries, etc.** They should not just given a consent form to sign with a bunch of legal information that no one ever reads. Especially, when working with a minor or a young adults whose brains are not yet fully developed to process all the ramifications.

With B's health history and the long list of family member's serious health issues, B should have been required to consult with an Endocrinologist, Oncologist, Primary Care Physician, Genetic Counselor, Neurosurgeon, Urologist, Cardiologist and a Psychiatrist prior to starting any hormones.

Instead, a **gynecologist** prescribed hormones to **my son** and within **four months** he ended up with **two brain tumors**, one in the pituitary gland the other in the left frontal lobe. I can provide mri scans from year prior to him taking hormones and mri 4 months after starting hormones. I am happy to provide medical records as well if you would like to see.

Happy to answer any questions you may have. I can be reached on my cell below.

C

708/373-5359

Dear. Dr. Vazquez and board members,

I am a mother of a young adult (she is 20 years old) who became confused about her gender as a teenager (around the age of 14). My daughter expressed no previous signs of gender confusion in her childhood. Her confusion began after she started hanging out with “friends” at school and meeting people online who identified as transgender. I want to give you a timeline of how this transgenderism played out for my daughter and me.

I believe my daughter may have been bullied in school and never really had a friend group and just wanted to fit in with a group. When she entered high school, she started to have a couple of friends. I was so excited for her and for them because she is the sweetest and kindest person they could have as a friend. As I started to learn more about these friends, they seemed to all be a part of the LGBTQ group and attended the GSA club at school. As I have gay friends, I thought no biggie we all need friends and didn't think much more about it. That was my first mistake as I learned most of the kids she hung around with at school and met online identified as transgender. I have also learned transgenderism has become a social contagion.

Additionally, I believe she had a teacher in high school who was also the leader of the GSA club that I believed helped kids at the school social transition while at school behind the parents' back. This teacher also had a son who began identifying as a girl and supported this transition.

I noticed one day my daughter had these massive what looked like burns on her arm. They were not burns, she was cutting herself (she was about 15 years old); She also told me she was hearing voices telling her to harm herself and making her feel she was nothing. I found a therapist I thought I could trust because I wanted to get my daughter help. This therapist seemed great and my daughter really liked her. I was so hopeful that this therapist would work on my daughter's self-esteem and how to appreciate herself just the way God made her. What I faced was a therapist who was against me and pushed my daughter against me as well. She gave my daughter information regarding gender care clinics as minor and my daughter was more focused now on the gender issue than how to learn to work on herself and overcome the struggles she was facing with herself.

Then at the age of 16 my daughter sustained a traumatic brain injury due to a car accident. She was in a coma for 9 days, had half of her skull removed and then put back in. She had to learn almost everything over again like walking, talking, dressing herself, most all basic life skills. During her recovery not once did gender come up, not once did she tell anyone that I know of or heard her say that she was a boy. It was clear this was a social construct and when taken out of the peer group even though she had a traumatic accident the trans identity was not there. I knew I needed to get her back in therapy because we have the TBI my daughter needed to understand and deal with and how it could/would affect her life and how she would cope and handle it and hopefully if the transgenderism came back up that could be dealt with. Of course, my daughter went through 2 therapists because she didn't like them and all she wanted was

her original therapist, the one who affirmed her. She could not go back to the original therapist and so eventually, my daughter just did not want to do therapy anymore.

My daughter finished her senior year of high school and started attending USF during COVID so you can imagine how that went. In July of 2020 (she is now 18 ½) I received a letter from CVS that the prescription for testosterone for my daughter had been approved. I was in total shock. How did this happen and when did she go to the doctor to get this approval. Well no thanks to Planned Parenthood, my daughter did not even have to go in person to Planned Parenthood. She had her appointment via tele-med due to COVID and was prescribed testosterone right away. A simple sign on this line on an implied consent form and Planned Parenthood set my daughter up to destroy her body and most likely give her an early death sentence due to the effects of a female taking a drug that is meant for a man.

I do want to let you know my daughter has stated testosterone gives her a euphoric feeling that is something a person who uses street drugs say. My daughter is killing herself as an illegal drug user kills themselves slowly by taking drugs. As if the testosterone was not enough, my daughter wants to get her chest cut off and a doctor is ready and willing to do it. Of course my daughter being a college student and only working part time she is unable to afford the surgery. My daughter then created a go fund me page to help pay for this surgery. In the fundraiser page my daughter states she struggles with cognitive issues and mental illness. Did you hear that? She is on testosterone and that has not made her mental state any better but no one cares. They just prescribe hormones meant for a man and willing to do surgery that is totally not needed to a person whom admits to having cognitive issues along with mental illness.

I cannot save my daughter from this nightmare because she is an “adult” but I am hoping Florida and this board will create a rule that will prevent doctors from being able to prescribe experimental puberty blockers, cross sex hormones and perform any type of gender affirming surgeries such as double mastectomies, breast augmentation, vaginoplasty or phalloplasty on minors .

I truly wish it would go even further. My hope is, after the age of 18. Extensive therapy and measures are would be put into place so it gives young adults time to figure out themselves and get help that is not in the form of irreversible damage. Most if not all of the individuals need help with mental illness that seems to be the driving force behind the transgenderism.

I want to thank you all for listening to my family’s story. Because of the lack of true care to help these kids and young adults deal with mental health issues it is tearing families apart like it has mine. I implore the board to please make a rule that will protect children from these experimental treatments and surgeries and advocate for ethical, evidence-based and compassionate treatment of these individuals. There is no test for “transgenderism.” There is no test to see which child will desist and which will persist. There is no test that will tell us which child will regret these irreversible treatments and which will not.

~ Christen Redding

To whom it may concern:

I am writing in regards to medical transition for minors with gender dysphoria. I understand the Florida Board of Medicine is making a decision concerning this topic. There is lack of evidence and possible concern for long term health affects for medical transition in minors. The Cass Review by Dr. Hilary Cass states on their website: "the Review is not able to provide advice on the use of hormone treatments due to gaps in the evidence base," <https://cass.independent-review.uk/publications/interim-report>. Numerous medical academic centers list on their websites the possible side effects from use of hormone treatment for medical transition: University of Rochester Medical Center - <https://www.urmc.rochester.edu/encyclopedia/content.aspx?contenttypeid=134&contentid=116>
Vanderbilt University Medical Center – <https://www.vumc.org/lgbtq/key-transgender-health-concerns>
Mayo Clinic – <https://www.mayoclinic.org/diseases-conditions/gender-dysphoria/in-depth/pubertal-blockers/art-20459075>
There should be more mental health assistance for minors instead.

Sincerely,
Jacqueline Fernandes, MD

Mr. Paul Vazquez,
Executive Director, Florida Board of Medicine
Florida Department of Health
Paul.Vazquez@flhealth.gov
BOM.MeetingMaterials@flhealth.gov

Dear Mr. Vazquez and Members of the Florida Board of Medicine:

As a practicing family physician in the State of Florida, I write to implore that the Florida Board of Medicine restrict the practice of “gender-affirming care”—including social gender transition, hormone therapy, and gender-reassignment surgery—for children and adolescents. The short- and long-term harms as a result of such “gender-reassignment” practices on children are severely damaging and irreparable, and medical and evidence-based studies do not support their use. Additionally, given that over 80% of children affected by gender dysphoria will eventually lose their desire to identify with their non-birth sex, it is professional dereliction of duty for the medical community to allow such procedures—which result in disfigurement, sterility, and other lifelong damage to bodily and mental health-- with the professional sanction of the Board of Medicine.

It is my sincere hope that the Florida Board of Medicine will restrict the use of such “gender-reassignment” practices for children and adolescents, in the interest of preserving the health and well-being of Florida’s children and families.

Sincerely,

James O. Breen, M.D.
Fort Myers, Florida

The American Academy of Pediatrics' Dubious Transgender Science

As other countries turn away from hormones and surgery, the AAP won't even allow a debate.

By Julia Mason and Leor Sapir

Aug. 17, 2022 6:17 pm ET

People celebrate an LGBT pride festival in Smyrna, Ga., June 25. PHOTO: ROBIN RAYNE/ZUMA PRESS

A spate of headlines this month declared that America's surge in transgender identification wasn't being caused by a social contagion. These articles were prompted by a new study by Jack Turban and colleagues in *Pediatrics*, flagship journal of the American Academy of Pediatrics. The study claimed that social influence isn't the reason that as many as 9% of America's youth now call themselves transgender. Thus, Dr. Turban argues, efforts in conservative states to regulate on-demand puberty blockers, cross-sex hormones and surgery must be resisted.

Yet Dr. Turban's study is deeply flawed and likely couldn't have survived a reasonable peer-review process. The swift response from the scientific community made both points

clear—with even those who support hormones and surgery for gender-dysphoric youth noting that Dr. Turban’s shoddy science undermined their cause.

Nevertheless, the media have promoted his work as a refutation of the claim that the wildfire spread of transgender identity is an example of social contagion—a phenomenon in which members of a group (mostly young and female) mutually influence one another’s emotions and behavior.

The Turban study rejects the social-contagion theory on the grounds that more biological boys than girls identified as trans in 2017 and 2019, according to data collected from 19 states by the Centers for Disease Control and Prevention’s Youth Risk Behavior Survey. But the researchers who helped design the CDC questionnaire explicitly warned that youths who identify as transgender may list their sex as their gender identity, making it impossible to discern who is male-to-female or female-to-male (a limitation Dr. Turban has acknowledged in the past).

In this latest study, he cites three sources suggesting that respondents interpret “sex” as “sex assigned at birth”—even though none of those studies says anything of the sort. To use a flawed sex statistic in an attempt to set aside the well-documented phenomenon of gender-dysphoric female teens’ flooding clinics is so amateurish that one can’t help but suspect bad faith.

The AAP has been giving Dr. Turban a platform for years, despite the mistakes that plague his research. *Pediatrics* published his highly flawed 2020 study alleging that puberty blockers reduce suicide in teens. The journal even chose the article as its “Best of 2020” despite receiving rebuttals that pointed out the rate of *attempted* suicide rate was twice as high among the puberty-blocked group and Dr. Turban hadn’t controlled for the possibility that better mental-health outcomes might be the result of factors other than hormonal intervention.

In his correspondence with physicians who asked how such a study could be named best of the year, Lewis First, editor in chief of *Pediatrics*, said that award is based on “website views and article downloads,” not “editorial choices.” In response to a rebuttal from one of us (Julia Mason), who warned that the AAP was encouraging the misleading idea that sex can literally be changed, a reviewer said that her statement shouldn’t be published as it could be “offensive to the pediatric readership of the journal.” *Pediatrics* seems to be basing its editing choices on political calculation and the sensibilities of trans-identified teens. One wonders how many pediatricians who rely on the journal for professional guidance are aware of these criteria.

The AAP has ignored the evidence that has led Sweden, Finland and most recently the U.K. to place severe restrictions on medical transition for minors. The largest pediatric gender clinic in the world, the U.K.’s Gender Identity Development Service, was ordered to shut down in July after an independent review expressed concerns about clinicians rushing minors to medical transition. Medical societies in France, Belgium and Australia have also sounded the alarm. The U.S. is an outlier on pediatric gender medicine.

A major reason for this is the capture of institutions such as the AAP. Last year a resolution was submitted to the AAP's annual leadership forum to inform the academy's 67,000 members about the growing international skepticism of pediatric gender transition. It asked for a thoughtful update to the current practice of affirmation on demand.

Even though the resolution was in the top five of interest based on votes by members cast online, the AAP's leadership voted it down. In their newsletter, they decried the resolution as transphobic and noted that only 57 members out of 67,000 had endorsed it. The following year, however, when only 53 members backed a resolution that supported affirmative intervention, the AAP allowed the motion to go through, saying that the previous year's measure was "soundly defeated" while this year's received "broad support." When members submitted another resolution to conduct a review of the evidence, the AAP enforced for the first time a rule that shut down member comments, effectively burying it.

The AAP has stifled debate on how best to treat youth in distress over their bodies, shut down efforts by critics to present better scientific approaches at conferences, used technicalities to suppress resolutions to bring it into line with better-informed European countries, and put its thumb on the scale at Pediatrics in favor of a shoddy but politically correct research agenda. Its preference for fashionable political positions over evidence-based medicine is a disservice to member physicians, parents and children.

Dr. Mason is a pediatrician. Mr. Sapir is a fellow at the Manhattan Institute.

OPINIONLETTERS

A Rare Reversal on Gender Transition Policy

The ‘vast majority of children’ receiving care shouldn’t be treated with hormones or surgery, says the American Academy of Pediatrics.

11:45 am ET

We are thrilled that the American Academy of Pediatrics (AAP) agrees that the “vast majority of children” who get “gender-affirming care” shouldn’t be treated with hormones and surgery, and in fact, need “the opposite” (Letters, Aug. 22). Today, however, when pediatricians refer gender dysphoric minors to gender clinics for assessment, they are effectively sending them to be medically transitioned.

A recent study from Seattle Children’s Hospital shows that within 12 months of the initial consult, 66% of adolescents had already been put on “gender-affirming” hormonal interventions. This likely understates the problem: Several states, including California, have passed laws that effectively ban psychotherapy designed to help youth feel comfortable in their bodies, calling it “conversion therapy.”

This is partly the consequence of the AAP’s own 2018 recommendations, which state that “watchful waiting,” an approach that emphasizes psychotherapy, is harmful and akin to conversion therapy. It defines “affirming” as social transition for children (new names and pronouns) prior to medicalization, which becomes more likely to follow. The only therapy

besides “hormone therapy” that the guidelines recommend is counseling for family members to accept that their child is transgender.

AAP’s past pronouncements have pressured schools across the country to facilitate students’ “social transition,” often without parental knowledge. These statements may also influence the coming Title IX rules.

In its letter, the AAP suggests that the U.K. is moving to emulate the U.S. in this arena. Yet Dr. Hilary Cass, who is leading the U.K. effort to restructure, writes that British clinicians have felt under pressure to adopt the American “affirmative approach,” which the clinicians find “unquestioning” and “at odds with the standard process of clinical assessment and diagnosis.”

The AAP must update its guidelines to specify what “the opposite” of hormones and surgery means. If it means developmentally informed psychotherapy—increasingly recommended by European countries—the AAP must work to destigmatize the treatment. It should also stop calling critics of the medicalized affirmation model “anti-trans,” and welcome scientific debate.

Julia Mason, M.D., and Leor Sapir, Ph.D.

Portland, Ore., and Boston

Dr. Mason, a pediatrician, is director of the Society for Evidence-based Gender Medicine. Mr. Sapir is a fellow at the Manhattan Institute.

The president of the AAP, Dr. Moira Szilagyi, gives away the game with her choice of language. It is not “anti-trans” for state legislatures to protect minors from irrevocable surgeries and treatments. It is not “anti-trans” to learn from Europe’s 15-year head start on treatment and revise accordingly. Dr. Szilagyi writes about “activists” in a derogatory manner, but she’s the only activist I see here. Physician, heal thyself.

OPINIONLETTERS

Academy of Pediatrics Responds on Trans Treatment for Kids

To ‘affirm’ a child or teen means destigmatizing gender variance and promoting the child’s self-worth.

12:37 pm ET

Regarding Julia Mason and Leor Sapir’s op-ed “The American Academy of Pediatrics’ Dubious Transgender Science” (Aug. 18): In its recommendations for caring for transgender and gender-diverse young people, the AAP advises pediatricians to offer developmentally appropriate care that is oriented toward understanding and appreciating the youth’s gender experience. This care is nonjudgmental, includes families and allows questions and concerns to be raised in a supportive environment. This is what it means to “affirm” a child or teen; it means destigmatizing gender variance and promoting a child’s self-worth. Gender-affirming care can be lifesaving. It doesn’t push medical treatments or surgery; for the vast majority of children, it recommends the opposite.

This isn’t the story that is being told by anti-transgender activists. No European country has categorically banned gender-affirming care when medically appropriate. Contrary to what Dr. Mason and Mr. Sapir claim, the U.K. isn’t moving away from gender-affirming care. It is moving toward a more regional, multidisciplinary approach, similar to what is practiced in the U.S.

The AAP is committed to following the evidence and basing our recommendations on the best science. When concerns are raised about a study in Pediatrics, the journal follows a standard process to investigate. Evidence review also is a normal part of the AAP's policy-writing process and doesn't require a resolution at its annual leadership conference.

Meanwhile, the anti-trans bills in state legislatures, the social-media attacks and the rise in misinformation has an impact. The ones who suffer are the young people who are trying only to live their lives as their true selves. The AAP will continue to stand up for all children and adolescents, including those who are transgender.

Moira Szilagyi, M.D.

President, American Academy of Pediatrics

Hello,

I am a medical doctor writing to express my recommendation to restrict medical practices such as rapid gender transition for children and adolescents. Although many children and adolescents experience identity confusion and questions about their sexuality, medical practices such as hormone therapy and gender affirmation surgeries can cause permanent harm and regret. I am concerned that children and adolescents do not have the decision-making capacity to provide informed consent for these treatments. Gonadotropin-releasing hormone (GnRH) agonists are sometimes used to delay puberty in order for an adolescent to choose a gender before hormones cause permanent physical changes. Long term therapy with GnRH agonists causes metabolic abnormalities, weight gain, and worsening of diabetes and osteoporosis. Gender affirmation surgeries cause permanent changes that a child or adolescent may ultimately come to regret. We need to protect our children from misguided medical practices that will ultimately cause more harm than benefit. Thank you for your consideration of these comments.

Sincerely,
Michelle Brosnan, MD

To whom it may concern,

I am not a scientist nor psychologist, I have no expertise in these fields. Before you disregard my input I ask that you consider this: I am a man, a husband, a parent, a public safety servant, a citizen, and like all humans a person who has experienced difficulties in life. After decades of practice in these fields you might call me an expert, just like you and billions of others.

Dumbing down the profession of medicine and the science of biology to accommodate the feelings of others does not make us better. In order to be an engineer one must know a certain amount of math otherwise the bridges will fall down. In order to maintain trust and respect for the medical profession one must know biology, otherwise peoples health will suffer. If basic biology is discarded for so-called social justice reasons where will the medical profession decide it is acceptable to “stick to the science” and where will it deviate for affective reasons? How will these future decisions be made, by whom, & what basis will determine the complete disregard of biology? What about immunology - can we disregard that? Can we disregard age? Genetics? There seems to be a disconnect between institutions and the people they are said to serve. Myself, neighbors, colleagues, friends and virtually anyone I run into laugh at the notion of this non-sense and are astonished institutions have allowed this imperialistic behavior to dominate their thinking. Since when is saying no to dogma and yes to truth a bad idea?

Our children will bear the brunt of these decisions not only because youth are the ones most likely to “transition” and then de-transition but also because allowing the trojan horse of “care” into “gender affirming care” will now cancel anyone who thinks differently than this new orthodoxy. The result of which is to be labeled ‘to not care.’ Under this pretense we parents know this political topic will make its way into the classrooms of public schools as they practice more and more *affective* education versus traditional education. Teachers who have absolutely no expertise in psychology and no moral authority divorce children from the values of their parents will then bring the post-modern gender debate into the classroom under the veil of “care.” Not only does this harm the education our children receive but it harms children who will undoubtedly be caught up in this non-sense and make life altering decisions that will only hasten their path to a life full of unnecessary difficulties. Those that say affective teaching does not take away from education have the same 8 hour day as anyone else, and any time spent on this non-sense is time not spent on actual education. If there are only 8 hours to teach and it is not spent on core subjects then yes, it is deteriorating education. The bitter irony of which is those kids who need good schools and good teachers the most will bear the brunt of the harm. Kids with stable homes will still have access to the accessories of education and behavioral standards that promote prosperity and sadly those kids whose only hope of receiving such guidance will receive *affective* psychological coddling instead. The deficit this

will create entering adulthood will be insurmountable and irreversible.

Perhaps the most nefarious thing of this whole situation is timing. For the last two years we were lied to by the “experts” and mainstream medical agencies such as the CDC, NIH, AMA. They cannot claim ignorance in regards to the vaccines, lockdowns, and masks because millions of people and thousands of doctors and scientists wished to have open dialogue using evidence. Instead they attacked any countering evidence or viewpoint as “not trusting science.” This clear lack of moral courage is EXACTLY why this nonsensical debate around gender is even occurring. The ego is a powerful thing and it was always comforting to know that science could be the objective judge, but not anymore. Too many physicians cannot admit they were lied to for 2 years due to ego and cannot admit they are wrong about the harms the gender debate does to children and adults alike. Do not let ego do any more damage to the medical profession or our children or their education. It’s time we all remember not only how to think but what thinking is. Think for yourself, show some courage and do not let the gender debate infiltrate our institutions under the false pre-tense of “care.” The medical profession has already suffered irreparable damage caused by disregarding scientists during a pandemic. Emboldening the gender topic will turn your “profession” into a pseudo-science that will be no more trust worthy than a snake oil salesman and has all the hallmarks of phrenology.

Thank you,

Concerned Citizen, Blue Collar Worker, and Parent

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

Dear Mr. Vazquez,

I am writing to express my significant concerns regarding the Standards of Care recently released by the World Professional Association for Transgender Health (WPATH), as well as a broader concern regarding the affirmative care model that encourages medical and surgical treatments for children with gender dysphoria. I have attached a submission document to this email detailing my concerns with the WPATH Standards of Care.

My name is James Esses. I am based in the United Kingdom and am the co-founder of a group called Thoughtful Therapists. We are qualified and trainee psychotherapists who advocate around the impact of gender ideology on the wellbeing of children and the need to ensure that exploratory therapy is protected for children struggling with gender dysphoria.

I previously practised as a criminal defence lawyer and have held various roles within the UK Civil Service, specialising in criminal law and justice.

I am currently bringing a high-profile case for discrimination, after I was expelled from my Masters' degree in psychotherapy for speaking out about concerns regarding medicalising children with gender dysphoria and launching a public petition to the UK government asking them to safeguard explorative therapy for children
- <https://www.crowdjustice.com/case/expelled-university-free-speech/>. To date I have raised over £100k from thousands of public donations.

Myself and colleagues have been conducting research and have come across significant safeguarding concerns regarding vulnerable children, often with co-morbidities such as autism, being unconditionally affirmed/encouraged to transition and then suffering as a result. There is evidence of children being affirmed in online communities (and even through charities such as Mermaids - in which, for example, they have offered to send breast binders to young girls behind parent's backs) before being signposted to private gender clinics and fast tracked onto puberty blockers/cross-sex hormones and even surgery, sometimes even during the initial consultation, without any genuine exploration, therapeutic support, etc.

I have parents, teachers, doctors, social workers and therapists reaching out to me daily with concerns in this space.

The tide is beginning to turn slowly. The Tavistock Clinic in London has been shut down, following longstanding concerns about safeguarding and risk of harm to children. Disciplinary action has also been taken against the founders of one of the major UK-based private gender

clinics, Gender GP, following them placing vulnerable children at risk of harm.

However, each day that goes by, more children are being pushed down a path of irreversible regret.

The WPATH Standards of Care, which unfortunately carry sway around the globe, pose an even greater risk to an already vulnerable group. My key concerns relating to this guidance, which I elaborate on further in my submission, are:

- The removal of minimum ages for medication and surgery;
- The use of ideologically-driven language;
- The promotion of breast binding and genital tucking;
- The alienation of parents;
- The encouragement of irreversible surgery;
- The abandonment of mental health safeguarding;
- The complete lack of studies and research;

I would be more than happy to discuss further.

Kind Regards,

James Esses

World Professional Association for Transgender Health (WPATH) – Standards of Care Version 8

On 6th September 2022, the World Professional Association for Transgender Health (WPATH) published their updated Standards of Care (Version 8).

WPATH were founded in 1979 and have stated that their purpose is to *“promote evidence-based care, education, research, advocacy, public policy, and respect in transgender health”*.

There have been concerns over the years that the organisation acts as more of a partisan lobby group, rather than an independent, safeguarding-focussed organisation, particularly given the make-up of senior members of WPATH, many of whom identify as ‘trans’ or ‘non-binary’ themselves and/or are activists in this space.

Gender ideology appears at the forefront of the organisation’s work. By way of example, WPATH run an ‘Online Sexuality Workshop’, which focusses on *“supporting trans erotic embodiments from a pleasure-centred praxis...working with children, adolescents...”*.

Furthermore, in the ‘recommended reading’ section on their website, they suggest the following ideologically driven books (amongst others):

- ‘Real Talk For Teens: Jump-Start Guide to Gender Transitioning and Beyond’, by Seth Rainess
- ‘Transgender Warriors: Making History from Joan of Arc to RuPaul’, by Leslie Feinburg

The latest version of the WPATH Standards of Care is extremely concerning from a medical ethics and child safeguarding perspective. WPATH state that *“these internationally accepted guidelines are designed to promote the health and welfare of transgender, transsexual and gender variant persons...”*

The most concerning aspects of Version 8 of the Standards of Care are as follows:

- **Ideologically Driven Language** – The guidelines feature language based in ideology, rather than medicine or biology, throughout. For example, irreversible medical and surgical interventions are referred to as *“gender-affirming health care”*. Double mastectomies are called *“chest masculinization surgery”*. Ideological terms such as *“cisgender”* are used, as well as the scientifically and factually inaccurate term *“sex assigned at birth”*. Regardless of the risks and impact on the safety and wellbeing of women, health providers are told to implement *“gender neutral toilets”*.
- **Removal of Minimum Ages for Irreversible Medicalisation** – Any nuanced concern for the welfare and wellbeing of vulnerable children is omitted. Particularly when we consider that gender dysphoria is a mental health condition and many young people suffering from gender dysphoria will have other co-morbidities or mental health

diagnoses. The guidelines have removed any minimum age limit for a child to be able to avail of puberty blockers, cross-sex hormones or sex-reassignment surgery (so long as that child has reached 'Tanner Stage 2' of puberty, which can be as young as 9 years old). Interestingly, minimum ages had been included in the originally published document before these were quickly removed via a 'correction' online. The guidelines state that double mastectomies, euphemistically called 'chest masculinization surgery', *"can be considered in minors"*. Equally, 'vaginoplasty' may be considered for under 18-year-olds. The guidelines make it clear that there should be no requirement for a child to have taken cross-sex hormones prior to availing of surgery, *"if not desired"* by a child – emphasising the consumeristic nature of these guidelines. Hormone treatment is recommended even though it can cause *"infertility"*.

- **Chest Binding/Genital Tucking** – Healthcare professionals are instructed to provide education to children on both 'chest binding' and 'genital tucking', on the basis that this will provide *"comfort"* and *"lower rates of misgendering"* for a young person. However, this is regardless of the fact that the former can cause pain, infection and even fractures and the latter can cause decreased sperm concentration.
- **Alienation of Parents** – Healthcare professionals are advised to *"challenge"* parents who are unsupportive of their child medically transitioning. Equally, they are recommended to prescribe hormone treatment for children without parental involvement, if such involvement would be *"harmful or unnecessary"*.
- **Focus on Irreversible Surgery** – The guidelines provide what appears to be a 'shopping list' of surgery that is recommended for children and adults with 'trans' identities. These include, but are not limited to:
 - Body contouring
 - Voice surgery
 - Hair transplant
 - Jaw augmentation
 - Liposuction
 - Brow lift
 - Lip shortening
 - Calf implant
 - Mastectomy
 - Hysterectomy
 - Vaginoplasty
 - Phalloplasty
- **Abandonment of Mental Health Safeguarding** – The guidelines explicitly state that therapy or counselling should *"never be mandatory"* before prescribing irreversible medication or surgery, including for children. Equally, therapeutic professionals are told that they must not impose their own narratives or preconceptions, yet are also told that they must be *"gender affirming"*. These principles are fundamentally incompatible.

- **Disregarding of Mental Ill-Health** – Clinicians are advised that not all mental illness *“can or should be resolved”* prior to prescribing irreversible medication or surgery. Equally, the guidelines state that hormone treatment should not be withheld simply because a child has a ‘neurodevelopment condition’.
- **Eunuchs** – A completely new chapter is dedicated to ‘Eunuchs’ who are individuals that are *“assigned male at birth and wish to eliminate masculine physical features or genitals”*. The guidelines appear to support individuals who seek *“castration”* and they are now deemed to fall under the *“gender diverse umbrella”*. From an ethical and therapeutic standpoint, this is deeply concerning.
- **Patients in Prison/Psychiatric Hospitals** – WPATH recommends that staff providing care to individuals resident in prisons or psychiatric hospitals should support them with *“gender-affirming surgical treatment...when sought by the individual without undue delay”*. This instruction for an unconditionally affirmative approach appears to throw any semblance of safeguarding out of the window.
- **Ignoring the Lack of Studies** – All of the above is recommend, notwithstanding the fact that WPATH acknowledges that *“the number of studies is still low”*, that *“there are few outcome studies that follow youth in adulthood”* and that *“no clinical studies have reported on profiles of adolescents who regret their initial decision”*.

The above is of significant concern as to the safeguarding of some of society’s most vulnerable children. This is particularly so when we considering the significant influence that WPATH have over the global landscape in gender medicine (especially given the fact that WPATH is a self-regulated membership body and in many ways can be considered ‘self-appointed experts’). This can be demonstrated by the fact that Susie Green, the CEO of the organisation Mermaids, which has received a lot of outrage around safeguarding practises, sits on the body responsible for revisions to the Standards of Care.

The ramifications are considerable. For example, the NHS refers to the WPATH Standards of Care in a variety of medical documents. The Scottish government themselves have acknowledged reliance upon the Standards of Care in their decision-making. The Standards of Care also featured heavily in the significant case of *Bell v Tavistock*.

These guidelines have also been used by numerous private health clinics throughout the UK, enabling them to justify the prescribing of irreversible hormones or performance of irreversible surgery. This includes the now-disgraced ‘Gender GP’ (with one of its founders recently having been expelled from the medical profession and the other undergoing a period of suspension for risks posed to vulnerable children).

Action must be taken to ensure that there is significant pushback from the UK to these WPATH guidelines and assurance that these will not change the medical and therapeutic landscape as regards the treatment for gender dysphoria, particularly for vulnerable children. This is one of the most concerning examples of ideology infecting medicine and this cannot be allowed to happen. The stakes are far too high.

Paul A. Vazquez, J.D.
Executive Director
Florida Board of Medicine

Dear Mr Vazquez,

I write in regard to your proposed rule for Affirmative Care for Gender Diverse people.

I am a consultant psychiatrist based in Melbourne, Australia. I have clinical experience with people who have gender dysphoria (GD), parents of GD youth, and people with regret/detransition. My clinical work has led me to closely review the professional literature, so that I could provide accurate information and recommendations to my patients - with a key aim being the provision of compassionate, evidence-based and least harm clinical care to youth with gender dysphoria.

I have authored several papers on this topic which have been published in peer reviewed medical journals. These papers include discussions of the weak evidence base for gender affirmative treatments and the issue of informed consent. I have attached copies of these papers to this email for your reference.

In my opinion, because of the limited evidence base for the medical and surgical treatments of GD youth (that means bias, confounding or placebo effect may be the cause of any of the reported mental health and quality of life outcomes) together with the associated risks (which include infertility, sexual dysfunction and later regret), these treatments should be viewed as experimental and only available under ethical review board approved clinical trials. In addition, prior to implementing medical and surgical interventions, careful and comprehensive assessment, stabilisation of any psychological conditions, a reasonable period of gender exploratory psychotherapy and an extended informed consent process are necessary.

I hope this email and the attached documents are of assistance to yourself and the Florida Board of Medicine as you consider this complex and important issue.

Yours sincerely,

Dr Alison Clayton

MBBS MPM FRANZCP

Commentary: The Signal and the Noise—questioning the benefits of puberty blockers for youth with gender dysphoria—a commentary on Rew et al. (2021)

Alison Clayton¹ , William J. Malone², Patrick Clarke³, Julia Mason⁴ & Roberto D'Angelo⁵

⁵Institute of Contemporary Psychoanalysis, Los Angeles, CA, USA

In less than a decade, there has been a sharp rise in the numbers of young people presenting with gender dysphoria (GD). Today, the majority are adolescents, many with post-puberty adolescent-onset transgender histories, and suffering from mental health and neurodevelopmental comorbidities (De Vries, 2020; Zucker, 2019). Furthermore, there is controversy and heated debate in the literature on this topic (Dubicka, 2021). This lack of scientific consensus highlights the need for any published literature on the topic of GD to be carefully evaluated.

In this commentary, we critically examine a systematic review of the evidence for puberty blockers for GD youth that was recently published in this journal (Rew, Young, Monge, & Bogucka, 2021). Our aim is to highlight problems with this review that compromise its findings and conclusions.

Brief description of Rew et al.'s (2021) study

Rew et al. described undertaking a “critical” and “systematic” literature review on the topic of puberty blockers for GD youth. They identified nine studies for review and, on the basis of these, concluded that puberty blockers have “few serious adverse outcomes,” and “several potential positive ones.” Rew et al.'s abstract highlighted two key conclusions: the “potentially life-saving benefits” of puberty blockers; and a need for rigorous research. Their “implications,” “conclusion,” and “key practitioner message” sections appeared to claim that the literature supports the use of puberty blockers for the early puberty subgroup of GD youth.

Overview of our concerns

We agree with Rew et al.'s conclusion that more rigorous research is required in the area of management of GD in youth. However, in our view, their review suffers from methodological oversights, including the omission of relevant studies and suboptimal analysis of the quality of the included studies. As a result, the authors overstate the certainty of the potential positive outcomes and minimize the potential adverse outcomes of puberty blockers. Importantly, their statement, that a “positive

outcome” of puberty blockers is “decreased suicidality in adulthood,” is a misinterpretation of a single cross-sectional study. This study's design was incapable of determining causation, and adult suicidality was not one of the measured outcomes (Turban, King, Carswell, & Keuroghlian, 2020).

Contrast Rew et al.'s (2021) conclusions with another recently completed systematic review of puberty blockers for GD youth, commissioned by England's NHS and conducted by The National Institute for Health and Care Excellence (NICE) (2020). The NICE review concluded that studies investigating the benefits or adverse effects of GnRH analogs (puberty blockers) were of “very low certainty using modified GRADE.” They noted that any outcome differences that were found could have represented changes of “questionable clinical value,” or, as the studies themselves were “not reliable,” could have been “due to confounding, bias or chance.” They suggest that if controlled studies are not possible, then reliable comparative studies are required.

These findings came just after NHS England suspended the use of puberty blockers for new patients under the age of 16, following the High Court's judgment that children so young could not consent to the unknown risks of these drugs. The Karolinska Institute in Sweden suspended the use of puberty blockers as treatment for GD youth outside of clinical trials following this review, citing multiple physical risks, including to bone development (Nainggolan, 2021). Finland also sharply curtailed the use of these drugs after their systematic review arrived at similar conclusions about the uncertain risk/benefit profile (COHERE, 2020).

We are concerned that Rew et al.'s review will mislead clinicians unfamiliar with the literature into prescribing puberty blockers to GD youth with confidence, when the only clinical stance supported by the evidence is that of extreme caution. This is also underscored by the fact that the research literature in this field is rapidly evolving. For example, a recently published study, that attempted to demonstrate the benefits of the Dutch puberty suppression protocol in the UK setting, failed to show any psychological benefit (Carmichael et al., 2021).

Limitations in study selection strategy

The review published by Rew et al. has important limitations that compromise its usefulness for clinical decision-making. Rew et al. identified only 151 potentially eligible studies, while the NICE review found 525 studies. One possible explanation for this could be their limited study search strategy. Another possible explanation is that Rew et al. did not conduct a comprehensive search so that, in omitting one of the largest electronic databases—EMBASE, they may have overlooked relevant evidence.

Notably, the final set of nine studies reviewed by Rew et al. is missing at least one key study on puberty blockers and psychosocial functioning (Costa et al., 2015), and two other studies examining the risks of puberty blockers on bone density (Joseph, Ting, & Butler, 2019; Klink, Caris, Heijboer, van Trotsenburg, & Rotteveel, 2015). It is unclear to us whether these studies were omitted due to the limited database search or whether the evaluators decided to exclude these studies, and if so for what reason. These three studies were all included in the NICE (2020) review. Although it has to be kept in mind that all the NICE reviewed studies' findings were assessed as "very low certainty," the Costa et al. study provided comparative evidence and found no significant difference in psychosocial functioning between a group of adolescents receiving puberty blockers plus psychosocial support, and a group receiving only psychosocial support, at eighteen months (the study end period) (Biggs, 2019). In addition, the Costa study was cited by the Finnish gender identity services in their policy change, which now recommends psychotherapy alone as first-line treatment.

Failure to adequately assess certainty of the study findings

It is our contention that the reviewers did not adequately assess the certainty of the reviewed studies' findings. For example, they used the Joanna Briggs Institute checklist to assess Turban et al. (2020), the study from which their message that puberty blockers reduce adult suicidality and have "potentially life-saving benefits" derives. This checklist can overemphasize whether studies report information and underemphasize the assessment of study validity. Below, we show how Rew et al. applied this tool to Turban et al. (2020), and the important study limitations it overlooked.

Was the exposure measured in a valid and reliable way? (Q3) Rew et al. answered "yes" to this question. We believe it should be "no." The exposure to puberty blockers was based on a self-report, with 73% of those respondents, who answered yes, claiming they began to use puberty blockers after the age of 18. It was noted that the respondents likely confused puberty blockers with other hormonal interventions (Biggs, 2020; D'Angelo et al., 2020). Although Turban et al. attempted to reduce the effects of this confusion by excluding certain participants from the sample, no adequate correction was possible. This introduced a significant risk of bias.

Were confounding factors identified and strategies to deal with them stated? (Q5, Q6) Rew et al. answered "yes" to both questions. We believe the answer to the latter question should be "no." For example, while one key confounding factor—prior mental health status—was indeed correctly identified by Turban et al., no strategy

was articulated to deal with it. When discussing their finding that puberty suppression is associated with lower lifetime suicidality, they acknowledged that "reverse causation cannot be ruled out: it is plausible that those without suicidal ideation had better mental health when seeking care and thus were more likely to be considered eligible for pubertal suppression" (Turban et al., 2020). This is one of the most serious limitations of the study, introducing a high risk of bias, and reducing the certainty of the findings.

In addition, while two questions ask about the subject selection criteria and whether the subjects and the setting were described in detail (Q1, Q2), these questions do not attempt to assess the impact of the sample composition. Affirmative ("yes") and "not applicable" answers to these questions, respectively, masked the fact that the study participants were not required to have a diagnosis of GD, and that the participant demographics were markedly different from the US population of transgender adults (D'Angelo et al., 2020), which negatively impacts the study's applicability/generalizability.

Rew et al. aggregated the answers to the checklist questions, with the Turban et al.'s study earning an 86% mark and a "good quality" rating. Even if we sideline the issue of any scoring inaccuracy, using such a simplistic scoring category is misleading since it implies that all questions are equally important, which is clearly not the case.

We also note, what appears to be, at least one error in Rew et al.'s assessment and reporting of study outcomes. In Table 2, they reported that Turban et al.'s positive outcome findings included decreased past-month psychological distress, past-month binge drinking, and lifetime illicit drug use. However, Turban et al.'s univariate analysis showed only one of these three outcomes, past-month psychological distress, showed any significant difference, and this significance disappeared once demographic variables were controlled for in the multivariable analysis.

A more rigorous tool to assess Turban et al.'s study would be ROBINS-I (The Risk of Bias of Non-randomized Studies of Interventions) (Sterne et al., 2016). This tool focuses on confounding, selection bias, classification and deviations from intervention, measurement of outcome, missing data, and selective reporting, and the extent to which the study design minimized biases and yielded trustworthy results. Given this, applying the ROBINS-I tool would find that the Turban et al.'s study is at a critical risk of bias.

Misleading statements regarding puberty blockers and suicidality

We are concerned that Rew et al.'s discussion of evidence about suicidality is unbalanced and misleading. Reading that puberty blockers had "positive outcomes [of] decreased suicidality in adulthood" will likely be understood as indicating causation. However, Turban et al. (2020), where this claim originates, noted that their study design did not allow for determination of causation, and "reverse causation" (individuals without suicidal ideation had better mental health and were more likely to be considered eligible for puberty blockers) was a plausible alternative explanation.

Further, there is a critical difference in meaning between "lifetime," and "adulthood." Not only does the

latter erroneously imply a pre-post effect (i.e., access to puberty blockers in childhood reduces suicidality in adults), which was not detectable in the study, but a measure of “adulthood suicidality,” which Rew et al. claim was impacted, was never included in the original study (Turban et al., 2020).

There is also unclear use of the term suicidality, which exaggerates the implication of Turban et al.’s findings. Suicidality is a broad term, which is comprised of suicide attempts, plans, and ideation, and indeed this was the manner it was used by Turban et al. It is also important to note that Turban et al. made no assessment of completed suicides. Turban et al. assessed six areas of suicidality (including recent and lifetime suicide attempts, recent ideation with plans, recent and lifetime ideation) and found no association between puberty blockers and suicidality measures on five of the six areas. The only association was with “lifetime suicidal ideation.” Of course, any suicidal ideation is concerning, but suicide attempts are generally considered of higher concern, in terms of suicide risk assessment, than suicidal ideation (Ryan & Oquendo, 2020).

Rew et al.’s inaccurate language further intensifies in the final sentence of their abstract, which described puberty blockers as “potentially life-saving.” This exaggerated claim is misleading, since there is no evidence to support it.

Absence of an appropriate process for making clinical recommendations

Finally, the authors appear to recommend the use of puberty blockers in the “key practitioner messages” box and in the “implications” section of their paper. Making recommendations requires not only evidence about benefits and harms on all health outcomes that are important for decision-making (which this review provides in a suboptimal way), but also considerations about patients values and preferences, ethics, acceptability, resources, costs, etc. (Andrews et al., 2013). All these considerations are balanced by making value judgments, which should be documented and reported explicitly and transparently. Rew et al. failed to do this, which, in our view, further undermines the credibility of their clinical practice recommendations.

Clinician reflections on the state of the GD literature

Rew et al.’s review illustrates a concerning trend, that we have observed in the GD literature, to overstate the evidence underpinning clinical practice recommendations for youth with GD. New publications reference prior ones with increasing and unwarranted confidence, and with the risk of misleading clinicians regarding the state of evidence. There is also a marked asymmetry in outcomes reporting: findings of positive outcomes of medical interventions are trumpeted in abstracts, while their profound limitations remain behind the paywall, thus, below the radar of busy clinicians.

Rew et al.’s paper demonstrates these types of issues. To start, the Turban et al.’s paper described a noncausal association between puberty blockers and “lifetime suicidal ideation,” carefully avoiding making a causal claim (although, arguably, implying it). Then, Rew et al., whose findings on suicidality are based solely on this Turban et al.’ study, rewrite this finding to create the strong

impression of causality—that puberty blockers reduce adult suicidality and are “potentially life-saving.” Subsequently, a recent Commentary and Editorial in the *Lancet* both directly state that puberty blockers reduce suicidality, and the latter adds the extraordinary claim that “removing these treatments is to deny life.” The only reference provided for these claims is the Rew et al. (2021) paper (Baams, 2021; *Lancet* editorial, 2021).

This resembles the game of “Telephone,” in which a message is whispered from person to person distorting the original meaning of the message. However, this is not a game, and these types of errors can cause harm. Clinicians relying on Rew et al.’s review are likely to misinform patients and families about the risk/benefit profile of puberty blockers. Can such patients really be considered as giving informed consent?

The clear signals emerging from the various reviews of the available evidence of the use of puberty blockers for GD youth are that there is very low certainty of the benefits of puberty blockers, an unknown risk of harm and there is need for more rigorous research. The clinically prudent thing to do, if we aim to “first, do no harm,” is proceed with extreme caution, especially given the rapidly rising case numbers and novel GD presentations. We must also, collectively, raise the bar on the quality of publications, in order to accurately educate clinicians and help patients make truly informed decisions that may impact for the rest of their lives.

Acknowledgements

The study received no external funding. Open Access fees were provided by the Society for Evidence-Based Gender Medicine. We would also like to thank the Society for Evidence-based Gender Medicine (SEGM) for providing access to several experts who helped shape this commentary and ensure its accuracy. Specifically, we would like to thank Dr. Romina Brignardello Petersen for contributing her methodological expertise; Dr. Michael Biggs for reviewing the accuracy of the claims relating to puberty blockers and suicidality made in this review, as well as relating to the developments in the United Kingdom; and to Ema Syrulnik for her help with the preparation of this manuscript. The authors have declared that they have no competing or potential conflicts of interest.

Ethical information

No ethical approval was required for this commentary.

BRIEF REPORT

Commentary on Levine: A Tale of Two Informed Consent Processes

Alison Clayton 

School of Historical and Philosophical Studies, University of Melbourne, Parkville 3010, Australia

ABSTRACT

This commentary compares two recently published informed consent recommendations for gender dysphoria. One key difference identified is in their assessment of the strength of the evidence base for the gender affirming treatment model. An evaluation of both authors' citations supports the claims of a weak evidence base for the use of puberty blockers and gender affirming hormonal treatments in youth with gender dysphoria. This commentary then reflects on the implications of this. In particular, it asks whether it would be best practice to provide gender affirming treatments for youth only under clinical research conditions, rather than as routine clinical practice.

Introduction

"Reconsidering Informed Consent for Trans-Identified Children, Adolescents and Young Adults" (Levine, Abbruzzese, & Mason, 2022) is a timely and important paper. This Commentary asks the question: How does Levine et al.'s recommended informed consent process compare to current informed consent practices for youth with gender dysphoria? This question is addressed through an evaluation and comparison of Levine et al.'s informed consent process with those of a recently published "Informed Consent Standards of Care" (AusPATH, 2022). A key difference is the respective authors' evaluation of the strength of the evidence base for the gender affirming treatment model. This Commentary interrogates the citations these authors use for their respective claims regarding the strength of the evidence base. It finds that Levine et al.'s claims of a weak evidence base are well supported. A second question then reflected upon is: Given the weak evidence base for gender affirming treatments for youth, should these interventions be only available as part of clinical research trials, rather than implemented as routine treatments?

Terminology

Terminology in this area of medicine is varied and complex. As we are discussing clinical treatment and informed consent, I use the medical nomenclature of gender dysphoria (GD) (American Psychiatric Association, 2013). When directly reporting from other publications I generally use their preferred terminology. Levine et al.'s paper considers informed consent as it pertains to children, adolescents and young adults. I use the generic term "youth" to describe this group. Gender affirming treatment (GAT) is used to refer to a broad range of affirming health care

approaches including: Support of, and assistance, with social gender transition, provision of puberty blockers, gender affirmative hormone treatment and surgery. Gender affirming hormones treatment (GAHT) refers to cross-sex hormones (estrogens and testosterone) and anti-androgens.

A comparison of Levine et al.'s recommended informed consent process with AusPATH's "Informed Consent Standards of Care"

Shortly after reading Levine et al.'s paper, particularly as an Australian psychiatrist, I was interested to read the Australian Professional Association for Trans Health's (AusPATH) "Australian Informed Consent Standards of Care for Gender Affirming Hormone Therapy," which were released on March 31, 2022 (AusPATH, 2022). Informed consent practices will vary across different settings. However, this recent "Informed Consent Standards of Care" provides a useful exemplar to flesh-out how Levine et al.'s recommended informed consent approach compares to current practice standards. AusPATH is an organization closely linked to WPATH (many AusPATH members, including the President and Vice-President, are also WPATH members). Thus, despite this Commentary's Australian focus, it also holds much relevance to the international context. (Of additional note, WPATH's "Standards of Care" are currently in flux, with the most recent edition not yet released in its final form, so it is not possible to evaluate any updated informed consent recommendations).

Levine et al. (2022) recommendations apply to all GAT available to GD youth. Frequent references are made to the clinical diagnoses of gender dysphoria (DSM) and gender incongruence (ICD). Levine et al. contend that an adequate informed consent process requires: Careful and thorough evaluation; assessment of capacity; involvement of parents; a full disclosure of the short and long-term risks and benefits; a discussion of the full range of alternative treatment options; and a disclosure of the weak evidence base for these interventions. The authors emphasize that informed consent needs to be a slow and thoughtful process, culminating in signed consent forms.

AusPATH (2022) focuses on the use of GAHT, although it also includes some discussion of social and surgical interventions, for trans people of all relevant ages. The trans person is described as the expert on their own gender and needs. There is no requirement for a psychiatric "gender assessment." It is only in the context of adolescents, under the age of 18, that any reference is made to the requirement for a gender dysphoria (DSM) diagnosis and there is also scant reference to gender incongruence (ICD) diagnosis. It is noted that the outlined informed consent model can be used for adolescents under the age of 18, but a discussion is included of the more complicated clinical and legal situation, in Australia, for this group. AusPATH's recommended informed consent approach coheres with Levine et al. (2022) in advising that the risks and benefits of the treatments should be discussed with the patient and, for patients under age 18, parents or guardians. In addition, they advise the patient should be informed of the limitations of the hormones to effect certain changes (for example, height) and they note the need for lifelong monitoring and review. Examples of written information sheets and consent forms for the patient and parent to sign are provided. The process of evaluation, informed consent, and initiating hormones is described as being able to be undertaken "in just one or two appointments," although it is noted that it may require more time.

Some of the important differences between these two informed consent approaches to highlight are:

- a. Levine et al. recommend a discussion of the limitations of the evidence base for GAT, whereas no mention of this is made by AusPATH.
- b. Levine et al. emphasize the evaluation and informed consent processes should be a slow process. AusPATH states that the process of assessment, education, informed consent and the initiation of hormones can be completed in as little as one session.

- c. Levine et al. recommend patients are informed of the risk of regret and detransition, whereas AusPATH does not mention this.
- d. Levine et al. require the clinician to discuss the full range of alternative treatment options. AusPATH does not note alternative treatment options and informed consent seems to be equated with affirmation, as they state: “The informed consent model of care is sometimes called affirmation enablement or ethical affirmation.”

These differences can be partly understood by differences in the authors’ evaluations of the evidence base of GAT. Levine et al. (2022) claim that the evidence base for the benefits of GAT is “widely recognized” as deficient and is of very low quality and certainty. AusPATH (2022) claim that there is a “significant” and “clear” body of evidence that GAT improves quality of life and leads to better mental health outcomes.

It has previously been noted that these types of contradictory opinions can be found in the professional literature and highlighted that the merits of the various claims need to be evaluated by a close reading of the cited primary sources (Clayton et al., 2021). To that end, I will interrogate the citations and ask: Do they support the authors’ claims? (Of course, the reader is free, and I would encourage it, to similarly evaluate my citations.) As both authors’ citations primarily focus on puberty blockers and GAHT, this, rather than social transition and surgical treatments, will be the focus of discussion in this commentary.

Reviewing Levine et al.’s claims of very low quality evidence for puberty blockers and gender affirming hormone treatments for youth with gender dysphoria

Levine et al., in support of their claims of a deficient and very low quality evidence base for puberty blockers and GAHT for adolescents, cite Hembree et al. (2017) and the National Institute for Health and Care Excellence (NICE) (2020a, 2020b). Hembree et al. (2017) rated the evidence for the use of puberty blockers and GAHT in adolescents as being either low or very low quality. NICE (2020a, 2020b) concluded that the studies investigating the benefits or adverse effects of puberty blockers and GAHT were uncontrolled observational studies, subject to bias and confounding. The studies’ quality was appraised with the Newcastle-Ottawa tool and certainty of outcomes by modified GRADE. All studies were rated as “poor quality” and all outcomes as “very low certainty.”

In sum, Levine et al.’s claims of a very low quality and certainty evidence base for puberty blockers and GAHT for adolescents appears to be well supported by the cited references.

Reviewing AusPATH’s claims of a clear and significant body of evidence for puberty blockers and gender affirming hormone treatments for trans people, including trans adolescents

AusPATH (2022) cite three sources to support their claim of a significant body of evidence showing that medical GAT improves psychological outcomes and improve quality of life. The first of these is a primary study reporting that access to GAHT in adolescence is associated with improved mental health outcomes among transgender adults (Turban, King, Kobe, Reisner, & Keuroghlian, 2022). This recent study has not yet been externally evaluated in a systematic review process. However, this study’s design (a non-probability cross-sectional survey) puts it at high risk of bias, and, as the authors themselves noted, it cannot determine causality. Further, the limitations of the source data have been the subject of previous critiques (D’Angelo et al., 2021).

Secondly, AusPATH (2022) cite their own public statement (AusPATH, 2021), which stated: “Medical and surgical affirmation can frequently alleviate gender-related distress and yield a variety of other benefits to the individual.” Sixteen references are cited in support of this statement, but no information is provided on the quality nor on the certainty of

findings. Three of these references are systematic reviews, one of which (White Hughto & Reisner, 2016) is the third citation in AusPATH (2022). This review of GAHT in transgender adults concluded that there was only “low quality” evidence that “suggests” GAHT “may” lead to psychological improvements and it recommended more prospective controlled trials be undertaken. All the reviewed studies were found to be at high risk of bias, and it was noted that they did not adjust for important confounders, for example concurrent psychotherapy or psychiatric medications. This conclusion does not appear to well support AusPATH’s(2022) claims of a clear and significant body of evidence to support the use of medical GAT.

However, could it be that the other studies and systematic reviews cited in AusPATH (2021) provide more solid evidence? AusPATH (2021) cites seven primary studies, either on puberty blockers or GAHT in youth. Five of these were evaluated by NICE (2020a, 2020b). As already discussed, all these studies were found to be of poor quality and provide very low certainty evidence. What did the other systematic reviews cited by AusPATH (2021) report?

Multiple systematic reviews of puberty blockers and gender affirming hormonal treatments for adolescents note the weakness of the evidence

For thoroughness, and to minimize risks of “cherry-picking” the evidence, I will expand beyond the three systematic reviews cited by AusPATH (2021) (which were: Mahfouda, Moore, Siafarikas, Zepf, and Lin (2017, Mahfouda et al., 2019); White Hughto and Reisner (2016)). Two other systematic reviews, Chew, Anderson, Williams, May, and Pang (2018) and Rew Young, Monge, and Bogucka (2021a) have been recently cited as support for strong claims of the benefits of puberty blockers and/or GAHT in adolescents (Baams, 2021; Tordoff et al., 2022). There is also a review by Baker et al. (2021) which was commissioned by WPATH and included both adolescent and adults.

A reading of these reviews reveals consistent comments noting the scarce and poor quality empirical evidence base underpinning the use of puberty blockers and GAHT. These reviews emphasize that the reviewed studies are mostly subject to high risk of bias and confounding and that more rigorous evidence is required. The Baker et al. (2021) review noted there was insufficient evidence to allow conclusions to be drawn regarding the impact of hormone therapy on death by suicide in transgender people. One review, Rew, Young, Monge, and Bogucka (2021a), appeared to claim a causal link between puberty blockers and decreased adult suicidality. However, following a published critique by Clayton et al. (2021) the authors clarified they were not making any causal claims and placed emphasis on their conclusion that more rigorous studies were required (Rew, Young, Monge, Bogucka, 2021b).

In sum, the findings of these reviews do not seem consistent with any claims, including those made by AusPATH (2022), that there is a significant or clear or robust body of evidence that puberty blockers and/or GAHT for GD youth improve mental health and quality of life outcomes. Furthermore, the two reviews discussed here that addressed GAHT in adults found the evidence to be similarly weak. The findings of these systematic reviews are more consistent with Levine et al.’s claims of a weak evidence base for these treatments.

Alternative approaches

As described by Levine et al., alternative treatment options for GD youth include various forms of psychotherapy, family therapy and group therapy. These are well described in the literature (for example see: Lemma, 2021; D’Angelo et al., 2021; Kozłowska et al., 2021; Hakeem, 2012). It is important to note, as Levine et al. emphasize, that these alternatives also lack a rigorous evidence base. However, also important, they do not hold the gravity of the potential injuries that do the hormonal and surgical treatments.

Therapeutic illusions and placebo effects: what weight should be given to clinical experience as evidence?

Some clinicians seem to claim that clinical experience stands as important evidence for the use of GAT (Olson-Kennedy, 2019; Pang, Wiggins, & Telfer, 2022). However, it is important to remember clinicians' testimonies of the success of the treatments they offer is known to be unreliable (Fanaroff et al., 2020). One example, noted as long ago as 1865, is that there had long been clinical consensus that the treatment of pneumonia by bloodletting was most efficacious, but comparative experimentation in the first half of the nineteenth century showed this to be "a mere therapeutic illusion" (Lilienfeld, 1982). Humans have a tendency to overestimate the effects of their actions, often called the "illusion of control." In medicine this may manifest as a "therapeutic illusion," whereby both doctors and patients may have an unjustified enthusiasm for a treatment (Casarett, 2016).

Placebo effects are rarely discussed by gender medicine clinicians and researchers (Clayton, 2022a). Contemporary placebo researchers describe placebo effects as the beneficial effects attributable to the brain-mind responses evoked by the treatment context rather than to the specific intervention (Wager & Atlas, 2015). Social stimuli and the whole therapeutic ritual, including medical marketing, affect the patient's neuro-psycho-biological state, and this in turn impacts, negatively or positively, on response to treatment (Benedetti, 2021). Thus, for treatments without a rigorous evidence base, especially those that are heavily promoted by clinicians, media, social media and celebrity culture, the possibility that any observed benefit may be due to the social and therapeutic milieu, rather than the specific effect of the intervention, needs to be considered. This is even more imperative if the interventions have high risk of serious and irreversible adverse effects.

Clinician experience should not be disregarded, but therapeutic illusions and placebo effects are two of the reasons why we need to have a great deal of caution in depending on clinical experience and clinical consensus as evidence for the effectiveness of medical interventions.

Implications of the weak evidence base for gender affirming treatments

Informed consent

AusPATH (2022) cite the Australian Commission on Safety and Quality in Healthcare's definition of informed consent. This notes that "accurate" and "relevant" information about the healthcare intervention, and alternative options, should be given to the patient. Levine et al. (2022) cite the American Academy of Pediatrics Committee on Bioethics and, similarly, this requires the provision of information on the risks, benefits, and uncertainties of the proposed treatments and alternative treatments. Both these definitions would seem to demand, as recommended by Levine et al., that an adequate informed consent process requires the weaknesses of the evidence base for GAT for GD youth and alternative treatment options to be carefully and thoroughly discussed in an unbiased manner with patients and parents/guardians. These definitions would also seem to necessitate a full and frank discussion of the foreseeable risks of regret and detransition.

There is a further implication of this weak evidence base that requires consideration.

Innovative clinical practice or experimental treatment?

Does the weak evidence of benefits and the adverse risks of GAT mean they should only be offered to GD youth under human research ethics committee approved clinical research conditions? Such an approach would help ensure that all involved (patients, parents and clinicians) are made fully aware of the weak evidence base, as well as contribute to the required rigorous research evidence. Of note, Sweden has recently made changes to their policies with moves in this direction (Socialstyrelsen, 2022).

A brief historical vignette might provide a stimulus to our thinking on these complex issues. From the 1960s until the 1980s, in many countries, children, many with no pathology apart from psychosocial problems considered to be due to their height were prescribed hormonal treatment by endocrinologists. At the time the hormones were declared safe, but years later disastrous long-term side effects became evident. Some of the children treated with cadaveric human growth hormone contracted Creutzfeldt-Jakob Disease (CJD), an aggressive early onset and fatal dementia (Clayton, 2022b; Cohen & Cosgrove, 2010).

In Australia, the Federal government initiated a judicial inquiry into the use of pituitary derived hormones and the Australian Human Pituitary Hormone Program. The report noted that it was a very narrow and a self-interested group, with multiple conflicts of interests, running the program. It found that *"the very power of regulation itself [was] placed in the hands of those who ought to have been the subject of regulation."* (Allars, 1994, p. 507). One key conclusion was that: *"it is a dangerous situation if no attempt is made to draw the lines between the ordinary exercise of clinical judgment, research, experiment and clinical trial, even if those lines be blurred. The absence of lines is most dangerous when new advances in medicine are being explored"* (Allars, 1994, p. 722). It recommended that the National Health and Medical Research Council (NHMRC) review its human experimentation guidelines to ensure that: *"It provides guidance with regard to decisions as to whether treatment in a therapeutic setting constitutes an experiment"* (Allars, 1994, p.723).

The NHMRC's current statement on ethical conduct in human research includes such a statement: *"This guidance applies to research, but sometimes the distinction between research and innovative clinical practice is unclear. For example, innovative clinical practice occurs on a spectrum from minor changes at the border of established practice that pose little change in risk to patient safety to novel interventions that should only be introduced as part of an ethically approved research protocol"* (NHMRC, 2007/2018, p. 24).

Where do we consider the novel and poorly evidenced GAT approach for GD youth to be on this "spectrum": toward the end of a minor change that poses little risk, or more toward the end of a major change with significant risk of harm to the patients?

Conclusion

This Commentary has demonstrated the deep uncertainty and the many unknowns that face GD youth, their parents and clinicians. Any claims of certainty are premature and risk more harm than benefit, including hindering the rigorous debate and research required to improve the state of knowledge in this area of medicine. In the meantime, as recommended by Levine et al. (2022), if gender affirming treatments are to be offered as routine treatment to youth, then a thoughtful, slow and thorough evaluation and informed consent process, undertaken in a therapeutic setting, would seem optimum care for these young patients. Another option that needs to be carefully considered is whether these interventions should only be offered as part of human research ethics committee approved clinical trials, rather than be implemented as routine treatment.

The Gender Affirmative Treatment Model for Youth with Gender Dysphoria: A Medical Advance or Dangerous Medicine?

Alison Clayton¹

Introduction

A knowledge of the history of medicine enriches our thinking about contemporary medical practices. The twentieth century saw many medical advances. It also saw multiple examples of what may be called dangerous medicine. Such medicine is invasive, risky, and lacking a rigorous evidence base, but is enthusiastically embraced and celebrated by members of the medical profession and the public. Then, with the passage of time, such medicine is viewed with more scepticism. It is recognized as not being as beneficial as claimed and as causing more harm than acknowledged. It comes to be mostly seen as misguided, occasionally even criminal. In this Letter, I use a historical frame to background a discussion of the gender affirmative treatment approach for youth with gender dysphoria (GD youth), particularly focusing on masculinizing chest surgery. I ask: Is this approach a medical advance or is it a contemporary example of dangerous medicine? My hope is that the ideas expressed in this Letter will helpfully contribute to the debate about this complex and controversial area of medicine.

Braslow (1997) discussed the history of twentieth century psychiatry as practiced in California state mental hospitals. He described how doctors can transform the harmful into the “therapeutic” with their implementation of invasive “treatments” on patients in their care. He gave an illustrative example of how a “woman’s body provided multiple sites for surgical interventions” that aimed to extinguish “pathological behavior.” He described a 28 year-old Californian “housewife,” Rose, admitted as an involuntary patient in 1944. In 1949, her disturbed mental state and uncooperative behavior led to her receiving a radical prefrontal lobotomy. A year later, her “amorous” behavior led her doctor to order a clitoral cauterization. The day following

this “minor procedure” it was noted she continued masturbating and a second clitoral cauterization was performed. Rose then developed the habit of biting people, the solution for which was teeth extraction (pp. 166–168).

This brief account of Rose evokes a range of emotions. I feel horror, sadness, anger, and fear. Why do I feel these emotions? I am a human and a woman. I have had the experience of being a patient in doctors’ hands, relying on their expertise, care, and conscientiousness. It is the stuff of nightmares to be totally dependent on physicians, who, even if well-meaning, are implementing ineffective, harmful, or punitive interventions. My emotional reaction to Rose’s story is made even more complex, because I am also a psychiatrist. Therefore, part of my horror in reading this history is that I am identified with those physicians implementing such “treatments.” I ask myself: How would I have treated patients as a psychiatrist in the 1940s? Would I have done what Rose’s psychiatrist did?

Another celebrated historical treatment was malaria fever therapy, which entailed deliberately inducing a malarial illness in patients suffering from general paralysis of the insane (GPI). GPI was a severe form of neurosyphilis and was a frequent cause of admission to the early twentieth century psychiatric institutions. Although risky, malaria therapy was claimed to be successful in curing some patients from this usually fatal disease. It was used from the 1920s until the 1950s, gradually being superseded by penicillin (Davis, 2008). The British psychiatrist Shaw (1929) offered a dissenting view on this celebrated treatment. He imagined a history of psychiatry in the year 2500 making a “curious and interesting commentary” about the people in the early twentieth century who engaged in an “organized attempt to deplete their insane population by infecting them with a disease known as malaria” (p. 15).

It is a curious experience reading Shaw’s words in 2021: past, present, and future become entangled. Contemporary historians are critical of “Whiggish” histories of medicine, which stand on a moral high ground to criticize the “bad old days” (Lerner & Caplan, 2016). However, others warn against using historical context as an exculpatory “moral shelter” (Reverby, 2018;

¹ School of Historical and Philosophical Studies, Faculty of Arts, The University of Melbourne, Melbourne, Victoria 3010, Australia

Sadowsky, 2017, p. 68). What happens if we turn the tables and ask: How would historical physicians report on medicine circa 2021, and how will it be reported 100 years hence? Such a thought experiment may help expand our thinking about contemporary medical practices. Here, I apply it specifically to the practice of masculinizing chest surgery for GD youth.

Twenty-First Century Medicine: Masculinizing Chest Surgery for Youth with Gender Dysphoria

Previously a rare phenomenon, increasing numbers of young people are presenting to clinicians with gender dysphoria. The largest group are natal female adolescents, many with a history of psychiatric illness or neurodevelopmental disorders (Tollit et al., 2021). Among this population, there is a “high demand” for surgical removal of breasts (Kuper et al., 2021; Telfer, 2019, p. 14) and this is being undertaken as routine treatment in patients as young as 13 (Olson-Kennedy et al., 2018). A number of clinicians argue that this surgery is an evidence-based intervention that improves mental health outcomes and that it is discriminatory for it not to be available (McDougall et al., 2021; Mehringer et al., 2021; Olson-Kennedy et al., 2018; Telfer, 2019).

Before discussing the evidence base, some explanations on terminology are required. The studies that I discuss mostly report on surgery for individuals less than 21 years old. A number of terms are used to describe this population, including “adolescents,” “minors,” and “youth.” I use the authors’ own terms when discussing their papers; otherwise, I use the term “youth.” “Chest dysphoria” is a recently created term meaning the discomfort with one’s breasts. The term “breasts” is largely absent in these academic publications as it “may cause distress for transgender males” (McDougall et al., 2021) and this seems part of broader pattern of removing this term from clinical language (Lehmann, 2021). The surgical terminology is also changing. “Mastectomy” is being replaced by terms such as “chest surgery,” “top surgery,” “masculinizing chest surgery,” or “chest contouring” (Cohen et al., 2019; McDougall et al., 2021; Mehringer et al., 2021; van de Grift et al., 2016).

There are only a handful of published studies focusing on the potential benefits of masculinizing chest surgery in youth. Marinkovic and Newfield (2017) published what they claimed was the first study reporting data on chest surgery in young adolescents. In this retrospective observational study of 14 postsurgical youth, nine of whom were under 18 years old, participants rated satisfaction with the aesthetic outcome of the procedure on a Likert-type linear scale. All reported high aesthetic satisfaction and most self-reported low complication rates and improvement in mood. The postsurgical clinical follow-up, 1.6 years on average, was described as mostly “uneventful.” However,

one participant, seven months after surgery, requested help to detransition and was subsequently lost to follow-up.

Olson-Kennedy et al. (2018), stating there were no prior “data documenting the effect of chest surgery on minors,” undertook a cross-sectional retrospective survey of 68 postsurgical transmasculine youth (72% of the eligible postsurgical population). In 49%, the surgery had been undertaken at younger than 18 years of age, with the youngest being age 13 and the oldest age 24. At the time of the survey, only 14% of the participants were more than 2 years post-surgery. The postsurgical participants were compared with a convenience and non-matched comparison sample of nonsurgical transmasculine youth. The outcome, chest dysphoria, was measured with an unvalidated scale and indicated that the postsurgical participants had less chest dysphoria than the nonsurgical participants. Another notable finding was that testosterone use was associated with increased chest dysphoria. It is important to note that, a few years prior to this study, Olson-Kennedy (2015) had already been promoting chest surgery for minors, describing it as easy, safe, available, and “absolutely life-saving.” This last claim seems contradictory to the 2018 paper which stated there were no previous data on chest surgery in minors. Olson-Kennedy (2015) also stated that “full gender-affirming surgery” in minors was “on the horizon” and noted “the difficulty of genital surgery is that it is surgical sterilization and people get super worked up about that...it is a barrier we have to over-come and I think we are going to.” It seems this barrier is already being over-come, as it has been reported that in the United States genital surgery is being undertaken on GD minors, as young as 15 years old (Milrod & Karasic, 2017).

Kuper et al. (2020) reported on short-term body dissatisfaction and mental health outcomes in 148 adolescents receiving gender affirmative medical treatments. Out of this group, 15 “affirmed males” obtained chest surgery, at an average age of 17.1 years (the youngest being 15.2 years). Kuper et al. found no significant correlation between chest surgery and psychological outcomes.

Lastly, Mehringer et al. (2021) reported a cross-sectional qualitative study of chest dysphoria in transmasculine youth. They selected 35 participants, of whom 30 completed the study. Of these, 47% had undergone chest surgery (on average 19 months previously), and 53% had not had surgery. Mehringer et al. concluded that the postsurgical cohort experienced “tremendous” benefits in chest dysphoria and a range of psychological outcomes; however, in my opinion, they did not provide enough detail for the reader to make an informed judgement regarding this latter claim.

To my knowledge, this is the main published evidence base for the potential benefits of masculinizing chest surgery in GD youth. Importantly, it appears that the chest surgery reported on in these studies was not undertaken as part of any human research ethics committee (HREC) approved clinical trial—as the surgery was undertaken prior to or separate from the research.

Reflections on the Evidence Base for Chest Surgery for Gender Dysphoric Youth

I now return to my previously posed question: How would historical medical practitioners comment on this surgical intervention? I imagine Shaw, in response to hearing about the surgical sterilization of vulnerable youth, drily commenting that the eugenic agenda of early twentieth century psychiatry and medicine might still be operative in 2021. Shaw might note that removing the term “breasts” from our language parallels early twentieth century English and American society, which was full of euphemisms to avoid distressing women. Freeman (1961), an American psychiatrist, whose lobotomy patients included distressed adolescents as young as age 12, might exclaim “and you judge me?!” Historical physicians would likely laugh at twenty-first century physicians’ claims that contemporary medical practices are based on rigorous evidence compared to the unscientific medicine of the past.

Indeed, many of the criticisms made about the inadequate evidence base of discredited historical treatments can be leveled against chest surgery for GD youth. The studies have significant methodological limitations which mean they are at critical risk of bias and cannot show that chest surgery is causally associated with short-term improved mental health outcomes. They do not provide any information on long-term outcomes and regret rates. Limiting features include the following: small and select samples; cross-sectional assessment; uncontrolled case series or comparative studies with non-matched control groups; high drop-out rates; short-term follow-up only; unvalidated measurement scales; and a failure to account for the impact of co-interventions and the placebo effect. Those advocating for chest surgery in youth make strong claims regarding the evidence base for this surgery in adults. However, these are also limited by similar shortcomings (Cohen et al., 2019). Furthermore, the research is notable for its failure to assess a role for psychological interventions which could be utilized, as a least harm intervention, until maturity is reached. One study, on adults, actually did discuss a possible role for psychological help with “body acceptance,” but it only came at the conclusion and as a suggestion for managing body image problems that remained post-mastectomy (van de Grift et al., 2016). In my opinion, it is surprising that clinicians and researchers claim chest surgery for GD youth is an evidence-based intervention, rather than acknowledging it is an experimental treatment that requires more rigorous and HREC approved research.

How will masculinizing chest surgery for GD youth be viewed by future generations? The enthusiasm for it, despite the lack of a rigorous evidence base, suggests that it may be seen as another example of what Valenstein (1986) called “great and desperate cures.” Valenstein noted that uncontrolled therapeutic experimentation in medicine is common and has the potential to inflict serious harm in the name of progress. He argued that

we need to draw lessons from history to help prevent the recurrence of such dangerous medicine. He also emphasized the role of personal ambition. The originators of the lobotomy, Moniz, and malaria therapy, Wagner-Jauregg, reached the pinnacle of medical ambition, each being awarded a Nobel Prize (ibid; Wagner-Jauregg, 1927). Valenstein argued for more regulation of innovative surgery, but also thought that such controls would be resisted “with argument that they will hamper progress and deprive desperate patients of help” and that “randomized control studies are unethical” (Valenstein, 1986, p. 297). This certainly parallels the arguments of those enthusiastically advocating for surgery for GD youth. Valenstein’s view was that “the negative effect of reasonable regulation was exaggerated, especially when compared with the cost of uncontrolled experimentation” (ibid).

What Can Historical Examples Teach Us about Possible Contributing Factors to Dangerous Medicine?

What factors, aside from the lack of a rigorous evidence base, might contribute to dangerous medical practices? Can history inform us anything about what might lead physicians to over-enthusiastically and prematurely embrace risky and unproven treatments? History suggests there is most likely a complex interplay of multiple factors, and I discuss some of these in this section. In the subsequent section, I return to discuss the gender affirmative treatment approach for GD youth and highlight some themes that may suggest some parallels with this history.

For physicians, “great and desperate” treatments could lead to “name and fame” and inculcate a sense of heroic doctor. For example, at the end of the nineteenth century, general paralysis of the insane confounded physicians’ therapeutic potency, leaving them just contemplating death “like men in a boat about to be swept over a fall, paralyzed with despair” (Godding, 1897). However, malaria therapy changed that and gave doctors a sense of potency and their patients a sense of hope (Braslow, 1997, p. 94; Grob, 1994, p. 180). Today, the efficacy of historical malaria therapy for GPI is questioned (Austin et al., 1992; Davis, 2008, p. 189; Frankenburg & Baldessarini, 2008; Scull, 2015). However, it certainly was effective in bolstering psychiatrists’ status. Ellery, the psychiatrist who introduced malaria therapy to Australia, described that it allowed psychiatrists to be considered “bona-fide clinicians,” who were no longer shunned as asylum medical officers just practicing “black magic” and “voodooism,” but instead “invited to medical meetings and listened to with interest” (Ellery, 1956, pp. 153–154).

An uncritical press portrayed the physicians implementing these treatments as bold medical heroes with the courage to take “desperate remedies” required to cure “desperate ills” (Hurn, 1998, p. 226). Malaria therapy was widely reported in the press with dramatic headlines and celebratory accounts. For example, in Australia, an article entitled “Doctor Mosquito” (1926)

promoted malaria therapy's "wonderful" benefits. In leading international newspapers, such as the *New York Times*, lobotomists were described as simply cutting out the "worry center" of the mentally ill, just as easily as they could remove an "appendix" or an "infected tooth" and bringing the patients a world "radiant with sunshine and kindness" (Harrington, 2019, p. 69; Pressman, 1998, p. 185; Scull, 2015, p. 317). These glowing portrayals, along with Nobel Prizes, gave these treatments a powerful authority, contributing to their rapid and widespread adoption by the medical community and leading patients and their families, including the rich and powerful, to seek them out (Diefenbach et al., 1999). Harrington (2019) reported on the tragic story of Rosemary Kennedy (President Kennedy's sister) who had a mild intellectual deficit. She was impetuous and the family feared an "embarrassing" pregnancy might result. In 1941, when she was 20, her father arranged for Freeman to lobotomize her. The operation was a disaster and Rosemary was institutionalized for the rest of her life.

Physicians can be confronted by patients whose illnesses, behaviors, and physicality undermine Western ideals of masculinity, femininity, and heterosexual norms. It may be that these patients are particularly at risk of dangerous medicine. General paralysis of the insane was a disease predominantly diagnosed in men in the prime-of-life. It was intimately linked with masculinity and sexuality, and deeply confronting to early twentieth century Anglo-European ideals of manhood. Men could turn from being rational and responsible citizens to filthy, raving, and violent—Mr Hyde, from *The Strange Case of Dr Jekyll and Mr Hyde*, could have been GPI personified (Swain, 2018). As the disease progressed, young men were reduced to "intellectual drivel and physical wreck," undergoing a "loathsome bodily decay" (Godding, 1897). In the early twentieth century, GPI's causation was definitively linked to syphilis and it then became linked to sexual morality. "Bad women" (prostitutes or promiscuous) were condemned for infecting men with venereal disease and, in various jurisdictions, criminal laws were introduced to detain such women. A World War I poster warned the soldiers against sexual liaisons: "A German Bullet is Cleaner than a Whore" (Brandt, 1985, p. 101). Given these attitudes, malaria therapy may have functioned, as did many previous treatments for syphilis, at least unconsciously, as a form of punishment as well as a treatment (Brandt, 1985, p. 12; Quérel, 1990, p. 59). A summary by the well-known popularizer of medical knowledge, de Kruif, suggests this underlying attitude: "Give your paretics the right kind of malaria...and though it burned them, the whole bodies of these paralytics seemed cleansed by the malaria fire... Thin washed out by the terrible fever...they began to turn into new people" (as cited in Braslow, 1997, p. 79).

Of note, malaria therapy was invented in 1917 in Vienna (Wagner-Jauregg, 1927). This was the penultimate year of World War I. Wagner-Jauregg's clinic, among others, "treated" World War I soldiers, suffering "war neurosis" (otherwise known as shell-shock), with painful electric current treatments, sometimes

applied to the genitals (Bogousslavsky & Tatu, 2013; Eissler, 1986). After the war, Wagner-Jauregg was officially investigated for cruelty and torture. Although he was cleared, a subsequent re-analysis of the investigation casts serious doubt on the impartiality of the judicial process (Eissler, 1986). The shell-shock patients were called "shirkers" and "tremblers," indicating the moral censure of such patients (Riebl & Sharp, 1992). The painful electric current "treatment" appears to be, in part, a punishment for the challenge these men represented to masculinity ideals, particularly in a nation at war (Mosse, 2000).

Many of the other somatic psychiatric treatments of the twentieth century were given predominantly to females. Pressman (1998) wrote that "an enduring mystery of the psychosurgery story, is why women were lobotomized nationally at a rate twice that of males" (p. 303). Braslow (1997) argued that the doctors entwined madness and unladylike behavior, and psychosurgery was seen as a potential intervention to restore femininity. In addition, women were "shackled, straightjacketed, bound and secluded" much more often than men (p. 157). Women who masturbated could be ordered to undergo clitoridectomy; men who masturbated and acted out "never lost their penises or testicles as a cure for these activities" (p. 168). In a feminist account, Showalter (1985) also portrayed psychiatry as a history of the colonization and subjugation of women.

Homosexuals' bodies have also been a favored site for experimental twentieth century medical and surgical interventions in which treatment, social control, and punishment goals blur. Metrazol convulsive therapy, chemical castration with estrogens, surgical castration, clitoridectomy, brain operations, and aversive electrotherapy were all utilized with the aim to either convert the homoerotic desires to heterosexual ones or to obliterate desires all together (Murphy, 1992). Sometimes, as in the example of the British mathematician, Alan Turing, the treatment was accepted as an alternative to imprisonment (Hodges, 2012). It is of note that during the 1990s AIDS epidemic, which disproportionately impacted the male homosexual community, malaria therapy was resurrected. It was speculatively and unethically trialed as a potential cure for AIDS (Nierengarten, 2003).

My final historical example is the hormonal treatment of "tall girls" and "short boys." From the 1960s through until the 1980s, large numbers of adolescents, who had no underlying medical pathology or hormonal abnormality, were prescribed hormonal treatment for their height (Cohen & Cosgrove, 2010). The reasons stated for such treatments, for what nowadays might be called "height dysphoria," included that adolescents were distressed, and their height had negative social impact. For example, "careers in classical ballet or being an airline hostess were closed" to "tall girls" and their prospects of finding a husband were jeopardized (Wettenhall et al., 1975). Some adolescents and their parents eagerly sought this treatment, led to it by the encouragement of physicians and school nurses, enthusiastic media promotion, and pharmaceutical companies' advertising. At the time, the hormones were declared safe, but years later

concerns emerged about long-term adverse effects, including impaired fertility and increased risk of cancers (Benyi et al., 2014; Venn et al., 2004). Some boys treated with growth hormone developed Creutzfeld–Jacob disease, an aggressive early onset and fatal dementia. In Australia, this led to a federal government inquiry and an apology. In France, criminal charges were laid against some of the physicians involved (Cohen & Cosgrove, 2009, pp. 262, 350). Importantly, there had been a lack of controlled trials to confirm the efficacy, either on improving psychosocial outcome or the impact on height, of these treatments. A retrospective cohort study of “tall girls” revealed that 42% of the study group regretted the hormonal treatment they received (ibid., p. 232). Tall girls and short boys may be a visual affront to some societal “ideals” of male strength female fragility. This seems another part of the story of medicine acting to reinforce society’s sex stereotypes, and for some patients it came at disastrous personal cost.

The Gender Affirmative Treatment Approach for Gender Dysphoric Youth: Medical Advance or Dangerous Medicine?

Masculinizing chest surgery is part of the controversial gender affirmative treatment approach to GD youth. This approach is underpinned by the view that a child or adolescent’s stated gender identity should be endorsed not questioned, and that they should be supported to undertake social transition, medical transition, masculinizing chest surgery, and, some also argue, genital surgery. Those advocating this approach consider these gender affirming treatments medically and ethically essential (Baams, 2021; de Vries et al., 2021; Transgender Health, 2020; Walch et al., 2021).

Others express concern about this approach (Biggs, 2020; D’Angelo et al., 2021; Levine, 2018, 2021; Malone, 2021). They note the limited and low-quality evidence base for the benefits, not only of mastectomy as I have done in this Letter, but for early social transition and the hormonal treatments for GD adolescents. Concerns are raised about the irreversible and long-term adverse impacts of these treatments on fertility and sexual function, as well as on bone, brain, and cardiovascular functioning. Concerns are expressed about the sharp, massive, and largely unexplained increase in GD youth, many with psychiatric and neurodevelopmental disorders, presenting to gender clinics. They caution against early social transition, hormonal, and surgical treatments of youth. Some ask: Why are these experimental interventions, with inherent risks and scarce, low-quality evidence for benefits, being implemented outside HREC regulated clinical trial settings?

The studies’ limitations also mean that regret and detransition rates are largely unknown. A widely cited study to support claims of less than 1% long-term regret rates is Wiepjes et al.

(2018). However, this study only reported on stringently defined regret (as recorded by the clinician in the clinical record plus the prescription of sex hormones consistent with natal sex) in those who underwent gonadectomy, and then continued in follow-up (and 36% of the study population dropped out of follow-up). The adolescent subgroup was carefully selected, being meticulously assessed and managed via the rigorous “Dutch protocol” (de Vries & Cohen-Kettenis, 2012) and the vast majority had a relatively short follow-up period. Most contemporary youth gender clinics do not follow the “Dutch protocol,” which further limits the applicability of this study’s regret rate findings. It is worth highlighting that Keira Bell, a well-known detransitioner, would not meet the criteria to be categorized as a regret case in the Wiepjes et al. study as she never underwent gonadectomy. Celebratory stories of medically and surgically transitioned young people are regularly promoted by physicians and the media (Alcindor, 2015; Cohen, 2021) adding to the impression of overwhelming beneficial outcomes of this treatment approach. However, there are now increasing reports in the medical literature of regret and detransition (Entwistle, 2021; Littman, 2021; Pazos-Guerra et al., 2020; Vandenbussche, 2021) and these give us cause to question the claims of negligible regret rates.

In response to my historical examples, some may argue that informed consent and patient autonomy differentiates contemporary medicine from historical medicine. However, many of these historical treatments did require informed consent, either from the patient or a family member. In addition, informed consent is complex. A necessary condition for it is clinician honesty, which is not met if clinicians overstate the evidence base or act as “cheerleaders” for transition (Clayton et al., in press; Levine, 2019). The contemporary portrayal of the principle of patient autonomy as a simple solution for bioethical quandaries has been challenged by Mol (2008). Mol illustrated that the notion of “patient as a customer autonomously choosing health care” is simplistic. Patients’ choices are deeply entangled with other factors, including the influence of their clinicians and medical marketing. Some readers may also reject my discussing contemporary medicine for GD youth along with what they may consider as cruel historical treatments. However, we need to remember that, for the most part, these treatments were not judged as cruel at the time of use, were widely celebrated, and were implemented by well-intentioned physicians who fervently believed that they were helping their patients.

This is also a controversial topic outside the medical field. Contemporary feminist academics have divided views on transgender issues and the medicalization of GD youth (Gillis et al., 2007; Riley & Pearce, 2018; Stock, 2021). Thus, while some express full support, others express concern that the medicalization of such youth is reinforcing sexual stereotypes and gender binaries. They argue that a deeper analysis is required to understand why so many young people, particularly natal

females, are now finding their natural bodies uninhabitable. Others are troubled with the fact that it is the powerful pharmaceutical and surgical industries that are creating trans-bodies.

Some influential LGBTIQ and parent groups are vocal in their support of affirmative treatments for GD youths, but other such groups express concern. Some consider that placing the label “trans” on gender non-conforming youth is an expression of the homophobia of our society. They are concerned that the hormonal and surgical interventions maybe a repetition, albeit unwittingly, of historical treatments that aimed at converting homosexual people to fit with heterosexual norms (Stock, 2021, pp. 83–84). There is emerging research data that support these concerns. Littman (2021), in her survey of 100 detransitioners, found 23% reported homophobia or difficulty accepting themselves as lesbian, gay or bisexual as a reason for their transition and subsequent detransition. The example of Iran is also often raised in this context. Jafari (2014) noted that Iran’s government boasts about their high rates of sexual reassignment surgeries as indicative of their commitment to human rights, and that some, including Western media sources, can portray the availability of such surgeries in Iran as liberal and progressive. Yet, in Iran, homosexuality is forbidden and punishable by the death penalty. To avoid this, homosexuals may have to undergo sexual reassignment surgery (see also Hamedani, 2014). Jafari (2014) commented that “ultimately the state’s goal—and the murkier side to this ‘liberal’ medico-legal development—is the assimilation of homosexual men and women within a binary gender paradigm” (p. 42). For more perspectives on the complexities of this situation in Iran and relevant cross-cultural issues, the interested reader is referred to Meyer (2016) and Sadjadi (2019).

Conclusion

How, then, do we best read the affirmative treatment approach for GD youth? Should it be read triumphantly as cutting-edge, ethical, and evidence-based medicine continuing on its progressive march of improving human life? Or is it a manifestation of dangerous medicine, that despite best intentions will cause more harm than benefit to vulnerable youths, and over which future historians and physicians will shake their heads?

Between the ages of 16 and 20, Kiera Bell identified as a man and took testosterone and underwent a double mastectomy. She then detransitioned. In a court testimony, she described her regret: “I felt like a fraud. . . more lost, isolated and confused than I did when I was pre-transitioned. . . only recently. . . I have started to think about having children and if that is ever a possibility, I have to live with the fact that I will not be able to breastfeed my children. . . I made a brash decision as a teenager. . . trying to find confidence and happiness. . . now the rest of my life will be negatively affected” (Bell, 2020, pp. 21–22). In these words, Bell holds herself responsible for making a “brash decision”

in her youth. This may be an indication of maturity and taking responsibility, but it also has a more concerning element—a victim blaming herself for mistreatment. In my view, the medical profession needs to consider whether, in its championing of the gender affirmative approach for GD youth, it is also acting brashly and making mistakes that will negatively impact some young people for the rest of their lives.

Dear Paul A. Vazquez, J.D.
Executive Director Florida Board of Medicine

I am a parent of a 16 year old girl, who identifies as transgender.

She might be a lesbian, but she is not transgender. She has struggled with mental health issues. We are constitutionally opposed to the affirmation model and hormonal/surgical interventions for our minor child. Historically, teenage females are plagued by social contagion issues including anorexia, bulimia, and cutting. We believe our daughter has been caught up in this latest social contagion like many other teens. She has always struggled socially, and gender ideology with its social justice aspect, has proved to be the answer for her to longing to belong and have friends. Nearly 25% of kids in her high school have recently claimed a trans identity.

Research is limited, and no consensus exists within the scientific community about possible causes of gender dysphoria and the most appropriate treatment options. We must secure a balanced treatment of political issues, which must take a child-centered, evidence-based approach, and take care not to express personal beliefs in ways that could exploit vulnerabilities. We should not for example, present childhood gender incongruence as an inherent and immutable phenomenon, as this is a contested idea not an established evidence-based fact.

The number of people who regret transition is unknown. Most who “desist” simply stop treatment and do not report their desistance to their providers. According to the ever-increasing numbers of people involved in online forums and groups of detransitioners, they do not have support from the medical or transgender communities. Many say they did not fully understand the magnitude of side effects, adverse outcomes, and risks involved in their transitions.

The human brain is not considered fully developed until approximately 25 years of age. According to psychological developmental stages of children and teenagers, forming identity is an important process. Erik Erikson’s psychosocial developmental stage of ‘Identity vs Role Confusion’ speaks perfectly to the normalcy of teens questioning their identities. Self-exploration is a normal part of growing up for everyone. The problem with claiming a trans identity is the irreversible damage that can be done with medical and surgical interventions. Children and teenagers are unable to provide true informed consent for such treatment. They are unable to fully understand the lifelong consequences of these decisions. Please consider this and

protect children from irreversible damage. When they are adults who can provide true informed consent, they can make these decisions for themselves.

Thank you most sincerely for your time and consideration.

John Warren

Understanding Your Positive *SDHB* Genetic Test Result

INFORMATION FOR PATIENTS WITH A **PATHOGENIC MUTATION** OR **VARIANT, LIKELY PATHOGENIC**

4 Things to know

1	<i>SDHB</i> mutation	Your testing shows that you have a pathogenic mutation or a variant that is likely pathogenic in the <i>SDHB</i> gene.
2	Non-cancerous tumor and cancer risks	You have an increased chance to develop paragangliomas (PGLs)/pheochromocytomas (PCCs), gastrointestinal stromal tumors (GISTs), and kidney cancer.
3	What you can do	There are risk management options to detect cancer early or lower your risk to develop cancer. It is important to discuss these options with your doctor, and decide on a plan that best manages your cancer risks.
4	Family	Family members may also be at risk – they can be tested for the <i>SDHB</i> mutation that was found in you.

SDHB Mutations in the Family

There is a 50/50 random chance to pass on an *SDHB* mutation to your sons and daughters. The image to the right shows that both men and women can carry and pass on these mutations.

Understanding Your Positive *SDHB* Genetic Test Result

INFORMATION FOR PATIENTS WITH A **PATHOGENIC MUTATION** OR **VARIANT, LIKELY PATHOGENIC**

Result	MUTATION	Your testing shows that you have a pathogenic mutation (a disease-causing change in the gene, like a spelling mistake) or variant that is likely pathogenic in the <i>SDHB</i> gene. Both of these should be considered the same type of positive result.
Gene	<i>SDHB</i>	Everyone has two copies of the <i>SDHB</i> gene, which we randomly inherit from each of our parents. Mutations in one copy of the <i>SDHB</i> gene can increase the chance for you to develop certain types of cancer and tumors.
Tumor/ cancer risks	INCREASED	You have an increased chance to develop a PGL/PCC (77-100% by age 70). PGLs/PCCs are rare tumors that affect your endocrine system, which makes and controls your hormones. <i>SDHB</i> -associated PGLs/PCCs have a high risk of becoming cancerous. You also have an increased risk for GISTs, which are rare tumors of the GI tract. PGLs/PCCs and GISTs are not typically cancerous, but may require treatment; some can become cancerous. Additionally, you have an increased risk for kidney cancer (up to 14%).
Management Options	FOR MEN & WOMEN	Options for screening and early detection may include imaging with CT scans or MRI, as well as blood and/or urine screening tests. Talk to your doctor about which options may be right for you.
Risk Management	VARIES	Risk management decisions are very personal, and the best option depends on many factors. Screening typically begins earlier than in the general population, and is often more frequently done. It is important to discuss these options with your doctor.
Family Members	50/50 CHANCE	Your close relatives (like your parents, brothers, sisters, children) have a 50/50 random chance of inheriting the <i>SDHB</i> mutation that you carry, and other family members (like your aunts, uncles, cousins) may also inherit it. Your relatives can be tested for this same mutation. Depending on the family history, those who DO NOT have it may not have an increased lifetime chance (above the general population) to develop cancer.
Next Steps	DISCUSS	It is recommended that you share this information with family members so they can learn more and discuss this with their healthcare providers.
Reach Out	RESOURCES	<ul style="list-style-type: none">▪ Pheo Para Alliance pheo-para-alliance.org▪ Pheo Para Troopers pheoparatroopers.org▪ Genetic Information Nondiscrimination Act (GINA) ginahelp.org▪ National Society of Genetic Counselors nsgc.org▪ Canadian Society of Genetic Counsellors cagc-accg.ca

Please discuss this information with your healthcare provider. The cancer genetics field is continuously evolving, so updates related to your *SDHB* result, medical recommendations, and/or potential treatments may be available over time. This information is not meant to replace a discussion with a healthcare provider, and should not be considered or interpreted as medical advice.

Dear Paul A. Vazquez, J.D.
Executive Director Florida Board of Medicine

I am a parent of a 16 year old girl, who identifies as transgender.

She might be a lesbian, but she is not transgender. She has struggled with mental health issues. We are constitutionally opposed to the affirmation model and hormonal/surgical interventions for our minor child. Early childhood gender dysphoria is not a new phenomenon. However, the existing literature on treatment and outcomes is largely based on early childhood gender dysphoria in male children. It may not apply to the current cohort of gender-questioning children who are older, predominantly female, and often presenting with a range of neurodevelopmental and mental health co-morbidities. Historically, teenage females are plagued by social contagion issues including anorexia, bulimia, and cutting. We believe our daughter has been caught up in this latest social contagion like many other teens. She has always struggled socially, and gender ideology with its social justice aspect, has proved to be the answer for her to longing to belong and have friends. Nearly 25% of kids in her high school have recently claimed a trans identity.

Recently, Great Britain commissioned a highly distinguished public health and pediatric expert to reconsider the affirmative model in the United Kingdom. Please consider with care the findings of the Cass Review interim report, which is an independent review of gender identity services for children and young people. It was ‘commissioned by NHS England and NHS Improvement in Autumn 2020 to make recommendations about the services provided by the NHS to children and young people who are questioning their gender identity or experiencing gender incongruence.’ In March 2022, the Cass Review submitted an interim report to NHS England. This interim report ‘[set] out [the] work to date, what [had] been learnt so far and the approach going forward.’

Dr Hilary Cass was appointed by NHS England and NHS Improvement to chair the Independent Review of Gender Identity Services for children and young people in late 2020. A former President of the Royal College of Paediatrics and Child Health from 2012-2015, Dr Cass recently finished a term as Chair of the British Academy of Childhood Disability (2017-2020). Although retired from clinical practice, she remains an honorary consultant pediatrician at Evelina London Children’s Hospital. Dr Cass is currently Chair of Together for Short Lives, and a Trustee for Noah’s Ark Children’s Hospice. She is also leading work on how to address the

challenges for both families and professionals in supporting the rising numbers of children with complex medical conditions and disability. Other recent roles include acting as the senior clinical advisor for Child Health for Health Education England. Prior to this, Dr Cass held a range of senior education and management roles in NHS hospital trusts and was previously Head of School of Paediatrics in London. Her consultant clinical practice was as a tertiary neurodisability consultant from 1992 to 2018 in three very different specialist centers, and she has published widely in this area.

Similar to America, there has been a recent significant increase in the number of referrals to the Gender Identity Development Service (GIDS) at the Tavistock and Portman NHS Foundation Trust. From a baseline of approximately 50 referrals per annum in 2009, there was a steep increase in 2014-15, and at the time of the Tavistock inspection, there were 2,500 children and young people being referred per annum, 4,600 children and young people on the waiting list, and a waiting time of over two years to first appointment. This surge in children seeking help for distress in relation to their sex is occurring in the context of an ongoing public debate around issues relating to sex, gender, and gender identity. Over the last few years, broader discussions about transgender issues have been played out in public, with discussions becoming increasingly polarized and adversarial.

Research is limited, and no consensus exists within the scientific community about possible causes and most appropriate treatment options. We must secure a balanced treatment of political issues, which must take a child-centered, evidence-based approach, and take care not to express personal beliefs in ways that could exploit vulnerabilities. We should not for example, present childhood gender incongruence as an inherent and immutable phenomenon, as this is a contested idea rather than an established evidence-based fact.

The number of people who regret transition is unknown. Most who “desist” simply stop treatment and do not report their desistance to their providers. According to the ever-increasing numbers of people involved in online forums and groups of detransitioners, they do not have support from the medical or transgender communities. Many say they did not fully understand the magnitude of side effects and risks involved in their transitions. The human brain is not considered fully developed until approximately 25 years of age. According to psychological developmental stages of children and teenagers, forming identity is an important process. Erik Erikson’s psychosocial developmental stage of ‘Identity vs Role Confusion’ speaks perfectly to

the normalcy of teens questioning their identities. Self-exploration is a normal part of growing up for everyone. The problem with claiming a trans identity is the irreversible damage that can be done with medical and surgical interventions. Children and teenagers are unable to provide true informed consent for such treatment. They are unable to fully understand the lifelong consequences of these interventions. Please consider this and protect children from irreversible damage. When they are adults who can provide true informed consent, they can make these decisions for themselves.

Thank you most sincerely for your time and consideration.

Good Morning,

I'm am writing you in regards to the upcoming meeting on the topic of gender. I am the mother of a 17 year old daughter who is currently suffering from gender dysphoria. My daughter was a typical Tom boy growing up and was comfortable in her skin until the age of 15. She started high school in a new area and was embraced by the LGBTQ kids. After a year of being in this friend group she started questioning her gender and started identifying as transgender. Her change and the language she started using did not seem authentic to her. She became severely depressed and suicidal. She said she needed testosterone and a double mastectomy immediately. As her parents, This sudden change shocked us and we began researching studies on long term testosterone use and gender surgery. This kind of research is severely lacking. We need proper studies on the long term use of testosterone, gender affirmative care and surgeries. Teenagers and young adults should not be making life long medical decisions without an extremely high bar set for informed consent. I am seeing more and more de transitions happening and I fear for my child's long term health and pursuit of happiness.

Thank you,

Jennifer Gunter

Hello,

As the parent of a teenager who has become entrenched in the gender ideology sweeping the western world, I would like to ask that you stay strong against the affirmative approach of care for young people who wish to transition. Watchful waiting is the key.

I know, because my son has been rushed to transition. It is the approach taken here in New Zealand and though I am not transphobic I worry about the huge increase in kids who are wishing to change their gender, and the way that they are being encouraged by people who should know better, who are telling them that it is possible to change sex.

I fear that in a few years, it will become clear that this is the 21st century's scandal and that many young people will regret the irrevocable changes that have been made to their bodies.

Thank you for reading this.

Gay Johnson,

To the Florida Board of Medicine:

In late 2020, NHS England and NHS Improvement appointed Dr Hilary Cass, a former President of the Royal College of Paediatrics and Child Health, to chair the Independent Review of Gender Identity Services for children and young people. Her work, the Cass Review, is an Independent Review of Gender Identity Services for Children and Young People and it outlines some of the specific safeguarding issues that surround gender-questioning children. Here is a brief summary:

From 2012-2015 there has been a huge increase in the number of children (predominantly female teenagers) seeking help for distress in relation to their biological sex. Research into this new phenomenon is limited. The lack of high-quality data from longitudinal studies together with the changing epidemiology means that no consensus exists about the possible causes for this recent surge in children wanting to change sex. Clinically trained professionals face difficulties in making diagnoses and recommending treatment. School staff are neither qualified to evaluate existing research nor clinically trained. Therefore, they cannot judge the appropriateness of, for example, socially transitioning children. It is an intervention with poorly understood outcomes that affects children's psychological development and potentially every aspect of their physical health.

Please advocate for a cautious approach that safeguards the health of children – whose decision making capacity does not mature until the age of 25 -- while we gather information to determine the causes and consequences of this complex issue.

Yours sincerely,

Jill Harris

Dear Mr. Vazquez,

regarding the international call for experiences that can help Florida medical board reach adequate decision regarding gender transition and health care of transgender people, I'm sending You some charts that depict sudden rise of gender dysphoria in Croatian adolescents.

The data shown on charts represents rapid rise of gender dysphoria in the sample of 587 children and adolescents (336 males and 251 females) during the seven years period.

Red line on the first chart are boys and on the second are girls.

Our national psychiatric association cannot explain this rise in any other way than social contagion, despite the voracious pressure from the trans activists to regard this phenomenon as a result of more liberated social climate.

This is a very serious issue that we here in Croatia are starting to address in terms of follow up studies of children with GD who entered the process of transition, and I will be available to You for our future findings.

Cordially Yours.

Dear Florida Board of Medicine,

Thank you for taking up the vital question of regulating the so-called "gender-affirming" hormones and surgeries for young people.

As parents of these children, we have seen some very well-meaning but misinformed doctors recommend these radical life-changing interventions sometimes on the first or second visit. The myth that our children are getting "assessments" is propagated widely, but no requirements have ever been clearly articulated about which child or young person distressed with their gender role will benefit vs will be harmed. This intervention sterilizes 100% of children if administered according to the Endocrine Society's recommendations.

Older adolescents can get hormones with no assessments at all, and have their healthy body parts amputated by eager surgeons on little more than self-declaration of "trans identity." Many of our children are gay and autistic. Many of these kids also have other Mental Health comorbidities, and have come to believe their very real distress is explained by the fact that they are "transgender" and that hormones and surgeries will help. They do not. We have seen our children's mental and physical health plummet following "gender-affirmation." We need a more nuanced and holistic approach to help them, instead of the irreversible treatments from gender-affirmation that sets them down the path of lifelong medication. Minors cannot provide informed consent to irreversible and unknown harms from gender-affirmative medical treatment. Their brain is not fully developed yet to comprehend the longer term risk from the so-called affirmative-treatment that interfere with their growth, sexual development, fertility and multi-system

We also encourage you to require exploratory psychotherapy and to issue a clear statement that psychotherapy for gender dysphoria is not conversion. Our children and families need safe non-invasive alternatives to radical experimentation known as "gender affirmation." The Florida Board of Medicine must use its authority to protect children and adolescents from misinformed and dangerous actions, and must allow its members to render evidence-based professional care.

Thank you for doing what you can to regulate this experiment on our vulnerable children.

rgds

Joselyn

Dear Mr Vazquez,

I am a retired obstetrician/gynecologist with more than 40 years of practice and experience as a medical school faculty member and I am writing to speak against the treatment of minors with medications or surgery that change the individual's birth gender. I feel strongly that there is insufficient evidence for this radical treatment. I think that mental health evaluation would be a more logical beginning of evaluation rather than jumping to changing gender. I do not say this out of a homophobic mindset, but I believe it is just bad medicine.

Also I do not believe that minors have the capability to fully understand the ramifications of using experimental drugs or surgery to make truly informed decisions.

Thank you for considering my opinion.

Yours truly,

John Coppes, MD MPH

Dear Florida Board of Medicine

I am writing to you today to demand that you reject the proposed guidance by Surgeon General Ladapo's Department of Health on Gender Dysphoria in Children and Adolescents.

Care providers, doctors, and leading medical associations have been clear that gender-affirming care is safe, effective, and evidence-based, and that it's literally lifesaving.

The issued guidance by the Dept. of Health and the studies used by this board are inaccurate and dangerous. This guidance is nothing more than another tool for the Governor to express his opposition to transgender individuals' existence.

The nation's leading health organizations support gender-affirming care for transgender and gender non-conforming people, including the American Academy of Pediatrics; the American Medical Association; The American College of Obstetricians and Gynecologists; The American College of Physicians; The American Psychiatric Association; The American Psychological Association; The American Academy of Family Physicians; The Endocrine Society; The Pediatric Endocrine Society; American Nurses Association; American Public Health Association; American Heart Association; National Association of Social Workers; World Medical Association; and The World Professional Association for Transgender Health, among others.

There is overwhelming evidence to support the positive mental health impacts of gender-affirming medical care for trans youth - including in some of the very studies cited by the DOH and Board of Medicine. Prohibiting social transition is clear government intrusion on personal and parental decision making. Numerous studies have found that after social transition, transgender youth report similar mental health levels to the general youth population, eliminating mental health disparities typically seen. When transgender youth are affirmed by people around them, reported rates of depression and suicidality drop significantly. This rule will deny them this life-saving treatment.

The Board must provide truthful information based on science and data as opposed to false statements based on prejudice and political agendas. The evidence is clear: denying transgender youth the ability to transition is dangerous, abusive, and life-threatening.

I urge you to reject this proposal.

Sincerely,

Alexis Maestre-Saborit

I am writing to the board to support a slow and cautious approach in the area of gender medicine, particularly in regards to the use of hormonal and surgical therapy. The push for Gender Affirming Therapy is based on a new paradigm rooted in the assumption that gender dysphoria is innate, but a review of the current literature suggests that this claim is founded upon unscientific gender ideology and lacks evidence base.

We are in an era where the current trend is to only practice evidence-based medicine. We should not abandon this approach because the topic is emotionally charged.

1) No Evidence that Transgender Interventions are Safe for Children

There is not a single long-term study to demonstrate the safety or efficacy of puberty blockers, cross-sex hormones and surgeries for transgender-believing youth. This means that youth transition is experimental, and therefore, parents cannot provide informed consent, nor can minors provide consent for these interventions. Moreover, the best long-term evidence we have among adults shows that medical intervention fails to reduce suicide.

a) Puberty blockers may cause mental illness

Puberty blockers may actually cause depression and other emotional disturbances related to suicide. In fact the package insert for Lupron, the number one prescribed puberty blocker in America, lists “emotional instability” as a side effect and warns prescribers to “Monitor for development or worsening of psychiatric symptoms during treatment”. Similarly, discussing an experimental trial of puberty blockers in the U.K., Oxford University Professor Michael Biggs wrote, “There was no statistically significant difference in psychosocial functioning between the group given blockers and the group given only psychological support. In addition, there is unpublished evidence that after a year on (puberty blockers) children reported greater self-harm, and the girls also experienced more behavioral and emotional problems and expressed greater dissatisfaction with their body—so puberty blockers exacerbated gender dysphoria”.

b) Puberty blockers may cause permanent physical harm

Temporary use of Lupron has also been associated with and may be the cause of many serious permanent side effects including osteoporosis, mood disorders, seizures, cognitive impairment and, when combined with cross-sex hormones, sterility.

c) Surgical interventions: physically healthy transgender-believing girls are being given double mastectomies at 13 and hysterectomies at 16, while their male counterparts are referred for surgical castration and penectomies at 16 and 17. This is particularly worrisome in that many studies show that those who have transitioned, will change their minds and detransition years later, up to 85% of the time.

2) The Myth about Suicide and Gender Dysphoric Children

Why would parents allow a gender-confused child to undergo these dangerous medical interventions? In many cases the answer is untruths and emotional blackmail. “If you don’t let me do this, I’ll kill myself,” they hear from their child. The threat of suicide is then reinforced by members of the transgender industry: “Would you rather have a live son or a dead daughter?” There is no long-term evidence that puberty-blockers, cross-sex hormones or “transition” surgeries prevent suicide. On the contrary, the best long-term

research shows that individuals who do go through medical transition kill themselves at a rate 19 times greater than the general population.

Swedish child and adolescent psychiatrist Sven Roman sums up the research: “There is currently no scientific support for gender-corrective treatment to reduce the risk of suicide”.
(//twitter.com/will_malone/status/1187082564458160131).

Psychologist Dr. Michael Bailey (Northwestern University) and Dr. Ray Blanchard (University of Toronto) agree: “The best scientific evidence suggests that gender transition is not necessary to prevent suicide... There is no persuasive evidence that gender transition reduces gender dysphoric children’s likelihood of killing themselves.” (//4thwavenow.com/2017/09/08/suicide-or-transition-the-only-options-for-gender-dysphoric-kids/;))

Many medical organizations around the world, including the Australian College of Physicians, the Royal College of General Practitioners in the United Kingdom, and the Swedish National Council for Medical Ethics have characterized these interventions in children as experimental and dangerous.

Thank you for your consideration,

R. Paul Post, MD, FAAFP

To Paul A Vazquez, J.D
Executive Director
Florida Medical Board

Dear Mr. Vazquez,

I write to ask that you consider the significant and irreversible damage of “gender affirming care” when applied to young people who are (developmentally appropriately) exploring their identities. Medicalisation of a gender identity, fixes that identity by sterilisation. I do not believe this abides in any way with the medical profession’s oath to “Do No Harm”.

I am a parent of a young man (18 years) who currently identifies as a woman and was prescribed progesterone and estrogen after two appointments with a GP he had never met before. My son was NOT DISTRESSED but he was convinced by social media, gender questioning friends and the cultural messages at large that if he doesn’t fit male stereotypes of our society, he must in fact be female and that he must medically transition. Of course, as adults we know that the way we feel about ourselves and the way we see the world changes dramatically from our views as eighteen year olds. When my son one day falls in love (he never has) or wants to have children (he says he doesn’t- again, developmentally appropriate) the choice to have a healthy intimate relationship or biological children will be gone.

I am also a practicing pharmacist and am concerned and alarmed at the lack of evidence for the benefit of medicalisation and horrified at what seems to be ignorance of significant other risks.

Young people requesting medical and surgical changes to their bodies that will sterilise them and fix them irreversibly, into an identity that should just be part of normal transient identity exploration should be given reassurance and psychological support if needed. Not experimental, irreversible, sterilising medical treatment. I ask you and the Board to be guided to Do No Harm where the risk of no medication is minimal and the risk of gender-affirming medicine is potentially catastrophic in young adults.

Regards,

Karen Thompson
Parent and Pharmacist

I am writing to comment on this purposed gender affirming care for minors. This nothing short of legal child abuse for CONFUSED children! Please let common sense prevail. The emotional state of children is what is fluid not a child's gender. Given time and space the child with gender confusion will affirm the gender given to him at birth.
And they will thank you for NOT giving in to this child manipulation!

Sincerely

Janice Neyer

To the Florida Board of Medicine,

In less than a decade, there has been a sharp rise in young people presenting with gender dysphoria (GD). The Transgender ideology threatens already at-risk sexual minority youth with experimental and unproven hormonal and surgical gender-affirming therapy [GAT]. GAT permanently and prematurely medicalizes children for a condition that overwhelmingly resolves by adulthood. GAT is not proven effective, not proven safe, does not reduce suicides, and is not the international standard of care for gender dysphoric minors.

The Natural History of Gender Dysphoria in Minors is Acceptance of Sex Assigned at Birth

It resolves on its own in 75-95% by adulthood.¹⁻⁵ Why medicalize children for life for a psychological process that usually resolves?⁶⁻⁸ These children and their families will often require counseling in the interim.

Comorbidities.

The overwhelming majority of youth with gender dysphoria have one, and likely more, additional mental health conditions, autism spectrum, adverse childhood events, and family issues that pre-date their gender incongruence.⁹⁻¹¹ These issues need counseling, not harmful hormones and mutilating surgery of healthy sexual organs.

Minors Cannot Give Truly Informed Consent.¹²

Children have developing brains, their minds change often, and they don't grasp long-term consequences.¹³⁻¹⁵

- Thus ruled the UK High Court in Bell vs. Tavistock in 2020.¹⁶
- Likewise the Swedish Pediatric Society and the Swedish National Council for Medical Ethics in 2019.¹⁷

There is No Medical Proof of the Long-Term Benefits or Safety of Hormonal Therapy or Surgical Transitioning.

- WPATH Standards of Care concurs.¹⁸
- The 2017 Endocrine Society Guidelines admit that GAT is only supported by "low" or "very low" evidence.¹⁹
- The UK's High Court in Bell vs. Tavistock (2020) ruled that GAT in minors was experimental, unproven and could not, in most cases, be given to minors under 16 without court order, and advised the same under 18.²⁰

Puberty Blockers chemically castrate both sexes at the level of the brain.²¹

- The puberty blocker Lupron's package insert warns of mood swings, depression, suicidal ideation and attempts.
- They risk infertility by blocking the maturation of sperm and eggs.²² Following PBA with cross-sex hormones assures sterility.²³
- They compromise bone mineral density and hinder brain development.^{24 25}
- Self-harm does not improve.^{26 27}
- They rob the minor of the puberty time frame shared with peers.²⁸
- Not proven fully reversible, long-term complications possible even if PBAs stopped early.²⁹

Cross-Sex Hormones^{30 - 36}

- Estrogen use in male biology increases the risks of blood clots (3-5 fold), heart attacks (doubling), strokes (3-5 fold), breast cancer, insulin resistance and more.
- Testosterone use in female biology increased the risks of heart attacks (fourfold), strokes, breast and uterine cancer, hypertension, severe acne and more.

GAT's Suicide Reduction Claim Is a Myth, used as emotional blackmail.^{37 38}

- Psychology professors J. Bailey and R. Blanchard stated: "There is no persuasive evidence that gender transition reduces gender dysphoric children's likelihood of killing themselves."³⁸
- The Lupron (the main puberty blocker in the US) package insert warns of "mood swings, depression, rare reports of suicidal ideation and attempt..."
- A 2011 Swedish study of all their post-sex reassignment adults showed a completed suicide rate 19 times that of the general population 10 year out with nearly 3 times the rate of psychiatric inpatient care.⁴⁰
- A 2011 long-term Dutch study of cross-sex hormone therapy revealed significantly increased mortality from multiple causes including suicide.⁴¹

The international standard of care for youth with GD is watchful waiting, including psychological evaluation and support of the child and family, not gender-affirming therapy (GAT).^{42 - 44}

The medical literature, as it moves from one publication to the next, repeatedly rushes to overstate the evidence underpinning clinical practice recommendations for youth with GD.⁴⁵ To make valid clinical judgments, we need more time, unbiased studies and long-term data.

Signed,

David C. Thorrez, MD FAAP

9/20/2022

Dear. Dr. Vazquez and board members,

I am a primary care provider and a mother of two beautiful girls ages 15 and 13. My 13 yr. old teen experienced trauma at her school in 6th and 7th grade. My daughter had a friend group that bullied her and dumped her. She found herself lonely and vulnerable and started to hang out with some girls that identified as transgender. My daughter noticed one of the transgender girls was self-harming/cutting herself. My daughter was so scared that her friend was going to hurt herself that she went to the school counselor to report it. This was in September 2021, when we finally met with the parents in March 2022, they told me they never received a call from the school counselor regarding their daughter's mental health state, they had no idea that their daughter had been socially transition in school, had a confidential transgender plan with new name and pronouns, and was even using opposite sex bathrooms. The school counselor is a mandatory reporter, but he did not notify that child's parents child of their daughter's mental illness and self-harming behavior. I had no idea my daughter's school was confusing children and affirming trans kids in 6th and 7th grade! I had no idea the school was teaching them about gender ideology and the gingerbread man. I think COVID in a way was a blessing in disguise, and I'm grateful for what COVID exposed. My daughter has been captured by an ideology based on lies thanks to Pasco County public school system, she can't even define what a woman is or means.

As a PCP, I immediately started to do more research and digging in, the more I looked, the more I found out about the damage we are doing to vulnerable children, teens, and young adults. Does the medical board of medicine know that there has been a sharp increase in teens suddenly thinking they are born in the wrong body and transgender. Comorbidities such as high functioning autism, eating disorders, ADHD, anxiety, and depression are seen in these kids, yet mental health is being neglected and most of my medical professionals' peers are only seeing this issue through an affirmation-only lens. As a provider I do a thorough history, lab work, imaging, and good physical exam on all my patients, I carefully come up with differential diagnoses, as I work towards a care plan. At no point in time do I allow my patients to dictate to me, self-diagnose and tell me what I should prescribe or how I should proceed. In the past few months, I have received too many calls from teens asking me if I can prescribe the wrong sex hormones, mostly testosterone for girls. My ethics, moral convictions of doing no harm, plus logic, do not allow me to harm children, teens, and young adults by prescribing wrong sex hormones and allowing them to continue to live in an alternate reality that only exists in their minds. The most popular medical services I offer in my primary care practice are weight loss and hormone optimization. If an anorexic or bulimic patient comes to me requesting weight loss services, should I prescribe phentermine, Saxenda or Semaglutide? According to the rationale we follow with transgenderism I should be prescribing weight loss medication to anorexics and bulimics regardless of their BMIs and their mental illness comorbidities. Will I risk a malpractice lawsuit or sanctions from the board of medicine if I do that?

Florida Board of Medicine it's time to act now. Parents no longer know how to protect their children; all guardrails and safeguarding have been removed. You hold the key to this problem and the future of our children rests in your hands, don't let this bloodbath of mutilated body parts stain your morals. Like many other parents, I had no choice but to remove both my kids from public

school in an effort to shield them from these lies. As a primary care provider, I've seen how this ideology is breaking families apart, and stealing our kids, not only all over Florida but worldwide. How many more children must we sacrifice? How many kids must we leave infertile? How many teen boys will we castrate? How many young girls' breasts will we cut off? How many failed vaginoplasty or phalloplasty are we willing to perform on minors? Healthcare disgusts me, I'm ashamed to be living during these times and be a part of this medical atrocity, even though I refuse to participate. What happened that all major professional organizations that have sold their souls and ethics to affirm this madness and delusion? How do people that do this great harm sleep at night? Please don't be one of those! Florida must lead by example.

I beg you to make a rule that will prevent doctors and nurse practitioners from being able to prescribe experimental puberty blockers, wrong sex hormones and perform any type of gender-affirming surgeries such as double mastectomies, breast augmentation, vaginoplasty, or phalloplasty on minors.

There is a lack of high-quality rigorous evidence-base surrounding this medical treatment and procedures, which makes them experimental in nature since the long-term consequences of these drugs being used on children/teens are relatively unknown. The Cass review just demonstrated the affirmation model is being rushed and does not work, and a more watchful waiting approach must be taken. There is also a lack of debate, or willingness to talk among medical professionals in this area because practitioners that speak out against these treatments being used on children are canceled. Alternate treatment options, such as mental health, are not being considered or even presented at this point in medicine. As I learned quickly from personal experience, sadly we can't even find mental health for kids, as this typically ends up in more affirmation and complete disregard of comorbidities. It is crystal clear to me that activism has not only infiltrated our medical community, but it has captured most medical professionals on this issue and biological reality is being ignored. The side effects we are aware of oftentimes lead to the sterilization of these individuals and the loss of any future sexual function when puberty blockers are used.

- Children and teen brains are not fully developed until age 25 and therefore they cannot give informed consent because they don't have the ability to fully understand the consequences of these treatments. Parents are also not being given the full picture and all treatment options available to them like the watchful waiting approach. They are being told to only affirm or their child will commit suicide. They are also not told that through the watchful waiting treatment approach, many of these children, upwards of 80%) would resolve their distress during or shortly after puberty.

- Proper assessments are not being done and there is little to no safeguarding in place before a child is placed on a medical pathway. Many of this new cohort of children/teens do not even meet the criteria for gender dysphoria, yet they are being treated medically for the "feeling" in their mind that they should be of the opposite sex. They are experiencing normal discomfort with their pubescent body, but are being convinced that any amount of discomfort with their body is an indication that they are "transgender." There is currently no coherent definition of the word transgender in the medical field.

- Co-morbid issues are being unchecked and unresolved in the name of gender-affirming care and patients and parents are being told that medical transitioning will fix their child's distress.

- We are now seeing the population of detransitioners increase every day because they come to the realization that medical transitioning did not fix their pain and many are stating their co-occurring mental health issues were ignored or not explored. Who is going to clean up this mess? The AMA? The APA?

- Medical organizations and associations are blindly adopting guidelines from WPATH without doing a proper review of the evidence being used for these guidelines. These guidelines are being pushed as actual standards of care, which is a gross misrepresentation of what these guidelines are. Further, professionals that are speaking out against these guidelines or advocating for a review of the existing literature are silenced through gaslighting or simply ignored as in the case of the American Academy of Pediatrics.

- Other countries like the UK, Sweden, Finland, and France are re-evaluating these medical treatments for children because they have done a rigorous review of existing literature and research and have come to the conclusion that the risks do not outweigh the benefits for children and their is just so much we don't know about the long-term consequences of these irreversible interventions.

The Tavistock Clinic just recently closed and is expected to see many lawsuits. These countries have either stopped medical transitioning minors or are advocating for great caution when medically treating children for gender dysphoria. They are all stating mental health treatment should be the first line of defense, which is not currently happening in the US.

- Despite what the media reports, these surgeries are occurring in children. Many hospitals state openly they are performing double mastectomies on children ages 16 and up and sometimes as young as 15, as stated in the new WPATH guidelines that were set to be released this month. In addition to the pediatric gender clinics in Florida hospitals providing these medical interventions, there are many private plastic surgeons, OBGYN offices, private endocrinologist offices, and pediatricians prescribing puberty blockers, and cross-sex hormones, and operating on minors. They claim parents give consent, but should a parent be allowed to consent to experimental medical treatments for their child for a mental health issue? Should parents be able to consent to amputating healthy body parts for their children and taking away their fertility and ability to have a child as an adult?

Florida Board of Medicine, please as a parent and a family primary care provider, I implore you to please make a rule that will protect our children from these experimental treatments and surgeries and advocate for ethical, evidence-based, and compassionate treatment of these individuals. Allow children to receive mental health services that allow for the exploration of root causes. There is no test for "transgenderism." There is no test to see which child will desist and which will persist. There is no test that will tell us which child will regret these irreversible treatments and which will not. I invite you to sit for a few hours and watch or listen to detransitioners stories, Florida must do better!

Sincerely,

Hilesca Hidalgo

9/20/2022

Dear. Dr. Vazquez and board members,

I am a primary care provider and a mother of two beautiful girls ages 15 and 13. My 13 yr. old teen experienced trauma at her school on 6th and 7th grade. My daughter had a friend group that bullied her and dumped her. She found herself lonely and vulnerable and started to hang out with some girls that identified as transgender. My daughter noticed one of the transgender girls was self-harming/cutting herself. My daughter was so scared that her friend was going to hurt herself that she went to the school counselor to reported it. This was in September 2021, when we finally met with the parents in March 2022, they told me they never received a call from the school counselor regarding their daughters' mental health state, they had no idea that their daughter had been socially transition in school, had a confidential transgender plan with new name and pronouns, and was even using opposite sex bathrooms. The school counselor is a mandatory reporter, but he did not notify that child's parents child of their daughter's mental illness and self-harming behavior. I had no idea my daughter's school was confusing children and affirming trans kids in 6th and 7th grade! I had no idea the school was teaching them about gender ideology and the gingerbread man. I think COVID in a way was a blessing in disguise, and I'm grateful for what COVID exposed. My daughter has been captured by an ideology based on lies thanks to Pasco County public school system, she can't even define what a woman is or means.

As a PCP, I immediately started to do more research and digging in, the more I looked, the more I found out of the damage we are doing to vulnerable children, teens and young adults. Does the medical board of medicine know that there has been a sharp increase in teens suddenly thinking they are born in the wrong body and transgender. Comorbidities as high functioning autism, eating disorders, ADHD, anxiety and depression are seen on these kids, yet mental health is being neglected and most of my medical professionals' peers are only seeing this issue through an affirmation only lens. As a provider I do a thorough history, lab work, imaging and good physical exam in all my patients, I carefully come up with differential diagnosis, as I work towards a care plan. At no point in time do I allow my patients to dictate to me, self-diagnose and tell me what I should prescribe or how I should proceed. In the past few months, I have received too many calls from teens asking me if I can prescribe wrong sex hormones, mostly testosterone for girls. My ethics, moral convictions of do no harm, plus logic, do not allow me to harm children, teens and young adults by prescribing wrong sex hormones and allowing them to continue to live in an alternate reality that only exist in their minds. The most popular medical services I offer in my primary care practice are weight loss and hormone optimization. If an anorexic or bulimic patient comes to me requesting weight loss services, should I prescribe phentermine, Saxenda or Semaglutide? According to the rationale we follow with transgenderism I should be prescribing weight loss medication to anorexics and bulimics regardless of their BMI's and their mental illness comorbidities. Will I risk a malpractice lawsuit or sanctions from the board of medicine if I do that?

Florida Board of Medicine its time to act now. Parents no longer know how to protect their children; all guardrails and safeguarding has been removed. You hold the key to this problem and the future of our children rest in your hands, don't let this bloodbath of mutilated body parts stain your morals. Like many other parents, I had no choice but to remove both my kids from public

school in an effort to shield them from these lies. As a primary care provider, I've seen how this ideology is breaking families apart, stealing our kids, not only all over Florida, but worldwide. How many more children must we sacrifice? How many kids must we leave infertile? How many teens boys will we castrate? How many young girls' breasts will we cut off? Dear Florida Medical Board,

As a mother of 18 years old son who suddenly declared himself a girl at age of 16. I quickly got a lesson in affirming care of gender industry. My son has always been a normal boy growing up, and at very young age, did not show any interest towards any "girlish" activities of things, as a matter fact, He did not wanted to be associated with anything girly as he has as sister. But that changed after he got online and started playing innocent online games like Minecrafts and Tetris around age 13. He himself said there are lots of older transgender woman on those platforms. He really stands no chance as he is a very impressionable young boy. Social media is one thing, but the most despicable thing is the compliant medical industries, doctors, and therapist who just rubber stamp when comes to transgender.

WPATH and the gender medical industry is a demagogue institution that needs to be exposed.

The Florida Board of Medicine must use its authority to protect children and adolescents from misinformed and dangerous actions and must allow its members to render evidence-based professional care. Minors cannot provide informed consent to irreversible and unknown harms of so-called "gender affirmative" medical treatments and surgeries. Gender confusion and body dysphoria require psychoeducation while comorbid psychopathology may require psychotherapy and psychopharmacology. "Puberty-blocking" drugs are misrepresented as "reversible pause buttons" while interfering with growth, sexual development, fertility, and multi-system functioning. The meteoric expansion of gender clinics is a preventable medical scandal in the making.

Thank you for being brave to stand up to all this.

Grace from New York.

Dear Paul,

Please accept my recommendations for Florida Board of Medicine to restrict “gender-affirming care”, including rapid gender transition for children and adolescents. The long-term harm of these interventions is clear. Please protect the youth of your state from unnecessary and lifelong harm.

Sincerely,

Melissa Colbern

Dear Mr. Vazquez,

We are an American family living in Canada, and closely following developments in the USA and beyond, regarding the care and treatment for children and youth who identify as transgender, nonbinary, or otherwise are questioning their gender and are distressed by their birth sex.

Our family is deeply impacted by this with one of our children now trans-identified and fixated on hormones and surgery. We have become aware that such "options" are risky, experimental, not evidence-based for youth, and, become a highly promoted pathway at the cost of evaluation and care that is holistic, exploratory, and considers the whole child and their mental and physical needs.

Here in Canada we were fortunate to find an evidence-based, open minded, non activist-driven therapist to help our child, but we know others in the USA and Canada are not as able to do this. Their children - like our own - are constantly told by adults in their lives, who may mean well, and online fora, that they must just go to a gender clinic to get testosterone / "HRT" and, as fast as possible, surgery. They believe despite no evidence in respect of this cohort of recently identified gender questioning youth whose #s are exponentially growing, that this will solve all the challenges they face.

Florida is taking the right approach by - like Sweden, and France, and other jurisdictions - sensibly putting the brakes on all but clinical trials when children and youth are involved.

I share this to provide a direct experience of my own family that is informed by the research and access to holistic care that I was fortunate to be able to obtain for my child. We love and support our child and have become very aware of how much

pressure she and children like her are under in our society to seek and fixate on medical and surgical "solutions" which are euphemized as "gender affirming care".

Thank you for hearing this comment.

Dear Florida Board of Medicine

I am writing to you from Australia. I am the parent of a young woman who declared that she was transgender at the age of 17, in late 2018. She had no history of gender dysphoria. Our daughter had been mentally unwell for 3 years prior to declaring that she was transgender. Our daughter had a hospital admission at the time she said she was transgender because she said she was suicidal. As a result of this admission, the hospital staff wanted to immediately refer our daughter to a paediatric endocrinologist to start testosterone. We did not agree to the referral, however, the staff made the referral (against our wishes) and intimidated us in front of our daughter, saying "Wouldn't you rather have a live son than a dead daughter?".

Our daughter turned 18 and became estranged from us. The endocrinologist gave our daughter testosterone at the second appointment, with no analysis of her mental health history. Our daughter took testosterone for 18 months.

Our daughter moved home in January 2022 after living out of our home for 3 years. She is 21 now and regrets taking testosterone. She asked us why was she allowed to take testosterone when she was so mentally unwell. Our daughter has been left with permanent and irreversible changes from the testosterone, including a deep voice, receding hairline & male pattern baldness, facial hair growth & increased body hair, redistribution of body fat, pain & atrophy of the uterus. She hates the way she looks and has barely left her bedroom all year. She has been suicidal.

I spoke at this Genspect Webinar about what our family has been through. I am the second speaker (about 45 minutes in).

Dear Florida Board of Medicine,

I am the parent of a gender questioning child. I understand that you are reviewing your policies on care for people questioning their gender I implore you to ensure that the current practices of uncritical "affirmation" of gender identities in children and young people (under age 25), and the use of radical, sterilizing medical and surgical interventions, be curtailed.

There is no evidence base for this, as the recent reports from your own state, from the UK (Cass report), Sweden and Finland, have shown. Authorities in Australia and France are also sounding the alarm.

The use of puberty blockers which sterilize and ruin sexual function is particularly horrible. Young adults (especially those with autism, mental illness or trauma) are also especially vulnerable as they can access these radical treatments quickly without guidance from their families.

Please visit the PITT substack for many heart rending stories of the harm being done to young people and their families.

<https://pitt.substack.com/>

I am personally seeing the harm being done to my own child by this approach. I am in Australia, where affirmation is widespread, and detransitioners are already beginning to speak out and launch court cases.

<https://www.smh.com.au/national/absolutely-devastating-woman-sues-psychiatrist-over-gender-transition-20220823-p5bbyr.html>

<https://archive.ph/PEHsV>

Cases here are skyrocketing here as well, but the gender doctors just attribute it to increased acceptance. The social contagion is obvious to families affected by this.

<https://www.abc.net.au/news/2022-03-14/takeover-young-australians-are-exploring-gender-more-than-ever/100890296>

The testimonies from many thousands of detransitioners are heart rending. This has got to stop - it is all based on a crazy ideology and SO MUCH harm is being done.

This subReddit had 23K members in March this year - now it has 38K and still rising rapidly

Public consultation

Interim service specification for specialist gender dysphoria services for children and young people

20 October 2022

Contents

Purpose of this document.....	3
Background	4
Interim service specification: the case for change	5
What are the proposed changes?	9
How will the proposed changes be implemented?	13
Give us your views on the proposed changes.....	14

Purpose of this document

NHS England is committed to working with a wide range of patients, patient groups and other stakeholders in the development of its commissioning of services. A public consultation is an opportunity to check whether proposals are right and supported, the public understand their impact, and identify any alternatives before decisions are made.

NHS England is the responsible commissioner for specialised services for individuals with gender dysphoria, and it is holding this consultation to seek views on a proposed interim service specification for services for children and young people with gender dysphoria- this represents phase 1 of our service transformation programme. Once agreed, this interim service specification will be operational for a limited time only until a new service specification is formed in 2023/24 following final advice from the independent Cass Review. This will be used by a new configuration of regional providers- representing phase 2 of our service transformation programme.

The public consultation will run for 45 days from **20 October to 4 December 2022**.

This consultation guide summarises the proposals and sets out:

- How care is currently provided.
- How the interim service specification could change care and the way that services are delivered, and the reasons for these changes.
- How the proposed changes will be implemented.

The document also has information about how you can share your views with NHS England. At the end of the consultation period, all feedback will be considered before the interim service specification is published.

We recommend that you read this consultation guide alongside the other documents published as part of the consultation. While this single consultation guide has been produced to summarise the proposals, the other documents provide additional detail.

Documents included in this consultation:

- **Interim service specification** – The service specification is a contractual document that describes the clinical service and sets out appropriate standards and quality measures that provider organisations must satisfy.
- **Equality and Health Inequalities Impact Assessment (EHIA)** – This document assesses the potential impact of the interim service specification on population groups that may be disproportionately affected by changes and make appropriate recommendations to mitigate any inequity.

Background

The term used to describe a discrepancy between birth-assigned sex and gender identity is 'gender incongruence'. Gender incongruence is frequently, but not universally, accompanied by the symptom of gender dysphoria: *"a disorder characterized by a strong and persistent cross-gender identification (such as stating a desire to be the other sex or frequently passing as the other sex) coupled with persistent discomfort with his or her sex"*.

There is currently only one provider of specialist services for children and young people (up to the 18th birthday) with gender dysphoria in England – this is the Gender Identity Development Service (GIDS) for children and adolescents, delivered by the Tavistock and Portman NHS Foundation Trust in London.

The GIDS is also directly commissioned by NHS Wales, and the changes described in this document will impact on patients who are the commissioning responsibility of NHS Wales.

Interim service specification: the case for change

In September 2020, NHS England commissioned an independent and wide-ranging review of gender identity services for children and young people. The Review, which is ongoing, is being led by Dr Hilary Cass, past president of the Royal College of Paediatrics and Child Health. It was established in response to a complex and diverse range of issues including:

1. A significant and sharp rise in referrals

In 2021/22 there were over 5,000 referrals into the Gender Identity Development Service (GIDS) run by the Tavistock and Portman NHS Foundation Trust. This compares to just under 250 referrals in 2011/12.

2. Marked changes in the types of patients being referred which are not well understood

There has been a dramatic change in the case-mix of referrals from predominantly birth-registered males to predominantly birth-registered females presenting with gender incongruence in early teen years. Additionally, a significant number of children are also presenting with neurodiversity and other mental health needs and risky behaviours which requires careful consideration and needs to be better understood.

3. Scarce and inconclusive evidence to support clinical decision making

This has led to a lack of clinical consensus on what the best model of care for children and young people experiencing gender incongruence and dysphoria should be; and a lack of evidence to support families in making informed decisions about interventions that may have life-long consequences.

4. Long waiting times for initial assessment and significant external scrutiny and challenge surrounding the clinical approach and operational capacity at GIDS

This has contributed to the current service being unable to meet the scale of rising demand and concerns being raised by healthcare regulators about the standard of care.

Next steps

In February 2022, Dr Cass published an interim report in which she set out initial findings and advice from her Review. She emphasised the need to urgently move away from the current model of a sole provider, and to establish regional services that work to a new clinical model that can better meet the holistic needs of a vulnerable group of children and young people. She began to describe the need for these new services to work as networked centres that connected with other local services including children and young people's mental health services and primary care to support all a patient's clinical needs.

In July, Dr Cass gave further advice on the core components of this model. [You can read the advice in full here.](#)

In summary, she has said:

- 'Regional centres should be led by experienced providers of tertiary paediatric care to ensure a focus on child health and development, with strong links to mental health services. These will generally be specialist children's hospitals.
- 'They should have established academic and education functions to ensure that ongoing research and training is embedded within the service delivery model'.
- 'The services should have an appropriate multi-professional workforce to enable them to provide an integrated model of care that manages the holistic needs of this population'.
- 'Staff should maintain a broad clinical perspective to embed the care of children and young people with gender uncertainty within a broader child and adolescent health context'.
- In view of the uncertainties surrounding their use, consideration should be given to the rapid establishment of the necessary research infrastructure to prospectively enroll young people being considered for puberty blocking drugs

into a formal research programme, with adequate follow-up into adulthood.

Establishing New (Phase 1) Services

Given the urgent need to stabilise service provision for patients and begin building a more resilient service by expanding provision, we are establishing two 'Phase 1'¹ services. Consistent with Dr Cass' advice, these services will be led by specialist children's hospitals and, once established, will take over clinical responsibility for and management of all current GIDS patients as part of a managed transition, and they will begin to see children and young people who are currently on the GIDS waiting list.

One Phase 1 service will be based in London and will be led by a partnership between Great Ormond Street Hospital for Children NHS Foundation Trust and Evelina London Children's Hospital (part of Guys and St Thomas' NHS Foundation Trust), with South London and Maudsley NHS Foundation Trust providing specialist CYP mental health support.

A second Phase 1 service will be based in the North West, led by a partnership between Alder Hey Children's NHS Foundation Trust and the Royal Manchester Children's Hospital (part of Manchester University NHS Foundation Trust), where both trusts also provide specialist CYP mental health services.

The Tavistock and Portman NHS Foundation Trust and the endocrine teams based at University College London Hospitals NHS Foundation Trust and Leeds Teaching Hospitals NHS Trust will play a vital role in supporting both Phase 1 services as they establish the new services building on their extensive experience of working with this patient group.

A single national transformation programme has been established to oversee a smooth and seamless transition for patients to the new Phase 1 services, including bringing the GIDS contract to a managed close because of these changes. The establishment of the Phase 1 services will happen as quickly as possible, but crucially at a pace that appreciates the complexity of the change, while minimising

¹ When NHS England announced plans in July 2022 to establish new services we referred to them as 'Early Adopter' service providers. We are now using the term 'Phase 1' service providers instead.

disruption and any additional anxiety for patients. The aim is for the Phase 1 services to be operational by Spring 2023.

The Phase 1 services will be commissioned against an interim service specification which will replace the current service specification used by the GIDS. There is now an urgent need to agree this specification to give the Phase 1 services time to recruit staff and set up the new services as quickly as possible.

The interim service specification builds out from the existing specification to both incorporate advice from the Cass Review following its extensive stakeholder engagement, and to provide points of clarification in certain areas. It has been worked up and endorsed by the Phase 1 providers, as well as senior clinical leads including the National Medical Director for Specialised Services, the National Clinical Director for Children and Young People and the Associate National Clinical Director for Children and Young People's Mental Health. It is important to note that this is an interim service specification to support the rapid mobilisation of the new Phase 1 services. It will be replaced in due course with a final service specification which will be subject to a further period of engagement and public consultation at a later date and once further advice has been received from Dr Cass as part of her ongoing independent review. This will mark the start of Phase 2 of our service transformation programme when additional regional services will be commissioned.

What are the proposed changes?

The interim service specification proposes the following changes and points of clarification over the current service specification.

1. Composition of the clinical team – substantive change

The current service specification for GIDS describes that the service is delivered through a specialist multidisciplinary team with contributions from specialist social workers, family therapists, psychiatrists, psychologists, psychotherapists, paediatric and adolescent endocrinologists and clinical nurse practitioners. *The new interim service specification proposes to extend the clinical team so that it is a more integrated multi-disciplinary team that, in addition to gender dysphoria specialists, will include experts in paediatric medicine, autism, neurodisability and mental health.*

The reason for this proposal is to respond to evidence that there is a higher prevalence of other complex presentations in children and young people who have gender dysphoria, that the Phase 1 services will also address, working with local services where appropriate. The proposal also responds to the findings of the Care Quality Commission's 2021 inspection report of GIDS, which highlighted the need for a better multi-disciplinary mix of care providers for some children and young people referred to the service. Furthermore, the interim advice of the Cass Review concluded (page 69) that "*a fundamentally different service model is needed which is more in line with other paediatric provision, to provide timely and appropriate care for children and young people needing support around their gender identity ... this must include support for any other clinical presentations that they may have*".

2. Clinical leadership – substantive change

The current service specification for GIDS does not describe criteria for the clinical lead for the service. *The new interim service specification proposes that the clinical lead for the service will be a medical doctor.*

The reason for this change is to reflect that the new integrated clinical teams will have a broader range of clinical disciplines, including medical professionals, who will be addressing a broader range of medical conditions in addition to gender dysphoria;

and that oversight of the service by a medical doctor is appropriate given that the service may provide medical interventions to some children and young people..

3. Collaboration with, and support for, referrers and local services – substantive change

The current service specification for GIDS describes a tiered approach for progression through the clinical pathway: the first tier involves meetings between the GIDS team and local professionals involved in the care of the child or young person and the second tier involves the child or young person accessing local services for mental health needs with GIDS offering advice to local services. There are numerous references in the current GIDS service specification to joint working between GIDS and local services including through consultation and liaison. However, GIDS has struggled to provide this support to local services in a consistent way given the constraints on the service. *The new interim service specification proposes to retain this tiered approach to progression through the pathway and describes a more structured approach for collaboration with local services in the interests of the child and young person; a referral to The Service will require a consultation meeting between the Phase 1 service and the relevant local secondary healthcare team and / or the GP. Where the outcome of the initial professional consultation between the Service and the referrer is that the patient does not meet the access criteria for The Service, the child or young person will not be added to the waiting list - but the family and professional network will have been assisted to develop their formulation of the child or young person's needs and a local care plan and will be advised of other resources for support that are appropriate for individual needs. The proposed interim service specification also proposes that not all children and young people who meet the access criteria will need to be seen directly by The Service. A key intervention that will be delivered by The Service is the provision of consultation and active support to local professionals, including support in formulation of needs and risks and individualised care planning. The level and type of consultation offered to the professional network will be determined according to the individual needs of each case and through a process of clinical prioritisation.*

4. Referral sources – substantive change

The current service specification for GIDS states that referrals can be made by staff in health and social services, schools, colleges of further education and by voluntary organisations. *The new interim service specification proposes that referrals may be made by GPs and NHS professionals.* The reason for the proposal is to ensure that children and young people are already engaged with the local health system before a referral is considered by a local health professional into the highly specialist gender dysphoria service, including for the reason that a proposed core feature of the new pathway is a consultation meeting between the specialist service and local health professionals before a referral can be considered for acceptance. The proposal would impact on fewer than 5% of referrals at current referral patterns, in that around 65% of referrals into GIDS are currently made by GPs and around 30% are made by NHS professionals. This proposal relates only to the interim service specification for the Phase 1 services. The interim report of the Cass Review begins to describe a future clinical pathway approach that operates within a managed clinical network, including other statutory agencies, and this pathway will be worked up by NHS England in the coming months through engagement with the Cass Review and other stakeholders.

5. Social transition – clarification

The current GIDS service specification acknowledges that social transition in pre-pubertal children is a controversial issue, that divergent views are held by health professionals, and that the current evidence base is insufficient to predict the long-term outcomes of complete gender-role transition during early childhood.

The interim Cass Report has advised that although there are differing views on the benefits versus the harms of early social transition, it is important to acknowledge that it should not be viewed as a neutral act. Dr Cass has recommended that social transition be viewed as an ‘active intervention’ because it may have significant effects on the child or young person in terms of their psychological functioning.

In line with this advice, the interim service specification sets out more clearly that the clinical approach in regard to pre-pubertal children will reflect evidence that in most cases gender incongruence does not persist into adolescence; and that for

adolescents the provision of approaches for social transition should only be considered where the approach is necessary for the alleviation of, or prevention of, clinically significant distress or significant impairment in social functioning and the young person is able to fully comprehend the implications of affirming a social transition.

Endocrine Interventions

Building the research protocol

The interim service specification reads:

"Consistent with advice from the Cass Review highlighting the uncertainties surrounding the use of hormone treatments, NHS England is in the process of forming proposals for prospectively enrolling children and young people being considered for hormone treatment into a formal research programme with adequate follow up into adulthood, with a more immediate focus on the questions regarding GnRHa. On this basis NHS England will only commission GnRHa in the context of a formal research protocol. The research protocol will set out eligibility criteria for participation."

In due course NHS England will share details of this work, including plans for how stakeholders and the public will be engaged and consulted on eligibility criteria.

Placing the use of GnRHa in the context of clinical research will have several important benefits:

- It responds directly to Dr Cass' advice that *'Without an established research strategy and infrastructure, the outstanding questions will remain unanswered and the evidence gap will continue to be filled with polarised opinion and conjecture, which does little to help young people, and their families and carers, who need support and information on which to make decisions'*. In this respect the NHS has the opportunity to make a major international contribution to the evidence base in this area.

- Secondly, it will ensure that there is greater transparency for children and their parents / carers around the uncertain clinical benefits and longer-term health impacts surrounding their use.
- Thirdly, it will further strengthen the consent and information sharing process to support informed decision making by young people.

Unregulated drugs

The current service specification for GIDS states that GIDS does not offer shared care with private clinicians, and that in cases where puberty blocking drugs or hormone drugs are prescribed or accessed outside the service, the GIDS will make the young person and their family aware of the risks, contraindications and any irreversible or partly reversible effects of any interventions, and will be unable to provide ongoing clinical supervision for the management of these interventions.

The proposed interim specification reads:

“Children, young people and their families are strongly discouraged from sourcing GnRHa and masculinising / feminising hormone drugs from unregulated sources or from on-line providers that are not regulated by UK regulatory bodies. In such cases The Service will make the child or young person and their family aware of the risks, contraindications and any irreversible or partly reversible effects of the drugs and will advise the GP to initiate local safeguarding protocols.

“Should a child or young person access GnRHa from unregulated sources or unregulated providers The Service will not assume responsibility for prescribing recommendations nor will it enter into shared cared arrangements in these circumstances.

“Where a child or young person has obtained masculinising / feminising hormones from an unregulated source (such as the internet) The Service will not accept clinical responsibility for management of the endocrine intervention.

“Where a child or young person has been prescribed masculinising / feminising hormones by an unregulated provider outside of the eligibility and readiness criteria described in the current NHS clinical commissioning policy The Service will not accept clinical responsibility for management of the endocrine intervention.”

The reason for the revised wording is to provide greater clarity and retain and strengthen current safeguards. Senior clinicians have advised NHS England on the need for the new interim service specification to have much clearer wording in this regard so that the interim service specification is less open to interpretation, so that young people, families and professionals are clear on the approach that will be adopted by the NHS in such cases.

How will the proposed changes be implemented?

The proposed interim service specification will inform how the Phase 1 services deliver care and support to young people referred into the gender identity service over the next year.

In parallel, the Cass Review will continue its work to describe the new clinical model to which the Phase 1 services and the new regional services will work in the future. Once Dr Cass has delivered this advice the NHS will build a new service specification and put it out for stakeholder engagement and formal public consultation.

Give us your views on the proposed changes

NHS England would like to hear what patients, parents and carers, clinicians, providers and other interested parties think about the proposed interim service specification for gender dysphoria services.

These are the questions we're asking as part of the public consultation:

- 1. In what capacity are you responding?** (Patient / Parent / Clinician / Service Provider / Other; If you have selected 'Other', please specify.)
- 2. Are you responding on behalf of an organisation?** (yes / no; If you have selected "yes", which organisation are you responding on behalf of?)
- 3. To what extent do you agree with the four substantive changes to the service specification explained above?**
 - A. Composition of the clinical team**
(Agree / Partially Agree / Neither Agree nor Disagree / Partially Disagree / Disagree; comments)
 - B. Clinical leadership**
(Agree / Partially Agree / Neither Agree nor Disagree / Partially Disagree / Disagree; comments)
 - C. Collaboration with referrers and local services**
(Agree / Partially Agree / Neither Agree nor Disagree / Partially Disagree / Disagree; comments)
 - D. Referral sources**
(Agree / Partially Agree / Neither Agree nor Disagree / Partially Disagree / Disagree; comments)
- 4. To what extent do you agree that the interim service specification provides sufficient clarity about approaches towards social transition?**
(Agree / Partially Agree / Neither Agree nor Disagree / Partially Disagree / Disagree; comments)

5. To what extent do you agree with the approach to the management of patients accessing prescriptions from un-regulated sources?

(Agree / Partially Agree / Neither Agree nor Disagree / Partially Disagree / Disagree; comments)

6. Are there any other changes or additions to the interim service specification that should be considered in order to support Phase 1 services to effectively deliver this service?

(comments)

7. To what extent do you agree that the Equality and Health Inequalities Impact Assessment reflects the potential impact on health inequalities which might arise as a result of the proposed changes?

(Agree / Partially Agree / Neither Agree nor Disagree / Partially Disagree / Disagree; comments)

You can provide your views with NHS England by completing the online survey:

<https://www.engage.england.nhs.uk/specialised-commissioning/specialist-gender-interim-specification>

Your views will help NHS England to further shape and refine this interim service specification for gender dysphoria services, until a new service specification is agreed in 2023, which will be informed by a full consultation and engagement process.

LETTER TO THE EDITOR

What Are We Doing to These Children? Response to Drescher, Clayton, and Balon Commentaries on Levine et al., 2022

Stephen B. Levine^a, E. Abbruzzese^b and Julia W. Mason^c

^aCase Western Reserve University Department of Psychiatry, 6415 Gates Mills Blvd, Mayfield Heights, 44124, United States; ^bSociety for Evidence-Based Gender Medicine, Twin Falls, 83301-5235, United States; ^cCalcgano Pediatrics, Gresham, Oregon

Introduction

In our paper, “Reconsidering Informed Consent for Trans-Identified Children, Adolescents, and Young Adults” (Levine, Abbruzzese, & Mason, 2022), we asserted that the consent process for youth gender transition is so problematic in much of the Western world that it can no longer be considered “informed.”

We reflected on how far the entire field of gender medicine has drifted from the principles of evidence-based medicine and the scientific method. Attempts to study the sharp rise of gender dysphoria in previously gender-normative teens (Bradley, 2022; Littman, 2018) are met with consternation by the gender-medicine establishment (World Professional Association for Transgender Health [WPATH], 2018). The significant rate of problematic adaptations, psychiatric symptoms, and self-harm in this youth cohort (Becerra-Culqui et al., 2018; de Graaf, Giovanardi, Zitz, & Carmichael, 2018; de Graaf et al., 2021; Kaltiala-Heino, Sumia, Työläjärvi, & Lindberg, 2015; Kozłowska, Chudleigh, McClure, Maguire, & Ambler, 2021; Strang et al., 2018; Thrower, Bretherton, Pang, Zajac, & Cheung, 2020) is explained away as merely manifestations of minority stress, with unsubstantiated claims that these mental health problems will resolve with gender transition—and *only* with gender transition. Efforts to help the distressed teens psychotherapeutically, which is the standard approach for all other types of psychiatric symptoms, are stigmatized as conversion therapy. The growing evidence of *detransition*, apparent in recent data (Boyd, Hackett, & Bewley, 2021; Hall, Mitchell, & Sachdeva, 2021; Roberts, Klein, Adirim, Schvey, & Hisle-Gorman, 2022), is either dismissed or recast as a benign gender journey (Turban, Loo, Almazan, & Keuroghlian, 2021), and the reports of regret by many of the detransitioners themselves are ignored (Littman, 2021; Vandenbussche, 2022). Perhaps most problematic, the information shared by gender clinicians with patients and families about “gender-affirming” interventions is markedly skewed: it overstates the demonstrated benefits of hormones and surgeries and trivializes their risks and the uncertainties of future outcomes.

Our critical ethical evaluation also included proposed solutions. We suggested that clinicians familiarize themselves with the difference between the classical early-onset of cross-sex identification, which typically spontaneously resolves before adulthood (Ristori & Steensma, 2016; Singh, Bradley, & Zucker, 2021), and the novel presentation of youth with postpubertal onset of gender dysphoria and a much wider range of gender identities, for whom the outcomes are unknown. We suggested that rather than merely deferring to their medical societies’ wholesale adoption of “gender-affirmative” guidelines from the gender medicine establishment, clinicians would benefit from scrutinizing the unconvincing results from key studies. We implored

clinicians to slow down and engage patients and families in thorough and thoughtful discussions not only of the possible benefits but also the significant risks and uncertainties inherent in a medically dependent lifetime.

The editor invited four respected academicians to write commentaries (Balon, 2022; Clayton, 2022; Drescher, 2022; de Vries, 2022). Two agreed that current trends are problematic and must be addressed to safeguard youth from harm (Balon, 2022; Clayton, 2022). Two disagreed, but in very different ways (Drescher, 2022; de Vries, 2022). Drescher took a decidedly civil rights-based perspective, arguing that while the evidence is low quality, ultimately, the principles of body autonomy should trump all other concerns. de Vries conceded that the evidence base for pediatric gender transition suffers from deficiencies but asserted that it is of sufficient quality to widely scale hormonal and surgical “gender-affirming” interventions.

Below, we provide our thoughts about the first three commentaries we received (Drescher, 2022; Clayton, 2022; Balon, 2022), starting with our response to Drescher. We have responded to de Vries (2022) in a separate forthcoming publication.

Response to Drescher

Drescher’s commentary (Drescher, 2022) illuminated the mindset of clinicians who are aware of the limitations of the evidence base of youth gender transition, yet actively promote medicalization while eschewing any noninvasive treatment alternatives. Drescher ridiculed the title of our publication (Levine et al., 2022) by naming his own commentary “Informed Consent or Scare Tactics?” Having carefully examined his objections to our paper, we, in turn, suggest that Drescher’s commentary would have been better titled “Risks, Schmisks”—as it succinctly summarizes his counterarguments.

Drescher mocked our suggestion for a slow and deliberate informed consent process for youth embarking on a medicalized lifetime with a skit in which a patient receives extensive disclosures of the risks of taking aspirin for a headache. While Drescher referred to his writing exercise as a “parody,” it is a generous description, and not just because some might find it lacking in humor; the situations he compares are not even remotely equivalent. Even prolonged aspirin use increases the absolute risk of severe bleeding by just 0.47% (Zheng & Roddick, 2019). In contrast, 100% of children will be rendered sterile if puberty is blocked at Tanner Stage 2 and followed with cross-sex hormones, as currently suggested by the Endocrine Society (Hembree et al., 2017). While the risks of exogenous sex hormones have been well-documented and led to a black box warning from the FDA (Jeffrey, 2003; Togun, Sankar, & Karaca-Mandic, 2022), there is now mounting evidence of the detrimental effects of puberty blockers on a range of physiological parameters (Nokoff et al., 2021) including bone density (Biggs, 2021; Klink, Caris, Heijboer, van Trotsenburg, & Rotteveel, 2015; Nokoff, Ma, Moreau, & Rothman, 2022). We think a better example of using comedy to make a point is a skit by comedian Bill Maher, who recently noted that bone density is “kind of important if you like having a skeleton” (Maher, 2022).

The exuberant irreverence of Drescher’s commentary extended to his discussion of the evidence base for youth gender reassignment, with the suggestion that the GRADE designation of *low-quality evidence* is merely a “a scary buzzword” (Drescher, 2022, p. 3). To clarify, the Grading of Recommendations Assessment, Development and Evaluation (GRADE) is an international best practice in evidence evaluation, which provides a structured way to assess key factors that increase or decrease confidence of findings in a body of evidence (GRADE Working Group, 2013). The GRADE ratings of “very low” and “low” quality—the only two ratings that the body of evidence for youth gender reassignment has ever received—indicate that *the true effect* of hormones and surgeries is likely *markedly different* from the results reported by the studies (Balslem et al., 2011; Reed & Guyatt, n.d.). The problem is *not* that the field of youth gender reassignment has not yet produced “enough” studies, as Drescher’s own phrasing of “low levels of evidence” suggests; the actual problem is that *none* of the numerous studies produced to date, individually or collectively as a body of evidence, are reliable or trustworthy. This is because

all the available studies are uncontrolled observational studies subject to bias, confounding, or chance (National Institute for Health and Care Excellence [NICE] 2020a, 2020b).

Drescher also incorrectly asserted that the reason the evidence base for gender transition has been graded as *very low/low quality* is due to the “absence of randomized clinical trials (RCTs)” (Drescher, 2022 p. 3). While it is true that data from a body of randomized *controlled* trials (whether the comparator is placebo or another active intervention) starts with the presumption of *high quality*, it can be downgraded to *low quality* if there are serious concerns arising from risk of bias, imprecision, inconsistency, indirectness, and publication bias. Conversely, non-randomized study of an intervention (e.g., an observational study) can be upgraded to *moderate* or *high quality* when there is a large magnitude of effect; a demonstrated dose-response relationship; and when the potential confounders are not expected to inflate the outcomes in a positive direction—in other words, when the research signals plausible, sizeable benefits (Reed & Guyatt, n.d.). The problem is *not* that quality research in the space of gender medicine is not feasible; it is that increasingly, gender clinicians who lead the studies view the matter as settled science, and as a result do not bother to design research capable of producing high or even moderate quality evidence. Even more troubling, when called out, such clinicians insist that using rigorous study designs in pediatric gender medicine is unethical (Turban, Almazan, Reisner, & Keuroghlian, 2022).

Nor is it correct to assume that randomization is unethical. According to the principle of research equipoise, “when there is uncertainty or conflicting expert opinion about the relative merits of diagnostic, prevention, or treatment options, allocating interventions to individuals in a manner that allows the generation of new knowledge (randomization)” is ethically permissible (London, 2017, p. 525). That “gender-affirming” interventions are administered to youth “based on very limited data” and that long-term outcomes are unknown has been acknowledged by even the most ardent proponents of pediatric gender transition (Olson-Kennedy et al., 2019, p. 2). Rigorous research has been conducted in other “high stakes” areas of medicine and has led to the development of highly effective treatments, as evidenced by the advances in pediatric oncology (Berg, 2007). Pediatric gender medicine cannot claim an exceptional status when it comes to the quality of research it must undertake.

Drescher is also incorrect in stating that “none of the surgical procedures ... are performed on children with GD/GI [gender dysphoria/gender incongruence]” (Drescher, 2022, p. 4). We have seen the claim that “gender-affirming surgery is not performed on children” repeated with increasing frequency. We are not sure whether this assertion hinges on the definition of a “child” as someone who has not yet had their 13th birthday; or if it is a case of blissful ignorance by those inexperienced with this patient population. Patients as young as 12-13 have been obtaining “gender-affirming” mastectomies in the United States for several years, as evidenced by the data from the National Institutes of Health (NIH)-funded research (Olson-Kennedy, Warus, Okonta, Belzer, & Clark, 2018, Figure); research from a large U.S. healthcare system (Tang et al., 2022, Figure 2); and a recent publication in JAMA Pediatrics (Ascha et al., 2022). The latter asserted strong benefits of mastectomies for youth based on the finding that the young people were no longer “dysphoric” about their chest appearance a mere 3 months post-surgery. Version 8 of the WPATH “Standards of Care,” published in September 2022, ratified the notion that surgeries should be available to youth when it removed previously stated minimum age limits for “gender-affirming” surgical procedures (Block, 2022; Coleman et al., 2022).

Setting Drescher’s misunderstanding of the evidence aside, his fundamental problem with our paper appears to be that we did not outline treatment alternatives to “gender affirmation” for youth gender dysphoria—beyond psychotherapy. Yet, psychotherapy is *exactly* what Sweden—the first country in the world to legally recognize transgender people—and Finland recommend as the first (and typically only) line of treatment for gender dysphoric youth (COHERE, 2020; Socialstyrelsen, 2022a, 2022b). The UK is now moving in a similar direction, calling on clinicians to lean on their existing skills in mental health support of gender dysphoric youth, and to not “exceptionalise gender identity issues” (Cass, 2022). With these recent changes, Europe is

returning to the proven axiom taught to medical students early in their training: “when you hear hoofbeats, think of horses not zebras.” In this context, the profound gender-related distress that has engulfed Western youth in recent years is much more likely to be a novel manifestation of the identity formation struggles of youth, rather than a rare intractable “mismatch” between the body and the brain that must be medically and surgically corrected.

We are puzzled about why Drescher, a psychoanalyst himself, dismissed the contribution of his own field to the management of gender dysphoria in youth by describing it as “just talk” (Drescher, 2022, p. 4). More disheartening, however, is that he chose to conflate psychotherapy for gender dysphoria with “conversion therapy.” The notion that psychotherapy was a missing element in their care was endorsed by detransitioners, who say that a better understanding of the nature of their gender distress would have helped them avoid irreversible and deeply regrettable medical interventions (Littman, 2021; Vandenbussche, 2022).

While Drescher appeared comfortable with recommendations to change anatomy, physiology, and create the need for lifelong “gender-affirming” interventions based on low quality evidence, he was quick to disdain the alternative of psychotherapy because it “lack[s]... empirical evidence” (Drescher, 2022, p. 4). It is, of course, untrue that psychotherapy for gender dysphoria in youth lacks “empirical evidence”; what it lacks is *high quality* evidence. Rigorous comparative trials of psychotherapeutic approaches to gender dysphoria in youth are urgently needed. However, if Drescher undertakes a literature search, he will discover that beyond the article by Schwartz (2021), to which he dedicated a significant part of his response, there is a growing body of (low quality) evidence that psychotherapy *can* ameliorate gender distress in youth and can reduce or eliminate the need for invasive medical interventions (Bonfatto & Crasnow, 2018; Churcher Clarke & Spiliadis, 2019; Evans, 2022; Hakeem, 2012; Lemma, 2018; Spiliadis, 2019). Psychotherapy to “resolve confusion [about gender feelings] and come to self acceptance was also a key part of the Dutch protocol (de Vries et al., 2006, p. 87).

The concern that vulnerable adolescents and young adults do not get appropriate mental health evaluation and treatment and are effectively rushed into transition, has been voiced not only by the “critics,” as Drescher asserts, but also by the supporters of “gender-affirmative” interventions such as Dr. Erika Anderson—a psychotherapist, transgender woman, and recent President of the US branch of WPATH, USPATH (Anderson, 2022). There is a convincing body of evidence that gender dysphoria frequently occurs in *lesbian and gay* youth (Bryant, 2006; Cantor, 2020, Appendix 1; Korte et al., 2008). It also disproportionately affects *autistic* youth (Bradley, 2022; Hisle-Gorman et al., 2019; Thrower et al., 2020), as well as vulnerable individuals who have experienced various forms of trauma (D’Angelo et al., 2021; Kozłowska et al., 2021). We would have expected Drescher to support the notion that young gay and autistic people suffering from gender dysphoria deserve access to noninvasive treatment alternatives that avoid life-long health risks and do not render them sterile.

A second reason for Drescher’s objection to our publication is that he viewed our recommendation for delay in irreversible medical interventions as putting the interests of “cisgender” gender dysphoric youth above the interests of “transgender” youth. We remind Drescher that the predictive validity of the youth gender dysphoria (or gender incongruence) diagnoses is unknown (Davy & Toze, 2018; Paris, 2015; Zucker, 2010), and that no criteria exist for how to reliably differentiate youth who will desist from a transgender identity as adults, from those for whom this identity will be life-long. That the majority of trans-identified *children* will not be trans-identified adults is well established (Ristori & Steensma, 2016; Singh et al., 2021). The notion that trans-identified *teens or young people* do not desist, which seems to have been uncritically adopted by gender clinicians, is patently untrue, as demonstrated by a growing number of studies of detransitioners, the majority of whom do not identify as transgender after they medically detransition (Littman, 2021; Vandenbussche, 2022). Recent data from gender clinics show that the rate of medical *detransition* is now reaching 10-30% within just a few years after the initiation of transition (Boyd et al., 2021; Hall et al., 2021; Roberts et al., 2022); this

percentage will likely grow as the patients reach the 10+ year mark when regret has been noted to typically emerge (Dhejne, Öberg, Arver, & Landén, 2014; Wiepjes et al., 2018).

Drescher chose to engage in ad hominem attacks on those involved in the publication of our paper. He referenced an anonymous libelous blog in his attempt to discredit the US registered nonprofit organization, the Society for Evidence-Based Gender Medicine (SEGM) and fanned the flames of baseless insinuations by inventing a non-existent association between SEGM and anti-homosexual groups. In questioning SEGM's goals, Drescher changed SEGM's name, substituting "evidence-based" with "empirical-based," and inadvertently revealed a lack of understanding of the difference between these two concepts. "Empirical-based" medicine relies on expert opinion backed by only minimal research. It is also known as "eminence-based." In contrast, the cornerstone of "evidence-based medicine" is a rigorous, impartial evaluation of the evidence to assess its certainty, which allows for truly informed decision-making (Drisko & Friedman, 2019). SEGM's stated goal is to help gender medicine move past its current "empirical-based" status and toward the rigorous principles of evidence-based medicine. While Drescher failed to identify any inaccuracies in the information disseminated by SEGM, he did find fault with the authors' disclosure of an association with SEGM. We remind him and other researchers that such disclosures are an ethical requirement for publications and are not optional. Unfortunately, disclosures of interest, including *conflicts of interest*, such as when pharmaceutical companies pay authors promoting the benefits of "gender-affirmative hormones," are often omitted, and only come to light months after the research conclusions have been widely publicized (Erratum for TURBAN 2019-1725., 2021). Another rarely disclosed conflict of interest in pediatric gender medicine is the fact that the investigators of the studies are commonly the same clinicians who are prescribing or administering "gender-affirming" interventions. This is perhaps the single most problematic source of bias in current research, since the investigators have a significant intellectual (and sometimes financial) stake in "demonstrating" that their work produced positive results (Boutron et al., 2022).

We invite Drescher to examine his own potential conflicts of interest and intellectual biases, including the possibility that his decade-long advocacy to de-pathologize gender dysphoria in the diagnostic categories of DSM and ICD (Drescher, Cohen-Kettenis, & Winter, 2012) may have created a confirmation bias. Had Drescher critically engaged with the fact that over 70% of gender dysphoric youth presenting for care had been diagnosed with a mental illness or neurocognitive disorder prior to the onset of gender dysphoria (Becerra-Culqui et al., 2018), perhaps he would see the reason behind the recommendation for psychotherapy as the first and even only line of treatment, pending reaching maturity.

We share Drescher's concerns about the politicization of transgender health care, as some states move to issue harsh penalties for those who provide gender transition services to minors. We agree that regulating treatments for gender dysphoria is best handled by the medical establishment self-correcting, rather than allowing politicians to make medical decisions. Drescher does not seem to realize, however, the extent to which his own attitude, shared by many gender clinicians, that youth gender transitions must continue without restraint before any reliable data are available, has contributed to this polarization. Drescher's concern for the wellbeing of gender dysphoric youth is palpable, and we share it, even if he finds that hard to believe. What the field needs now is more reliable outcome data, not more passion and political rhetoric.

Response to Clayton

In the process of comparing our informed consent recommendations to those authored by WPATH's affiliate AusPATH, Clayton revealed that the guidance widely used in Australia and New Zealand is not entirely data dependent. Given AusPATH's close links to WPATH, we agree with Clayton that her commentary "holds much relevance to the international context" (Clayton, 2022b p. 1).

Clayton juxtaposed two sets of opposing claims regarding the evidence for “gender affirmation” of youth: the claim by advocates of this practice who insist that data show significant benefits and low risks, and the assertions of critics that the benefits are highly uncertain, and the risks are significant. She suggested that this contradiction may be resolved by engaging in “close reading of the cited primary sources” (Clayton, 2022b p. 3). As Clayton’s prior research demonstrated, there is a troubling “asymmetry” in how the results from gender clinics-based research are frequently reported: “[f]indings of positive outcomes of medical interventions are trumpeted in abstracts, while their profound limitations remain behind the paywall, thus, below the radar of busy clinicians” (Clayton et al., 2022, p. 3). Once the individual studies are scrubbed of uncertainty in the abstracts, the evidence enters a new cycle of laundering where “[n]ew publications reference prior ones with increasing and unwarranted confidence” (Clayton et al., 2022, p. 3).

Unfortunately, not only individual studies, but even systematic *reviews of evidence*, which generally reside on the highest rung of the evidence pyramid, can suffer from bias. Clayton’s prior research focused on a problematic “systematic review” by Rew, Young, Monge, and Bogucka (2021), which exemplified a “concerning trend to overstate the evidence underpinning clinical practice recommendations for youth with GD [gender dysphoria]” (Clayton et al., 2022, p. 3).

We see similar problems in the review commissioned by WPATH as the basis for its “Standards of Care 8” (Baker et al., 2021). This review failed to examine any *physical health* risks of hormonal interventions and found only low-quality or insufficient evidence of *psychological* benefits due to high risk of bias in study designs, small sample sizes, and confounding with other interventions. This did not preclude the authors from endorsing “hormone therapy,” including puberty blockers and cross-sex hormones for youth as an “essential component of care” (Baker et al., 2021, p. 13.). These conclusions, which cannot be substantiated by the review’s actual findings, have since been used by WPATH to issue the recommendations to treat gender dysphoria medically, stating that “delay in transition” is rarely advisable and should only be used as a “last resort” (Coleman et al., 2022, p. S37).

It is worth noting that Baker, the lead author of the WPATH-commissioned systematic review, appears to have coauthored another highly flawed evidence review widely known by its pithy subtitle, “What We Know” (Frank & Baker, 2018). Baker’s commitment to generating research that furthers a policy agenda to promote access to hormones is well-publicized (Health Policy Research Scholars, 2019). Had the goal been scientific accuracy, rather than political advocacy, the title of that review would have been “What We *Don’t* Know.”

It is notable that when led by researchers with no intellectual or financial conflicts of interest, evidence reviews universally find the benefits of pediatric gender reassignment unconvincing, and the unquantified risks of harm alarming. This includes recent evidence reviews commissioned by health authorities in the UK (NICE, 2020a, 2020b); Sweden (SBU, 2022); Finland (Pasternack, Söderström, Saijonkari, & Mäkelä, 2019), and most recently, the state of Florida in the United States (Brignardello-Peterson & Wiercioch, 2022).

Clayton reminded readers that advancing from the current lack of evidence requires rigorous study designs capable of generating high quality evidence. She illustrated the importance of rigorous research designs by invoking the *placebo effect*—the well-established powerful influence of “the whole therapeutic ritual, including medical marketing” that “affects the patient’s neuro-psycho-biological state...” (Clayton, 2022b, p. 5). Clayton questioned the extent to which the observed short-term improvement reported by uncontrolled studies may be subject to the placebo effect, with clinicians themselves operating under a “therapeutic illusion” enabled in part by the widespread promotion of the expected benefits of gender transition in “social media, and celebrity culture” (p. 5). She noted that when “interventions have high risk of serious and irreversible adverse effects” (p. 5), rigorous study designs that control for these factors are essential.

Clayton also reflected on the blurred line that separates “innovative clinical practice,” which can be offered widely by any willing provider, from “research,” which is subject to a tightly

regulated process. She questioned whether “affirming” interventions for youth can only ethically be performed in research settings, in view of these interventions’ irreversible effects and the risks involved to very young individuals. This is the direction that Sweden recently assumed (Socialstyrelsen, 2022a, 2022b). In the U.S., such a change is not likely to come from the Federal government, but it can take place at the state level, as U.S. laws delegate the responsibility to regulate the practice of medicine to individual states. If this were to happen, gender clinics in participating states might be more motivated to design research that generates useful data to answer the unanswered questions about outcomes.

Having interrogated the evidence, Clayton concluded, “[a]ny claims of certainty are premature and risk more harm than benefit” and observed that the gender medicine establishment’s misguided insistence that the science is settled “hinder[s] the rigorous debate and research required to improve the state of knowledge in this area of medicine” (Clayton, 2022b, p. 6). Clayton’s overview of medicine’s misadventures detailed in her previous publication (Clayton, 2022a), and in the relevant examples in her present commentary (Clayton, 2022b), provide a powerful argument to all clinicians to reconsider their informed consent processes for youth gender transitions. We highly recommend her erudite commentary to all individuals in the field.

Response to Balon

Balon reinforced, elaborated, and provided historical perspective of the importance of a “serious, thorough, and careful” legal and ethical informed consent process (Balon, 2022, p. 3). His epigram, “*Whatever you do, do it deliberately and consider the end*” (Balon, 2022, p. 1) indicated his grasp of the central issue of our contribution—our concern about the proliferation of gender transitions undertaken in youth, despite the unknown long-term outcomes of these radical interventions. He sagely observed that in 2012, when the requirement for psychiatric evaluation was waived to enable patients to efficiently obtain hormones (Coleman et al., 2012), the protection of patients and their families was jeopardized.

Balon agreed that the process of medical gender transition of youth is often undertaken in a way that is not truly informed: “Similar to Levine et al. (2022), I am also not sure whether, with the increased incidence of gender identity variation, all parties involved in the informed consent process are well and appropriately informed and educated” (Balon, 2022, p. 1). He recognized the difficulty of obtaining informed consent from patients and families when the clinicians themselves do not have reliable information: “the word informed does not relate “just” to patients’ (and their families) side of the informed consent equation, but also to the clinicians’ side. It is obvious that our state of knowledge regarding appropriate and timely gender transition (whatever the intervention is) and its consequences is not where we would like it to be” (Balon, 2022, p. 1).

Balon emphasized how far the field of gender medicine is from a rational dispassionate heuristic embrace of the disagreements: “It seems that most of the time ideology, emotions and personal convictions beat knowledge and evidence in these debates” (Balon, 2022, p. 3). Balon’s plain language summary of the current situation is apt: “Simply said, the ship has sailed, and we assume that its course is correct, and landing will be correct and the life after will be happy. Is that so, though?” (Balon, 2022, p. 1). Alarmed by the “possibility of underlying belief systems replacing scientific evidence,” Balon encouraged all parties to continue the scientific debate, “agree to disagree and through our disagreement and continuous study of gender and transgender issues continue to improve the care of our patients.” Balon reminded all those involved in the debate that there is “[u]ltimately, just one side to this debate...the patient side” (Balon, 2022, p. 3).

Just as it is the legal right of parents to not vaccinate their children or refuse medical services that violate religious or cultural beliefs, you cannot take away a parent's right to seek care their child requests for gender affirmation. To do this would be no different than requiring a child to be vaccinated for COVID: it is a parent's right to choose. There is no evidence of negative impacts of gender affirming care. There is, however, a correlation of childhood suicide and denial of assistance for gender affirmation. Do you really want to regulate healthcare this much, and for something purely political with no scientific merit to ban?

I am a pediatrician with expertise in child abuse and general pediatrics. What is happening in pediatrics in regards to gender affirmation is irresponsible at best and borders on child abuse. Children lack the decision making skills of adults- they are not mature enough to drink alcohol, drive cars, or vote. They are certainly are not developmentally able to make permanent life altering decisions about their bodies.

Moreover adolescence is a time of intense confusion and desire to “fit in” with their peers; they need guidance, counseling and sometimes therapy to address issues of isolation, depression, and gender dysphoria.

Permanent decisions about their bodies should be made when they are through the throes of adolescence.

Florida has an opportunity to be a leader in the country in protecting these children and finally bringing common sense to this national debate.

Subject: The Consequences of your Action will kill my paramedic mother
Date: Sunday, October 23, 2022 11:26:37 PM

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

’,

Lots of people have already sent your board many messages on the topics of trans healthcare. I know you won't read this, you're being paid not to. That's the thing about corruption. You don't care who suffers as long as there is coins in your pockets.

But I want to speak to you about my mother, a paramedic and whom worked in the field of medicine for over 40 years. She dedicated her life to saving lives, putting her own life on the line day after day. My mother is not trans or non binary, she's not even part of the LGBT community. She's my mom.

She was diagnosed with an aggressive form of Breast Cancer that consumes and infests on the Estrogen in her body. Within a month it advanced through stage 3 into stage 4.

BECAUSE of your so called medical board's actions, she had to fight her doctors in the state community healthcare program for access to a doctor to check her. They dismissed her concerns. Told her to lose weight and take blood pressure meds. The Doctor's the state used proved either lazy or incompetent or both.

And ER doctor at ORMC found her cancer by accident in an xray of her stomach.

BECAUSE of your so called medical board's actions, she had to fight to get an approval to remove both of her breasts because of the chilling effect your board had on attacking trans men impacting women's healthcare. That delay allowed the cancer to spread to her lymph nodes.

She's had to have 4 surgeries now because of that delay. Her body is covered in scars and she'll never be able to have reconstruction. All because you wanted to deny healthcare to trans men, My mother suffers needlessly.

My mom is now on chemo, a form that includes a block for estrogen in her body so the remaining cancer can starve and die faster than it can consume my mother and kill her. It'll be her life for the next 7 years, maybe the rest of her life which your medical boards political short sighted arrogance and greed has shorted.

BECAUSE of your so called medical board's actions, when my mom was in recovery from her many surgeries and infections she got inside the hospital, I had to fight nurses and doctors to give her the life saving chemo she needed only because they objected on religious grounds to

saving my mom's life with a hormone blocker or they were concerned they'd be punished by your asinine actions. Just rumor of what corrupt machinations your board was up to was enough to threaten her fight against cancer.

BECAUSE of your so called medical board's actions, Medicaid and my insurance both tried to drop my mother on trumped up reasons, but largely because they didn't want to cover anything that might be remotely related to trans healthcare. I had to foot the bill for her cancer treatment and bankrupted me in a month. I don't come from wealth, my mom and I fought and clawed and struggled to get out of poverty and now we're decending back into because of you. We were notified again this week the state medicaid is trying to terminate her coverage.

Because of your so called medical board's action, that monster that calls himself the florida governor and all the dirty money that's flowing into your pockets by christoascists waging the dumbest of all culture wars, My mom is going to suffer and die.

So I'm writing this letter to tell you to stop your madness. Stop this Death Panel you call a board of medicine.

You're killing my mother.

And damn you all.

Trans people did nothing to deserve this amount of cruelty from you and neither did my mother.

damn you all.

,

I'm Olivia, and gender affirming hormone therapy saved my life. I was 16 and was baker acted for attempted suicide. I knew I was trans since I was 16, and despite my parents support I was afraid of moving forward with my transition. Like all trans kids, it was a huge decision and I didn't make it lightly. It takes teams of professionals who did not make it easy to get on hormones. It is not a choice that is ever made on a whim. Transitioning saved my life, and countless others. The rate of attempted suicide decreases exponentially when a trans person, especially a young trans person, gets access to hormones. I bet you to not cave to the political pressure surrounding this issue, but to listen to those trans healthcare actually effects. I beg you to not change the availability of hormones to young trans people. If you do, the blood of many children will be on you.

Dear Florida Board of Medicine,

Please consider my submission of an op-ed I recently wrote on The Federalist on the ethics of gender-affirming surgery for the upcoming meeting of the Florida Board of Medicine on this issue. I believe that gender dysphoria is a psychiatric illness, and the use of medical treatments such as puberty blockers and hormones or surgical castration and mutilation on these mentally ill children and adults is a horrible violation of medical ethics and should be illegal.

I am a professor of neurosurgery at the Renaissance School of Medicine at Stony Brook University in New York. I trained in neurosurgery at the University of Miami. I have 40 years of surgical and teaching experience in medicine, and I am the director of the neurosurgery residency program at my medical school.

I hope the Board will decide to ban this practice and sanction the doctors who do it. Please let me know if I can be of any help in this important matter.

Sincerely,

Michael Egnor MD
Professor of Neurosurgery
Renaissance School of Medicine
Stony Brook New York.

<https://thefederalist.com/2022/09/23/operating-on-healthy-bodies-defies-surgical-ethics-and-trans-people-are-no-exception/>

Operating On Healthy Bodies Of Transgender People Defies Ethics

Surgical removal of healthy organs is not a treatment for mental illness. Gender dysphoria should be treated with psychiatric therapy.

Operating on Healthy Bodies Defies Surgical Ethics, And Trans People Are No Exception

Surgical removal of healthy organs is not a treatment for mental illness. Gender dysphoria should be treated with psychiatric therapy.

Michael Egnor, MD

As a pediatric neurosurgeon, I have followed the [proliferation of surgical procedures for “gender affirmation”](#) with increasing dismay. That public schools now advocate such treatments to young children is particularly alarming. I say this based not on personal opinion but on 35 years of experience as a surgeon and instructor of surgeons.

I teach at a medical school and I am residency director for neurosurgery in my institution. This means I am in charge of training young neurosurgeons. I emphasize to medical students and resident neurosurgeons that the first and most fundamental responsibility a surgeon has to his patients is to make an appropriate initial decision as to whether or not to operate. A surgeon’s first responsibility, when treating a patient with a potentially surgical disorder, is to determine whether or not surgery is in the patient’s best interest. A well-performed operation is still malpractice (or even assault) if it is not done for valid medical reasons. Operating for marginal (or less) indications is more common than most of the public realizes—after all, surgeons are paid (quite well) to operate, and they rightly take pride in operating with skill. To be paid handsomely for what you love to do is a privilege, a joy and a very dangerous temptation. Not every patient who consults a surgeon really needs surgery—often, non-surgical treatment is more effective and less risky.

Thus, when I quiz my students and residents about treatment options for various conditions, I always insist that they begin with discussion of non-surgical treatments. Honest and conscientious surgeons only do surgery when less invasive options are inadequate and there are clear justified indications for surgery. The patient’s health, not the surgeon’s ego, is paramount. This is basic surgical ethics.

So-called 'Gender Affirmation' surgery violates ethics

Surgery for “gender affirmation” or “sex reassignment” grossly violates the ethical canons I have taught, that were taught to me, and that were taught to all surgeons until very recently.

Such surgery entails radical and irreversible operations *on normal healthy organs*—mastectomy performed on normal breasts, amputation of the normal penis and scrotum (with construction of an opening to imitate a vagina), excision of the normal uterus and ovaries (with construction of a skin-tube to imitate a penis), among other procedures. These procedures are permanently disfiguring and render patients sterile.

What is the ethical basis for such mutilating surgery performed on perfectly healthy organs? It is a basic principle of medical ethics that surgeons are under no obligation to perform surgery on healthy body parts simply because a patient requests it. In fact, a surgeon is generally obligated to *refuse* to damage a patient's normal organs or body parts just because the patient wants it done—e.g., it is unethical for a general surgeon to amputate a patient's normal healthy arm or leg just because the patient requests it (this is a [real issue](#)), or remove a patient's healthy eyes or a healthy part of a patient's brain, simply because of a patient's request. There are patients who suffer greatly from [Body Integrity Image Disorder](#), but it is a *psychiatric* condition, not a surgical condition. Surgical mutilation is not a treatment for psychiatric illness.

Patients with [Gender Dysphoria](#) obviously share much in common with patients with Body Integrity Image Disorder—it may reasonably be understood as a variant of it. Under what circumstances are radical and permanent surgical procedures justified for these patients?

Mental not physical illness

To consider the ethics of surgical treatment for Gender Dysphoria, I note that these patients are mentally ill. I don't mean this term in a derogatory sense. I mean it in a *medical* sense. Patients presenting to a physician for Gender Dysphoria are certainly ill, in that they are seeking medical help. If they were not ill, they wouldn't be going to a doctor. And Gender Dysphoria is a mental, rather than physical illness, because the sexual organs of people with Gender Dysphoria are functioning normally. There is nothing physically wrong with the penis and testicles of a trans-woman, or with the uterus and ovaries of a trans-man. The illness is mental—the patient does not feel like his or her biological sex and does not want to be his or her biological sex. This of course can cause great suffering—it is a real illness—but the suffering is mental, not physical.

The primary justification for radical medical and surgical 'treatment' of Gender Dysphoria is that it reduces the risk of suicide, but this is not supported by the [evidence](#). Furthermore, the assertion 'I'm going to kill myself if doctors don't mutilate my body' emphasizes the psychiatric, rather than physical, nature of Gender Dysphoria illness. There are well established treatments for suicidal ideation, none of which entail the destruction of normal body parts by hormonal castration or surgical mutilation.

Gender Dysphoria is not a surgical, nor even a medical, illness. It is a psychiatric illness, and should be treated by psychiatric therapy, not by hormones or by scalpels. It is to the great discredit of the medical profession that we perform and sanction these radical operations. Surgery for Gender Dysphoria is profoundly unethical according to generally accepted standards of surgical practice. Surgeons should not deliberately destroy normal organs or body parts. _

-
Patients with Gender Dysphoria have a psychiatric illness, and our efforts at treatment of this condition should be directed to the psychiatric issues involved, for which there are [good and established principles of care](#). It is to the psychiatric care and social support of people with Gender Dysphoria—not dangerous and radical medical or surgical interventions— that our resources should be devoted.

Dr. Egnor is a professor of neurosurgery and pediatrics at the Renaissance School of Medicine in Stony Brook, New York.

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of

WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

Subject: Gender-Affirming Care Has Saved My Daughter
Date: Tuesday, October 18, 2022 4:42:10 PM

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

,

As the mother of a young trans woman, I've seen firsthand how gender-affirming healthcare has made a huge and positive change in her life. Prior to taking female hormones after going through puberty, she was depressed, wouldn't engage with family/others, and just hid behind a hoody sweatshirt and computer. We had no idea what was going on and were quite worried. Since opening up to us and starting hormones 13 months ago, I have a happy daughter who is enthusiastic about life and now enjoys being around people. She's a amazing young woman instead of a hidden young man. I'm so glad to have her in our family and to no longer worry that I would discover my child had ended their life by suicide. It was that bad.

All young people who need gender-affirming care should have access to it. I request that the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that "gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals."
