As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that "gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals."

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts "dangerous governmental intrusion into the practice of medicine." The AMA cited that "trans and non-binary gender identities are normal variations of human identity and expression" and that "evidence has demonstrated that forgoing gender-affirming care can have tragic consequences." Furthermore, the AMA asserted that "Decisions about medical care belong within the sanctity of the patient-physician relationship."

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-

affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

As a citizen of Florida, and as the parent of a transgender son, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state. Restricting gender-affirming care is, in essence, telling transgender children their lives don't matter. And that is unacceptable.

My son is 18 now, but he came out of transgender at 14, I can attest without a shred of doubt that had he not been given access to gender-affirming care, he very likely would not be with us anymore. The research supports the importance of allowing transgender children and their parents to determine with their doctors the appropriate care. It is not the government's decision to make.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that "gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals."

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts "dangerous governmental intrusion into the practice of medicine." As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state. As a licensed mental health clinician, I urge you to NOT give in to politics of this state and follow the guidance of the various medical associations which have made CLEAR the need for life saving treatment for trans and non-binary youth and adults. THIS IS NOT ABOUT POLITICS, these are lives in your hands.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. As a citizen of Florida, the proposal that medical standards be set for political purposes is appalling and should appall every public official. For children, to deny medical care that has been shown to reduce rates of suicide in a group tragically most prone to suicide would be inhumane. For adults, let our medical profession give them peace and an ability to be comfortable in their own skin.

I urge the Florida Board of Medicine to abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of

WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of

I run a charter school that is welcoming to Trans students. We have several whose families mentioned that we are the first school where they feel safe. I urge you not to abandon these young people. All they need is love, just like every other young person in your lives.

It's not fair for these kids having to go through the same nightmarish things I have to during my transition. They should be able to get on puberty blockers and decide for themselves later in their lives. Puberty blockers are safe.. Often life saving for CIS and trans people alike. In fact my sister who is CIS would probably not be alive without them. She started menstruation when she was 6 and they were so bad that she would become so anemic that she would pass out. She I now 32 with a happy baby boy and that couldn't have happened without being on blockers first.

If I was on blockers during my teenage years I would most likely have not attempted killing myself multiple times... Nor be afraid of loosing control of myself because the hormones I was being flooded with went against the very fiber of my soul and mind. I would give anything to have been able to transition in my teenage years and these kids deserve to have that ability for the whopping 1% of the population we take up. You know what you should do and if you do not help these children be their true selves and dodge going through the literal hell it is to go through the wrong puberty then I guess we will not be seeing you in the good afterlife.

A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of

WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of

WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

Subject: SUICIDE PREVENTION: Gender Affirming Care for Trans and Gender Diverse Youth
Date: Tuesday, October 18, 2022 5:08:40 PM

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

As a citizen of Florida and a licensed mental health provider, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender affirming care and ensure uninterrupted access to care for transgender and gender diverse minors and adults throughout the state.

Transgender and gender diverse youth and adults have existed as long as people have existed. Our existence will not be snuffed out by prejudiced regulation. Measures to restrict or eliminate care will serve to place a higher strain on already stretched thin mental health services in the state, as further people are victimized and traumatized by actions unsupported by peer-reviewed evidence. We deserve better. Transgender and gender diverse people are not second class citizens or any less deserving of comprehensive care.

While many myths seem to be circulating about what gender affirming care looks like for youth, it's often conveniently overlooked that the same types of care are available to cisgender youth. Puberty blockers or GRnH agonists were created with the intent of pausing precocious puberty in cisgender children. Cisgender teen girls can obtain hormone therapy - by way of contraceptives. Cisgender adolescents may obtain elective surgeries like rhinoplasty, breast augmentation, and breast reduction. While these are available to cisgender youth as elective procedures, there is no evidence based basis to prevent access to medically necessary and lifesaving care, by way of the same interventions to transgender and gender diverse youth.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that "gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals."

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts "dangerous governmental intrusion into the practice of medicine." The AMA cited that "trans and non-binary gender identities are normal variations of human identity and expression" and that "evidence has demonstrated that forgoing gender-affirming care can have tragic consequences." Furthermore, the AMA asserted that "Decisions about medical care belong within the sanctity of the patient-physician relationship."

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of

WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

This is not a political issue, it's a health issue that needs to be driven by science and experience. So many trans people are vulnerable--either through suicide or by murder. We need to normalize a full spectrum of genders and celebrate their humanity.

I am a citizen of Florida whose mom received great care in the last years of her life from a transgender doctor. So many of us are opposed to people we don't know but find friends when we get to know them.

Having gotten to know people who are or want to be transgender, my heart goes out to them. Some are depressed or suicidal due to not having support or suffering discrimination or abuse. Please open your hearts and minds to transgender care.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that "gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals."

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts "dangerous governmental intrusion into the practice of medicine." The AMA cited that "trans and non-binary gender identities are normal variations of human identity and expression" and that "evidence has demonstrated that forgoing gender-affirming care can have tragic consequences." As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of

WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of

WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of

WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

As a parent, I personally know the pain my son experienced until he received the gender-affirming care he needed. If he could not live as his authentic self, he didn't want to live. We were fortunate to find gender affirming healthcare at Arnold Palmer Hospital. As an adult, he hasn't completely transitioned medically because it is cost prohibitive. Would you deny your child life sustaining medical treatment if they were suffering. I doubt it!

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that "gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals."

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of

WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

As a Registered Nurse, mother of three, and citizen of Florida, I am requesting that the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state. I am also a PhD student studying at the University of South Florida in Tampa. My field of research is negative health impacts of stigma and repressive policies on sexual and gender diverse persons. I have first-hand experience working with transgender patients, teaching them how to inject their gender affirming hormone therapy. There is nothing more cruel than to deny this population the care they need, based on antiquated ideas of gender identity. Research into the biological basis of diversity in gender identity published in the journal Behavioral Genetics (Polderman et al., 2018) indicates that there is a biological diversity underlying gender identity development, and that awareness of this foundational for reducing health disparities and promoting human rights for sexual and gender minorities.

Just this month, Liu et al. explicated the negative health outcomes in the sexual and gender diverse population due to stigma and archaic ideas medicalizing transgender identity as a mental illness. Published in the New England Journal of Medicine, this group of distinguished researchers and physicians from Harvard Medical School and Massachusetts General Hospital concluded that it is incumbent upon the health care sector to equitable care experiences and health outcomes for sexual and gender diverse populations. To act in contradiction to what is generally accepted medical practice is an affront to the profession and demonstrates a severe knowledge gap in the Florida medical community.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.”

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about

medical care belong within the sanctity of the patient-physician relationship.”

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

I would be happy to come and bear witness to my personal experience with the importance of gender affirming hormone therapy in this population, and to share my research insights with you. I cannot ask you more strongly not to reverse years of medical practice and research, and return to a repressive, medically inaccurate model.

,

As someone that lost his cousin to suicide because her friends and family weren't supportive enough of her decision to seek gender affirming care, I am strongly opposed to any measure counteracting it. She was a good kid that deserved an understanding and supportive network, and she died because she didn't have it.

It's just hurtful and unnecessary.

Longwood, Florida 32750

Florida Board of Medicine,

2360 people have signed a petition on Action Network telling you to Support Gender Affirming Care for Trans Youth in Florida.

Here is the petition they signed:

We, the undersigned, strongly condemn the Florida Board of Medicine's recent decision to begin the rule-making process to create Florida-specific "standards of care" for gender-affirming healthcare for transgender, non-binary, and gender-diverse youth. Despite the Board of Medicine's claims to be an apolitical body acting on behalf of all Florida residents, the board meeting on August 5th, 2022, revealed an explicitly political agenda. Governor Ron Desantis' hand-picked appointees on the Board of Medicine initiated these proceedings as one of several policy attacks on LGBTQ+ people in Florida.

We condemn the actions of Governor Ron DeSantis, Surgeon General Ladapo, the Florida Board of Medicine, and the Florida Department of Health, for their intentional misrepresentation of scientific research, their deliberate exclusion of the vast body of scientific research that demonstrates the benefits of gender-affirming healthcare, and their assertion of the explicitly transphobic, scientifically debunked, so-called "social contagion theory." We also condemn the Florida Board of Medicine's decision to call on the overtly transphobic, biased, and discredited Dr. Quentin Van Meter. Van Meter's "American College of Pediatricians" organization is an anti-LGBTQ+ hate group, not a medical authority.

For those involved who took the Hippocratic oath to 'do no harm,' we need you to know — this is harm.

We further condemn the actions of Florida Board of Medicine members during the meeting. Through intentionally intrusive and leading questions, they disrespected those opposing the rule-making petition, including respected clinicians and trans/non-binary youth and adults who shared personal testimonies. The Board of Medicine also failed to question or moderate public comment from those who spoke in favor of the petition, even when they employed dehumanizing, racist, and transphobic rhetoric and hate speech. And their calculated decision to end public comments 90 minutes early silenced dozens of trans activists and allies who waited hours to speak.

Additionally, we condemn the anti-trans violence that occurred before, during, and after the meeting. The Board of Medicine inappropriately chose to hold a public meeting concerning the health of citizens statewide on private property in South Florida, failing to provide safe restroom options for all people in attendance. Meanwhile, officers from the Broward Sheriff's Office (BSO) targeted, profiled, and arrested LGBTQ+ attendees, and security and building staff harassed them. Finally, attendees were subjected to targeting and intrusive surveillance by representatives of the extremist groups "Let Kids Be Kids Coalition" and "Moms for Liberty."

Surgeon General Ladapo, the Florida Board of Medicine, and the Florida Department of Health have made myriad false claims about evidence-based gender-affirming care (pubertal suppression, hormonal and surgical treatments, and social transition support). Meanwhile, a robust body of research confirms the benefits, safety, and life-saving medical necessity of this care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies

published from 1991 to 2017 found that “gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals.” Decades of literature indicate that the accessibility of both medical and social transition support contributes to a better quality of life for trans and gender-diverse people.

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts “dangerous governmental intrusion into the practice of medicine.” The AMA cited that “trans and non-binary gender identities are normal variations of human identity and expression” and that “evidence has demonstrated that forgoing gender-affirming care can have tragic consequences.” Furthermore, the AMA asserted that “Decisions about medical care belong within the sanctity of the patient-physician relationship.”

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

Existing international standards of care already offer clear guidance for providing these treatments in safe, affirming, and supportive ways. The Florida Board of Medicine’s decision to open rule-making on treatments that have not resulted in complaints or disciplinary hearings, and which impact a very small percentage of the population, further indicates a political agenda. Legislative attacks against trans and gender-diverse people, especially youth, are rising across the country. The Florida Board of Medicine’s decision serves not to protect ALL youth, but rather to harm trans and gender-diverse youth for political gain.

We would like to address the following points that the Florida Board of Medicine misused to justify restricting access to gender-affirming care for minors:

- While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for minor patients.
- Several studies included in the August 5th public book of materials were intentionally misrepresented, and materials did not include recent and relevant research on the demonstrated benefits of gender-affirming care. Furthermore, researchers involved in several of these studies stated their findings were intentionally misconstrued and misused by Florida’s Board of Medicine.
- The politically-charged claim that young transgender and non-binary children are going through a temporary phase—that around 80% of them will spontaneously “desist” gender incongruence and identify as cisgender by natal puberty—is rooted in biased and scientifically flawed studies, and is not supported by sound scientific evidence. The studies cited by the Board were marred by sample bias, scooping up large numbers of gender nonconforming children never tested for clinical gender incongruence. One of these studies even misrepresented youth who missed follow-up interviews as “desistance.” Furthermore, the “80% desistance” myth is refuted by ongoing longitudinal studies of gender incongruent youth who socially transitioned in childhood. A 2022 article in the journal, *Pediatrics*, found only

2.5% (not 80%) reverted to their birth-assigned gender and identified as cisgender, five years after initial social transition.

- In recent years, a pseudo-scientific diagnostic label of “rapid-onset gender dysphoria” (ROGD) has been widely publicized. This myth posits that the rising visibility of trans and non-binary adolescents accessing medical services represents an “epidemic” of “social contagion” and “mental illness,” rather than the emergence of gender-diverse youth who had been forced to hide their existence in prior generations. “ROGD” is not a legitimate medical term. It is not recognized by any major professional association and is based on extremely biased surveys of members of known anti-trans hate organizations. The “ROGD” stereotype fails fundamental scientific principles by conflating correlation with causality. [This is analogous to the history of left-handedness in the U.S., which appeared to increase four-fold in the early 20th century because of growing social acceptance. Left-handed people in prior generations had simply not been allowed to exist in society and were repressed into invisibility.]

We will not remain silent as the powers that be in Florida attempt to strip rights from our youth. We demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors throughout the state. If Florida-specific standards of care are adopted, they must reflect the most current version of WPATH Standards of Care and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

We also demand that the Florida Board of Medicine do the following:

- Center the voices and experiences of trans and gender-diverse youth and their families in all future public meetings and decision-making processes related to this topic. Florida also has a wealth of dedicated and knowledgeable LGBTQ+ organizations and medical professionals who can provide informed counsel to the Board. Additionally, the Florida Board of Medicine should seek input and guidance from LGBTQ+ communities for the duration of this process.
- Prohibit Dr. Quentin Van Meter from participating in future discussions and decision-making related to gender-affirming care in Florida. Dr. Van Meter’s affiliations with anti-LGBTQ+ hate groups and the 2020 decision of a Texas judge to disqualify him from testifying on gender-affirming care demonstrate that he is not a “subject matter expert.” Van Meter aims to undermine care for transgender people and to spread anti-LGBTQ rhetoric under the guise of “science.”
- Conduct an unbiased review of scientific data related to gender-affirming care. If the Board of Medicine’s rule-making process is truly to be based on science, the Board of Medicine must examine all available and legitimate data, rather than cherry-picking and misrepresenting studies to support political agendas.
- Consult legitimate resources on transgender experiences and gender identity prior to holding future discussions of gender dysphoria. Comments from members of the Board revealed a lack of basic knowledge regarding transgender topics. There are reputable entities that offer introductory content on gender diversity and the experiences of gender-diverse individuals.
- Center the physical safety of transgender participants in all future public meetings. Meetings must be held at accessible public property venues with gender-inclusive restrooms. Failure to provide suitable accommodations for transgender and non-binary attendees at meetings of tremendous relevance to their health is unacceptable. It is impossible to equitably and meaningfully participate in discussions while simultaneously fearing repercussions and attacks.

We won’t be silent, and we won’t be silenced.

Sincerely,
The Undersigned

As a trans and genderqueer person and as a mental health clinician specializing in the care of trans and gender diverse people, I stand behind the evidence-based science that gender affirming medical interventions are life-saving and medically necessary for those who seek them out. I do not stand for fearmongering, trans-based prejudice, or actions to undermine the safety and lives of trans and gender diverse Floridians.

I support you 100%

39. Aden Paull (*ZIP code:*)

40. Emily Lynch (*ZIP code:*)
This is life saving reversible care recommended by doctors across the world. There is no more danger here than any pediatric medicine, and arguably less so than most. This is like a panic over Children's Motrin. The only difference is that its basis is in the very idea that transness should be forbidden. But considering the evidence that it greatly reduces suicide and depression, while, again, being entirely reversible, should be enough to say that the fears surrounding this are overblown. Let qualified well respected doctors, not ideologues with lobbying money from the Koch Brothers, decide your children's healthcare. Because the former actually cares about their well-being.

Showing support for ALL youth in need of gender affirming care, in particular the trans youth of FL.

208. Lorelai Silva (*ZIP code:*)

Support us, let us live in peace. I genuinely hope this rule is blocked.

209. Brandi Skipalis (*ZIP code:* 32218)

It is unethical to base medical rule-making on biased misinformation and disinformation, ignoring the actual science and experts on gender dysphoria and transition-related healthcare, and creating new "standards of care" that ignore the actual, long-established standards of care that already exist. Any rulemaking MUST include recent, peer-reviewed research and listen to the voices of actual experts in this field.

To: Florida Board of Medicine

From: [Your Name]

We, the undersigned, strongly condemn the Florida Board of Medicine's recent decision to begin the rule-making process to create Florida-specific "standards of care" for gender-affirming healthcare for transgender, non-binary, and gender-diverse youth. Despite the Board of Medicine's claims to be an apolitical body acting on behalf of all Florida residents, the board meeting on August 5th, 2022, revealed an explicitly political agenda. Governor Ron Desantis' hand-picked appointees on the Board of Medicine initiated these proceedings amidst a series of policy attacks on LGBTQ+ people in Florida.

We condemn the actions of Governor Ron DeSantis, Surgeon General Ladapo, the Florida Board of Medicine, and the Florida Department of Health, for their intentional misrepresentation of scientific research, their intentional exclusion of the robust body of scientific research that demonstrates the benefits of gender-affirming healthcare, and their assertion of the explicitly transphobic, scientifically debunked, so-called "social contagion theory." We also condemn the Florida Board of Medicine's decision to call on the overtly transphobic, biased, and discredited Dr. Quentin Van Meter. Van Meter's "American College of Pediatricians" organization is an anti-LGBTQ+ hate group, not a medical authority.

Those involved who swore a Hippocratic oath to 'do no harm' should be ashamed.

We further condemn the actions of Florida Board of Medicine members during the meeting. Through intentionally intrusive and leading questions, they disrespected those opposing the rule-making petition, including respected clinicians and trans/non-binary youth and adults who shared personal testimonies. The Board of Medicine also failed to question or moderate public comment from those who spoke in favor of the petition, even when they employed dehumanizing, racist, and transphobic rhetoric and hate speech. And their calculated decision to end public comments 90 minutes early silenced dozens of trans activists and allies who waited hours to speak.

Additionally, we condemn the anti-trans violence that occurred before, during, and after the meeting. The Board of Medicine inappropriately chose to hold a public meeting concerning the health of citizens statewide on private property in South Florida, failing to provide safe restroom options for all people in attendance. Meanwhile, officers from the Broward Sheriff's Office (BSO) targeted, profiled, and arrested LGBTQ+ attendees, and security and building staff harassed them. Finally, attendees were subjected to intrusive surveillance by representatives of the extremist groups "Let Kids Be Kids Coalition" and "Moms for Liberty."

Surgeon General Ladapo, the Florida Board of Medicine, and the Florida Department of Health have made myriad false claims about evidence-based gender-affirming care (pubertal suppression, hormonal and surgical treatments, and social transition support). Meanwhile, a robust body of research confirms the benefits, safety, and life-saving medical necessity of this care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that "gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals." Decades of literature indicates that the accessibility of both medical and social transition support contributes to a better quality of life for trans and gender-diverse people.

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts "dangerous governmental intrusion into the practice of medicine." The AMA cited that "trans and non-binary gender identities are normal variations of human identity and expression" and that "evidence has demonstrated that forgoing gender-affirming care can have tragic consequences." Furthermore, the AMA asserted that "Decisions about medical care belong within the sanctity of the patient-physician relationship."

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

Existing international standards of care already offer clear guidance for providing these treatments in safe, affirming, and supportive ways. The Florida Board of Medicine's decision to open rule-making on treatments that have not resulted in complaints or disciplinary hearings, and which impact a very small percentage of the population, further indicates a political agenda. Legislative attacks against trans and gender-diverse people, especially youth, are rising across the country. The Florida Board of Medicine's decision serves not to protect ALL youth, but rather to harm trans and gender-diverse youth for political gain.

We would like to address the following points that the Florida Board of Medicine misused to justify restricting access to gender-affirming care for minors:

While Florida currently does not have state-specific standards for providing gender-affirming care, that does not mean that such care is unregulated in the state. Providers follow standards set by the World Professional Association for Transgender Health (WPATH), which have been developed over decades (beginning with Version 1 in 1979). WPATH's Standards of Care 7 include the following safeguards:

- Minor patients should be thoroughly evaluated by mental health providers and be given parental consent before starting gender-affirming treatment.
- Trans adolescents (at Tanner Stage 2 of natal puberty) can be offered puberty-suppressing hormones, which are fully reversible and low-risk based on all available medical literature, until the patient and their caregivers can make informed age-appropriate decisions about hormone therapies.
- Gender-affirming genital surgery is not carried out on children. Genital surgeries are only offered for adult patients.
- Several studies included in the August 5th public book of materials were intentionally misrepresented, and materials did not include recent and relevant research on the demonstrated benefits of gender-affirming care. Furthermore, researchers involved in several of these studies stated their findings were intentionally misconstrued and misused by Florida's Board of Medicine.
- The politically-charged claim that young transgender and non-binary children are going through a temporary phase—that around 80% of them will spontaneously “desist” gender incongruence and identify as cisgender by natal puberty—is rooted in biased and scientifically flawed studies, and is not supported by sound scientific evidence. The studies cited by the Board were marred by sample bias, scooping up large numbers of gender nonconforming children never tested for clinical gender incongruence. One of these studies even misrepresented youth who missed followup interviews as “desistance.” Furthermore, the “80% desistance” myth is refuted by ongoing longitudinal studies of gender incongruent youth who socially transitioned in childhood. A 2022 article in the journal, *Pediatrics*, found only 2.5% (not 80%) reverted to their birth-assigned gender and identified as cisgender, five years after initial social transition.
- In recent years, a new pseudo-scientific diagnostic label of “rapid-onset gender dysphoria” (ROGD) has been widely publicized. This myth posits that rising visibility of trans and non-binary adolescents accessing medical services represents an “epidemic” of “social contagion” and “mental illness,” rather than emergence into human society of gender diverse youth who had been forced to hide their existence in prior generations. “ROGD” is not a legitimate medical term. It is not recognized by any major professional association and is based on extremely biased surveys of members of known anti-trans hate organizations. The “ROGD” stereotype fails fundamental scientific principle by conflating correlation with causality. [This is analogous to the history of left-handedness in the U.S., which appeared to increase four-fold in the early 20th century because of growing social acceptance. Left-handed people in prior generations had simply not been allowed to exist in society and were repressed into invisibility.]

We will not remain silent as the powers that be in Florida attempt to strip rights from our youth. We demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors throughout the state. If Florida-specific standards of care are adopted, they must incorporate by reference the most current version of WPATH Standards of Care. As WPATH's Standards of Care Version 8 is soon to be released, any state-specific standards must be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

We also demand that the Florida Board of Medicine do the following:

- Center the voices and experiences of trans and gender-diverse youth and their families in all future public meetings and decision-making processes related to this topic. Florida also has a wealth of dedicated and knowledgeable LGBTQ+ organizations and medical professionals who can provide informed counsel to the Board. Additionally, the Florida Board of Medicine should seek input and guidance from LGBTQ+ communities for the duration of this process.
- Prohibit Dr. Quentin Van Meter from participating in future discussions and decision-making related to gender-affirming care in Florida. Dr. Van Meter's affiliations with anti-LGBTQ+ hate groups and the 2020 decision of a Texas judge to disqualify him from testifying on gender-affirming care demonstrate that he is not a "subject matter expert." Van Meter aims to undermine care for transgender people and to spread anti-LGBTQ rhetoric under the guise of "science."
- Conduct an unbiased review of scientific data related to gender-affirming care. If the Board of Medicine's rule-making process is truly to be based on science, the Board of Medicine must examine all available and legitimate data, rather than cherry-picking and misrepresenting studies to support political agendas.
- Consult legitimate resources on transgender experiences and gender identity prior to holding future discussions of gender dysphoria. Comments from members of the Board revealed a lack of basic knowledge regarding transgender topics. There are reputable entities that offer introductory content on gender diversity and the experiences of gender-diverse individuals.
- Center the physical safety of transgender participants in all future public meetings. Meetings must be held at accessible public property venues with gender-inclusive restrooms. Failure to provide suitable accommodations for transgender and non-binary attendees at meetings of tremendous relevance to their health is unacceptable. It is impossible to equitably and meaningfully participate in discussions while simultaneously fearing repercussions and attacks.

We will not be silent, and we will not be silenced.

Trans kids lives matter and they deserve the healthcare that is best for them.

566. Emily Bergland (ZIP code:)
Transgender affirming care saves life. Research shows that children have awareness and understanding of their gender around age 3-5 (this is separate from their sex assigned at birth) and by age 14 are cognitively developed enough to make decisions on their health and bodies. Numerous healthcare organizations have made recommendations about the benefits of trans youth being able to take hormone blockers, hormone therapy and too surgeries after meeting various criteria. If this bill passes trans youths' mental well-being will decrease and suicide rates will increase.

567. Elizabeth Corwin (ZIP code:)

568. Angela Aylward (ZIP code:)
The way our government is treating people with marginalized genders & sexualities abhorrent. Gender affirming care & support for LGBTQIA+ youth & adults are lifesaving.

570. erin (ZIP code:)
Protect Healthcare for all.

571. E-T Cresswell (ZIP code:)

572. Ennio (ZIP code:)
I know the Bush loyalist DeSantis wants to DESTROY the lives of Children and especially trans children. Desantis must be really happy to REPLACE Donald Trump after screwing him over on his own doorstep after Trump helped elevate him.

Now this puppet of Glenn Youngkin, who also backstabbed Trump like many jealous and cowardly

republicans did, wants to further make Florida a bigger punching bag. Desantis and these Republicans like the Bush, Cheney, Kissinger, Crenshaw, Cruz, McConnell, and Glen Youngkin are the core reason why Trump has less presidential terms than Obama.

Trans people and kids were more loyal to Trump than that flip-flopper, and these cowardly backstabbers who screwed over Trump want to harm kids while stealing tax breaks, social security, and turning White Americans into third class minorities.

The U.S. Census shows that White people are now officially second class citizens to Hispanic-Whites, thanks to Ron Desantis, George Bush, Mitch McConnell, Dick Cheney, Liz Cheney, Rick Scott, and Ted Cruz. They are most likely fist bumping on their vacations while they continue to feed dirty food and water while stealing money off white people as if they were second class minorities on the US census.

I bring this up because as much as I want to protect the only people who did not betray us, or hurt us in any way like the cowardly DeSantis, I know he is going to disregard the signature.

So it's best to destroy his presidential chances to replace Trump by bringing inconvenient truths about him... like the amount of money people are gonna pay in a few years because of him failing against Disney, or that he human trafficked people with your taxpayer money, smuggling immigrants inside the country and people liking that. They prefer immigrants and Trans People than illegal, cheating, lying, backstabbing, spineless, and brainless Republican leeches like Bush and Desantis that made Trump a 1 term President.

By some miracle that Desantis leaves kids alone, and stop defunding their future, only then the inconvenient truths that made Trump a 1 term president and white Americans second class minorities would stop too.

But I know that won't happen, even though I request the board to stop trying to take away gender affirming care.

573. Ed Averill (*ZIP code:*)

It's mean, not helpful, for bigoted politicians to pretend to play doctor. Please let the medical profession do their best in serving people who have gender issues.

574. Zen Nelson (*ZIP code:*)

575. Virginia Hamner (*ZIP code:*)

Please do not take health care away from trans people. It's lifesaving care.

576. Alea Schroeder (*ZIP code:*)

Gender affirming care has proven on the national level of medical care to save lives and reduce suicide ideology significantly among trans youth. Please don't let Florida go backwards.

577. Sam Skeels (*ZIP code:*)

I'm a graphic designer who has expressed interest in trans rights advocacy, but my situation is very limiting. I am afraid to be myself in public, in my area, as well.

586. Eleanor McDonough (*ZIP code:*)

587. Eli Cazares (*ZIP code:*)

588. E Schmidt (*ZIP code:*)

589. Michael Tasdoul (*ZIP code:*)

To disallow affirming care is tyranny. It is a malicious effort against existing diversity to simplify control over a populace to meet one's own ends and not those of the people. "Honoring" the GROUP of constituents standing against exposure to INDIVIDUALITY is criminal. To be born under that caliber of governance is imprisonment not freedom.

613. Kai Hunt (*ZIP code:*)

Kai

614. Emmy Kenny (*ZIP code:*)

Gender affirming care saves lives! The standard of care should be to SUPPORT trans patients instead of taking away what little medical care they currently have access to. Don't be a political pawn at the expense of our children.

615. Elissa Thomas (ZIP code:)

616. Erica Musser (ZIP code:)

617. Stacey Kroto (ZIP code:)

618. Elena Nickerson (ZIP code:)

619. Erica Gruda (ZIP code:)

620. Samantha Sigmon (ZIP code:)

Support trans youth!

621. Susan Lee (ZIP code:)

As a decades-long citizen of Florida, I am appalled that any body that alleges to be a "Board of Medicine" in this state could POSSIBLY do anything but listen to the total agreement between the American Medical Association (AMA), American Academy of Pediatrics (AAP), Children's Hospital Association (CHA), and other much more expert associations and organizations that have studied and researched the "standards of care" for ALL people and patients withOUT the hate and TOXIC atmosphere that the Florida GOP and far-right have thrown into the stereotypes that are baseless and riddled with unconstitutional bigotry, since our government in this country is REQUIRED to separate all religions from laws (and NOT discriminate either).

All these major medical and children-oriented medical associations have found and determined in their research and study that the absolutely ESSENTIAL healthcare for transgender, non-binary, and gender-diverse youth IS exactly what groups such as Equality Florida has been telling you AND the parents of these youth--AND THE YOUTH THEMSELVES!--which is the gender-affirming care.

It is essential, NOT abuse. It is YOU who are abusing the youth by trying to take it away, which not only harms them physically, but also harms them emotionally by falsely telling them something is wrong with them, that they are in your EVIL AND ARROGANT AND BIGOTED VIEW, they are somehow "lesser," though they are actually NO DIFFERENT from you. A tiny tweak of nature, sure; but every single person is different from EVERY OTHER PERSON by a tiny tweak of nature.

Keep YOUR PERSONAL, PRIVATE RELIGION out of anyone else's life. Yes, you have the right to your beliefs, but ONLY FOR RUNNING YOUR OWN LIFE, NEVER TO RUN ANYONE ELSE'S LIFE. That's where it becomes UNCONSTITUTIONAL. EVERY OTHER PERSON is guaranteed the right to his/her/their OWN PERSONAL, PRIVATE RELIGIOUS FREEDOM, TOO, RATHER THAN YOUR RELIGION.

SO, listen to the AMA, AAP, and CHA, and understand that the Florida GOP and Dr. Ladapo are completely wrong, while the experts know what they're talking about, and so do the parents of the transgender youth and those youth!

Thank you.

622. Eric Repphun (ZIP code:)

Seriously, stop harming vulnerable kids for hateful political nonsense. Gender-affirmative care is safe,

effective, and has been around for almost 100 years. There is no real debate, so stop this harmful garbage. Now is a time for people with serious solutions to very real problems, so it's time you left the building.

623. Elizabeth Hart Whelan (*ZIP code:*)

810. Carmelena Machevelli (ZIP code:)

811. Rowan Landers (ZIP code:)

Banning gender-affirming care for children - for anyone - will kill people. It will kill those who are trying to live and let live and it will kill those for whom you are completely depriving of any kind of support system. If you want to claim to be the pro-life party, you need to start proving it by LETTING PEOPLE LIVE.

1060. Kelsie Lawhorn (*ZIP code:*)

1061. Kendal Hopkins (*ZIP code:*)

1062. Kendra Alves (*ZIP code:*)

Unless you live this, and understand it, you should stay out of our lives.

1063. Kendra Jordan (*ZIP code:*)

1064. Kendrick Meek (*ZIP code:*)

1065. Kensi Mills (*ZIP code:*)

Trans children are so vulnerable and go through so much torment in their lives. Dealing with gender dysphoria as a child and having no way to treat it or seek help to treat it and instead trying to reinforce

a different gender that may not be right for them is wrong.

These kids have some of the best medical professionals in the country if not the world who only do what is best for each child involved and allows the child time to decide for themselves what is best while following a detailed long existing timeline of therapy, puberty blockers if needed then hormones later in their teens and then surgery.

Stop treating these kids like they're nothing more then a political pawn in a game. Trans kids are just like every other child out there and deserve to be treated like it.

1123. Katie Kezelian (*ZIP code:*)

1124. Kathryn McKechnie (*ZIP code:*)

1125. Karen Estrin (*ZIP code:*)

Transition care for transgender youth is necessary and beneficial to their well being. There have always been transgender people throughout history, The aim of this non science based policy is of denying treatment is to marginalize and delegitimize them. The results of this will put transgender youth at greater risk of being physically and emotionally bullied, make transition more difficult with age, and increase suicide rates. In what world is this a positive outcome?

1126. Nui Rios (*ZIP code:*)

1127. Kyle Maharlika (*ZIP code:*)

1128. Kyle Belz (*ZIP code:*)

1129. Kylie Aoibheann (*ZIP code:*)

Access to gender affirming medical care (such as hormone replacement therapy) is one of the only scientifically proven ways to improve the wellbeing and livelihood of transgender people - and prevent mental illness and suicide. Other proven things include social acceptance (being called a preferred name and pronouns ect.) and access to clothing of the gender the individual identifies with. To deny gender affirming care is to deny basic medical treatment.

This is especially egregious, when the number of people who express any kind of regret whatsoever after accessing gender affirming care is miraculously low (about 3%), especially when compared with any of their medical treatment (up to 30% of patients regret having a knee replacement). The amount of people who detransition is much lower than this; and of those who do express such regret about accessing gender affirming care, a great many do so because they face too many social barriers living their authentic self (not because they are not actually transgender). To put this into context, only 5% of people who detransition do so because transitioning medically wasn't right for them.

When seen this, the scientifically-proven benefits of gender affirming care vastly outweigh any possible risks. Access to gender affirming care saves lives - but restriction to it, will destroy many.

1130. Kylie Case (*ZIP code:*)

1131. Lorenzo Canizares (*ZIP code:*)

Human Rights covers all humans.

1343. Michelle Augustus (*ZIP code:*)

1344. Maxwell Petcoff (*ZIP code:*)

1345. Maxine McKinnell (*ZIP code:*)

1346. Max Preston (*ZIP code:*)

1347. Maxwell Matchim (*ZIP code:*)

1348. Maureen Kinlaw (*ZIP code:*)

As a resident of Florida I am disgusted by the efforts to block and legislate care for Trans youth and adults by people with no understanding of this issue. This should be between an individual and their

Healthcare team. No exceptions.

1349. Maya Saunders (ZIP code:)

How about you guys like, don't ban it?

1350. Jennifer Mayer (ZIP code:)

1351. Gwyn Petersen (ZIP code:)

1352. Michael Binford (ZIP code:)

Trans people need our care and support

1353. An anonymous signer (ZIP code:)

1354. Marcais Jackson II (ZIP code:)

1355. Janet Brown (ZIP code:)

1356. Maureen Lee Cote (ZIP code:)

1357. Debra McConnaughey (ZIP code:)

1358. Molly McGoldrick (ZIP code:)

1359. Michael Collins (ZIP code:)

1360. McKenna Vanhorn (ZIP code:)

My cousin is transgender. Without gender affirming care, he would not be happy, healthy, and thriving today. All individuals deserve access to care to help them thrive.

1361. MARIA MANDRY (ZIP code:)

1362. Maria Mejia (ZIP code:)

What if it's your kid that wants to kill himself because of this restriction to the freedom to be who they are?

1363. Matthew McNutt (ZIP code:)

1364. Aiden McRoberts (ZIP code:)

1365. Sujatha Prabhakaran (ZIP code:)

Gender affirming care is truly life saving. Restricting care only serves to hurt patients & does nothing to protect some of the most vulnerable people in our society.

1366. Maryann D'Aquino- Tearle (*ZIP code:*)

1367. Meagan Cahuasqui (*ZIP code:*)

1368. Mechi Luna (*ZIP code:*)
Let's move forward not backwards

1369. Mead Overbeck (*ZIP code:*)

1370. Abbey Crnich (*ZIP code:*)

1371. Mary-Elizabeth Estrada (*ZIP code:*)

1372. Jeremiah Villarreal (*ZIP code:*)

1376. Melanie Lock (*ZIP code:*)

1377. Melanie Lachs (*ZIP code:*)

1378. Melanie Sutterfield (*ZIP code:*)
Why are people afraid of us? Why do you fear different? If it's for religion reasons then please read your book again. As in your own book... Fear is the tool of the devil and so is hate. Trans people just want to exist. They don't want to be in your lives or force themselves on you. Just visible, just living.

1379. Mackenzie Steele (*ZIP code:*)

1380. Melissa Kelley (*ZIP code:*)

1381. Melissa Lyon (*ZIP code:*)

1382. Martha Padilla (*ZIP code:*)
I support this important issue

1383. Meta Ellis (*ZIP code:*)

1384. Luke Metzger (*ZIP code:*)

1385. Mindy Grimes-Festge (ZIP code:)

1386. Gabriela Contreras (ZIP code:)

1387. Maude Hamer (ZIP code:)

You leave my precious grandchild alone!

What you are doing to these children's medical access is not what this gal was taught in church on Sunday.

Trans people are children of God and deserve healthcare!

1388. Michael Hunter (ZIP code:)

1389. Mica Ravan (ZIP code:)

They have no right telling us or anyone what too call our selfs we need our own country

1390. Michael Ducharme (ZIP code:)

I have personally read this petition and I support it in the strongest possible terms.

Using cherry-picked, unscientifically collected research conducted by organizations with known transphobic agendas to inform trans healthcare is deplorable.

Conducting "public" meetings regarding the future of trans healthcare in locations where trans individuals are harassed and not provided safe restrooms is deplorable.

Reducing trans youth freedom and access to life-saving healthcare is deplorable and will **kill young members of your own community**.

I beg you to examine your conscience and have an impartial review conducted on the effects and benefits of gender affirming healthcare, or consult one of the existing meta-analyses of such research. Please make your policy understanding that gender affirming healthcare improves trans youth wellbeing and quality of life.

1391. Michael Eidson (ZIP code:)

1392. Michael Galvez (ZIP code:)

1393. Michaela Kerls (ZIP code:)

An outright ban takes important decision making ability away from the doctors and patients who know and understand their own needs best.

1394. MICHELE DRUCKER (ZIP code:)

This is such an egregious safety violation for families and children. This is what happens in totalitarian regimes. Are you going to put a numbered tattoo on these children next?

1395. Michele Castania (ZIP code:)

1396. Michelle Knight (*ZIP code:*)

1397. michelle isgut (*ZIP code:*)

1398. Michelle Kenoyer (*ZIP code:*)

1399. Carol Jennings (*ZIP code:*)

1448. Mattea Spielbauer (*ZIP code:*)

1449. Marian Starkey (*ZIP code:*)

1450. Meredith Thigpen (*ZIP code:*)

1451. Andy Dawkins (*ZIP code:*)

1452. Carrington Boyd (*ZIP code:*)

1453. Muse Sawyer (*ZIP code:*)

1454. Sonia Battrell (*ZIP code:*)

There is no legitimate reason to withhold appropriate affirming care from transgender people of any age.

1455. Gerald Johnson (*ZIP code:*)

I don't have a trans child and yet my concern is parental rights - for all parents. We have a Florida Constitutional right to privacy and government mandating the type of health care anyone's children must or must not receive is the very definition of an unconstitutional governmental intrusion. Which freedoms will you take away next?

I believe that Florida Board of Medicine must abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to such care because it is blatantly unconstitutional and a step down a very slippery slope we don't want to traverse.

1456. Marsha Fisher (*ZIP code:*)

1457. Malaclypse Codie (*ZIP code:*)

Trans rights are human rights

1458. Anne Barela (*ZIP code:*)

I support gender affirming care for all

1459. Dan Stein (*ZIP code:*)

1460. Nache Atkins (*ZIP code:*)

1461. Nadley Nazaire (*ZIP code:*)

1462. Nafiza Sinha Ray (*ZIP code:*)

1463. Abby Herman (*ZIP code:*)

I'm a trans educator who interacts with youth on a regular basis. They are absolutely fully capable of understanding what it means to be trans. Make the correct and humane choice to protect trans youth's access to gender-affirming care.

1464. Nancy Ellman (*ZIP code:*)

1465. Nancy McLain (*ZIP code:*)

1466. Nancy Metayer (*ZIP code:*)

1467. Nancy Rojas (*ZIP code:*)

1535. Lin Coolidge (ZIP code:)

1536. Chantal Miller (ZIP code:)

1537. Mari Arroyave (ZIP code:)

This is fucking bullshit. All this ban will do is kill kids. Fuck you and whoever came up with the dumbfuck idea of denying healthcare to children

1538. James Price (ZIP code:)

1539. Whitney Guevara (ZIP code:)

1540. MAE ARONHALT (ZIP code:)

Trans kids deserve just as much liberation as the rest of the trans community.

1541. Olivia Westone (ZIP code:)

I knew it a very young age I was transfeminine! It wasn't until later in life that I was able to access the medically necessary care! Let's not deprive others of their gender affirmation the way I was!

1542. Jack Onderdonk (ZIP code:)

1543. Kristi Cowles (ZIP code:)

Keep stupid christians out of the mix!! Support Gender Affirming Care

1544. Kathy Brown (ZIP code:)

1545. Tony SanFilippo (ZIP code:)

1546. Drew Amelia (ZIP code:)

Screw these bigots I'm furious trans kids need so much more support and access to help than they're currently getting

1547. Selene Padilla (ZIP code:)

1548. Paul Waijman (ZIP code:)

1549. Paige Reckenwald (ZIP code:)

1550. Pamela Pegahi (ZIP code:)

1551. Paola Linares (ZIP code:)

1552. Sharad Davis (ZIP code:)

1553. Joy Weiss (ZIP code:)

Florida, you are not the sole authority on gender care. Please, listen to the guidance of the wider medical community and protect the mental health of transgender, non-binary, and intersex youth by supporting their gender affirming care

1554. MacKenzie Finnegan (ZIP code:)

Trans rights are human rights

1555. Patrice Yang (ZIP code:)

1556. Patrice Harris (ZIP code:)

This shouldn't ever be a discussion. Everyone deserves healthcare including Trans youth.

1557. Patrick Mckee (ZIP code:)

Medical decision belong between a patient and their doctor. Gender affirming care is essential for mental health and wellness.

1558. Patrick Dassow (ZIP code:)

1559. Patti Johnston (ZIP code:)

1560. Pat Zanger (ZIP code:)

Gender-affirming care is part of comprehensive health care which should be available to all without prejudice. Creating a "registry" of anyone undergoing medical treatment violates patient/ doctor

privilege!

1561. Paulette Vélez (*ZIP code:*)

These continuous homophobic and transphobic acts, policies, and laws are despicable.

1562. Rev. Robert Townsend (*ZIP code:*)

1563. Peter Easton (*ZIP code:*)

Support strongly

1564. Penny Cooke (*ZIP code:*)

1565. Laura Perkins (*ZIP code:*)

1566. Peter Lorenzo (*ZIP code:*)

1567. Peter Butzin (*ZIP code:*)

I have already signed the petition as an individual, but am trying to now sign on as the United Church in Tallahassee, for which I serve as its Moderator.

1568. Peter Horstman (*ZIP code:*)

1569. Eleanor Cuallado-Keltsch (*ZIP code:*)

1570. Peyton Byers (*ZIP code:*)

1571. An anonymous signer (*ZIP code:*)

1572. PFLAG Sarasota (*ZIP code:*)

We stand for trans.

1573. Patricia Sardina (*ZIP code:*)

1574. Patricia Moore (*ZIP code:*)

1575. Phillip Carter (*ZIP code:*)

1576. Phoenix Artifex (*ZIP code:*)

Gender affirming care is necessary health care and saves lives

1577. Amber Soler (*ZIP code:*)

1599. Alfredo Olvera (*ZIP code:*)
Signing in support: Dolphin Democrats

1600. Joel Price (*ZIP code:*)

1601. Elisabeth Price (*ZIP code:*)
Treating someone as though they belong to a gender that is not theirs is abuse. Don't do it!

1602. PRISCILLA RICHARDSON (*ZIP code:*)

1603. Frank Mueller (*ZIP code:*)

1604. Prudence Gill (*ZIP code:*)
Protect all of God's children and all of our beautiful incredible ways of being! We have no right to cause harm to anyone just because they are different from earth. God loves all his children, and so should we.

1605. Prue Ricci (*ZIP code:*)

1606. Skye Boyd (*ZIP code:*)
If you do this you're violating your hippocratic oath

1607. Lucas Navarro (*ZIP code:*)

1608. Paul Rafferty (*ZIP code:*)

1609. Otto Norton (*ZIP code:*)

1610. An anonymous signer (*ZIP code:*)

1611. Paul Wolfson (*ZIP code:*)

1612. Katherine Walton-Elliott (*ZIP code:*)
Blocking gender affirming care would be a breach of the hippocratic oath. We know that gender affirming care is incredibly effective at treating gender dysphoria, we know that reversible puberty blockers given in childhood are safe. We also know that without this care trans kids and teens experience massively increased self harm and suicide rates. To block this care being given would be an appalling breach of trust, and as a nurse would force me to chose between what is right for my patients and what medical professional organizations are demanding for political purposes. It would be abhorrent.

1613. Em M (*ZIP code:*)
It is abhorrent that you are even considering this ban seriously. Trans youth exist. They deserve

healthcare. Leave this issue to them, their guardians, and doctors.

1614. Quinn Cowan (*ZIP code:*)

1615. Nat Hemel (*ZIP code:*)

1616. Tiago Quintana (*ZIP code:*)

1617. Rebecca Fiore (*ZIP code:*)

1618. Rachelle DeBevits (*ZIP code:*)

1619. Matthew Raab (*ZIP code:*)

1620. Rachel DiPietro (*ZIP code:*)

1621. Rachel Lumpkins (*ZIP code:*)

1622. Rachel Logan (*ZIP code:*)

1623. Rachel Sallustio (*ZIP code:*)

1624. Rachel Godfrey (*ZIP code:*)

1625. An anonymous signer (*ZIP code:*)

1626. Rachel Bernard (*ZIP code:*)

I support gender care for trans people!!! Ron Desantis is nuts!!!!

1627. Rachle Sullivan (*ZIP code:*)

1628. Patricia Racz (*ZIP code:*)

1629. Santina Lampman (*ZIP code:*)

Gender affirming care has been shown to reduce suicides. Regardless of your "personal" feelings, anything we can do to give kids a better shot at living is great in my book. And at the end of the day. Their gender identity, has no effect on you personally, but a huge impact on them. Let them be them, and give them the care they need between them and their doctors.

1630. Amanda Nguyen (*ZIP code:*)

1631. Rachel Fisher (*ZIP code:*)

1632. Raven Ash (*ZIP code:*)

Trans rights are human rights.

1633. Randee Lefkow (*ZIP code:*)

1634. Rocky Ramirez (*ZIP code:*)

1635. Ashley Hall (*ZIP code:*)

Gender affirming care is life saving and should not get ripped away and doom transgender people to severe depression and suicide. You should be ashamed for even considering removing it.

1636. Krysta Lepinski (*ZIP code:*)

1637. Raven Lyden (*ZIP code:*)

There is no scientific basis for removing gender affirming care from hundreds of people in the state. This care saves and improved lives, and it's removal does nothing for anyone.

1638. Ray Simms (*ZIP code:*)

1639. Ruth Batista (*ZIP code:*)

1640. Ronnie Boerner (*ZIP code:*)

1641. Rebecca Charvet (*ZIP code:*)

Medical care is not about personal beliefs.

Medical care is private between a patient & their medical team.

Appropriate medical care is a human right.

1642. Rachael Huntington (*ZIP code:*)

1643. Rob Wilson (*ZIP code:*)

1644. Rachel Coldbreath (*ZIP code:*)

Trans kids will exist whether you like it or not. The only question is: are you going to help them exist, or make them suffer?

1645. Rebecca Davis (*ZIP code:*)

Stop oppressing and killing Trans people.

1646. Robyn Dawson (*ZIP code:*)

1647. Robyn Dawson (*ZIP code:*)

Stop trans genocide

1713. Erin Williams (ZIP code:)

I sign this to oppose the harmful and dangerous actions of the Florida Board of Medicine based on corrupted and misleading science being used to create rules to annihilate and exterminate transgender children, teens and adults by preventing us from coming into existence.

Trans people have existed as an amazing part of the human adventure in cultures around the world across all of history emerging naturally and independently of one another.

The actions taken by the Florida Board of Medicine are driven whole by greed and politics and hatred.

Accepting myself as trans, now and always, has led me back to spirituality, love and family and healing

I don't have much to fight back with, but I can say my peace for vitriol, hate & corruption of the Florida Board of Medicine ends me. maybe it'll change your minds, maybe not.

But I grew up hearing the living memory of holocaust survivors and soldiers that fought the nazis

AND

I know exactly what kind of people you folks on the Florida Board of Medicine are

1802. Serra Reid (*ZIP code:*)

1803. Susan (*ZIP code:*)

1804. Seth Tigarian (*ZIP code:*)

As a trans person who grew up in Florida, I can tell you that denying trans kids even the most basic care will result in dead trans kids, not cis kids.

1805. Chelsy Almeda (*ZIP code:*)

1806. Theodore Hunter (*ZIP code:*)

1807. Julie Torkomian (*ZIP code:*)

1808. Susan Haines (*ZIP code:*)

1809. Shaquille Davis (*ZIP code:*)

1810. Shalvia Verdell (*ZIP code:*)

Trans youth have a right to self-determination and agency over their own bodies. Taking away gender-affirming care is taking away their right to that agency. It is life-saving care.

1811. Shana Friedman (*ZIP code:*)

1812. shane soria (*ZIP code:*)

1813. Shane Horsman (*ZIP code:*)

Gender affirming care is life saving. Banning it would not protect youth, only harm them.

1814. Elizabeth Bennet (*ZIP code:*)

Gender affirming care IS LIFE SAVING CARE

1815. Shannon Fortner (*ZIP code:*)

Access to affirming care is crucial for. our LGBTQ+ folk. We are trying to stop suicidal attempts and yet we are trying to take access away. This is discrimination in full effect. This is not a choice of red or blue, this about life saving care for our communities. We have come so far and now a political platform is erasing the lives being saved over power.

1816. Shannon Gardner (*ZIP code:*)

1817. Seneca Harberger (*ZIP code:*)

1818. sharon mirabal (*ZIP code:*)

1819. Sheila Allison-Wells (*ZIP code:*)

1820. Phoenix Cantu (*ZIP code:*)

Transgender folks regardless of age are the gender they identify as. For many like my spouse knew who they were when they were children and preventing gender affirming care and not having acceptance for transgender folks has been shown to increase suicide rates. Any legislation against LGBT+ folks is telling people to kill themselves.

1821. Shed Boren (*ZIP code:*)

Let us be guided by the science and not the vitriol

1822. sheila jaffe (*ZIP code:*)

Where are Parental Rights now for their children?

1823. Sheila Gluck (*ZIP code:*)

1824. Sheila Weiss (*ZIP code:*)

1825. Shelley Markus (*ZIP code:*)

1826. Shelley Hill (*ZIP code:*)

1827. Michelle Vallet (*ZIP code:*)

Let trans kids access the care they need to live their best lives. These decisions belong with children and their families. Nobody else.

1828. Shelly Hodgson (*ZIP code:*)

1829. Sheree Rust (*ZIP code:*)

Stop removing healthcare from Americans. LGBTQ+ folks deserve equal protection under the law.

1830. Sherilyn M Adler, Ph.D. (*ZIP code:*)

1831. Aaron Collins (*ZIP code:*)

Trans rights are human rights!!! Trans health care is a basic human right!! Protect trans youth!! Help prevent trans and trans youth suicide!!

1832. Sherry McKee (*ZIP code:*)

1833. Sherry Rogers (*ZIP code:*)

Come to your senses. Medical care should not be adjudicated by bureaucrats.

1834. Jo Shim (*ZIP code:*)

1835. Shimon Cohen (*ZIP code:*)

Trans youth should be supported and not used as political pawns. The health profession has a duty to do no harm. That means providing support for trans youth.

1836. Shirley Herman (*ZIP code:*)

1837. Andrew Hjortshoj (*ZIP code:*)

1838. Alex Bann (*ZIP code:*)

1839. Sue Hurtado (*ZIP code:*)

One day it may be your child or grandchild who may NEED this medical care to save their life. When you know better, do better!

1840. Sidney Torres (*ZIP code:*)

1841. Sidonie McDowell (*ZIP code:*)

1842. Silvia Mantilla (*ZIP code:*)

1843. Heather Simpson (*ZIP code:*)

I am a proud mother of a transgendered child. This policy will hurt my child. Please listen to scientists and parents and physicians and stop.

1844. Katie Rodrigues (*ZIP code:*)

I grew up in a Christian, conservative home, in a Christian, conservative school and, for a time, held Christian, conservative beliefs myself. I was not exposed to the LGBTQ community except for hateful jokes or derogatory comments. Despite all of this, I am still a member of the LGBTQ community. Coming out of that sheltered life and realizing LGBTQ people were just like myself and others I knew, was rattling and it changed me.

LGBTQ youth and adults just want to be happy, healthy and of sound mind.

People who are non-LGBTQ are allowed to get surgery to change their appearance (BBL, boob jobs, Botox) but there's an imaginary line you decide others can't cross?

Denying us access to basic rights regardless of our identity is unethical and morally corrupt.

1845. Michaela Sisitsky (*ZIP code:*)

1846. Sarah Robertson (*ZIP code:*)

It only hurts when care is DENIED. It hurts absolutely NO ONE to allow kids to be themselves. Love will win!!!!!!!!!!!!

2076. Danielle Rendleman (ZIP code:)

I knew I was trans when I was 4, now I'm 30 years old and still struggling to undo the damage that

was done by going through the “wrong” puberty. Transitioning changed my life for the better, allowing me to finally focus on contributing to the world around me. All the actual research shows that acceptance of transitioning among family and peers is suicide prevention, and people are statistically more likely to experience regret for literally every other surgery than any procedure performed on a trans person as a part of that person’s transition. Do you want trans people to be fully-functioning members of society? Because allowing people who experience gender dysphoria to have the option to safely—and privately—transition, is how you’ll accomplish that.

This government mandate telling parents they have no control over the health care decisions for their children is severely misguided. Taking away our right to make health care decisions for our children is a slippery slope that opens the door to more and more incursions into how we raise our children.

Using trans children, of which there are only a tiny number in Florida, doesn't fool me. It's always easiest to set the precedent with "out" groups. That is why, despite not having a trans child, I am 100% aware of and against a government mandate vetoing parental rights over the health care decisions for their children.

Once you've infringed on something so fundamental as the health care decisions for our children, every other parental right is a legitimate target. When did Republicans become the party of government mandates and infringing on parental rights?

I recognize that you are political appointees placed there by the Governor to do his bidding but since he is seriously misguided on how this will play out, I hope that you will save him from himself and re-vote on the Aug 5 decision to take away parent rights, and terminate the rule-making process. Thank you.

2140. Jeffrey Jones (ZIP code:)

While I do not have a trans child, as a parent I am appalled at this attempted government mandate taking away parent's rights to decide the health care for their children. Next you'll be telling us we can't get our children vaccinated or they can't go to co-ed summer camp. Once you've infringed on something so fundamental as the health care of our children, everything else is a legitimate target. When did Republicans become the party of government mandates and infringing on parental rights?

Dear Committee Members,

I believe that all patients with gender dysphoria should be treated with counseling and support until they are adults. Many children have psychological issues and unhappiness. The increase in number of patients recently raises alarm about the etiology of this.

I am concerned that if radical treatment is taken at an early age that is not reversible, we will be sadly disappointed. This present day “fad” of irreversible treatment may turn out to be as regretted as frontal lobotomies in the last century.

Paul A. Vazquez, J.D.
Executive Director
Florida Medical Board

Dear Mr. Vazquez,

I am attaching a detailed report for the Florida Medical Board as you discuss the safety and efficacy of medical interventions for those who experience sex-discordant gender identity, particularly adolescents with gender dysphoria. As you know, much of the public discussion on this issue is filled with unjustified ideological assertions and emotive arguments. The medical profession is called to base care decisions on objective scientific evidence for both safety and efficacy. In many areas of medicine, there is insufficient evidence to make definitive conclusions. In such circumstances, a cautious approach is deemed most prudent. When new experimental treatments are attempted, our profession has established standards for mitigating risk to study subjects. Unfortunately, in the field of gender medicine, ideology and politics have usurped these standard practices. I applaud the Medical Board of the State of Florida for their efforts to consider relative merits and concerns of the affirmative model of care to individuals suffering from gender dysphoria. As needed, I am happy to provide additional information to the board.

Sincerely,

Paul W Hruz MD PhD
Associate Professor of Pediatrics
Associate Professor of Cellular Biology and Physiology

**Expert Physician Report for the
State of Florida's Medical Board Meeting on September 30, 2022**

**PAUL W. HRUZ, M.D., Ph.D.
September 20, 2022**

This report provides information that is essential for the Medical Board of the State of Florida as it considers the best approach for the care of individuals who experience sex-discordant gender identity. For each of my opinions detailed below, I provide relevant published scientific literature and other publicly available information. Copies of cited sources can be provided on request.

- 1. In my opinion, there is a serious lack of quality scientific evidence regarding the safety and efficacy of gender affirming medical interventions for individuals who experience sex discordant gender identity. Use of such medical interventions remains a highly controversial and experimental approach.**

Pediatric patients referred to our practice for the evaluation and treatment of gender dysphoria are cared for by an interdisciplinary team of providers that includes a psychologist and pediatric endocrinologist who have been specifically chosen for this role based upon a special interest and professional knowledge and training in this previously rare patient population. Due to the documented, important, ethical concerns regarding the safety, efficacy, and scientific validity of controversial, unproven, and experimental treatment paradigms, I have not personally engaged in the delivery of gender affirming medical interventions to children with gender dysphoria. Given the unproven long-term benefits and the well-documented risks and harms of “transitioning” children, I decline to participate in such experimental treatments until the science has proven that the relative risks and benefits of this approach warrant such procedures.

My decision is strengthened by the knowledge that the vast majority of children who report gender dysphoria will, if left untreated, grow out of the problem — a natural coping-developmental process — and willingly accept their biological sex. Despite differences in country, culture, decade, follow-up length and method, multiple studies have come to a remarkably similar conclusion: very few gender dysphoric children still want to transition by the time they reach adulthood. Many turn out to have been struggling with sexual orientation issues rather than sex discordant “transgender” identity. The exact number of children who experience realignment of gender identity with biological sex by early adult life varies by study.

Estimates within the peer reviewed published literature range from 50-98%, with most reporting desistance in approximately 85% of children prior to the widespread adoption of the “gender affirmation only” approach. Thus, desistance (*i.e.*, the child accepting their natal, biological sex identity and declining “transitioning” treatments) is the outcome for the vast majority of affected children who are not actively encouraged to proceed with sex-discordant gender affirmation.

Since there are no reliable assessment methods for identifying the small percentage of children with persisting sex-gender identity discordance from the vast majority who will accept their biological sex, and since puberty blocking treatments, hormone transition treatments, and surgical transition treatments are all known to have potentially life-long devastating, negative effects on patients, I and many colleagues view it as unethical to treat children with an unknown future by using experimental, aggressive, and intrusive gender affirming medical interventions.¹

2. Peer-reviewed, published research in credible science-medical journals.

My opinions as detailed in this report are based upon my knowledge and direct professional experience in the subject matters discussed. The materials that I have relied upon are the same types of materials that other experts in my field of clinical practice rely upon when forming opinions on the subject including hundreds of published, peer reviewed scientific research (and professional) articles.

As discussed in detail in this report, the extant published literature on the use of puberty blockers, cross-sex hormones and gender affirming surgeries are based, almost entirely, upon studies with major methodological limitations.²

This includes:

- Significant recruitment biases including internet-based convenience sampling;

¹ See Cantor, *Do Trans-Kids stay Trans- When The Group Up?*, Sexology Today, available at http://www.sexologytoday.org/2016/01/do-trans-kids-stay-trans-when-they-grow_99.html (providing summary of multiple research studies); *see also infra*, publications reviewed in detail below.

² See Hruz, *Deficiencies in Scientific Evidence for Medical Management of Gender Dysphoria*, Linacre Q 87(1): 34-42, doi: 10.1177/0024363919873762 (2020).

- Relatively small sample sizes for addressing a condition that is likely to be multifactorial;
- Short term follow-up;
- Lack of randomization to different treatment arms;
- Failure to even consider alternate hypotheses;
- Failure to include proper control groups and, in many studies *no* control group at all;
- Reliance on cross sectional sampling that may identify associations, but *cannot* establish causal relationships between intervention and outcome;
- A high rate of patients lost to follow up in longitudinal analyses which is relevant to questions of regret, desistance and completed suicide;
- Biased interpretation of study findings with a goal of validating *a priori* conclusions rather than seeking evidence to disprove the null hypothesis;
- Ignoring starkly contradictory research documenting the lack of effectiveness of “transitioning” procedures, the low quality of research in this area, and the ongoing contentions and disagreements over this highly controversial, experimental medical field.

3. Basis for my opinions.

My opinions documented in this report are based on my:

- (1) knowledge, training, and clinical experience in caring for thousands of patients over many years;
- (2) detailed methodological reviews of hundreds of relevant peer-reviewed science publications;
- (3) consults, discussions, and team analyses with colleagues and other experts in the field, including attendance and participation in various professional conferences;
- (4) publications in peer reviewed scientific journals;
- (5) editorial work for peer reviewed scientific journals; and
- (6) peer reviewed research grant receipt and review work.

The materials I have relied upon in preparing this report are the same types of materials that experts in my field of study typically and regularly rely upon when forming opinions on these subjects.

In addition to peer reviewed published research articles related to gender affirming medical interventions (see specific citations below), I also cite a wide variety of peer reviewed, published, scientific journal evidence documenting the recent, very public, disclosures of the multiple and serious methodological errors, failures, and defects of “transitioning treatment” research. Specific examples include:

- *The Branstrom Long-Term Treatment Outcome Study*. The historic Branstrom report is a peer reviewed, published, scientific journal article that documents a long-term treatment (10+ years) outcome research investigation testing the effects of hormonal and surgical “transitioning” treatments on patients. This historic research found no reliable benefits from these disfiguring-sterilizing “treatments,” as well as evidence suggesting *increased* suicide attempts and anxiety disorders following the “gender transitioning” treatments. In addition, detailed methodological critiques discovered significant research errors by the authors that appear to support the investigative theory that the authors had initially attempted to manipulate and misreport the findings of the study.³ The authors ultimately recanted their initial misreporting and agreed that their study produced no reliable evidence of benefits for gender reassignment hormone and surgical treatments. This historic investigation has helped to generate a profound collapse of support for these experimental procedures across Europe.⁴

³ See, *infra* for detailed notes and review with multiple citations.

⁴ See SEGM, *Correction of a Key Study: No Evidence of “Gender-Affirming” Surgeries Improving Mental Health*, available at https://segm.org/ajp_correction_2020 (Aug. 30, 2020; last accessed June 29, 2021); Van Mol et al., *Gender-Affirmation Surgery Conclusion Lacks Evidence*. *Am. J. Psych.* 177(8): 765-66 (2020).

- *The National Finland Review Recommending Suspension of Transitioning Treatments for Children as they Remain Experimental and of Uncertain Benefit.* A National Science Review in Finland carefully examined all relevant science and suspended transition treatments for minors under age 16.⁵ This official peer review recommends that psychotherapy should be the first line of treatment for gender dysphoric youth.⁶ “Cross-sex identification in childhood, even in extreme cases, generally disappears during puberty . . . The first-line treatment for gender dysphoria is psychosocial support and, as necessary, psychotherapy and treatment of possible comorbid psychiatric disorders . . . No gender confirmation surgeries are performed on minors . . . Potential risks of GnRH therapy include disruption in bone mineralization and the as yet unknown effects on the central nervous system . . . there are no medical treatments [for transitioning] that can be considered evidence-based . . . In cases of children and adolescents, ethical issues are concerned with the natural process of adolescent identity development, and the possibility that medical interventions may interfere with this process. It has been suggested that hormone therapy (e.g., pubertal suppression) alters the course of gender identity development; i.e., it may consolidate a gender identity that would have otherwise changed in some of the treated adolescents. The reliability of the existing studies with no control groups is highly uncertain, and because of this uncertainty, no decisions should be made that can permanently alter a still-maturing minor’s mental and physical development . . . A lack of recognition of co-morbid psychiatric disorders common among gender-dysphoric adolescents can also be detrimental. Since reduction of psychiatric symptoms

⁵ See SEGM, *One Year Since Finland Broke with WPATH “Standards of Care”* available at: https://segm.org/Finland_deviates_from_WPATH_prioritizing_psychotherapy_no_surgery_for_minors (July 2, 2021).

⁶ See Palveluvalikoima, *Recommendation of the Council for Choices in Health Care in Finland (PALKO/COHERE Finland): Medical Treatment Methods for Dysphoria Related to Gender Variance In Minors* (2020).

cannot be achieved with hormonal and surgical interventions, it is not a valid justification for gender reassignment. A young person's identity and personality development must be stable so that they can genuinely face and discuss their gender dysphoria, the significance of their own feelings, and the need for various treatment options. For children and adolescents, these factors are key reasons for postponing any interventions until adulthood... In light of available evidence, gender reassignment of minors is an experimental practice.”⁷

- *Sweden's Flagship Karolinska Hospital Suspends Transitioning Treatments for Children Under 16 and Requires Research Oversight for Patients Under 18.*

In Sweden, the world-renowned Karolinska Hospital reviewed the current research and suspended pediatric gender transitions for patients under 16 outside of experimental, monitored clinical trials settings as of May 2021. Treatment will focus on psychotherapy and assessment.⁸ The “Dutch protocol” for treating gender dysphoric minors has been discontinued over concerns of medical harm and uncertain benefits. This new Swedish policy is consistent with Finland's recently revised guidelines and changes in England's policies as well as the Arkansas legislation in the U.S. All have been changed to prioritize psychological interventions and social support in contrast to medical interventions, particularly for youth with no young childhood history of gender dysphoria (presently the most common patient presentation).⁹

⁷ See *id.*; *supra*, note 5.

⁸ See SEGM, *Sweden's Karolinska Ends All Use of Puberty Blockers and Cross-Sex Hormones for Minors Outside of Clinical Studies*, available at: https://segm.org/Sweden_ends_use_of_Dutch_protocol (May 5, 2021); see also, Karolinska Policy Change K2021-3343, translation available at: <https://segm.org/sites/default/files/Karolinska%20Policy%20Change%20K2021-3343%20March%202021%20%28English%2C%20unofficial%20translation%29.pdf> (March 2021); Karolinska Guideline K2021-4144, translation available at: <https://segm.org/sites/default/files/Karolinska%20Guideline%20K2021-4144%20April%202021%20%28English%2C%20unofficial%20translation%29.pdf> (April 2021).

⁹ See *id.*

- A Sweden National Review Documents “Low Quality Research” in this Experimental and Controversial Field.¹⁰ “This report was commissioned by the Swedish government and is a scoping review of the literature on gender dysphoria in children and adolescents. The report can be a basis for further evaluation of risk of bias and evidence.” The Swedish national review reported: “No relevant randomized controlled (treatment outcome) trials in children and adolescents were found.” The review also reported “Conclusions:”
 - We have not found any scientific studies which explains the increase in incidence in children and adolescents who seek the health care because of gender dysphoria.
 - We have not found any studies on changes in prevalence of gender dysphoria over calendar time, nor any studies on factors that can affect the societal acceptance of seeking for gender dysphoria.
 - There are few studies on gender affirming surgery in general in children and adolescents and only single studies on gender affirming genital surgery.
 - Studies on long-term effects of gender affirming treatment in children and adolescents are few, especially for the groups that have appeared during the recent decennium . . .
 - Almost all identified studies are observational, some with controls and some with evaluation before and after gender affirming treatment. No relevant randomized controlled trials in children and adolescents were found.
 - We have not found any composed national information from Sweden on: [] the proportion of those who seek health care for gender dysphoria that get a formal diagnosis [, nor] the proportion starting endocrine treatment to delay puberty [, nor] the proportion starting gender affirming hormonal treatment [, nor] the proportion subjected to different gender affirming surgery.
- UK Researchers, Courts, and Other Reviewers Highlighted the Paucity of Quality Research, Limitations, Defects, and Risks in the Still Experimental, Controversial “Gender Transitioning” Treatment Field. The British official

¹⁰ See Sweden SBU Policy Review, *Gender Dysphoria in Children and Adolescents: An Inventory of the Literature*, SBU Policy Support No. 307, available at: <https://www.sbu.se/307e> (2019).

medical review office (the National Institute of Health and Care Excellence, or “NICE”) published reports on transitioning science.¹¹ An official review found, “[t]he evidence for using puberty blocking drugs to treat young people struggling with their gender identity is ‘very low.’” NICE said existing studies of the drugs were small and “subject to bias and confounding.” The assessment of the evidence into the drugs was commissioned by NHS England. It is part of a review into gender identity services for children and young people.¹² The NICE review noted it was difficult to draw conclusions from existing studies because of the way they had been designed. They were “all small” and did not have control groups, which are used to directly compare the effect of different treatments. There were other issues with the studies too, such as not describing what other physical and mental health problems a young person may have alongside gender dysphoria.

The British NICE service also reviewed the evidence base for cross-sex hormones.¹³ The review found the evidence of clinical effectiveness and safety of cross-sex hormones was also of “very low” quality, explaining “[a]ny potential benefits of gender-affirming hormones must be weighed against the largely unknown long-term safety profile of these treatments in children and adolescents with gender dysphoria.” Both documents were prepared by NICE in October 2020 and will now help inform Dr. Hilary Cass's independent review into NHS gender identity services for children and young people.¹⁴

This British study conclusion noted: “We found no evidence of change (no

¹⁴ See also Carmichael et al., *Short-Term Outcomes of Pubertal Suppression in a Selected Cohort of 12 to 15 Year Old Young People with Persistent Gender Dysphoria in the UK*, medRxiv, doi: 10.1101/2020.12.01.20241653 (published online Dec. 2, 2020).

improvement) in psychological function with GnRHa treatment as indicated by parent report (CBCL) or self-report (YSR) of overall problems, internalizing or externalizing problems or self-harm....”

Puberty blockers used to treat children aged 12 to 15 who have severe and persistent gender dysphoria had no significant effect on their psychological function, thoughts of self-harm, or body image, a study has found. However, as expected, the children experienced reduced growth in height and bone strength by the time they finished their treatment at age 16.¹⁵ Regarding the UK’s Tavistock and Portman NHS Trust’s Gender Identity Development Service’s experimental trial of puberty blockers for early teenagers with gender dysphoria, Oxford’s Professor Michael Biggs wrote, “To summarize, GIDS launched a study to administer experimental drugs to children suffering from gender dysphoria . . . After a year on GnRHa [puberty blockers] children reported greater self-harm, and girls experienced more behavioral and emotional problems and expressed greater dissatisfaction with their body—so puberty blockers actually exacerbated gender dysphoria.”¹⁶

As Griffin et al. discussed, “[a]s there is evidence that many psychiatric disorders persist despite positive affirmation and medical transition, it is puzzling why transition would come to be seen as a key goal rather than other outcomes, such as improved quality of life and reduced morbidity. When the phenomena related to identity disorders and the evidence base are uncertain, it might be wiser for the profession to admit the uncertainties.” In addition,

¹⁶ See also Griffin et al., *Sex, Gender and Gender Identity: A Re-Evaluation of the Evidence*, BJPsych Bulletin 45(5):291-99, doi:10.1192/bjb.2020.73 (2021).

Griffin et al. wrote: “Transgender support groups have emphasized the risk of suicide. After controlling for coexisting mental health problems, studies show an increased risk of suicidal behaviour and self-harm in the transgender population, although underlying causality has not been convincingly demonstrated.”¹⁷ In sum, political activists and too many providers have used a fear of suicide to push experimental unproven, hazardous treatments.

- *Review of the World Professional Association for Transgender Health’s (WPATH) Controversial and Outdated Treatment “Standards”*. A 2021 review found WPATH standards “incoherent.”¹⁸ Both WPATH and Endocrine Society guidelines have recently been assessed for quality by a systematic review, which found them to be of low quality. Specific to WPATH, the reviewers noted the difficulty of even extracting clear recommendations, describing the WPATH guidelines as “incoherent.” Standards of care should provide practitioners with evidence-based standards by which they may reliably inform the patient of projected outcomes and do so with a known error rate. Such data is the starting point for obtaining informed consent, which is not provided by either of these guidelines. The WPATH current version 7 standards violate minimal ethical and quality standards set by national organizations that review and post medical treatment standards including the National Academy of Medicine. WPATH board members suffer from serious financial conflicts of interest (e.g., virtually all WPATH BD members obtain most of their personal income from performing the very same “treatments” they are supposed to evaluate objectively). In addition, the minimal length of time treatment standards must be refreshed is every five years and WPATH version 7 is now nearly *ten* years old and thus far past its useful “shelf life.”

¹⁷ See Marshall et al., *Non-Suicidal Self-Injury and Suicidality in Trans People: A Systematic Review of the Literature*, Int. Rev. Psychiatry 28(1):58–69, doi: 10.3109/09540261.2015.1073143 (2016).

¹⁸ See Dahlen et al., *International Clinical Practice Guidelines for Gender Minority/Trans People: Systematic Review and Quality Assessment*, BMJ Open, 11(4):e048943, doi: 10.1136/bmjopen-2021-048943 (2021).

Given that the most current research¹⁹ are sharply critical of the ongoing failure of random control trials and the generally very low-quality evidence in this controversial field (the 10 year old WPATH version 7 standards have aged very poorly indeed and should be viewed as hazardous to patients.)

- *The UK High Court in the Bell Litigation – after hearing from multiple international expert witnesses – found transitioning treatments to be “experimental”.* In an internationally reported case, the High Court of London ruled these “gender transitioning” treatments were “experimental,” ordering protections for children who could not consent to such hazardous treatments given the lack of evidence of benefits and clear evidence of risks (*e.g.*, sterilization).

The court’s order that judges should oversee the consent of minors on a case-by-case basis was overturned on appeal — as the appeals court returned consent duties to medical providers — but left intact the trial court’s opinion that the evidence produced during the hearing demonstrated “gender transitioning treatments” remain controversial with serious risks of irreversible harm (including sterilization of the patient) and of unproven benefit.²⁰

“Children under 16 with gender dysphoria are unlikely to be able to give informed consent to undergo treatment with puberty-blocking drugs, three High Court judges have ruled . . . Given the long-term consequences of the clinical interventions at issue in this case, and given that the treatment is as yet innovative and experimental, we recognize that clinicians may well regard these as cases where the authorization of the court should be sought prior to commencing the clinical treatment . . . The judges also pointed to the lack of evidence about the long-term effects of puberty blockers.”²¹

¹⁹ Including, *e.g.*, the long-term Branstrom and Hisle-Gorman treatment outcome studies, the British NICE review, the Sweden review, the Finland review, the British Dr. Cass national review and others.

²¹ *Id.*

- *The British Independent Review of Gender Identity Services for Children and Young People: Interim Report by National Expert, Dr. Hilary Cass, M.D., was Published in February 2022.* The Dr Cass interim review concluded that “Evidence on the appropriate management of children and young people with gender incongruence and dysphoria is inconclusive both nationally and internationally.” Dr. Cass notes that “There is lack of consensus and open discussion about the nature of gender dysphoria and therefore about the appropriate clinical response.”²²
- *The Society for Evidence Based Gender Medicine (SEGM) Review Summarizes the Health Risks of Transitioning.* Consistent with changes in policy in Sweden, Finland, England, and Arkansas — due to much negative research findings over recent years — SEGM, a collection of national and international experts in the field, published a research summary documenting the serious health risks of “transitioning treatments” compared to the well-known lack of evidence of reliable benefits for such treatments.²³
- *The Cochrane Review Found Insufficient Evidence of Benefits.* The widely respected Cochrane Review examined hormonal treatment outcomes for male-to-female transitioners over 16 years. They found “insufficient evidence to determine the efficacy or safety of hormonal treatment approaches for transgender women in transition.” It is remarkable that decades after the first transitioned male-to-female patient, quality evidence for the benefit of transitioning is still lacking.²⁴

²² See The Cass Review, *Interim Report*, available at: <https://cass.independent-review.uk/publications/interim-report/>).

4. **A March 2021 study – with the largest sample yet – is consistent with the new direction for Finland, Sweden, the UK, and France – show that most young gender dysphoric children, if left alone, grow out of the problem with no medical intervention.²⁵**

“Watchful waiting” is the recommended treatment: in the past, 67% of children meeting the diagnostic criteria for gender dysphoria no longer had the diagnosis as adults, with an even higher 93% rate of natural resolution of gender-related distress for the less significantly impacted cases.²⁶

5. **Experts are uniformly concerned with, and baffled by, the unexplained rapid and extreme demographic shifts in patient age and sex. Such shifts produce serious concerns about whether decades of previous research—done on a very different population group—even apply to the current patient cohort.**

For decades, transgender patients were mostly older adults or very young boys. Over the last few years, a tsunami of teenaged girls has flipped the demographics of transgender patients—now up to 7 to 1 teen girls. Many experts have noted that the previous research on trans patients cannot be relied upon when the patient group has so rapidly and mysteriously been transformed. In sum, the newly presenting cases are vastly overrepresented by adolescent females, the majority of whom also have significant mental health problems and neurocognitive comorbidities such as autism-spectrum disorder or ADHD.²⁷ The most recent evidence supports the emerging theory of social

²⁵ See Devita et al., *A Follow-Up Study of Boys with Gender Identity Disorder*, *Frontiers in Psychiatry* doi: 10.3389/fpsy.2021.632784 (March 2021).

²⁷ See de Graaf & Carmichael, *Reflections on Emerging Trends in Clinical Work with Gender Diverse Children and Adolescents*, *Clin. Child Psychology & Psychiatry*, 24(2): 353-64 (2018).

contagion as estimates of sex-discordant gender identity are rocketing upwards from 1 in 10,000 to “the number of U.S. transgender-identified youth may be as high as 9%.”²⁸

This unexplained, radical transformations of demographics does not happen in actual illnesses (cancer, heart disease, anxiety disorders, etc.), but is tragically consistent with previous mental health system disasters such as the once very rare “multiple personality disorder” and “recovered repressed memory” patients that radically increased in the 1990s.

Dr. Thomas Steensma, a prominent investigator of the Dutch protocol—the original model for transitioning treatments—has recently noted, “[w]e don’t know whether studies we have done in the past can still be applied to this time,” specifically because of the unexplained surge in female adolescents reporting gender dysphoria. “Many more children are registering, but also of a different type . . . Suddenly there are many more girls applying who feel like a boy . . . now there are three times as many females as males.” He concluded with the warning that “[w]e conduct structural research in the Netherlands. But the rest of the world is blindly adopting our research.”²⁹

6. Examples of limited, low quality, and defective research.

The hazards of making treatment recommendations based on studies with major methodological weaknesses can be readily seen by considering representative studies used by advocates of medical gender affirmation to justify this approach. For example:

- The study by De Vries and colleagues³⁰ is often cited to support longitudinal evidence of benefit from pubertal blockade. Although improvements in mood were observed and changes in the risk of behavioral disorders with pubertal

²⁸ See Kidd et al., *Prevalence of Gender-Diverse Youth in an Urban School District*, *Pediatrics* 147(6):e2020049823, doi: 10.1542/peds.2020-049823 (2021).

²⁹ See Tetelepta, *More Research is Urgently Needed into Transgender Care for Young People*: “Where Does the Large Increase of Children Come From?” AD, translation available at: <https://www.voorzij.nl/more-research-is-urgently-needed-into-transgender-care-for-young-people-where-does-the-large-increase-of-children-come-from/> (Feb. 27, 2021).

³⁰ de Vries et al., *Puberty Suppression in Adolescents with Gender Identity Disorder: A Prospective Follow-Up Study*, *J. Sex, Med.* 8(8):2276-83, doi: 10.1111/j.1743-6109.2010.01943.x (2011).

blockade were found over baseline, this study had no control group. Thus, the authors were unable to determine the basis of this improvement. The authors acknowledge that psychological support or other reasons may have contributed to (or wholly caused) this observation. It is also important to note that gender dysphoria itself *did not diminish* in study subjects, and there were *no changes* in body image-related distress.

- The study by Turban and colleagues³¹ is often cited as proof that pubertal blockade prevents suicide in transgender youth. However, this study used an unreliable, biased sampling methodology. As stated in the paper, the authors considered “a cross-sectional online survey of 20,619 transgender adults aged 18 to 36 years” from the 2015 U.S. Transgender Survey. This was an online survey of transgender and “genderqueer” adults recruited from trans-friendly websites. Among the many problems with this sampling methodology, there is *no* evidence of study subject identities, *no* way to assess for potential false subjects, and *no* medical diagnosis for entry. *No causation can be determined from this retrospective, cross-sectional design.* Furthermore, the study failed to even assess desisters and regretters. Turban claimed that desisters and regretters would “not be likely” in this study group, which also only included adults. Thus, the study “does not include outcomes for people who may have initiated pubertal suppression and subsequently no longer identify as transgender.”

Turban’s misleading claim of lower suicidal ideation for treated patients excluded the most seriously mentally ill patients that would have been *denied* affirmation treatment. Those who received treatment with pubertal suppression, when compared with those who wanted pubertal suppression but did not receive it, had lower odds of lifetime suicidal ideation (adjusted odds ratio = 0.3; 95% confidence interval = 0.2– 0.6). In Table 3 of the paper, under

³¹ Turban et al., *Pubertal Suppression for Transgender Youth and Risk of Suicidal Ideation*, Pediatrics 145(2):e20191724, doi: 10.1542/peds.2019-1725 (2020).

“Suicidality (past 12 months)” reductions for suppressed group vs. non-suppressed were seen for ideation (50.6% vs. 64.8%) and “ideation with plan” (55.6% vs. 58.2%). However, it is essential to note that suicidal “ideation with plan and suicide attempt” for the hormone suppressed group, in raw numbers, *increased* after treatment to 24.4% vs. 21.5% for the “non-treatment group.”

The most clinically significant result in this study — that Affirmation Treatments *did not prevent serious suicide attempts* — was *improperly and/or unethically ignored by the authors*. “Suicide attempts resulting in inpatient care” = 45.5% for suppression groups vs. 22.8% for those who did not receive pubertal suppression. Although the result of increased suicide attempts did not reach “statistical significance”, the clinical significance of this finding cannot be ignored. It would be most reasonable to conclude from an observation of 45% attempted suicide requiring hospitalization in the treated arm that the intervention was unsuccessful in improving health. Turban et al. ignored their own findings that a history of puberty suppression was associated with a persistence of serious suicide attempts. In sum, the Turban 2020 Pediatrics study, based on an unverified U.S. Transgender Online Survey, tells us little about the effects of puberty suppression on children with gender dysphoria.³²

- The 2021 study of Bustos et al.³³ attempts to provide a systematic review of 27 observational or interventional studies that report on regret or detransition following gender-transition surgeries. A total of 7,928 subjects were included in their meta-analysis. The authors concluded that only 1% or less of those who had gender-transition surgeries expressed regret. It is important to

³² See Biggs, *Puberty Blockers and Suicidality in Adolescents Suffering from Gender Dysphoria*, Arch. Sex. Behav. 49:2227-29, doi: 10.1007/s10508-020-01743-6 (2020); and the multiple Letters to the Editor that criticized the multiple methodological errors in this study, available at: <https://pediatrics.aappublications.org/content/145/2/e20191725/tab-e-letters#re-pubertal-suppression-for-transgender-youth-and-risk-of-suicidal-ideation>.

³³ See Bustos et al., *Regret After Gender-affirmation Surgery: A Systematic Review and Meta-analysis of Prevalence*, Plast. Reconstr. Surg. Global Open 9(3):e3477, doi: 10.1097/GOX.0000000000003477 (2021).

understand the serious methodological limitations and high risk of bias contained within the analysis in the 2021 Bustos et al. study.³⁴ This includes failure to include major relevant studies addressing this question,³⁵ inaccurate analysis within one of the studies considered,³⁶ and the general lack of controlled studies (thus no causal conclusions are possible), incomplete and generally short-term follow-up, large numbers of lost subjects, and lack of valid assessment measures in the published literature addressing this question. As noted by Expósito-Campos & D'Angelo (2021),³⁷ moderate to high risk of bias was present in 23 of the 27 studies included in the analysis. Furthermore, 97% of subjects analyzed were found within studies deemed to be of fair to poor scientific quality. Thus, this study cannot be used as strong support for the contention that regret is rare.

- The 2018 paper by Wiepjes et al.³⁸ is a retrospective review of records from all patients of the Center of Expertise on Gender Dysphoria gender clinic in Amsterdam from 1972-2015. While the study appears to report on the regret rates among a large cohort of adolescents (812) and children (548), regret is only reported for children and adolescents who had undergone gonadectomy once over 18 years of age. Of the adolescents, 41% started puberty suppression. Of those who started GnRH agonists, only 2% stopped this intervention (meaning that 98% of those who started puberty suppression progressed to cross-sex hormone therapy). An additional 32%, having already completed puberty, started cross-sex hormone therapy without use of a GnRH agonist. Classification of regret was oddly restricted, requiring physician

³⁴ See Expósito-Campos & D'Angelo, *Letter to the Editor: Regret after Gender-Affirmation Surgery: A Systematic Review and Meta-analysis of Prevalence*, *Plast. Reconstr. Surg. Global Open* 9(11): e3951, doi: 10.1097/GOX.0000000000003951 (2021).

³⁵ See Dhejne et al., *An Analysis of All Applications for Sex Reassignment Surgery in Sweden, 1960-2010: Prevalence, Incidence, and Regrets*, *Arch. Sex. Behav.* 43(8):1535-45 (2014).

³⁶ Wiepjes et al., *The Amsterdam Cohort of Gender Dysphoria Study (1972-2015): Trends in Prevalence, Treatment, and Regrets*, *J. Sex. Med.* 15(4):582-90, doi: 10.1016/j.jsxm.2018.01.016 (2018).

³⁷ *Supra*, note 31.

³⁸ *Supra*, note 33.

documentation of patient verbalized regret after gonadectomy and start of sex-concordant hormones to treat the iatrogenic hypogonadism. This means there are significant limitations to the conclusions that can be drawn from 2018 paper by Wiepjes et al. There is no discussion in this paper regarding adolescent regret of use of puberty blockers, cross-sex hormones, or mastectomies. Importantly, 36% of patients were lost to follow-up. This is notable given that gonadectomy iatrogenically induces the pathologic state of primary hypogonadism. Affected patients have a lifelong dependency for exogenously administered sex-steroid hormones, and thus an acute need for ongoing follow-up. The number of lost subjects who experienced regret or completed suicides is simply unknown, a serious defect as most patients with “regret” are expected to just walk away and thus rarely come back to the clinic and express regrets to anyone much less the physician who “transitioned” them. It is also significant that the average time to regret was 130 months — far longer than virtually all transitioning studies followed patients. The authors themselves acknowledge that it may be too early to predict regret in patients who started hormone therapy in the past 10 years.

- The 2021 study by Narayan et al.³⁹ examines anonymous survey results from 154 surgeons affiliated with WPATH. The response rate for this survey was 30%. Of the respondents, 57% had encountered patients with surgical regret. It is important to recognize that this study was specifically directed toward patients who had undergone surgical transition. Acknowledged biases of this study included selection bias, recall bias, and response bias. This type of study cannot accurately identify the prevalence in the transgender population as a whole and is particularly limited in the ability to assess potential for regret in the pediatric population.

³⁹ Narayan et al., *Guiding the Conversation-Types of Regret After Gender-Affirming Surgery and Their Associated Etiologies*, Ann. Translational Med. 9(7):605, doi: 10.21037/atm-20-6204 (2021).

- The 2018 Olson-Kennedy paper⁴⁰ presents the results of a survey of biologically female patients with male gender identity at the lead author's institution using a novel rating system for "chest dysphoria" created by the study authors. There were an equal number (68) of nonsurgical and post-surgical subjects surveyed. Those who had undergone bilateral mastectomies were reported to have less chest dysphoria than those who did not receive this intervention. Limitations of this study include convenience sampling of nonsurgical study subjects with high potential for selection bias, cross-sectional design (*e.g.*, thus no causal conclusions are possible), and lack of validation of the primary outcome measure. Test validation is particularly relevant in assessing adolescent questionnaires due to a variety of cognitive and situational factors in this population.⁴¹ Rigorous validation methods have been previously used in several other established questionnaires addressing adolescent self-perception.⁴² As previously noted, this study cannot provide information about a causal relationship between the intervention and outcome observed.
- The 2021 Almazan study⁴³ attempts to address mental health outcomes in relation to gender-transition surgery. As previously noted, this study relies upon data from the highly unreliable 2015 U.S. Transgender Survey. Limitations and weaknesses of this survey tool include convenience sampling, recruitment of patients through transgender advocacy organizations, demand

⁴⁰ Olson-Kennedy et al., *Chest Reconstruction and Chest Dysphoria in Transmasculine Minors and Young Adults: Comparisons of Nonsurgical and Postsurgical Cohorts*, JAMA Pediatr. 172(5):431–36, doi: 10.1001/jamapediatrics.2017.5440 (2018).

⁴¹ See Brener et al., *Assessment of Factors Affecting the Validity of Self-Reported Health-Risk Behavior among Adolescents: Evidence from the Scientific Literature*, J. Adolesc. Health 33(6):436–57, doi: 10.1016/s1054-139x(03)00052-1 (2003).

⁴² See Palenzuela-Luis et al., *Questionnaires Assessing Adolescents' Self-Concept, Self-Perception, Physical Activity and Lifestyle: A Systematic Review*, Children (Basel) 9(1):91, doi: 10.3390/children9010091 (2022).

⁴³ Almazan & Keuroghlian, *Association Between Gender-Affirming Surgeries and Mental Health Outcomes*, JAMA Surgery 156(7):611–18, doi: 10.1001/jamasurg.2021.0952 (2021).

bias (a.k.a. the good subject effect), a high number of respondents who reported having not transitioned medically or surgically (and reported no desire to do so in the future), and several other serious data irregularities. One notable data irregularity was that a high number of respondents reported that their age was exactly 18 years — a highly unlikely result indicting fraudulent responses on the anonymous “survey” where no actual, living respondent was ever seen, heard, or evaluated. As noted by D’Angelo and colleagues, these irregularities raise serious questions about the reliability of all USTS data⁴⁴ and therefore, the reliability of conclusions based on that data.

- The paper by Mehringer⁴⁵ provides a summary of qualitative interviews with 30 transmasculine youth (biological females who identify as men) with comparison between those who underwent bilateral mastectomy (n=14) and those who did not receive this intervention (n=16). Mean time from surgery was only 19 months. No validated objective measures were used to assess mental health. There are numerous potential confounding variables (*e.g.*, psychological co-morbidities, testosterone exposure, family dynamics) that could be responsible for the subjective perceptions of the study subjects. As a cross-sectional survey at a single center, the study methodology cannot establish a causal relationship between intervention and outcome. At best, the study can be used for hypothesis generation. It does not establish the efficacy of this approach, nor does it consider whether alternate approaches could achieve the desired outcome.

⁴⁴ D’Angelo et al., *One Size Does Not Fit All: In Support of Psychotherapy for Gender Dysphoria*, Arch. Sex. Behav., 50(1):7–16, doi: 10.1007/s10508-020-01844-2 (2021).

⁴⁵ Mehringer et al., *Experience of Chest Dysphoria and Masculinizing Chest Surgery in Transmasculine Youth*, Pediatrics 147(3):e2020013300, doi: 10.1542/peds.2020-013300 (2021).

- The study by Julian et al.⁴⁶ is also often used as evidence of the efficacy of gender affirming surgery. This study is an internet based cross sectional survey of 684 transgender youth (mean age 16 years) who reported having "chest dysphoria" with 89% (n=608) reporting use of chest binding and 11% (n=76) who did not engage in this practice. The study utilized the non-validated chest dysphoria scale described above for the 2018 Olson -Kennedy study. This study methodology has high potential for recruitment bias. Furthermore, as a cross-sectional study, it cannot establish causal relationships in study parameters. Since it addressed breast binding and not surgery, it does not provide data on the safety and efficacy of bilateral mastectomies in gender dysphoric youth.
- The study by Sood et al.⁴⁷ is yet another study that is used to support treatment efficacy. This is a single cite cross-sectional survey of 156 adolescent female subjects who completed the unvalidated chest dysphoria rating scale of Olsen-Kennedy described above. The study reports an association between report of chest dysphoria and the presence of anxiety and depression. As noted above, this study cannot establish a causal relationship between these study parameters. Furthermore, it does not address whether or not gender-affirming surgery (specifically bilateral mastectomy) is safe or effective in resolving associated psychological distress.

7. There are major and highly significant differences between male and female responses to many drugs, including sex hormones.⁴⁸

⁴⁶ Julian et al., *The Impact of Chest Binding in Transgender and Gender Diverse Youth and Young Adults*, J. Adolesc. Health 68(6):1129-34, doi: 10.1016/j.jadohealth.2020.09.029 (2021).

⁴⁷ Sood et al., *Association of Chest Dysphoria with Anxiety and Depression in Transmasculine and Nonbinary Adolescents Seeking Gender-Affirming Care*, J. Adolesc. Health 68(6):1135-41, doi: 10.1016/j.jadohealth.2021.02.024 (2021).

⁴⁸ See, e.g., Madla et al., *Let's Talk About Sex: Differences in Drug Therapy in Males and Females*, Adv. Drug Deliv. Rev. 175:113804, doi: 10.1016/j.addr.2021.05.014 (2021).

Giving estrogen to a biological male is not equivalent to giving the same hormone to a biological female. Likewise, giving testosterone to a biological female is not equivalent to giving the same hormone to a biological male.⁴⁹ Differences are not limited to pharmacokinetic effects but are present even at the cellular level.⁵⁰ Failure to acknowledge these differences can have tragic consequences. For example, in addition to the inherent sterilizing effect of cross-sex hormone administration, non-physiological levels of estrogen in males has been shown to increase the risk of thromboembolic stroke above the incidence observed in females.⁵¹

8. Biological basis of sex.

Reliance upon external phenotypic expression of primary sexual traits is a highly accurate, reliable, and valid means to assign biologic sex. In over 99.9% of cases, this designation will correlate with internal sexual traits and capacity for normal biologic sexual function. Sex is therefore not “assigned at birth” but is rather recognized at birth. In my opinion, this view is generally accepted by the relevant scientific communities in endocrinology, psychiatry, neonatology, biology, genetics, gynecology, and other fields.

9. Disorders of sexual development are very rare.

Due to the complexity of the biological processes that are involved in normal sexual development, it is not surprising that a very small number of individuals are born with defects in this process (1 in 5,000 births). Defects can occur through either inherited or *de novo* mutations in genes that are involved in sexual determination or through environmental insults during critical states of sexual development. Persons who are born

⁴⁹ See, e.g., Soldin & Mattison, *Sex Differences in Pharmacokinetics and Pharmacodynamics*, Clin. Pharmacokinetics 48(3):143–57, doi: 10.2165/00003088-200948030-00001 (2009); Pogun & Yazarbas, *Sex Differences in Drug Effects*, Encyclop. Psychopharmacology (Springer, Stolerman, ed.), doi: 10.1007/978-3-540-68706-1_209 (2010).

⁵⁰ See, e.g., Walker et al., *Matters of the Heart: Cellular Sex Differences*, J. Mol. & Cell. Cardiology 160:42–55, doi: 10.1016/j.yjmcc.2021.04.010 (2021).

⁵¹ See, e.g., Getahun et al., *Cross-Sex Hormones and Acute Cardiovascular Events in Transgender Persons: A Cohort Study*, Ann. Inter. Med. 169(4): 205–13, doi: 10.7326/M17-2785 (2018).

with such abnormalities are considered to have a disorder of sexual development (DSD). Most often, this is first detected as ambiguity in the appearance of the external genitalia. Such detection measurements are reliable and valid and accepted by the relevant scientific community. In my opinion, this view is generally accepted by the relevant scientific communities in endocrinology, neonatology, gynecology, psychiatry, biology, genetics, and other fields.⁵²

10. The ethical foundations of medicine – “first do not harm.”

The fundamental purpose of the practice of medicine is to treat disease and alleviate suffering. An essential tenet of medical practice is to avoid doing harm in the process. Efforts to rely upon clear, valid, reliable, and definitive evidence on how to best accomplish treatment goals is the essential ethical, professional, scientific, and clinical goals of physicians. Proponents of gender reassignment surgery for adolescents violate this essential principle by using experimental treatments on vulnerable populations without properly informing them of the actual risks and limitations of the treatments.⁵³

11. The Endocrine Society recognizes that the quality of evidence for “affirmative” treatments is currently “low or very low” (“estimate of effect is very uncertain”).

There is no general acceptance of these treatments in the relevant scientific community. The error rate is unknown and could be very high. The Endocrine Society published 2009 clinical guidelines for the treatment of patients with persistent gender dysphoria.⁵⁴ The recommendations include temporary suppression of pubertal development of children with GnRH agonists (hormone blockers normally used for

children experiencing precocious puberty) followed by hormonal treatments to induce the development of secondary sexual traits consistent with one's gender identity. In developing these guidelines, the authors assessed the quality of evidence supporting the recommendations made with use of the GRADE (Recommendations, Assessment, Development, and Evaluation) system for rating clinical guidelines. As directly stated in the Endocrine Society publication, "the strength of recommendations and the quality of evidence was low or very low." According to the GRADE system, low recommendations indicate that "[f]urther research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate." Very low recommendations mean that "any estimate of effect is very uncertain."⁵⁵ An updated set of guidelines was published in September of 2017.⁵⁶ The low quality of evidence presented in this document persists to the current day, as the controversy over these "treatments" is accelerating in recent years.

12. Administering hormones to a child whose gender dysphoria highly likely (80%+) to resolve is risky, unscientific, and unethical.

Iatrogenic damages, including life-long sterility, stunted growth, increased heart attack risk, etc., are often irreversible. Treatment of gender dysphoric children who experience persistence of symptoms with hormones (pubertal suppression and cross-hormone therapy) carries significant risk. It is generally accepted, even by advocates of transgender hormone therapy, that hormonal treatment impairs fertility and often result in sterility, which in many cases is irreversible.⁵⁷

⁵⁵ See Guyatt et al., *GRADE: An Emerging Consensus on Rating Quality of Evidence and Strength of Recommendations*, BMJ 2008(336):924, doi:10.1136/bmj.39489.470347.AD (2008).

⁵⁶ See *supra*, note 52.

⁵⁷ See Nahata et al., *Low Fertility Preservation Utilization Among Transgender Youth*, J. Adolescent Health 61(1):40-44, doi:10.1016/j.jadohealth.2016.12.012 (2017).

Emerging data also show that treated patients have lower bone density which may lead to increased fracture risk later in life.⁵⁸ Other potential adverse effects include disfiguring acne, high blood pressure, weight gain, abnormal glucose tolerance, breast cancer, liver disease, thrombosis, and cardiovascular disease.⁵⁹

13. Long term effects are unknown.

Such treatments are not generally accepted by the relevant scientific community and have no known nor published error rate. Since strategies for the treatment of transgender children as summarized by the Endocrine Society guidelines are relatively new, long-term outcomes are unknown. Evidence presented as support for short-term reductions in psychological distress following social transition in a “gender affirming” environment remains inconclusive. When considered apart from advocacy-based agendas, multiple potential confounders are evident. The most notable deficiencies of existing research are the absence of proper control subjects and lack of randomization in study design.⁶⁰

Although appropriate caution is warranted in extrapolating the outcomes observed from prior studies with current treatments, adults who have undergone social transition with or without surgical modification of external genitalia continue to have *rates of depression, anxiety, substance abuse and suicide far above the background population*.⁶¹

Endocrinology & Metabolism 102(11):3914–23, doi: 10.1210/jc.2017-01643 (2017).

⁶⁰ See Hruz, *Deficiencies in Scientific Evidence for Medical Management of Gender Dysphoria*, Linacre Q 87:34-42, doi:10.1177/0024363919873762 (2020).

⁶¹ See Adams et al., *Varied Reports of Adult Transgender Suicidality: Synthesizing and Describing the Peer-Reviewed and Gray Literature*, Transgender Health 2(1):60-75, doi:10.1089/trgh.2016.0036 (2017);

14. Medical treatments contrary to the science could result in irreversible harms to many patients who would otherwise have recovered naturally from gender dysphoria.

Of particular concern is the likelihood that naively requested gender transition “treatments” and social changes could interfere with known very high rates of natural-untreated resolution of sex-gender discordance. Any activity that encourages or perpetuates transgender persistence for those who would otherwise desist could cause significant harm, particularly in light of the current treatment paradigm for persisting individuals. As noted, sterility can often be expected with hormonal or surgical disruption of normal gonadal function.⁶²

15. “Gender affirmative” treatments damage or destroy healthy bodily organs, leading to loss of essential bodily functions (e.g., medically induced sterilization).

Despite the fact that gender dysphoria represents a psychological condition (as catalogued in the DSM since the third edition of this publication), some conceptualize the condition as a medical illness similar to cancer. When considered from this viewpoint, the goal of “treatment” is to alter the appearance of the body to conform to a patient’s perceived sexual identity, including the physical removal of unwanted “diseased” sexual organs. Since undesired body parts are fully formed and functional prior to hormonal or surgical intervention, the result of these “therapies” is injury to innate sexual ability. In particular, loss or alteration of primary sexual organs leads directly to impairment of reproductive potential. Recognition of this obvious consequence is the basis for the

see also Dhejne et al., *Long-Term Follow-Up of Transsexual Persons Undergoing Sex Reassignment Surgery: Cohort Study in Sweden*, PLoS One 6:e16885, doi:10.1371/journal.pone.0016885 (2011).

⁶² See Cheng et al., *Fertility Concerns of the Transgender Patient*. Translational Andrology & Urology 8(5):209-218. doi: 10.21037/tau.2019.05.09 (2019).

development of new arenas of medical practice where there is an attempt to restore what has been intentionally destroyed.⁶³

16. No competent, scientifically valid, and reliable cost-benefit analysis has been done on “gender affirmative” treatments.

When the FDA tests a drug, the safety analysis looks at all related risks. Specifically, the drug must not only be effective, but it must not cause side effects that are more damaging than the proposed treatment. This is a key weaknesses in the affirmation model of care. Not only have the “treatments” *not* been proven reliably effective compared to *no* treatment, they are proposed against the existing knowledge of well-documented, long-term health problems and damages (e.g., testosterone use by transgender men increases the risk of fatal heart disease, estrogen use by transgender women increases risk of blood clots and strokes, gender transition treatments—if completed—can cause life-long sterility, etc.).

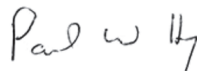

17. Summary opinions.

- There are no long-term, peer-reviewed published, reliable and valid, research studies documenting the number or percentage of patients receiving gender affirming medical interventions, including surgery, who are helped by such procedures.
- There are no long-term, peer-reviewed published, reliable and valid, research studies documenting the number or percentage of patients receiving gender affirming medical interventions, including surgery, who are injured or harmed by such procedures.
- Patients suffering from gender dysphoria or related issues have a right to be protected from experimental, potentially harmful treatments lacking reliable

⁶³ See, e.g., Ainsworth et al., *Fertility Preservation for Transgender Individuals: A Review*, Mayo Clin. Procs. 95(4):784-792, doi:10.1016/j.mayocp.2019.10.040 (2020).

and valid, peer reviewed, published, long-term scientific evidence of safety and effectiveness.

- Gender transition “affirmation” medical treatments, including surgery, for gender dysphoria and “transitioning” have no known, peer reviewed and published error rates—the treatments and assessment methods lack demonstrated, reliable and valid error rates.

Members of the Committee,

The major gender affirming clinic in Great Britain has been closed. The reason was a lack of careful studies including sufficient followup and the sudden uptick of cases that looked more like a passing fancy in most children than a real phenomenon. Certainly any life altering treatments and surgery should be only undertaken after serious psychological evaluation and when the individual is no longer a minor.

The incidence of gender dysphoria is rapidly increasing in this ideological climate. Many disorders such as personality disorders which are often worse during teenage years are affected by this. For this reason and an appeal to simple common sense, as well as the principle of first do no harm, I would oppose gender affirming procedures under the age of 18. It is also my sad conclusion that the governing bodies of medicine have been affected by advocacy and ideology and cannot be fully trusted in these matters.

Dear Members of the Boards:

I am a board-certified child and adolescent psychiatrist, a distinguished fellow of both the American Psychiatric Association and the American Academy of Child and Adolescent Psychiatry. I have worked in solo private practice for 34 years, but I teach pediatric residents and child and adolescent psychiatry fellows at University of California, Irvine/ Children's Hospital of Orange County.

Over the last five years, I have treated at least a dozen children and adolescents with gender dysphoria. My experience has been similar to that reported in the literature: almost all of them are gay and lesbian with depression and anxiety; many are on the autism spectrum, their focus on gender transition is fueled by their on-line activities, and the traditional treatment of "watchful waiting" combined with treating the other psychiatric conditions, as well as incorporating family therapy into our visits, has been helpful.

I also note that the literature on which treatment with puberty blockers and cross-sex hormones is based, is very thin. I don't believe this is a scientific basis for recommending social and medical treatment for minors.

Sincerely yours,

Lawrence J. Budner, M.D.

I am a board-certified internist and endocrinologist. I have practiced in northern Ohio since 1986. I am also a Certified Physician Investigator. I have been the principal investigator for over 100 clinical trials involving both adults and children.

Physicians have 3 fundamental responsibilities: we must use our expertise to **diagnose** and to **care** for our patients. And we must be certain that our patients understand and fully **consent**.

Diagnosis of a medical condition is not delegated to the patient, because it requires expert medical evaluation. Physicians who see a child with distress, possibly related to gender, should not agree to the child's diagnosis any more than they would agree with a child who thinks he or she has diabetes or cancer.

Once the physician is confident in the diagnosis, he or she can weigh the best **care** or treatment for that patient. A cardinal principle is: "first do not harm".

Finally, physicians must obtain informed **consent**, especially for any experimental intervention. Ethical practice prohibits children from providing consent. Children cannot fully comprehend risks versus benefit, and at most can provide assent to a parental decision. Children must obtain consent from their legal guardian or parent for any medical treatment or surgery. Treatment for gender dysphoria should not be an exception to this requirement.

I stopped accepting new patients with gender dysphoria because I discovered that most had stories of traumatic childhoods and co-morbid depression. Most had inadequate psychologic evaluation before they were "cleared" for treatment. Hormonal treatment did not resolve those underlying psychologic issues.

Parents are often told if they fail to go along with hormonal interventions for their child with gender dysphoria, he or she will commit suicide. However, the best evidence proves this to be

completely false. A long-term study of adults in Sweden found that despite cross sex hormones and surgical reassignment surgery, there was a 19-fold higher suicide rate and a 3-fold higher overall mortality in transgender persons as compared to the control population.

The only study on hormonal treatment of gender dysphoria in minors is the so called the Dutch study. That study found no improvement in depression, anxiety or anger after treatment in a small group of 55 children.

To summarize, there are NO studies that demonstrate clear benefit with hormonal or surgical treatment for children with gender dysphoria. There is increasing evidence of harm with puberty blockers and cross sex hormones—damaging bone health, cardiovascular health and fertility. A paper published this year in the Endocrine Society's key journal described the evidence on hormonal interventions for "gender diverse adolescents" as sparse, of low quality and with potentially irreversible side effects.

And GnRH analogues, so called puberty blockers, are not FDA approved for treating gender dysphoria. All these facts mean that puberty blockers and cross sex hormones are experimental interventions for gender dysphoria. The SAFE Act aims to protect children from these experimental therapies.

There are an increasing number of people who were given hormonal or surgical treatment for gender dysphoria who later regret such treatment. I estimate that 75% of my adult patients failed to persist in their treatment with me. Recently, I saw a man who regretted having his testicles removed within one year of that surgery.

I oppose anti-scientific politicized studies with predetermined outcomes that endangers the physical and mental health of children and instead call for true scientific research.

I believe that 'gender affirming care' has gotten way ahead of the science.

The evidence supports a social contagion phenomenon to explain the grouping of transgender kids, especially girls in certain schools and socioeconomic situations.

Assessment of gender dysphoria must be thorough and review all diagnostic options first, long before considering hormones or other irreversible medical and surgical approaches NOT supported by well documented research.

Truly,
David Schechter MD

To Who It May Concern:

First and foremost, any medical procedure that is elective and not a lifesaving emergency, should be discussed with and signed for by the legal parent of any minor. A minor should not have any legal authority to sign any consent form for any treatment, drug, injection, procedure, or surgery. There should be no exceptions to this.

Second, although Gender Dysphoria is a recognized diagnosis, it in no way mandates that injections, drugs, counseling, or any type of procedure, be it surgical or otherwise is the treatment.

Any type of coercion of a minor child that involves a discussion of permanent surgery, specifically the removal of sex organs and creation of gender altering appendages or hormone treatment is nothing less than child abuse.

LGBTQ+ clubs, phone lines on school websites and counselors should be banned from any school website, or printed matter, be it an email, text or other form of verbal or written discussion without full disclosure and written consent of the parent.

Subject: Gender Dysphoria Hormone and Surgical Mistreatment

I am writing in my capacity as a practicing Internist for over 40 years with extensive clinical experience.

Please consider:

1. There is no known gene or measurable laboratory parameter for the Gender Dysphoria (G.D.) condition
2. Accordingly, it is incorrect to label G.D. a medical disorder or disease.
3. As such, any labeling of self or someone as having G.D. is subjective, and subject to change based on knowledge and circumstances.
4. There are well-founded, longstanding psychologic and psychiatric disorders that are treated accordingly.
5. Gender Dysphoria, to the extent that it really exists within younger people, best fits in the realm of a psychologic and or psychiatric condition.
6. Other delusional conditions, such as anorexia nervosa and zoanthropy (where a person believes himself to be an animal) are treated for what they are, with cognitive and psychotropic therapy, not with surgery or medications aimed to irreversibly alter the physical body.
7. The general popular media explosion of articles about Gender Dysphoria should absolutely not distort the subject, nor control the narrative of what is its proper management and treatment.
8. G.D. patients are being subjected to unproven, irreversibly, hormone therapy and body-altering surgery. Simply put, this is harmful for those who can't or don't know better, and is gross malpractice.
9. That major medical organizations support any form of such treatment is of no consequence in this case. Such organizations supported lobotomies and other now-abandoned, ineffective, and harmful practices.
10. Please take a stand to protect those at risk from those advancing the distortion and misuse of Medicine and Surgery.

Stop this abuse before it affects more people, be it anyone, your constituents, or extended family.

Respectfully,

HILLEL S. HAMMERMAN, MD

I have practiced over forty years in the field of Orthopaedic Surgery. While I do not treat children for gender dysphoria, I feel I can comment in general about potentially harmful treatment and disforming surgery being performed without proper grade I level study.

At best, use of puberty blockers and long term hormone in children is investigational. In other words experimental. Some proponents of this extreme treatment tell the patients and their parents that the effects are reversible. That is nonsense. For this reason alone, at least, there should be restrictions on who should be licensed to administer this treatment, and extremely close oversight. Someone has to tell these patients and their families the truth of irreversibility.

The fact that "top" and "bottom" surgery can be performed successfully is not in doubt. Surgeons can do remarkable things. However, **should** these mutilating procedures be performed on children is in great doubt. Again, some patients are told that this is reversible. Of course that is not true. The long term outcomes of these "gender affirming" procedures is unknown and could lead to horrendous consequences.

Activists and physicians motivated by profit have driven this harmful fad. These activists have also infiltrated formerly reliable organizations such as the AMA.

Since these venerable organizations have abandoned our axiom, by which all physicians should follow, "do no harm", I urge you to take up this rule when deciding whether Florida will protect our children, or let politicians and extremists take control away from parents and practicing physicians.

Jonathan Kates MD

October 24, 2022

To: Boards of Medicine and Osteopathic Medicine Joint Rules/Legislative Committee
From: Alberto Cairo PhD, Knight Chair and Associate Professor at the University of Miami

Dear board members,

I'm submitting the present letter and this recently published article
<https://www.thebulwark.com/the-people-he-needs-to-be-hurting/>
as my testimony. I'm also sending them both as PDF documents.

Your discussion on Friday, October 28, 2022 follows a request from Florida's Surgeon General, **Dr. Joseph A. Ladapo**. In this letter I'll be using him as a proxy for his team at the Department of Health. Because I'm the father of a minor diagnosed with gender dysphoria, I've thoroughly studied the same research about the benefits and possible side effects of youth gender-affirming care that Dr. Ladapo used in his request —and more. However, Dr. Ladapo and I have reached opposite interpretations.

Allow me first to discuss our respective qualifications. Dr. Ladapo holds an MD and PhD in Health Policy, but his work has been largely focused on cost-effectiveness analysis, particularly related to cardiovascular disease. He has no experience whatsoever in gender dysphoria or gender-affirming care. None.

I'm a PhD professor, chair, and an expert in the public understanding of statistics, science, and data visualization. I also have first-hand experience of what gender-affirming care looks like, which is very different to the caricatures, exaggerations, and carefully cherry-picked horror stories offered by extremist media.

Therefore, Dr. Ladapo and I are both reasonably qualified to assess research outside our respective areas of expertise. We're absolute equals. However, Dr. Ladapo's assessment of youth gender-affirming care might end up prevailing over mine. He may dictate what my family —and other families like mine— can or can't do. I find this prospect appalling and demeaning.

Dr. Ladapo claims that youth gender-affirming care should be banned as a treatment for gender dysphoria because there isn't "conclusive evidence" of its benefits. For the sake of brevity, I won't explain in depth why this statement is nonsense; I'll just say that evidence in many areas of medical research isn't —and won't ever be— fully "conclusive". Medical decisions are individualized, and always made under various degrees of uncertainty.

My interpretation of the most up-to-date research on gender dysphoria and gender-affirming care largely —but not entirely— aligns with every single major medical organization in this country: Current standards of care based on ever-evolving evidence are good enough for families to weigh uncertainties and make slow, deliberate, and cautious decisions about their children in conversation with their healthcare providers.

The state —meaning Dr. Ladapo, his DoH, and you, the Board of Medicine— ought not to interfere with this process by shrinking the range of choices families have. Or, much worse, by removing all choice.

Let me ask each of you, particularly those of you who have children: If you were in my position, and a type of healthcare your family might need one day were prohibited, wouldn't you be enraged by such blatant state overreach? As experts, wouldn't you feel insulted if another researcher who isn't more qualified than you to assess scientific evidence imposed his interpretation on you? Be honest; of course you would. I'm certain that you'd be where I am right now, writing a letter like this.

Dr. Ladapo and Governor Ron DeSantis like to boast about being advocates for parental rights and individual freedom. Unless both are being mightily hypocritical, they —and you, the Board of Medicine— must accept the rights of all parents to decide what is best for their children.

All the best,

A handwritten signature in black ink, appearing to read "Alberto Cairo", with a long, sweeping horizontal line extending to the right.

Alberto Cairo
Knight Chair at the University of Miami

CULTURE WAR

The People He Needs to Be Hurting

Understanding Ron DeSantis's crusade against transgender care.

by ALBERTO CAIRO · OCTOBER 24, 2022

There's a quote from a [2019 New York Times story](#) that haunts me to this day. The *Times* reporter was describing the negative economic impacts that President Donald Trump's [government shutdown](#) had on rural towns in the Florida Panhandle. A woman who had voted for Trump told the *Times*: "He [Trump]'s not hurting the people he needs to be hurting."

I remembered those words while reflecting on what the Florida Board of Medicine may do soon: [severely restrict or ban youth gender-affirming care](#). Today my son, a transgender boy, is among the "people he needs to be hurting"—though now the "he" is Governor Ron DeSantis, working through his [political hack](#) of a surgeon general, [Joseph Ladapo](#).

On October 28, the Florida Boards of Medicine and Osteopathic Medicine are [planning to discuss](#), and probably [confirm](#), [guidelines](#) that Ladapo issued in April prohibiting gender-affirming treatments for minors, including [social transitioning](#). Ladapo's recommendations are part of [a broader campaign against transgender care](#) which at times has been motivated by ignorance, zealotry, [and rank partisan politics](#).

Ladapo's guidelines, which go against [current standards](#) of care [used by all major medical organizations](#), are based on [cherry-picked](#) and [misrepresented](#) evidence as well as the testimony of [a few carefully chosen](#) anti-LGBTQ "[experts](#)." Ladapo's recommendations have already had a chilling effect on Florida hospitals; some have [stopped accepting new patients needing care for gender dysphoria](#) in anticipation of coming changes in state law.

The reason Ladapo is seeking to ban youth gender-affirming care is the "lack of conclusive evidence" of its benefits. This is one of the [oldest tricks](#) of [science deniers](#). Science—particularly medical and mental health science—is rarely "conclusive" in the sense of absolute certainty that Ladapo is using. Science—again, particularly medical and mental health science—is an ongoing process of managing uncertainties and trade-offs.

Research on gender-affirming care has many uncertainties, but a majority of up-to-date scholarship suggests that it is beneficial. As happens with any other medical treatment, there are potential side effects to puberty blockers—which have been used for decades with no public outrage about it—or hormone treatments that can be assessed and monitored for every person. From what research we have at the moment, their benefits outweigh possible side effects. And there are *no* negative medical side effects to social transitioning.

* * *

A handful of vocal right-wing grifters have been pushing the idea that youth gender-affirming care is some sort of free-for-all, where anything goes and there are no guidelines or best practices and the doctors are all woke activists.

This is not true. Let me tell you what youth gender-affirming care looks like based on my experience as a parent: It is a long, cautious, and individualized process that involves teams of therapists, psychologists, medical doctors, patients, and families. The recent book *A Girlhood*, by Carolyn Hays, is an excellent primer on what navigating this process looks like, and also on the fears and threats that families of transgender youth often endure.

Regret rates from gender-affirming care are small. There are people who have detransitioned, or wish to do so, and they should receive all the help they need. But the evidence suggests that there are many more people who'd benefit from the care that the Florida Board of Medicine may ban if it adheres to Ladapo's request. The fact that some people cease or revert treatments is not a reason to deny those treatments to a larger population.

Restricting gender-affirming care would take a broad brush to a complex reality. It would ignore differences between patients. And it would also deprive families of autonomy. I work at the intersection of data and scientific literacy, and I don't want someone as politically motivated as Joseph Ladapo to dictate what healthcare my family—or any other family—can or cannot access. I'd prefer to rely on actual standards and let families decide for themselves.

This is, after all, what “parents' rights” is all about.

* * *

The problem is that arguing about science, liberty, or autonomy is beside the point. What's happening in Florida has nothing to do with science; it's all about fueling political polarization. Ron DeSantis is a man of theoconservative and authoritarian inclinations, as his rhetoric and actions suggest, and he has presidential ambitions. He's also a keen observer of what his most ardent supporters want, such as the desire to attack those whose existence they find offensive while claiming that they do it for our own good.

Those who support DeSantis's crusade against families with trans kids should beware. History teaches that when you choose leaders to hurt people you hate, they eventually end up hurting the people you love, too.

Arguments of "protecting children" mean nothing when you blatantly ignore what the vast majority of experts and the children themselves are saying is ignored.

Restricting medical care for transgender individuals will undoubtedly put you on the wrong side of history. To do so would make you the same type of person as those who ignored and even stoked the flames of homophobia during the AIDS crisis, leading to stigmas against the gay community and thousands of unnecessary deaths, including my uncle's.

As a citizen of Florida, I demand the Florida Board of Medicine abandon all efforts to restrict access to gender-affirming care and ensure uninterrupted access to care for transgender and gender-diverse minors and adults throughout the state.

A robust body of research confirms the benefits, safety, and life-saving medical necessity of gender-affirming care. A Cornell University meta-analysis of 55 primary peer-reviewed research studies published from 1991 to 2017 found that "gender transition, including medical treatments such as hormone therapy and surgeries, improves the overall well-being of transgender individuals."

Last year, the American Medical Association (AMA) formally urged governors to oppose state legislation that would prohibit medically necessary gender transition-related care for minor patients, calling such efforts "dangerous governmental intrusion into the practice of medicine." The AMA cited that "trans and non-binary gender identities are normal variations of human identity and expression" and that "evidence has demonstrated that forgoing gender-affirming care can have tragic consequences." Furthermore, the AMA asserted that "Decisions about medical care belong within the sanctity of the patient-physician relationship."

Additional policy statements and guidance from expert bodies of medical and mental health professionals, including the National Association of Social Workers, the American Academy of Child and Adolescent Psychiatry, the American Academy of Pediatrics, the Endocrine Society, the National Alliance on Mental Illness, and the United States Professional Association for Transgender Health recognize the evidence and myriad benefits of gender-affirming care and the importance and nature of the patient/provider relationship, which ensures clinically appropriate plans of care for each individual.

While Florida currently does not have state-specific standards for providing gender-affirming

care, that does not mean that such care is unregulated in the state. Providers follow extensive Standards of Care set by the World Professional Association for Transgender Health (WPATH). Developed over decades (beginning with Version 1 in 1979, with Version 8 released just this month) on the basis of sound research, ethical principles, and accumulated expert knowledge, these guidelines offer safeguards and insights for providing gender-affirming care for gender-diverse patients.

If Florida-specific standards of care are adopted, they must reflect the most current version of WPATH Standards of Care (Version 8), and be maintained and updated on an ongoing basis to reflect future updates to the WPATH Standards of Care.

Dear Florida Board of Medicine,
Good afternoon. Thanks for the board's commitment to Floridian's health care. My name is Patricia and writing from Protect Our Vulnerable. Teenagers need accessible care regarding improved mental health. We should draw the line at sex changes and if any hormone blockers might interfere with ability having families at a adult age. If a teenage can take a hormone blocker now have a family when fully grown for the sake of mental health care provide services. Thanks for listening.
Regards,

Patricia Ann Swaim Faella

At birth, each individual has the cell clusters in the hypothalamus that determine their gender-related preferences, including affinity for the same gender.
Initiating treatment at a young age to alter this is questionable, in view of how the individual is hard-wired in their brain.

MEETING MINUTES

I. CALL TO ORDER

The meeting was called to order at 8:01 A.M. EST on Friday August 5, 2022, by Dr. David Diamond, M.D., Chair.

Participants in this public meeting were made aware that these proceedings were being recorded and that an audio file of the meeting would be posted to the Board's website.

A. ROLL CALL

Roll call was conducted by Cherise Strickland, Program Operations Administrator. Those present for all, or part of the meeting included the following:

Members Present:

David Diamond, M.D., Chair
Kevin Cairns, M.D., Vice-Chair
Scot Ackerman, M.D.
Ravi Chandra, M.D.
Amy Derick, M.D.
Patrick Hunter, M.D.
Luz Pages, M.D.
Eleonor Pimentel, M.D.
Hector Vila, M.D.
Michael Wasylik, M.D.
Zachariah Zachariah, M.D.
Nicole Justice, ESQ., Consumer Member

Members Absent:

Wael Barsoum, M.D.
Maria Garcia, Esq., Consumer Member
Nicholas Romanello, Esq., Consumer Member

Department of Health Prosecutors Present:

Chad Dunn, Esq. Kristen Suarez, Esq.
Kristen Summers, Esq. Andrew Pietrylo, Esq.
Hunter Pattison, Esq.

Staff Present:

Jenifer Wenhold, Division Director
John Wilson, General Counsel
Paul A. Vazquez, J.D., Executive Director
Edward Tellechea, Board Counsel
Cassandra Fullove, Paralegal
Bettye Cherise Strickland, Program Operations Administrator
Wendy Alls, Program Operations Administrator
Shaila Washington, Regulatory Supervisor
Cyra Williams, Regulatory Specialist III
Brad Dalton, Public Information Officer

Court Reporter:

Magnolia Court Reporting
Heather Howard
(888) 811-3048

B. OPENING REMARKS

Mr. Vazquez provided opening remarks. He reminded the audience that this is a publicly noticed meeting and is being recorded for the public record.

II. DISCIPLINARY CASE SCHEDULE

Jeng Y. Lin, M.D. – Settlement Agreement.....3

License Number: ME41890

(PCP: No current members)

Allegations of the Administrative Complaint: Violations of §458.331(1)(t)1, §458.331(1)(q), and §458.331(1)(m), F.S.

Action taken: A motion was made to accept the settlement agreement, seconded, and carried unanimously.

Costs: A motion was made to impose costs of \$5,000.00, seconded and carried unanimously.

Penalty imposed:

- Letter of concern.
- Fine \$5,000.
- Costs \$5,000.00
- CME – Laws, Rules, and Ethics (5 hours)
- Drug Course (5 hours)
- Records Course (3 hours)
- Risk Management (5 hours)
- Quality Assurance Consultation/Risk Management Assessment – Engage a certified professional independent risk manager to review Respondent’s current practice within 60 days, and to report the quality assurance report to the Board’s Probation Committee within six (6) months.

Jason J. H. Song, M.D. – Settlement Agreement.....6

License Number: ME123792

(PCP: Dr. Zachariah and Ms. Garcia)

Allegations of the Administrative Complaint: Violations of §456.072(1)(bb), F.S.

Action taken: A motion was made to accept the settlement agreement, seconded, and carried unanimously.

Costs: A motion was made to impose costs of \$1,941.38, seconded and carried unanimously.

Penalty imposed:

- Letter of Concern.
- Fine \$2,500.
- Costs \$1,919.81.
- CME - Lecture/Seminar on Wrong Site Surgeries to medical staff at an approved medical facility (1 hour).
- CME - Risk Management (5 hours).

Maxime J.M. Coles, M.D. – Settlement Agreement.....8

License Number: ME130590

(PCP Dr. Vila and Ms. Garcia)

Allegations of the Administrative Complaint: Violations of §458.331(1)(b) and §458.331(1)(kk), F.S.

Action taken: A motion was made to accept the settlement agreement, seconded, and carried unanimously.

Costs: A motion was made to impose cost of \$585.00, seconded, and carried unanimously.

Penalty imposed:

- Letter of concern.
- Fine \$1,500.
- Costs \$585.00.
- CME – Laws, Rules, and Ethics (5 hours).

Louis Gutierrez, M.D. – Settlement Agreement.....9

License Number: ME55602

(PCP: Dr. Vila)

Allegations of the Administrative Complaint: Violations of §458.331(1)(t)1, F.S.

Action taken: A motion was made to accept the settlement agreement, seconded, and carried unanimously.

Costs: A motion was made to impose cost of \$4,971.67, seconded, and carried unanimously.

Penalty imposed:

- Letter of concern.
- Fine \$4,000.
- Costs \$4,971.67.
- CME – Subjects related to Obstetrics and Gynecology, including discussions of hypoxic ischemic encephalopathy; Risk Management (5 hours).

Jennifer E. Payne, M.D. – Settlement Agreement.....22

License Number: ME118750

(PCP: Dr. Zachariah and Ms. Garcia)

Allegations of the Administrative Complaint: Violations of §456.072(1)(cc), F.S.

Action taken: A motion was made to accept the settlement agreement, seconded, and carried unanimously.

Costs: A motion was made to impose cost of \$3,309.63, seconded, and carried unanimously.

Penalty imposed:

- Letter of concern.
- Fine \$2,500.
- Costs \$3,309.63.

- CME - Risk Management (5 hours).
- Presentation of a one (1) hour lecture on Retained Foreign Bodies to medical staff at an approved medical facility within six (6) months of the date of the Final Order.

Raul D. D. Correa, M.D. – Recommended Order, Case Number 2021-21736.....1

Raul D. D. Correa, M.D. – Recommended Order, Case Number 2021-30940.....2

License Number: ME79321

(PCP: Dr. Pages and Ms. Garcia)

Allegations of the Administrative Complaint: Violations of §458.331(1)(nn), by violating §456.072(1)(ss), by committing an act that constitutes a violation of §794.011; §456.072(1)(v) through a violation of §456.063(1); §458.331(1)(j) as defined and/or prohibited in §458.329 through Rule 64B8-9.008. The same allegations were applied to both administrative complaint cases.

Dr. Diamond provided opening statements and instructions on how the proceedings would be conducted.

Dr. Correa was not present and was represented by Bruce Lamb, Esq.

Ms. Summers represented the Department.

Following opening remarks, Mr. Lamb proceeded summarizing their 35 exceptions to the proposed recommended order.

Action taken: Each exception was heard individually with respondent’s counsel and Department’s counsel given testimony. All 35 exceptions were denied by the Board by individual vote.

Ms. Summers requested a motion to adopt the allegations of fact in the Administrative Complaint as the findings of fact to the Board.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Summers requested a motion to adopt the Administrative Law Judge’s Conclusions of Law as the Board Conclusions of Law.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Summers requested a motion that the Board enter a final order complying with the Administrative Law Judge’s recommendation of revocation of license, imposing a fine of \$10,000, and imposing cost for the investigation and prosecution of this case.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Summers request a motion to bifurcate the cost of the case and come back at later date for a cost motion.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Respondent’s counsel requested a stay pending a potential appeal. The Department requested the Board deny the request as the physician constitutes a danger to the public.

Action taken: A motion was made to deny the Respondent’s counsel’s request, seconded, and carried unanimously.

Penalty imposed:

- Revocation of license.

Jeffery D. Morgan, M.D. – Recommended Order.....28

License Number: ME103348

(PCP: No current members)

Dr. Diamond provided opening statements and instructions on how the proceedings would be conducted.

Dr. Morgan was not present and was not represented by counsel.

Mr. Dunn and Ms. Suarez represented the Department.

Following opening remarks, Ms. Suarez proceeded with summarizing the proposed recommended order and case details.

Ms. Suarez requested a motion to deny all of respondent’s exceptions due to §120, F.S., for failing to notate page number or paragraph of the exceptions.

Action taken: A motion was made to reject respondent’s exceptions in total, seconded, and carried unanimously.

Ms. Suarez requested a motion to adopt the allegations of fact in the Administrative Complaint as the findings of fact to the Board.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Suarez requested a motion to adopt the Administrative Law Judge’s Conclusions of Law as the Board Conclusions of Law.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Suarez requested a motion that the Board enter a final order complying with the Administrative Law Judge’s recommendation of revocation of license and impose cost for the investigation and prosecution of this case.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Dunn requested a motion to impose costs of \$54,939.39.

Action taken: A motion was made to impose costs, seconded, and carried unanimously.

Penalty imposed:

- Revocation of license.
- Costs \$54,939.39.

John A. G. Sampson, M.D. – Settlement Agreement.....4

License Number: ME121890

(PCP: Mr. Romanello)

Allegations of the Administrative Complaint: Violations of §458.331(1)(t), F.S., §458.331(1)(nn), F.S. by violating Rule 64B88-9.009(2)(f), F.A.C., and §458.331(1)(k), F.S., and §458.331(1)(nn) and/or 458.328(1)(g) by violating Rule 64B8-9.001, F.A.C.

Dr. Sampson was present and was represented by Monica Felder, Esq.

Ms. Summers represented the Department.

After opening remarks and discussion, the following action was taken:

Action taken: A motion was made to reject the settlement agreement as presented, seconded, and carried unanimously.

Action taken: A motion was made to accept amended settlement agreement, seconded, and carried unanimously.

Respondent chose to respond to the agreement within 7 days of filing.

Penalty imposed:

- Fine \$20,000.
- Costs \$4,626.65.
- CME - Laws, Rules, and Ethics (5 hours).
- CME - Medical Records (5 hours).
- CME - Lecture/Seminar on complications related to liposuction and gluteal fat grafting at an approved medical facility (1 hour).
- Restriction on Practice – Permanently restricted from performing gluteal fat grafting.
- Restriction on Practice – Permanently restricted from serving as the Designed Physician of an office surgery center.
- Quality Assurance Consultation/Risk Management Assessment – Engage a certified professional independent risk manager to review Respondent's current practice within 60 days, and to report the quality assurance report to the Board's Probation Committee within six (6) months.

Herbert M. Bertram, III, M.D. – Settlement Agreement.....5

License Number: ME78271

(PCP: Dr. Zachariah and Ms. Garcia)

Allegations of the Administrative Complaint: Violations of §456.072(1)(bb), F.S.

Dr. Bertram was present and represented by Mandy Smith, Esq.

Ms. Suarez represented the Department.

After opening remarks and discussion, the following action was taken:

Action taken: A motion was made to accept the settlement agreement, seconded, and carried unanimously.

Penalty imposed:

- Letter of Concern.
- Fine \$7,500.

- Costs \$4,146.01.
- CME - Lecture/Seminar on Wrong Site Surgeries (1 hour).
- CME - Risk Management (5 hours).

Roger S. Gorman, M.D. – Settlement Agreement.....7

License Number: ME50540

(PCP: Dr. Chandra)

Allegations of the Administrative Complaint: Violations of §458.331(1)(t), F.S. and §458.331(1)(m), F.S.

Dr. Gorman was present and represented by Matthew M. Fischer, Esq.

Mr. Pietrylo represented the Department.

After opening remarks and discussion, the following action was taken:

Action taken: A motion was made to reject the proposed settlement agreement and amend the terms, seconded, and carried unanimously.

Action taken: A motion was made to accept the amended settlement agreement, seconded, and carried unanimously.

Respondent chose to respond to the agreement within 7 days of filing.

Penalty imposed:

- Letter of Reprimand.
- Fine \$10,000.
- Costs \$6,836.68.
- CME - Medical Records (3 hours).
- CME - Managing Hypotension During Surgical Procedures (10 hours).
- CME - Anesthesiology During Surgical Procedures (10 hours).
- CME - Risk Management (5 hours).
- Evaluation by Florida CARES, Center for Personalized Education for Professional (CPEP), the UC San Diego PACE program, or another equivalent program preapproved by the Board (within 9 months).
- Probation with direct supervision (until evaluation).

Yvelice A. Villaman-Bencosme, M.D. – Determination of Waiver.....10

License Number: ME64482

(PCP: Dr. Barsoum and Mr. Romanello)

Allegations of the Administrative Complaint: Violations of §458.331(1)(c), F.S.

Dr. Villaman-Bencosme was not present and not represented by counsel.

Mr. Dunn represented the Department.

Mr. Dunn requested a motion from the Board that no Election of Rights had been received and finding that Respondent waived his right to elect his avenue of resolution by failing to timely reply to the properly noticed Administrative Complaint.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Dunn requested a motion to adopt the allegations of fact in the Administrative Complaint as the findings of fact to the Board.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Dunn requested a motion to adopt the Conclusions of Law.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Dunn requested a motion for imposition of penalty.

After discussion, the following action was taken:

Action taken: A motion was made to impose penalty, seconded, and carried unanimously.

Mr. Dunn request a motion for imposition of costs total \$554.97.

Action taken: A motion was made to impose costs, seconded, and carried unanimously.

Penalty imposed:

- Revocation of license.
- Costs \$554.97.

Kathleen A Cullen, M.D. – Determination of Waiver.....11

License Number: ME70549

(PCP: Dr. Wasylik and Mr. Romanello)

Allegations of the Administrative Complaint: Violations of §458.331(1)(b), F.S.

Dr. Cullen was not present and not represented by counsel.

Mr. Pietrylo represented the Department.

Mr. Pietrylo requested a motion from the Board that no Election of Rights had been received and finding that Respondent waived his right to elect his avenue of resolution by failing to timely reply to the properly noticed Administrative Complaint.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Pietrylo requested a motion to adopt the allegations of fact in the Administrative Complaint as the findings of fact to the Board.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Pietrylo requested a motion to adopt the Conclusions of Law.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Pietrylo requested a motion for imposition of penalty.

After discussion, the following action was taken:

Action taken: A motion was made to reject the Departments recommended penalty, seconded, and carried unanimously.

Action taken: A motion was made to amend the penalty imposed, seconded, and carried unanimously.

Mr. Pietrylo requestion a motion for imposition of costs.

Action taken: A motion was made to waive costs, seconded, and carried unanimously.

Penalty imposed:

- Revocation of license.

Thomas D. Nielson, M.D. – Determination of Waiver.....12

License Number: ME124462

(PCP: Dr. Zachariah)

Allegations of the Administrative Complaint: Violations of §458.331(1)(b), F.S. and §456.072(1)(w), F.S.

Dr. Nielson was not present and not represented by counsel.

Ms. Summers represented the Department.

Ms. Summers requested a motion from the Board that no Election of Rights had been received and finding that Respondent waived his right to elect his avenue of resolution by failing to timely reply to the properly noticed Administrative Complaint.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Summers requested a motion to adopt the allegations of fact in the Administrative Complaint as the findings of fact to the Board.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Summers requested a motion to adopt the Conclusions of Law.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Summers requested a motion for imposition of penalty.

After discussion, the following action was taken:

Action taken: A motion was made to impose penalty, seconded, and carried unanimously.

Ms. Summers requestion a motion for imposition of costs.

Action taken: A motion was made to waive costs, seconded, and carried unanimously.

Penalty imposed:

- Revocation of license.

Arthur D. Barnes, M.D. – Hearing Not Involving Disputed Issues of Material Fact.....13

License Number: ME30183

(PCP: Dr. Wasylik and Mr. Romanello)

Allegations of the Administrative Complaint: Violations of §458.331(1)(b), F.S. and §456.072(1)(w), F.S.

Dr. Barnes was not present and not represented by counsel.

Mr. Dunn represented the Department.

Mr. Dunn requested a motion to accept the exhibits of the case into evidence.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Dunn requested a motion to adopt the allegations of fact in the Administrative Complaint as the findings of fact of the Board.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Dunn requested a motion finding the respondent in violation of Florida Statutes as charged in the Administrative Complaint.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Dunn requested a motion for the imposition of penalty.

After discussion, the following action was taken:

Action taken: A motion was made to impose penalty, seconded, and carried unanimously.

Mr. Dunn requested a motion to impose costs of \$109.85.

Action taken: A motion was made to waive costs, seconded, and carried unanimously.

Penalty imposed:

- Letter of Concern.

Joan C. McTigue, P.A. – Hearing Not Involving Disputed Issues of Material Fact.....14

License Number: PA1763

(PCP: Dr. Vila)

Allegations of the Administrative Complaint: Violations of §458.331(1)(s), F.S. and §456.072(1)(hh), F.S.

Ms. McTigue was not present and not represented by counsel.

Ms. Summers represented the Department.

Ms. Summers requested a motion to accept the exhibits of the case into evidence.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Summers requested a motion to adopt the allegations of fact in the Administrative Complaint as the findings of fact of the Board.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Summers requested a motion finding the respondent in violation of Florida Statutes as charged in the Administrative Complaint.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Summers requested a motion for the imposition of penalty.

After discussion, the following action was taken:

Action taken: A motion was made to impose penalty, seconded, and carried unanimously.

Ms. Summers requested a motion to impose costs of \$3,696.63.

Action taken: A motion was made to impose costs, seconded, and carried unanimously.

Penalty imposed:

- Fine \$5,000.
- Costs \$3,696.63.
- Respondent's license to practice medicine in the State of Florida is hereby SUSPENDED until such time as she demonstrates the ability to practice medicine with reasonable skill and safety.

Yao C. Ong, M.D. – Hearing Not Involving Disputed Issues of Material Fact.....15

License Number: ME52118

(PCP: Dr. Wasylik and Mr. Romanello)

Allegations of the Administrative Complaint: Violations of §458.331(1)(t), F.S.

Dr. Ong was not present and represented by William D. Bonezzi, Esq.

Mr. Dunn represented the Department.

Mr. Dunn requested a motion to accept the exhibits of the case into evidence.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Dunn requested a motion to adopt the allegations of fact in the Administrative Complaint as the findings of fact of the Board.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Bonezzi was recognized by Dr. Diamond and presented to testimony on behalf of Dr. Ong.

Mr. Dunn requested a motion finding the respondent in violation of Florida Statutes as charged in the Administrative Complaint.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Dunn requested a motion for the imposition of penalty.

After discussion, the following action was taken:

Action taken: A motion was made to impose penalty, seconded, and carried unanimously.

Mr. Dunn requested a motion to impose costs of \$6,242.84

Action taken: A motion was made to impose costs upon reinstatement of license, seconded, and carried unanimously.

Penalty imposed:

- Letter of concern.
- Fine \$5,000.
- Costs \$6,242.84 to be paid after the license is reinstated.
- CME - Risk Management (5 hours).
- CME - Pathological Interpretation & Diagnosis (3 hours).

Seth L. Matarasso, M.D. – Hearing Not Involving Disputed Issues of Material Fact.....16

License Number: ME147296

(PCP: Dr. Zachariah and Ms. Garcia)

Allegations of the Administrative Complaint: Violations of §458.331(1)(b), F.S. and §456.072(1)(w), F.S.

Dr. Matarasso was not present and not represented by counsel.

Ms. Suarez represented the Department.

Ms. Suarez requested, on behalf of the Department, a motion to accept the exhibits of the case into evidence.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Suarez requested a motion to adopt the allegations of fact in the Administrative Complaint as the findings of fact of the Board.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Suarez requested a motion finding the respondent in violation of Florida Statutes as charged in the Administrative Complaint.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Suarez requested a motion for the imposition of penalty.

Following discussion, the following action was taken:

Action taken: A motion was made to impose penalty, seconded, and carried unanimously.

Ms. Suarez requested a motion to impose costs of \$91.54.

Action taken: A motion was made to impose costs, seconded, and carried unanimously.

Penalty imposed:

- Letter of concern.
- Fine \$1,000.
- Costs \$91.54.
- CME - Laws, Rules, and Ethics (5 hours).

Roy Hammonds, P.A. – Hearing Not Involving Disputed Issues of Material Fact.....17

License Number: PA9110400

(PCP: Dr. Zachariah and Ms. Garcia)

Allegations of the Administrative Complaint: Violations of §458.331(1)(b), F.S.

Mr. Hammonds was present and not represented by counsel.

Ms. Suarez represented the Department.

Ms. Suarez requested a motion to accept the exhibits of the case into evidence.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Suarez requested a motion to adopt the allegations of fact in the Administrative Complaint as the findings of fact of the Board.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Hammonds presented his case before the Board.

Ms. Suarez requested a motion finding the respondent in violation of Florida Statutes as charged in the Administrative Complaint.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Suarez requested a motion for the imposition of penalty.

After discussion, the following action was taken:

Action taken: A motion was made to impose penalty, seconded, and carried unanimously.

Ms. Suarez requested a motion to impose costs of \$307.24.

Action taken: A motion was made to impose costs, seconded, and carried unanimously.

Penalty imposed:

- Letter of reprimand
- Fine \$1,000
- Costs \$307.24
- CME – Laws, Rules, and Ethics (5 hours).

Francesco Cabrera, M.D. – Hearing Not Involving Disputed Issues of Material Fact.....18

License Number: ME64467

(PCP: No current members)

Allegations of the Administrative Complaint: Violations of §456.072(1)(II), F.S.

Dr. Cabrera was present and represented by Allen R. Grossman, Esq.

Mr. Dunn represented the Department.

Mr. Dunn requested a motion to accept the exhibits of the case into evidence.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Dunn requested a motion to adopt the allegations of fact in the Administrative Complaint as the findings of fact of the Board.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Grossman was recognized by Dr. Diamond and presented testimony on behalf of Dr. Cabrera.

Mr. Dunn requested a motion finding the respondent in violation of Florida Statutes as charged in the Administrative Complaint.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Dunn requested a motion for the imposition of penalty.

After discussion, the following action was taken:

Action taken: A motion was made to impose penalty, seconded, and carried unanimously.

Mr. Dunn requested a motion to impose costs of \$61.03.

Action taken: A motion was made to waive cost, seconded, and carried unanimously.

Penalty imposed:

- Revocation of license.

Mircea A. Morariu, M.D. – Hearing Not Involving Disputed Issues of Material Fact.....19

License Number: ME78844

(PCP: Mr. Romanello)

Allegations of the Administrative Complaint: Violations of §458.331(1)(c), F.S.

Dr. Morariu was present and not represented by counsel.

Mr. Pattison represented the Department.

Mr. Pattison requested a motion to accept the exhibits of the case into evidence.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Pattison requested a motion to adopt the allegations of fact in the Administrative Complaint as the findings of fact of the Board.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Dr. Morariu provided his testimony about his case.

Mr. Pattison requested a motion finding the respondent in violation of Florida Statutes as charged in the Administrative Complaint.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Pattison requested a motion for the imposition of penalty.

After discussion, the following action was taken:

Action taken: A motion was made to impose penalty, seconded, and carried unanimously.

Mr. Pattison requested a motion to impose costs of \$4,052.90.

Action taken: A motion was made to waive cost, seconded, and carried unanimously.

Penalty imposed:

- Revocation of license.

Richard M. Wolff, M.D. – Hearing Not Involving Disputed Issues of Material Fact.....20

License Number: ME36950

(PCP: Dr. Zachariah and Ms. Garcia)

Allegations of the Administrative Complaint: Violations of §458.331(1)(b), F.S. and §458.331(1)(kk), F.S.

Dr. Wolff was not present and not represented by counsel.

Ms. Suarez represented the Department.

Ms. Suarez requested a motion to accept the exhibits of the case into evidence.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Suarez requested a motion to adopt the allegations of fact in the Administrative Complaint as the findings of fact of the Board.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Suarez requested a motion finding the respondent in violation of Florida Statutes as charged in the Administrative Complaint.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Suarez requested a motion for the imposition of penalty.

After discussion, the following action was taken:

Action taken: A motion was made to impose penalty, seconded, and carried unanimously.

Ms. Suarez requested a motion to impose costs of \$61.03.

Action taken: A motion was made to impose cost, seconded, and carried unanimously.

Penalty imposed:

- Letter of concern.
- Fine \$2,000.
- Costs \$61.03.
- CME – Laws, Rules, and Ethics (5 hours).

Weilee Yeh, M.D. – Hearing Not Involving Disputed Issues of Material Fact.....21

License Number: ME72540

(PCP: Dr. Pimentel and Ms. Garcia)

Allegations of the Administrative Complaint: Violations of §458.331(1)(b), F.S. and §456.072(1)(w), F.S.

Dr. Yeh was not present and not represented by counsel.

Ms. Summers represented the Department.

Ms. Summers requested a motion to accept the exhibits of the case into evidence.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Summers requested a motion to adopt the allegations of fact in the Administrative Complaint as the findings of fact of the Board.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Summers requested a motion finding the respondent in violation of Florida Statutes as charged in the Administrative Complaint.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Ms. Summers requested a motion for the imposition of penalty.

After discussion, the following action was taken:

Action taken: A motion was made to impose penalty, seconded, and carried unanimously.

Ms. Summers requested a motion to impose costs of \$73.24.

Action taken: A motion was made to impose cost, seconded, and carried unanimously.

Penalty imposed:

- Letter of concern
- Fine \$2,000
- Costs \$73.24
- CME – Laws, Rules, and Ethics (5 hours)
- Respondent’s license to practice medicine in the State of Florida is hereby SUSPENDED until such time as he demonstrates to the Board that his license is unencumbered and free from any restrictions or conditions in any and all jurisdictions where he is licensed.

Jorge I. Gaviria, M.D. – Hearing Not Involving Disputed Issues of Material Fact.....23
License Number: ME94318
(PCP: Dr. Ackerman and Mr. Romanello)

CONTINUED TO THE OCTOBER MEETING

Ted D. Friehling, M.D. – Hearing Not Involving Disputed Issues of Material Fact.....24
License Number: ME150732
(PCP: Dr. Pages)

Allegations of the Administrative Complaint: Violations of §458.331(1)(b), F.S. and §456.072(1)(w), F.S.

Dr. Friehling was not present and not represented by counsel.

Mr. Pietrylo represented the Department.

Mr. Pietrylo requested a motion to accept the exhibits of the case into evidence.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Pietrylo requested a motion to adopt the allegations of fact in the Administrative Complaint as the findings of fact of the Board.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Pietrylo requested a motion finding the respondent in violation of Florida Statutes as charged in the Administrative Complaint.

Action taken: A motion was made in the affirmative, seconded, and carried unanimously.

Mr. Pietrylo requested a motion for the imposition of penalty.

After discussion, the following action was taken:

Action taken: A motion was made to impose penalty, seconded, and carried unanimously.

Mr. Pietrylo requested a motion to impose costs of \$21.80.

Action taken: A motion was made to impose cost, seconded, and carried unanimously.

Penalty imposed:

- Costs \$21.80.
- CME – Laws, Rules, and Ethics (5 hours).
- Respondent’s license to practice medicine in the State of Florida is hereby **SUSPENDED** until such time as he demonstrates to the Board that his license is unencumbered and free from any restrictions or conditions in any and all jurisdictions where he is licensed.

Donald M. Botta, Jr., M.D. – Voluntary Relinquishment.....25

License Number: ME110682

(PCP: Dr. Pimentel)

Action taken: A motion was made to accept the voluntary relinquishment, seconded, and carried unanimously.

Robert Weinstein, M.D. – Motion to Vacate Final Order.....29

License Number: ME27163

Mr. Pietrylo represented the Department and provided an overview of the reasoning to vacate the final order.

Action taken: A motion was made to vacate the final order, seconded, and carried unanimously.

Jorge A. Gallo, M.D. – Petition for Modification of Final Order.....30

License Number: ME58146

(PCP: Dr. Vila)

Dr. Gallo was not present and represented by William Carcioppolo, Esq.

Mr. Pietrylo represented the Department.

After discussion, the following action was taken:

Action taken: A motion was made to deny the petition to amend the final order, seconded, and carried unanimously.

Andre M. Brooks, M.D. – Petition to Lift Practice Restriction (WITHDRAWN).....	31
License Number: ME59444	
(PCP: No current members)	

III. REPORTS & REMARKS (Part I)

Department Remarks.....	36
-------------------------	----

Mr. Dunn presented an update to the Department’s staffing.

Mr. Pietrylo presented the Appellate Report and Year-Old Case Report to the Board members.

Action taken: A motion was made to continue the prosecution of one year old or older cases, seconded, and carried unanimously.

Chair Recognition Award.....	40
------------------------------	----

- Daniel R. Bergholz – University of Miami Miller School of Medicine
- Allison Chin – Florida International University Herbert Wertheim College of Medicine
- Zaimary Meneses – Charles E. Schmidt College of Medicine at Florida Atlantic University
- Amr El-Talla – Nova Southeastern University College of Allopathic Medicine

IV. EXEMPTIONS

Timothy J. Davis, P.A. – AHCA Exemptions.....	33
---	----

Mr. Davis’ counsel provided statements on behalf of Mr. Davis for the AHCA exemptions.

Action taken: A motion was made to accept the AHCA exemption, seconded, and carried unanimously.

Gilberto Vega, M.D. – AHCA Exemptions.....	34
--	----

Dr. Vega provided statements for the AHCA exemptions.

Action taken: A motion was made to accept the AHCA exemption, seconded, and carried unanimously.

V. PETITION FOR DECLARATORY STATEMENT

Andres I. Beregovich, Esq. – RE: 64B8-9.009(2)(e), (f), F.A.C. Standard of Care for Office Surgery.....	32
---	----

Mr. Beregovich provided statements for clarification for a declaratory statement on the referenced rule.

Action taken: A motion was made to deny the declaratory statement on grounds of lack of standing, seconded, and carried unanimously.

VI. DISCUSSION

Discussion on Letter from Dr. Joseph A. Ladapo, M.D. Ph.D., State Surgeon General, dated June 2, 2022, Related to Gender Dysphoria in Children and Adolescents.....	26
---	----

Petition to Initiate Rulemaking Setting the Standard of Care for Treatment of Gender Dysphoria.....39

Mr. Vazquez provided statements on the conduct of the discussion and reminded everyone that this is a publicly noticed meeting and is being recorded.

Dr. Diamond provided opening statements on the purpose of the discussion.

Dr. Ladapo begin the discussion by thanking the Board for the work that has been done and that continues to be done. Dr. Ladapo provided the Board and public with statements regarding gender dysphoria.

Mr. Wilson was recognized to present the petition to initiate rulemaking setting the standard of care for the treatment of gender dysphoria. Mr. Wilson wanted to remind all in attendance that this is the start of the rulemaking process, and nothing will be set in rules based on this vote.

Dr. Diamond recognized Dr. Michael Haller, M.D., Pediatric Endocrinologist, to provided statements and present his research on gender dysphoria.

Dr. Diamond recognized Dr. Quentin Van Meter, M.D., Pediatric Endocrinologist, to provided statement and present his research on gender dysphoria.

After a robust discussion between the Board and the invited physicians, Dr. Diamond invited the public to make statements. Individuals were called randomly from the speaker cards completed prior to the discussion. There were multiple individuals who spoke for and against the petition.

After public comments, the following action was taken:

Action taken: A motion was made to accept the petition, seconded, and carried with one vote in opposition.

VII. REMARKS & REPORTS (Part II)

Board Chair's Remarks.....No tab

No comments.

Board Counsel's Remarks.....No tab

No comments.

Board Director's Remarks.....35

No comments.

Council on Physician Assistants Report.....No tab

Dr. Chandra provided the report from the July 28, 2022, Council of Physician Assistants meeting.

Action taken: A motion was made to approve the minutes, seconded, and carried unanimously.

Credentials Committee Report.....No tab

Dr. Ackerman provided the report from the August 4, 2022, Credentials Committee meeting.

Action taken: A motion was made to approve the minutes, seconded, and carried unanimously.

Boards of Medicine and Osteopathic Medicine's Joint Committee on Surgical Care/Quality Assurance Committee Report.....37

Dr. Cairns provided the report from the August 4, 2022, Joint Committee on Surgical Care/Quality Assurance meeting.

Action taken: A motion was made to approve the minutes, seconded, and carried unanimously.

Rules/Legislative Committee Report.....No tab

Dr. Zachariah was not present at the time of the report discussion.

Action taken: A motion was made to table the report, seconded, and carried unanimously.

Probation Committee Report.....No tab

Dr. Pages provided the report from the July 28, 2022, Probation Committee meeting.

Action taken: A motion was made to approve the minutes, seconded, and carried unanimously.

Finance & Process Accountability Meeting Report.....No tab

Ms. Justice provided the report from the July 28, 2022, Finance & Process Accountability meeting.

Action taken: A motion was made to approve the minutes, seconded, and carried unanimously.

Approval of Meeting Minutes.....27

Action taken: A motion was made to approve the minutes, seconded, and carried unanimously.

Ratification of Applicants Pursuant to Chapter 458, F.S.....38

Action taken: A motion was made to approve the ratification list of applicants, seconded, and carried unanimously.

June 2, 2022

Florida Board of Medicine
4052 Bald Cypress Way Bin C-03
Tallahassee, FL 32399-3253

Members of the Board,

On April 20, 2022, the Florida Department of Health (Department) released guidance on the treatment of gender dysphoria for children and adolescents. As State Surgeon General, I recommended against certain pharmaceutical, non-pharmaceutical, and surgical treatments for gender dysphoria. The recommendations are based on a lack of conclusive evidence and the high risk for long-term, irreversible harms from these treatments.

Since then, the Agency for Health Care Administration (Agency) has conducted a full review to determine if these treatments are "consistent with generally accepted professional medical standards (GAPMS) and not experimental or investigational." The Agency's review included an overview of systematic reviews on puberty blockers, cross-sex hormones, surgeries, or a combination of interventions.

While some professional organizations, such as the American Academy of Pediatrics and the Endocrine Society, recommend these treatments for "gender affirming" care, the scientific evidence supporting these complex medical interventions is extraordinarily weak. For instance, the overview conducted by Dr. Brignardello-Peterson and Dr. Wiercioch states that "there is great uncertainty about the effects of puberty blockers, cross-sex hormones, and surgeries in young people with gender dysphoria."

The current standards set by numerous professional organizations appear to follow a preferred political ideology instead of the highest level of generally accepted medical science. Florida must do more to protect children from politics-based medicine. Otherwise, children and adolescents in our state will continue to face a substantial risk of long-term harm.

The Agency ultimately concluded that "Available medical literature provides insufficient evidence that sex reassignment through medical interventions is a safe and effective treatment for gender dysphoria." I encourage the Board to review the Agency's findings and the Department's guidance to establish a standard of care for these complex and irreversible procedures.

Sincerely,

Joseph A. Ladapo, MD, PhD
State Surgeon General

FLORIDA DEPARTMENT OF HEALTH RELEASES GUIDANCE ON TREATMENT OF GENDER DYSPHORIA FOR CHILDREN AND ADOLESCENTS

Contact:

Communications Office

NewsMedia@flhealth.gov

850-245-4111

Tallahassee, Fla. — Today, the Florida Department of Health released guidance regarding the treatment of gender dysphoria for children and adolescents. This guidance uses the most up-to-date scientific data available, and it prioritizes the overall health and well-being of Florida's children and adolescents. The [Department's guidance is available here](#).

"The federal government's medical establishment releasing guidance failing at the most basic level of academic rigor shows that this was never about health care," said State Surgeon General Joseph Ladapo. "It was about injecting political ideology into the health of our children. Children experiencing gender dysphoria should be supported by family and seek counseling, not pushed into an irreversible decision before they reach 18."

Countries such as Sweden, Finland, France, and the United Kingdom are currently reviewing, reevaluating, stopping, or advising caution on the treatment of gender dysphoria in children and adolescents.

The Department crafted this guidance using published and peer-reviewed data that calls into question the motives of the federal HHS. Guidance of this magnitude requires a full, diligent understanding of the scientific evidence.

The current evidence does not support the use of puberty blockers, hormone treatments, or surgical procedures for children and adolescents, considering:

- 80% of those seeking clinical care will lose their desire to identify with the non-birth sex,
- the importance of puberty to brain development, with the pre-frontal cortex (which is responsible for executive functions, such as decision making) continuing to develop until [approximately 25 years of age](#),
- and the potentially irreversible consequences such as cardiovascular disease, osteoporosis, infertility, increased cancer risk, and thrombosis.

Alongside the guidance released today, the [Department released a fact check that details the claims made by HHS, available here](#).

About the Florida Department of Health

The Florida Department of Health, nationally accredited by the [Public Health Accreditation Board](#), works to protect, promote, and improve the health of all people in Florida through integrated state, county, and community efforts.

Treatment of Gender Dysphoria for Children and Adolescents

April 20, 2022

The Florida Department of Health wants to clarify evidence recently cited on a [fact sheet](#) released by the US Department of Health and Human Services and provide guidance on treating gender dysphoria for children and adolescents.

Systematic reviews on hormonal treatment for young people show a trend of [low-quality evidence](#), small sample sizes, and medium to high risk of bias. A paper published in the [International Review of Psychiatry](#) states that 80% of those seeking clinical care will lose their desire to identify with the non-birth sex. [One review concludes](#) that "hormonal treatments for transgender adolescents can achieve their intended physical effects, but **evidence regarding their psychosocial and cognitive impact is generally lacking.**"

According to the [Merck Manual](#), "gender dysphoria is characterized by a strong, persistent cross-gender identification associated with anxiety, depression, irritability, and often a wish to live as a gender different from the one associated with the sex assigned at birth."

Due to the lack of conclusive evidence, and the potential for long-term, irreversible effects, the Department's guidelines are as follows:

- [Social gender transition](#) should not be a treatment option for children or adolescents.
- Anyone under 18 should not be [prescribed puberty blockers](#) or [hormone therapy](#).
- [Gender reassignment surgery](#) should [not be a treatment option](#) for children or adolescents.
 - Based on the [currently available evidence](#), "encouraging mastectomy, ovariectomy, uterine extirpation, penile disablement, tracheal shave, the prescription of hormones which are out of line with the genetic make-up of the child, or puberty blockers, are all clinical practices which run an **unacceptably high risk of doing harm.**"
- Children and adolescents should be provided social support by peers and family and seek counseling from a licensed provider.

These guidelines do not apply to procedures or treatments for children or adolescents born with a genetically or biochemically verifiable [disorder of sex development](#) (DSD). These disorders include, but are not limited to, 46, XX DSD; 46, XY DSD; sex chromosome DSDs; XX or XY sex reversal; and ovotesticular disorder.

The Department's guidelines are consistent with the federal Centers for Medicare and Medicaid Services [age requirement for surgical and non-surgical treatment](#). These guidelines are also in line with the guidance, reviews, and [recommendations](#) from [Sweden](#), [Finland](#), the [United Kingdom](#), and [France](#).

Parents are encouraged to reach out to their child's health care provider for more information.

Mission:

To protect, promote & improve the health of all people in Florida through integrated state, county & community efforts.

Treatment of Gender Dysphoria for Children and Adolescents - Fact Check -

This fact check covers the claims made by the Health and Human Services (HHS) Offices of Population Affairs (OASH) [fact sheet](#).

HHS Claims that treatments including irreversible surgeries, such as mastectomies and penectomies, "improves mental health and overall well-being."

Facts:

- The [research used to support](#) cannot infer causation; the researchers state as much in the Limitations. The researchers stated, "it is possible that those who historically have higher rates of depression and suicidal thoughts and behaviors are also less able to seek or obtain GAHT [hormone treatment]."
- A [systematic review on hormonal treatment](#) of young people with gender dysphoria concludes that "low-quality evidence suggests that hormonal treatments for transgender adolescents can achieve their intended physical effects, but evidence regarding their psychosocial and cognitive impact are generally lacking." The cited evidence had small sample sizes and medium to high risk of bias.
- A [small study](#) on 44 patients in the United Kingdom failed to show any psychological benefit to puberty blockers on children aged 12 to 15.

HHS Claims that surgeries and other potentially permanent pharmaceutical interventions "have been demonstrated to yield lower rates of adverse mental health outcomes, build self-esteem, and improve overall quality of life..."

Facts:

- A paper published in [International Review of Psychiatry](#) states that **80% of those seeking clinical care will lose their desire to identify with the non-birth sex.**
- The cited [psychosocial overview](#) is a **case study of a single patient**, and it outlines the authors' views.
- The [second article cited](#) is an online survey completed by 288 U.S. transgender adults, not children and adolescents.
- In May of 2021, Sweden's Karolinska Institute [suspended the use of puberty blockers](#) for those under the age of 18 due to the potentially irreversible consequences such as cardiovascular disease, osteoporosis, infertility, increased cancer risk, and thrombosis.

Florida Department of Health**Office of the State Surgeon General**

4052 Bald Cypress Way, Bin A-00 • Tallahassee, FL 32399-1701

PHONE: 850/245-4210 • FAX: 850/922-9453

FloridaHealth.gov**Accredited Health Department**
Public Health Accreditation Board

- [According to a study in Neurolmage](#), “pubertal development was significantly related to structural volume in all six regions [in brain regions of interest] in both sexes,” meaning that the process of puberty is important to brain development.
- A November 2020 [systematic review published in Cochrane](#) “found insufficient evidence to determine the efficacy and safety of hormonal treatment for transgender women in transition.”

HHS Claims that their approach “is critical in fostering better outcomes.”

Facts:

- According to the [first resource cited](#) in the OHSA fact sheet, of “those who received [GAHT]... a greater proportion reported that they struggled to meet basic needs or were just able to meet them, compared to those who wanted GAHT but did not receive it.”
- “[A recent Finnish study](#)... reported on the effect of initiating cross-sex hormone therapy on functioning, progression of developmental tasks of adolescence, and psychiatric symptoms. This study found that during cross-sex hormone therapy, problems in these areas did not decrease”
- The second study cited in this section is partly refuted by the third. The third [study states](#) that “transitioning socially is beneficial for children with GD **could not be supported from the present results.**”

Conclusion:

The current evidence does not support the use of puberty blockers, hormone treatments, or surgical procedures for children and adolescents, considering:

- 80% of those seeking clinical care will lose their desire to identify with the non-birth sex,
- the importance of puberty to brain development, with the pre-frontal cortex (which is responsible for executive functions, such as decision making) continuing to develop until [approximately 25 years of age](#),
- and the potentially irreversible consequences such as cardiovascular disease, osteoporosis, infertility, increased cancer risk, and thrombosis.

Gender-Affirming Care and Young People

What is gender-affirming care?

Gender-affirming care is a supportive form of healthcare. It consists of an array of services that may include medical, surgical, mental health, and non-medical services for transgender and nonbinary people.

For transgender and nonbinary children and adolescents, early gender-affirming care is crucial to overall health and well-being as it allows the child or adolescent to focus on social transitions and can increase their confidence while navigating the healthcare system.

Why does it matter?

Research demonstrates that gender-affirming care improves the mental health and overall well-being of gender diverse children and adolescents.¹ Because gender-affirming care encompasses many facets of healthcare needs and support, it has been shown to increase positive outcomes for transgender and nonbinary children and adolescents. Gender-affirming care is patient-centered and treats individuals holistically, aligning their outward, physical traits with their gender identity.

Gender diverse adolescents, in particular, face significant health disparities compared to their cisgender peers. Transgender and gender nonbinary adolescents are at increased risk for mental health issues, substance use, and suicide.^{2,3} The Trevor Project's 2021 *National Survey on LGBTQ Youth Mental Health* found that 52 percent of LGBTQ youth seriously considered attempting suicide in the past year.⁴

A safe and affirming healthcare environment is critical in fostering better outcomes for transgender, nonbinary, and other gender expansive children and adolescents. Medical and psychosocial gender affirming healthcare practices have been demonstrated to yield lower rates of adverse mental health outcomes, build self-esteem, and improve overall quality of life for transgender and gender diverse youth.^{5,6} Familial and peer support is also crucial in fostering similarly positive outcomes for these populations. Presence of affirming support networks is critical for facilitating and arranging gender affirming care for children and adolescents. Lack of such support can result in rejection, depression and suicide, homelessness, and other negative outcomes.^{7,8,9}

Common Terms:

(in alphabetical order)

Cisgender: Describes a person whose gender identity aligns with their sex assigned at birth.

Gender diverse or expansive: An umbrella term for a person with a gender identity and/or expression broader than the male or female binary. Gender minority is also used interchangeably with this term.

Gender dysphoria: Clinically significant distress that a person may feel when sex or gender assigned at birth is not the same as their identity.

Gender identity: One's internal sense of self as man, woman, both or neither.

Nonbinary: Describes a person who does not identify with the man or woman gender binary.

Transgender: Describes a person whose gender identity and/or expression is different from their sex assigned at birth, and societal and cultural expectations around sex.

Gender-Affirming Care and Young People

Affirming Care	What is it?	When is it used?	Reversible or not
Social Affirmation	Adopting gender-affirming hairstyles, clothing, name, gender pronouns, and restrooms and other facilities	At any age or stage	Reversible
Puberty Blockers	Using certain types of hormones to pause pubertal development	During puberty	Reversible
Hormone Therapy	Testosterone hormones for those who were assigned female at birth	Early adolescence onward	Partially reversible
Gender-Affirming Surgeries	<p>Estrogen hormones for those who were assigned male at birth</p> <p>“Top” surgery – to create male-typical chest shape or enhance breasts</p> <p>“Bottom” surgery – surgery on genitals or reproductive organs</p> <p>Facial feminization or other procedures</p>	Typically used in adulthood or case-by-case in adolescence	Not reversible

Gender-Affirming Care for Transgender and Gender Diverse People

What is gender-affirming care?

Gender-affirming care is a supportive form of healthcare. It consists of an array of services that may include medical, surgical, mental health, and non-medical services for transgender and nonbinary people.

FALSE

Most children identifying as transgender will detransition following the onset of puberty.

For transgender and nonbinary children and adolescents, early gender-affirming care is crucial to overall health and well-being as it allows the child or adolescent to focus on social transitions and can increase their confidence while navigating the healthcare system.

Truth**Common Terms:**
(in alphabetical order)

Cisgender: Describes a person with their sex assigned at birth.

Gender diverse or expansive: An umbrella term for a person with a gender identity and/or expression broader than the male or female binary. Gender minority is also used interchangeably with this term.

Gender dysphoria: Clinically significant distress that a person may feel when sex or gender assigned at birth is not the same as their identity.

Gender identity: One's internal

Why does it matter?

Research demonstrates that gender-affirming care improves the mental health and overall well-being of gender diverse children and adolescents.¹ Because gender-affirming care encompasses many facets of healthcare needs and support, it has been shown to increase positive outcomes for transgender and nonbinary children and adolescents.

Gender-affirming care is patient-centered and treats individuals holistically, aligning their outward, physical traits with their gender identity.

Truth

"Gender affirming" care is not the standard of care. It consists of experimental and investigational medical treatments that will cause irreversible changes and long-term side

MISLEADING

effects. Transgender and gender diverse adolescents, in particular, face significant health disparities compared to their cisgender peers. Transgender and gender nonbinary adolescents are at increased risk for mental health issues, substance use, and suicide.^{2,3} The Trevor Project's 2021 *National Survey on LGBTQ Youth Mental Health* found that 52 percent of LGBTQ youth seriously considered attempting suicide in the past year.⁴

Nonbinary: Describes a person who does not identify with the man or woman gender binary.

Transgender: Describes a person whose gender identity and or expression differs from their sex assigned at birth, and societal and cultural expectations around sex.

LOW QUALITY

No reliable evidence shows that gender dysphoria significantly increases the risk of suicide.

Healthcare environments increases the risk of suicide. Outcomes for transgender, nonbinary, and other gender expansive children and adolescents. Medical and psychosocial gender affirming healthcare practices have been demonstrated to yield lower rates of adverse mental health outcomes, build self-esteem, and improve overall quality of life for transgender and gender diverse youth.^{5,6} Familial and peer support is also crucial in fostering similarly positive outcomes for these populations. Presence of affirming support networks is critical for facilitating and arranging gender affirming care for children and adolescents. Lack of such support can result in rejection, depression and homelessness.^{7,8}

Truth**Truth****FALSE**

No high — or even moderate — quality studies exist demonstrating the long-term benefits of "gender affirming" care. In fact, evidence to the contrary show that these treatments worsen mental health and increase suicidality.

Gender Affirming Care and Young People

Truth

There is no verifiable research showing the safety of puberty blockers for non-FDA approved uses. Nor do any studies *guarantee* the reversibility in this age group. Rather, evidence shows that normal bone density cannot fully be reestablished.

Affirming Care	What is it?	When is it used?	Reversible or not
Social Affirmation	Adopting gender-affirming hairstyles, clothing, name, gender pronouns, and restrooms and other facilities	At any age or stage	Reversible
Puberty Blockers	Using certain types of hormones to pause pubertal development	During puberty	Reversible
Hormone Therapy	Testosterone hormones for those who were assigned female at birth Estrogen hormones for those who were assigned male at birth	Early adolescence onward	Partially reversible
Gender-Affirming Surgeries	"Top" surgery – to create male-typical chest shape or enhance breasts "Bottom" surgery – surgery on genitals or reproductive organs Facial feminization or other procedure	Typically used in adulthood or case-by-case in adolescence	Not reversible

FALSE

MISLEADING

Truth

The use of cross-sex hormones can cause permanent infertility.

Lack of credible evidence for adults and children.

REVIEW ARTICLE

Gender dysphoria in childhood

Jiska Ristori^a and Thomas D. Steensma^{b,c}

^aDepartment of Experimental, Clinical and Biomedical Sciences, Careggi University Hospital, Florence, Italy; ^bDepartment of Medical Psychology, VU University Medical Centre, Amsterdam, the Netherlands; ^cCentre of Expertise on Gender Dysphoria, VU University Medical Center, Amsterdam, the Netherlands

ABSTRACT

Gender dysphoria (GD) in childhood is a complex phenomenon characterized by clinically significant distress due to the incongruence between assigned gender at birth and experienced gender. The clinical presentation of children who present with gender identity issues can be highly variable; the psychosexual development and future psychosexual outcome can be unclear, and consensus about the best clinical practice is currently under debate.

In this paper a clinical picture is provided of children who are referred to gender identity clinics. The clinical criteria are described including what is known about the prevalence of childhood GD. In addition, an overview is presented of the literature on the psychological functioning of children with GD, the current knowledge on the psychosexual development and factors associated with the persistence of GD, and explanatory models for psychopathology in children with GD together with other co-existing problems that are characteristic for children referred for their gender. In light of this, currently used treatment and counselling approaches are summarized and discussed, including the integration of the literature detailed above.

Introduction

Children can vary in the extent to which they show gender role expressions, behaviours, interests, and preferences. For most children these expressions are largely congruent with their experience of being male or female – their gender identity – and in line with the gender assigned at birth. This is in contrast to children who experience gender dysphoria (GD). These children show extreme and enduring forms of gender nonconforming/gender variant behaviours, preferences, and interests because they do not identify with their birth-assigned gender. Because of the incongruence between their assigned gender and experienced gender, these children may experience clinically significant distress and are consequently often in need of clinical attention (American Psychiatric Association, 2013).

Although there has been much opposition against diagnosing GD in prepubescent children, primarily due to the stigmatizing effect of having a mental disorder (e.g. Drescher, 2013), the condition is included in the current edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-5) (American Psychiatric Association, 2013) as well as in the *International Classification of Diseases* (ICD-10; World Health Organization, 1992). The World Health Organization

(WHO) is, however, in the process of revising the tenth version of the ICD; but instead of removal of the childhood diagnosis the terminology will most likely be changed from ‘gender identity disorder of childhood’ into ‘gender incongruence of childhood’ (Drescher, Cohen-Kettenis, & Winter, 2012).

According to the DSM-5, a diagnosis of GD of childhood can be made if a child experiences a marked incongruence between one’s experienced/expressed gender and assigned gender, of at least 6 months’ duration, as manifested by six out of eight criteria. One *sine qua non* criterion must be the experience of a strong desire to be of another gender or an insistence to be another gender. In addition to this, there are two criteria focusing on anatomic dysphoria; a dislike of one’s sexual anatomy and the desire for primary/secondary sex characteristics of the experienced gender. In addition there are five behavioural criteria. The behavioural criteria concern the preference for cross-dressing; adopting cross-gender roles in fantasy play; a strong preference for toys, games and activities of the other gender; a preference for playmates of the other gender; and a strong aversion or rejection of typically gender congruent roles, interests, preferences and behaviours. Furthermore, the condition is associated with clinically

significant distress or impairment in social, school, or other important areas of functioning (American Psychiatric Association, 2013).

Valid information on the prevalence of childhood GD is not available yet due to the absence of formal prevalence studies. An estimate of the prevalence of gender nonconforming/gender variant behaviours can, however, be made on the basis of studies where the Child Behavior Checklist (CBCL) (Achenbach & Edelbrock, 1983) was used. On the CBCL – a parent-report questionnaire on behavioural problems – two items are related to gender variance: Item 5 ('Behaves like opposite sex') and item 110 ('Wishes to be of opposite sex'). Information from the Dutch normative sample of the CBCL shows that in children, both items are more frequently endorsed by parents of girls than of boys; 'Behaves like opposite sex' in 2.6% of the boys and 5.0% of the girls, 'Wishes to be of opposite sex' in 1.4% of the boys and 2.0% of the girls (Verhulst, van der Ende, & Koot, 1996). These findings are in concordance with data from the normative sample of the CBCL in North-America (Achenbach & Edelbrock, 1981; Zucker, Bradley, & Sanikhani, 1997), and are largely replicated in a study of Dutch twins ($N=23,393$) at ages 7 and 10 (Van Beijsterveldt, Hudziak, & Boomsma, 2006). Therefore, gender variance/gender nonconformity seems to be present in a small percentage of children and is more prominent in girls than in boys.

Interestingly, from what we know about the referrals to specialized gender identity clinics, the sex ratios for referred prepubescent children have always been in favour of natal men, which may be a direct effect of a difference in increased acceptance of masculinity in girls compared to femininity in boys (e.g. Blakemore, 2003; Cohen-Kettenis et al., 2003; Steensma et al., 2014; Wallien, Veenstra, Kreukels, & Cohen-Kettenis, 2010; Zucker, Wilson-Smith, Kurita, & Stern, 1995). Over the last decades the reported sex ratios have, however, gradually changed. For example, in the period before 2000 the ratio between boys and girls was 5.75:1 in Canada and 2.93:1 in the Netherlands (Cohen-Kettenis et al., 2003). In the period after 2000, the sex ratios decreased in Canada to 3.41:1 (2008–2011) for boys and girls respectively (Wood et al., 2013); and a similar pattern was observed in the Netherlands with a sex ratio of 1.68:1 between 2008 and 2011 (Steensma, 2013). For both countries this change in ratios is caused by fewer referrals of boys. Although empirical evidence is currently not available, the decrease of referrals in boys may indicate an increasing tolerance over time towards gender nonconforming behaviours in both countries.

Psychological functioning, social tolerance, and other co-existing problems

Besides the gender nonconforming presentation, children with GD who are referred to clinical settings have been shown to be more psychologically vulnerable in comparison to non-referred controls (Bates, Bentler, & Thompson, 1973, 1979) and in comparison to the general population (e.g. Cohen-Kettenis et al., 2003; Singh, Bradley, & Zucker, 2011; Steensma et al., 2014). Furthermore, these studies show that these psychological problems are more of an internalized nature (such as depression, social withdrawal, and anxiety), instead of an externalizing nature (such as aggression) (Bates et al., 1973, 1979; Coates & Person, 1985; Rekers & Morey, 1989; Zucker & Bradley, 1995; Cohen-Kettenis et al., 2003; Steensma et al., 2014). However, as Zucker, Wood, and VanderLaan (2014) recently concluded from their summary of studies reporting on the psychological functioning of gender-referred children, there is a considerable variability across the different studies. For example, the percentage of clinical-range cases reported in studies using the total behaviour problem score of the CBCL, ranged from 12.5% up to 84% of the described children over the different studies (for an overview see Zucker et al., 2014).

To understand this association between GD and the variability of psychological functioning within the population of children with GD, the empirical literature indicates the effect is largely mediated through social (in)tolerance towards gender nonconformity/gender variance. Indeed, a wide range of studies in children from the general population showed that gender nonconforming behaviour is often evaluated negatively by other children (e.g. Carter & McCloskey, 1984; Levy, Taylor, & Gelman, 1995; Ruble et al., 2007; Signorella, Bigler, & Liben, 1993; Stoddart & Turiel, 1985). Peer relations in general are therefore poorer for clinically referred children with GD than for non-referred children/youth (e.g. Cohen-Kettenis et al., 2003; Zucker et al., 1997, 2012); and, as we might expect, poor peer relations are associated with a negative well-being and poor psychological functioning in children with GD (e.g. Cohen-Kettenis et al. 2003; Steensma et al., 2014). Consequently the variability in psychological functioning detailed within the literature is likely inversely correlated with the intensity of social intolerance experienced by the children with GD. For example, a cross-national study between children referred for their gender from Canada and from the Netherlands showed a much higher prevalence of emotional and behavioural problems in the Canadian children than in the Dutch children. Interestingly, quality of peer relations rather

than IQ, parental social class, marital status, or ethnicity, turned out to be the strongest predictor in both countries. Furthermore, the quality of peer relations was lower in Canada than in the Netherlands. This indicates that psychological functioning is highly dependent upon how gender nonconformity is accepted within a certain culture or environment (Steensma et al., 2014).

However, this may not be the only factor that results in poorer psychological functioning. Over the years other models postulated in the literature focused, for example, upon generic risk factors for psychopathology and behavioural problems (such as parental psychopathology, social class background) in relation to GD; and considered them as an inherent cause of psychological problems in children with GD. Evidence for these relations is, however, still scarce and both models are under-studied in comparison to other factors such as social (in)tolerance (Zucker et al., 2014).

As far as co-occurring problems in children with GD are concerned, the relationship between Autistic Spectrum Disorders (ASD) and GD is important to mention. Although there are few studies investigating the relationship between the two, one study by de Vries, Noens, Cohen-Kettenis, van Berckelaer-Onnes, & Doreleijers (2010) showed that in a sample of 108 gender-referred children ASD was present in 6.4% of the children. This is significantly higher than the prevalence of 0.6–1% of ASD in the general population (Fombonne, 2005). Corresponding with these findings, a study by VanderLaan et al. (2015) of children referred for gender studied obsessional interests – which may be an indication of ASD – and showed that obsessions were more frequently reported by children referred for their gender in comparison with the general population. With regard to how ASD and GD are related, the question arises as to whether GD is an expression of ASD, or whether ASD is a symptom of GD; alternatively, of course, the two may be present without being related to each other (see van der Miessen et al., this issue).

Psychosexual development and related factors for persistence of GD

A central question in the counselling of children with GD is what their psychosexual outcome will be. Will the child grow up and identify as a gay man, lesbian woman, bisexual man or woman, or heterosexual man or woman without experiencing feelings of gender incongruence which require any intervention; or will the child need medical treatment in the future because the gender dysphoric feelings will persist and further intensify?

To date, there are 10 prospective follow-up studies described in the literature, together reporting on 317 gender nonconforming children who were followed-up in adolescence or early adulthood. The follow-up information in Zucker & Bradley (1995) is not included in this summary. In personal correspondence with Dr. Zucker it became clear that the 45 cases described are also included in the samples of Drummond, Bradley, Peterson-Badali, & Zucker (2008) (5 natal girls) and Singh (2012) (40 natal boys).

The conclusion from these studies is that childhood GD is strongly associated with a lesbian, gay, or bisexual outcome and that for the majority of the children (85.2%; 270 out of 317) the gender dysphoric feelings remitted around or after puberty (see Table 1).

However, there may be a number of arguments to nuance this high percentage of desistence. As is shown in Table 1 there is much variation in the reported persistence rates between the studies, ranging from 2% to 39%. Interestingly the studies before the year 2000 reported much lower persistence rates in comparison to the more recent studies after the year 2000. Furthermore, the persistence rates reported in two Canadian studies (Drummond et al., 2008; Singh, 2012) were identical (12%) but clearly lower in comparison to the follow-up study by Wallien & Cohen-Kettenis (2008) from the Netherlands. The explanation for these differences may be threefold:

First, the variation in intensity of GD in the children included differs across studies: The lower persistence rates in the earlier studies, compared to the more recent studies after 2000, may be the result of the inclusion of less extreme cases in the earlier studies than in later studies. For example, before the publication of DSM-III in 1980 there was no formal diagnosis of GD for children (Drescher, 2014). It could therefore be that the children included in the studies before 1980 would in retrospect not meet the full criteria for a diagnosis. Also, the recent

Table 1. Follow-up studies in children with GD.

Study	Sample	Age at follow-up (range)	Persistence rate
Bakwin (1968) Lebovitz (1972) Zuger (1984) Money & Russo (1979) Davenport (1986) Kosky (1987)	55 natal boys	13–36	9% (5 out of 55)
Green (1987)	44 natal boys	19 (14–24)	2% (1 out of 44)
Drummond et al. (2008)	25 natal girls	23 (15–37)	12% (3 out of 25)
Wallien & Cohen-Kettenis (2008) Singh (2012)	40 natal boys 14 natal girls 139 natal boys	19 (16–28) 21 (13–39)	39% (21 out of 54) 12% (17 out of 139)

studies consisted of clinically referred samples of children, which was not the case for the earlier studies. For example, in the study by Green (1987) the sample of feminine boys was recruited through advertisement.

Secondly, and in line with the intensity explanation, there are possible cultural differences in referral: As described earlier, the sex ratios of child referrals in Canada are historically in greater favour of boys than girls as compared to the Netherlands. This may indicate that femininity in boys is experienced as more problematic in Canada –resulting in more referrals of boys with less extreme GD than in the Netherlands. As a result, the persistence rates are higher in the Netherlands compared to Canada.

Thirdly, we can consider the time of follow-up: As can be seen in Table 1, the time of follow-up differed across the studies and one could hypothesize that the studies with a later follow-up age (of older adolescents or adults) and those having a longer follow-up time, would report higher persistence rates than the studies where the follow-up took place at a younger age (i.e. shorter follow-up time). This trend is however not observed over the reported studies. To test this hypothesis, Steensma & Cohen-Kettenis (2015) recently published a report on the first 150 childhood cases from Amsterdam, the Netherlands, and checked whether a longer follow-up period would result in higher persistence rates. The children were at the time of first assessment – between 5 to 12 years old and between 19 to 38 years of age at the time of follow-up. Out of the 150 cases, 40 re-entered the clinic during adolescence (12–18 years of age) and turned out to be persisters (26.7%). However, after checking the files of the adult clinic (which sees nearly all adults with gender dysphoria in the Netherlands), it appeared that five individuals applied for treatment after the age of 18, raising the persistence rate to 30% and showing the importance of long-term follow-ups. Based on this information, it seems reasonable to conclude that the persistence of GD may well be higher than 15%. However, desistence of GD still seems to be the case in the majority of children with GD.

Two other clinically relevant questions are (1) whether we know anything with regard to the factors that are associated with the persistence or desistence of childhood GD and (2) how the process of persistence or desistence is experienced.

As to the factors associated with the persistence of GD, knowledge is still limited but fortunately slowly increasing. A central finding from all quantitative studies focusing on the topic is that the persistence of GD is most closely linked to the intensity of the GD in childhood and the amount of reported cross-gendered behaviour; in other words the more intense GD is in

childhood, and the more cross-gendered behaviour is reported by parents or through self-report, the higher the chance that the GD persists (Drummond et al., 2008; Singh, 2012; Steensma, McGuire, Kreukels, Beekman, & Cohen-Kettenis, 2013; Wallien & Cohen-Kettenis, 2008). In addition to this, several other factors are linked to persistence of GD: For example, Steensma et al. (2013) and Wallien & Cohen-Kettenis (2008) showed that the persistence rate is generally higher in natal girls than in natal boys; And Steensma et al. (2013) and Singh (2012) found that the assessment age in childhood was higher in children where the GD persisted than for desisters; Further, Singh (2012) reported a higher social class in the parents of desisters compared to the parents of persisters.

In addition, Steensma et al. (2013) found that a social transition in childhood, especially in natal boys, and verbal identification with the desired/experienced gender was predictive for the persistence of GD. Interestingly, the identification finding was reported in an earlier qualitative study by Steensma, Biemond, de Boer & Cohen-Kettenis (2011) who observed differences in reported experiences of GD between persisters and desisters who were interviewed. For example, the persisters explicitly indicated that they felt they *were* the 'other' sex and the desisters indicated that they only *wished* they were the 'other' sex. The primary aim of the Steensma et al. (2011) study was to get a better understanding of the processes that contribute to the persistence and desistence of childhood GD. By interviewing adolescents (14 persisters, 11 desisters) who all fulfilled the DSM-IV or DSM-IV-TR criteria of a gender identity diagnosis in childhood (APA, 1994, 2000), it became clear that the period between 10 and 13 years was considered crucial. Both persisters and desisters stated that the changes in their social environment, the anticipated and actual feminization or masculinization of their bodies, and the first experiences of falling in love and sexual attraction in this period, contributed to an increase (in the persisters) or decrease (in the desisters) of their gender related interests, behaviours, and feelings of gender discomfort.

Treatment and counselling of children with GD

Over the last decade, the care for prepubescent children with GD has been rapidly changing and there is a growing number of specialized gender clinics for young people (Hsieh & Leininger, 2014; Khatchadourian, Ahmed, & Metzger, 2014; Riittakerttu, Sumia, Työläjärvä, & Lindberg, 2015). Best clinical practice in gender referred children is still controversial and raises debates among dedicated professionals. General agreement does, however, exist that the care for children with

GD should be focused on reducing the child's distress related to their GD; on help with other psychological difficulties; and optimizing psychological adjustment and wellbeing (e.g. Byne et al., 2012; Coleman et al., 2011). As for the counselling of the gender dysphoric feelings in children with GD; empirical treatment models do not exist and general consensus between clinicians is not always easy to obtain (Byne et al., 2012). In the current professional literature, three treatment models for the care of gender variant children can be distinguished (e.g. Byne et al., 2012; Drescher, 2013) and it is these to which we now turn.

The first approach focuses on working with the child and caregivers to lessen cross-gender behaviour and identification, to persuade the child that the 'right gender' is the one assigned at birth (Giordano, 2012), to decrease the likelihood that GD will persist into adolescence, and prevent adult transsexualism. Critics of this approach have linked it to 'reparative therapy', a term more commonly used to describe efforts to change same sex attraction to heterosexuality in gay adults or 'pre-homosexual' children (Drescher, 2013). In the past, such behavioural and psychodynamic therapies to lessen the GD have been largely used in children with GD with overall unsatisfactory results (Byne et al., 2012; Möller, Schreier, Li, & Romer, 2009). Instead, children often seem to become distressed if their preferences and/or behaviours are blocked (Richardson, 1999). At present, interventions aimed to lessen GD are referred to as unethical by the World Professional Association for Transgendered Health (WPATH: Coleman et al., 2011) and many other international professional organizations. The American Academy of Child & Adolescent Psychiatry, for example, has explicitly formulated their position against any psychological treatment aimed to change gender nonconforming behaviours (Adelson, 2012).

The second approach is focused on dealing with the potential social risks for the child (Byne et al., 2012). Because its aim is to allow the progress of the GD in the child to unfold in a natural way, it is often referred to as 'watchful waiting' (Drescher, 2013). Counselling based on this approach may include interventions that focus on the co-existing problems of the child and/or the family; helping parents and the child to bear the uncertainty of the child's psychosexual outcome; and providing psycho-education to help the child and the family to make balanced decisions regarding topics such as the child's coming out, early social transitioning, and/or how to handle peer rejection or social ostracism. In practice, the child and parents are encouraged to find a balance between an accepting and supportive attitude toward GD, while at the same time protecting the child against

any negative reactions and remaining realistic about the chance that GD feelings may desist in the future. Parents are encouraged to provide enough space for their child to explore their gender dysphoric feelings, while at the same time keeping all future outcomes open (e.g., de Vries & Cohen-Kettenis, 2012; Di Ceglie, 1998, 2014).

The third approach is focused on affirming the child's (trans)gender identification and helps the child to build a positive self-identity and gender resilience. In particular, the child is supported in transitioning to the desired/experienced gender role. The rationale for supporting social transition before puberty is that children can revert to their originally assigned gender if necessary since the transition is solely at a social level and without medical intervention (e.g. Byne et al., 2012; Drescher, 2013; Hill, Menvielle, Sica, & Johnson, 2010). Critics of this approach believe that supporting gender transition in childhood may indeed be relieving for children with GD but question the effect on future development. The debate thereby focuses on whether a transition may increase the likelihood of persistence because, for example, a child may 'forget' how to live in the original gender role and therefore will no longer be able to feel the desire to change back; or that transitioned children may repress doubts about the transition out of fear that they have to go through the process of making their desire to socially (re)transition public for a second time (Steensma, 2013). The fact that transitioning for a second time can be difficult was indeed shown in the qualitative study by Steensma et al. (2011) where children who transitioned early in childhood reported a struggle with changing back to their original gender role when their feelings desisted, with the fear of being teased or excluded by their peers reported as the main reason for this.

Unfortunately, empirical answers about the best way to counsel children with GD and their caregivers are currently not available. The WPATH have therefore formulated a balanced position in their Standards of Care (Coleman et al., 2011), where clinicians are encouraged to help families by providing information about what is known about the development of children with GD and to help them to make decisions where the potential benefits and challenges of particular choices are weighted.

Conclusion

According to the DSM-5 diagnostic criteria for gender dysphoria, children with GD experience clinically significant distress because of the incongruence between their assigned gender at birth and experienced gender (APA, 2013). The clinical presentation of children who

present with gender identity issues is characterized by gender-nonconformity and a vulnerability to having psychological problems – primarily of an internalized nature (e.g. Cohen-Kettenis et al., 2003; Steensma et al., 2014), and an increased likelihood of ASD symptomatology (de Vries et al., 2010; VanderLaan et al., 2015). The extent and intensity of all three characteristics can be variable.

When considering the development of children with GD; studies show that gender dysphoric feelings eventually desist for the majority of children with GD, and that their psychosexual outcome is strongly associated with a lesbian, gay, or bisexual sexuality which does not require any medical intervention, instead of an outcome where medical intervention is required (e.g. Drummond et al., 2008; Wallien & Cohen-Kettenis, 2008; Singh, 2012). Factors predictive for the persistence of GD have been identified on a group level, with higher intensity of GD in childhood identified as the strongest predictor for a future gender dysphoric outcome (Steensma et al., 2013). The predictive value of the identified factors for persistence are, however, on an individual level less clear cut, and the clinical utility of currently identified factors is low.

Taken together this shows that there can be a great variability with regard to presentation of children with GD and their psychosexual outcome. The counselling of children with GD can therefore be complex and clinically challenging. To date, there is general agreement that the care for children with GD should not be aimed at avoiding adult same sex attraction or transsexualism; that no medical intervention should be provided in childhood (before puberty); that counselling should therefore be focused on reducing the child's distress related to the GD, on help with other psychological difficulties, and on optimizing psychological adjustment and wellbeing (e.g. Byne et al., 2012; Coleman et al., 2011).

However, besides these basic clinical values, there is currently no general consensus about the best approach to dealing with the (uncertain) future development of children with GD, and making decisions that may influence the functioning and/or development of the child – such as a social transition. Different clinical approaches are presented in the literature, and indeed taking the variability in presentation of children with GD into account, it seems important to underline that a 'one size fits all' approach is not best practice for children with GD. Therefore, different kinds of treatment options should be available which respect the unique needs of every child. In particular, the child's clinical psychological profile and gender development, as well as the contextual psychosocial characteristics of the child's

family (e.g. belief system, supportive behaviours, access to health care) should always be taken into account in order to make balanced decisions. Currently, the limited empirical evidence in favour of a particular treatment makes treatment of teenagers with GD a controversial issue that raises intense, and often polarized, debate. Therefore, studies comparing different psychological treatment options are needed as well as research which aims to identify the factors involved in the persistence process of GD on an individual level. The primary goal is therefore to determine the safest and most efficacious mental and medical approach for the individual child with GD.

Hormonal Treatment in Young People With Gender Dysphoria: A Systematic Review

Denise Chew, BBmed,^a Jemma Anderson, MBBS,^b Katrina Williams, MBBS, MSc, PhD, FRACP, FAFPHM,^{a,c,d}
Tamara May, BA, BSc, GDipPsych, PGDipPsych, PhD,^{a,c,d,e} Kenneth Pang, MBBS, BMedSc, FRACP, PhD^{a,c,d,f,g}

CONTEXT: Hormonal interventions are being increasingly used to treat young people with gender dysphoria, but their effects in this population have not been systematically reviewed before.

OBJECTIVE: To review evidence for the physical, psychosocial, and cognitive effects of gonadotropin-releasing hormone analogs (GnRHa), gender-affirming hormones, antiandrogens, and progestins on transgender adolescents.

DATA SOURCES: We searched Medline, Embase, and PubMed databases from January 1, 1946, to June 10, 2017.

STUDY SELECTION: We selected primary studies in which researchers examined the hormonal treatment of transgender adolescents and assessed their psychosocial, cognitive, and/or physical effects.

DATA EXTRACTION: Two authors independently screened studies for inclusion and extracted data from eligible articles using a standardized recording form.

RESULTS: Thirteen studies met our inclusion criteria, in which researchers examined GnRHas ($n = 9$), estrogen ($n = 3$), testosterone ($n = 5$), antiandrogen (cyproterone acetate) ($n = 1$), and progestin (lynestrenol) ($n = 1$). Most treatments successfully achieved their intended physical effects, with GnRHas and cyproterone acetate suppressing sex hormones and estrogen or testosterone causing feminization or masculinization of secondary sex characteristics. GnRHa treatment was associated with improvement across multiple measures of psychological functioning but not gender dysphoria itself, whereas the psychosocial effects of gender-affirming hormones in transgender youth have not yet been adequately assessed.

LIMITATIONS: There are few studies in this field and they have all been observational.

CONCLUSIONS: Low-quality evidence suggests that hormonal treatments for transgender adolescents can achieve their intended physical effects, but evidence regarding their psychosocial and cognitive impact are generally lacking. Future research to address these knowledge gaps and improve understanding of the long-term effects of these treatments is required.

Transgender is a term used to describe an individual whose inner gender identity differs from their sex assigned at birth. This mismatch can cause distress and functional impairment, resulting in gender dysphoria (GD) or what was previously termed “gender identity disorder” (GID).^{1,2}

Several hormonal treatment options are available for GD, the appropriateness of which depends on developmental stage. For instance, puberty can frequently exacerbate GD because of the development of unwanted secondary sexual characteristics,³ which can be reversibly suppressed by using gonadotropin-releasing hormone analogs (GnRHAs).^{4,5} In comparison, gender-affirming hormones (GAHs; also known as cross-sex hormonal therapy) allow individuals to actively masculinize or feminize their physical appearance to be more consistent with their gender identity. As GAHs are only partially reversible, they are generally used only once an individual reaches the legal age of medical consent, which varies across countries.⁵ In addition, antiandrogens, such as spironolactone and cyproterone acetate, can be used to counter the effects of testosterone in birth-assigned male individuals,^{6,7} whereas progestins, such as norethisterone and medroxyprogesterone, are often employed to suppress menses in younger birth-assigned female individuals.

Authors of multiple studies have investigated the physical and psychosocial effects of different hormonal interventions in adults with GD. GAHs have been examined most extensively, with authors of systematic reviews indicating that GAHs improve multiple aspects of psychosocial functioning,^{8,9} although they also increase serum triglycerides and risk of cardiovascular disease (including venous thrombosis, stroke, myocardial infarction, and

pulmonary embolism).^{10–12} Studies of antiandrogens in transfemale adults have revealed that cyproterone acetate is able to reduce levels of testosterone, whereas spironolactone has a synergistic effect with estrogen in improving both physical and hormonal outcomes.¹³

In contrast, studies of different hormonal treatments in young people with GD are scarce, meaning that clinicians have often had to extrapolate from adult studies. This is problematic for several reasons. Firstly, adolescence is a period of rapid development across multiple domains,¹⁴ and studies of hormonal treatments in adults with GD may not readily translate to adolescents. Secondly, some hormone treatments used in young people with GD (eg, GnRHAs and progestins) are either not commonly used in adults with GD or are used in adults for different reasons (eg, GnRHAs for prostate cancer).¹⁵ Finally, hormonal dosing regimens in adolescents with GD are frequently different from those used in adults, which is likely to affect outcomes.

Our purpose in this systematic review is, therefore, to evaluate the currently available evidence about the physical, psychosocial, and cognitive effects of different hormonal therapies in transgender youth. By doing so, we can directly inform clinical practice involving this population and highlight existing knowledge gaps.

METHODS

Eligibility Criteria

Studies were considered eligible if participants were given hormonal treatment (GnRHAs, GAHs, antiandrogens, or progestins) and if analysis of psychosocial, cognitive, and/or physical effects of these hormones were included. Participants had to be younger than 25 years of age and described

as transgender or diagnosed with GD and/or GID according to the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition*; *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*; or *International Classification of Diseases* criteria. This age range was selected to be consistent with the definition of adolescence used by the recent *Lancet* Commission on Adolescent Health.¹⁶ Studies were excluded if the effects of hormonal therapy could not be separated from gender-affirming surgery, which could cause potential issues related to interpretation of results. We included all published study designs in any language, but conference abstracts or studies in which researchers failed to report results at the group level with at least 10 individuals were excluded.

Study Identification

The Medline (Ovid) and Embase (Ovid) databases were searched for references from January 1, 1946, to June 10, 2017, by using thesauri and/or keywords. PubMed was searched by using keywords to retrieve electronic publications and items not indexed in Medline. The Medline search strategy was adapted for use in Embase and PubMed with the main search terms as follows: (GD or transsexualism or “sexual and gender disorders” or transgender persons or gender identity), (drug therapy or therapeutic use or [hormonal or hormone*] or *steroids or exp gestagen or exp antiandrogen), and (adolescen* or pediatric* or pediatric* or youth* or teen or teens or teenage*). Detailed search histories are available on request. Additional items were identified by manually searching reference lists of relevant retrieved articles. Two reviewers independently assessed all study titles and abstracts to determine inclusion, with the full text being subsequently retrieved for potentially eligible studies to assess final suitability. Any disagreements

were resolved with discussion and consensus was reached for final articles.

Data Extraction

Two reviewers, working independently and in duplicate, used a standardized form to extract methodological, demographic, and outcome data. Data extracted included reported youth characteristics (number of participants pre- and posttreatment, participant age range, diagnosis of GD, birth-assigned sex, and gender identity), hormonal therapy features (type, dose, route, duration of treatment), study design, and outcomes of interest (length of follow-up duration, follow-up outcome measures, and treatment effect on outcome measures).

Quality Assessment

Risk of bias in studies was assessed by 2 authors working independently using a modified version of the Quality in Prognosis Studies (QUIPS) tool from a previous study.¹⁷ The original QUIPS tool¹⁸ was modified because confounders or prognostic factors were not analyzed in this review and thus did not apply.

Review Protocol

A detailed protocol is available at PROSPERO (identifier 42017056670).

Statistical Analysis

Effect sizes were calculated for results with reported means and SDs,^{19–27} according to a previous study.²⁸ Unadjusted effect sizes using the posttest SD were calculated for the majority of studies, with an adjusted effect size using the experimental SD calculated only for 1 study with comparison between groups.²⁴

Meta-analysis

Meta-analysis was planned for outcomes examined by 3 or more studies but was unable to be

conducted because individual outcome effect sizes were available for a maximum of 2 studies.

RESULTS

Study Selection

The study selection process is depicted in Fig 1. Eighty-three potentially relevant studies were retrieved, of which 13^{19–27,29–32} met the inclusion criteria and were systematically analyzed. In Table 1, we summarize the main characteristics of these 13 studies, and their key physical, psychosocial, and cognitive findings are outlined in Tables 2, 3 and 4, respectively. Because research from the same cohort was described in 2 of the studies,^{26,27} they were considered as 1 study.

Quality Appraisal

In all studies, there was a medium to high risk of bias (Table 5). In most studies, there were only small sample sizes (minimum of 21 and maximum of 201), with <50 participants in 38.5% of the studies. There were controls in only 2 studies, and all studies were conducted in clinical populations. There was often significant loss to follow-up, attributed partially to most studies being retrospective with missing data. Overall, the tools used to measure the specific outcomes were valid and reliable, although there was no blinding or randomization in any of the studies.

PHYSICAL EFFECTS

All relevant results are shown in Table 2.

Sex Hormones and Secondary Sexual Characteristics

GnRHs

GnRHs were successful in suppressing sex hormone secretion with significant decreases in gonadotropin,²⁹ estradiol,

and testosterone^{19,21,29} levels, although 1 study only revealed a significant decrease in transfemale adolescents (birth-assigned male individuals identifying as female individuals).¹⁹ There was decreased testicular volume in transfemale adolescents^{19,21,29} and cessation of menses in transmale adolescents (birth-assigned female individuals identifying as male individuals),²¹ although the latter often occurred after a withdrawal bleed in postmenarchal individuals. Furthermore, GnRHs were shown to decrease luteinizing hormone (LH) and follicle-stimulating hormone (FSH).^{19,21}

Progestin

Researchers in 1 study examined the effects of the progestin lynestrenol³⁰ in transmale adolescents. Although there was no report of the efficacy of lynestrenol in stopping menses, there were significant reductions in levels of serum sex-hormone binding globulin (SHBG) and LH, in addition to a significant increase in free testosterone (fT). FSH, estradiol, testosterone, and anti-Müllerian hormone had nonsignificant decreases.³⁰

Antiandrogen

In one study, researchers studied the effects of the antiandrogen cyproterone acetate alone in transfemale adolescents.²² It was effective in significantly suppressing endogenous sex hormones with significant reductions in testosterone and dehydroepiandrosterone in addition to nonsignificant decreases in estradiol and fT after 12 months, with no significant changes in LH, FSH, and SHBG. Cyproterone acetate was associated with a marked increase in prolactin of ~2.5-fold that exceeded the normal reference range after 6 months but returned to the normal range after 12 months. No clinical consequences, including galactorrhea, were reported. Furthermore, 55.6% of participants

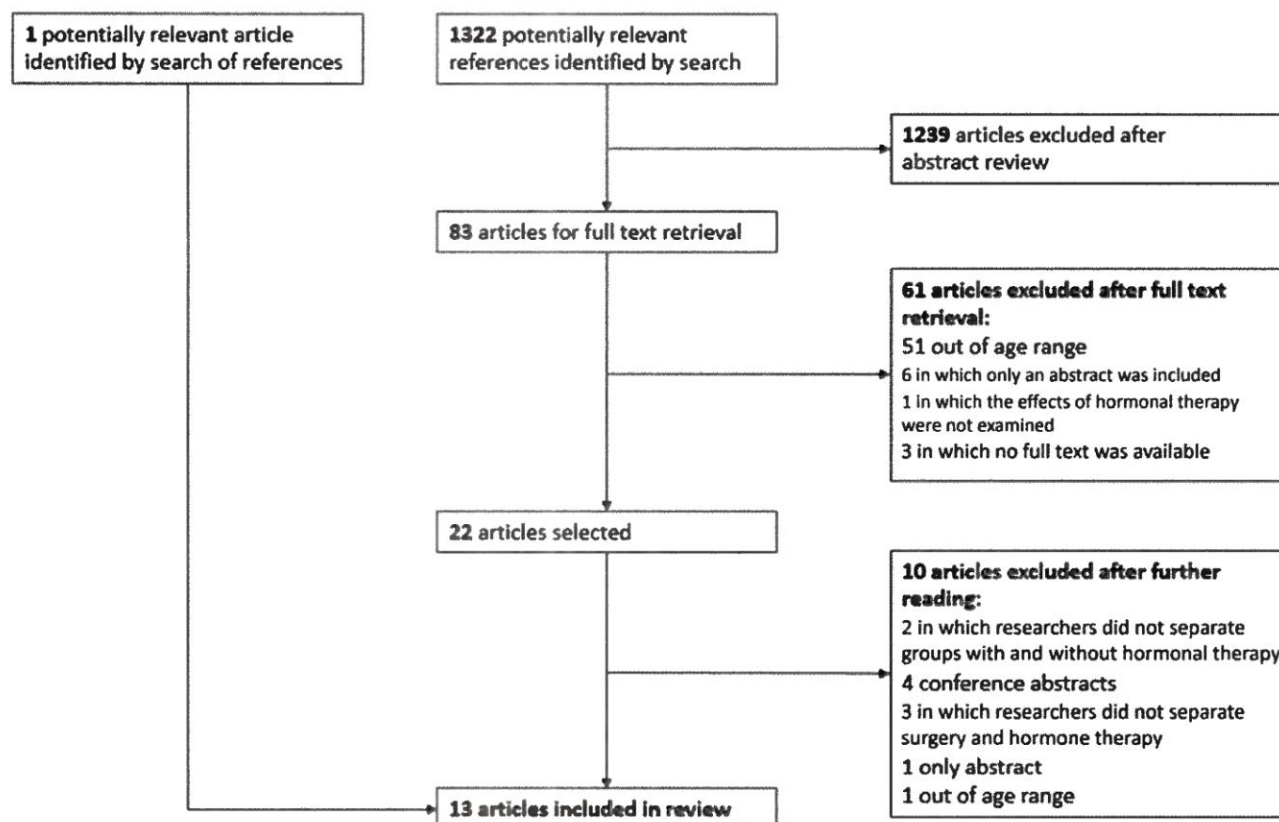

FIGURE 1
Flow diagram of study selection.

also reported decreased facial shaving frequency.²²

Estrogen

Estrogen was successful in feminizing physical sex characteristics.^{22,29} In 1 study, 66.7% of participants reached Tanner B3 stage (increase in breast and areola size), and 9.5% reached Tanner B4 (secondary mound created by areola and papilla) after treatment with cyproterone acetate and estrogen for at least 6 months.²² However, breast development was found to be objectively dissatisfactory and subjectively less in size than expected for the majority.²² There was a significant increase in serum estradiol after 6 months that reached the female reference range, whereas total testosterone decreased after 1 to 3 months to be outside of the male reference range.^{22,32} Prolactin was unchanged.²²

Testosterone

Testosterone resulted in virilization, including lower voice, clitoral enlargement, and body hair growth in a masculinized pattern.²⁹ Menses ceased in most transmale adolescents within 6 months, with an average time to cessation of 2.9 months.²⁰ Testosterone resulted in increased total testosterone and FT,^{20,30,32} with most participants reaching levels within the normal male range after 6 months,^{20,30} as well as significant decreases in LH and FSH.³⁰ This was accompanied by a decline in estradiol levels after 6 months,^{20,30,32} which was statistically significant in 2 studies^{20,30} but nonsignificant in 1 study.³²

Side Effects

GnRHAs

Hot flashes were a common side effect in transmale adolescents

treated in late puberty (Tanner stages B4 and B5), although these decreased in frequency over time.²⁹ No other short-term side effects, including local reactions, were reported.

Progestin

Lynestrenol was evaluated as relatively safe, with the most common side effects being initial metrorrhagia (48.7%), headaches (12.1%), hot flashes (9.8%), and acne (which increased from 14.6% to 28.6%).³⁰

Antiandrogens

Treatment with cyproterone acetate was evaluated to be relatively safe, with the most common side effect being fatigue (37%).²²

Estrogen

Side effects reported with combined estrogen and cyproterone acetate

TABLE 1 Characteristics of 13 Studies on Hormonal Treatments in Transgender Youth

Study	Type of Study	Sample (N)	Gender Identity	Age, y \pm SD	Loss to Follow-up, %	Effects Analyzed	Treatment	Duration of Treatment, y	Outcomes Examined
Delemarre-van de Waal and Cohen-Kettenis ²³	Prospective, longitudinal	21	11 transmale adolescents with GID, 10 transfemale adolescents with GID	Not mentioned	0	Physical	GnRHa	2 y or longer	Sex hormones and secondary sexual characteristics, safety profile, BMD, growth, and body composition

TABLE 2 Continued

Study	Treatment	Outcome					
		Testosterone, Estradiol, and Gonadotropin Levels	Anthropometric Measurements	BMD	Body Composition	Safety Profile	Other Physical Effects
Jarin et al ³²	GAH (estrogen)	Increase ^b in estradiol levels, decrease ^b in testosterone levels	—	—	No significant change in BMI (no results for height and/or wt), no significant changes in LDL, HDL, total cholesterol, triglycerides, and triglyceride to HDL ratio	—	No significant changes in BP (systolic and diastolic); initial decrease in Hct and Hb but returned to baseline; no significant changes in SUN, creatinine, prolactin, AST, or HbA1c; decrease ^b in ALT
Tack et al ²²	Antiandrogen (cyproterone acetate)	No significant changes in LH and FSH, decrease ^a in SHBG, decrease ^b in testosterone, nonsignificant decrease ^c in estradiol and fT, decrease ^b in dehydroepiandrosterone, decreased facial shaving frequency (55.60%). Breast development: Tanner B2 (14.8%) and B3 (14.8%)	Increase ^b in height, decrease ^b in height compared with male peers	—	No clinically important or statistically significant changes in wt and BMI, decrease ^b in triglycerides, no significant changes in total cholesterol, HDL, and LDL	Breast tenderness (7.4%), emotionality (11.10%), fatigue (36%), hot flashes (3.7%)	Increase ^b in prolactin (no clinical galactorrhea); decrease ^b in creatinine, Hb and Hct, but not outside of reference ranges; no significant changes in AST and ALT; no significant change in thyrotropin and fT4
Tack et al ²²	Combination of antiandrogen (cyproterone acetate) and GAH (estrogen treatment)	Decrease ^b in LH, decrease ^c in FSH, increase ^b in SHBG, increase ^b in estradiol, decrease ^b in testosterone and fT, no significant change in dehydroepiandrosterone, decreased shaving need (71.40%). Breast development: Tanner B3 (66.7%) and B4 (9.50%)	Increase ^b in height, decrease ^b in height compared with male peers	—	Breast tenderness (57.1%), emotionality (28.60%), hunger (24%), fatigue (14%), hot flashes (14.3%)	Increase ^b in BMI after 6–12 mo but BMI still less compared with Flemish male peers, increase ^c in wt, no significant changes in LDL, total cholesterol, HDL, and triglyceride levels	No significant changes in Hb and Hct, increase ^b in creatinine after 12 mo, no significant changes in AST and ALT, no significant change in thyrotropin and free thyroxine, decrease ^b in prolactin

Note that transmale adolescents are birth-assigned female individuals who identify as male individuals, whereas transfemale adolescents are birth-assigned male individuals who identify as female individuals. AMH, anti-Müllerian hormone; SUN, serum urea nitrogen; —, not applicable.

^a Indicates that a *P* value was not calculated.

^b Indicates significant change (*P* < .05).

^c Indicates nonsignificant change (*P* > .05).

TABLE 3 Psychosocial Effects of Hormonal Treatments in Transgender Youth

Study	Treatment	Outcome					
		Global Functioning	Depression	Anger and Anxiety	Behavioral and Emotional Problems		GD and Body Image
de Vries et al ²⁷ (de Vries et al ²⁶) ^a	GnRHa, GAH (not assessed)	Increase ^b (increase ^c)	Decrease ^b	Decrease ^c	CBCL: decrease ^b in total and internalizing scores, decrease ^b (decrease ^c) in externalizing scores	YSR: decrease ^b in total and internalizing scores, decrease ^b (decrease ^c) in externalizing scores	No significant effect ^d
Costa et al ²⁵	GnRHa	Increase ^e	—	—	—	—	—

Although influential articles in this field, Cohen-Kettenis and Van Goozen³³ and Smith et al³⁴ were unable to be included in our study because of their focus on patients after sex reassignment surgery. CBCL, Child Behavior Checklist; YSR, Youth Self Report; —, not applicable.

^a These 2 studies involved the same cohort and were therefore considered as 1 study. Parentheses are used to indicate the results of the earlier study²⁶ in which researchers examined a smaller subset of the cohort subsequently examined in the previous study.²⁷

^b Indicates significant change ($P < .05$).

^c Indicates nonsignificant change ($P > .05$).

^d It is important to note that the Utrecht Gender Dysphoria Scale that was used to measure GD in this study has various limitations, especially in relation to individuals who have already undergone social transition. Thus, the reported lack of improvement in GD here may reflect a lack of sensitivity in detecting psychological benefits. For example, it has been indicated in clinical experience that GnRHs help to satisfy the desire to prevent development of unwanted secondary sex characteristics (which is a criterion for GD under the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* in young adolescents), but the Utrecht Gender Dysphoria Scale does not have any items that address this issue.

^e Indicates that a P value was not calculated.

TABLE 4 Cognitive Effects of Hormonal Treatments in Transgender Youth

Study	Treatment	Outcome	
		Executive Functioning	Mental Rotation
Staphorsius et al ²⁴	GnRHa	No significant effect on Tower of London performance scores except for decrease ^a in accuracy in suppressed transfemale adolescents (but this was thought to be chance finding because of small sample size), no significant change in overall global functioning, exaggerated sex-typical brain activation of regions of interest	—
Burke et al ²³	GnRHa, GAH (testosterone treatment)	—	Inferred effect of GnRHa (transmale adolescents) At baseline, showed masculinized mental rotation—associated brain activation Testosterone treatment (transmale adolescents) Increase ^b in performance in mental rotation tasks, similar to control girls; increase ^a in bilateral parietal and left frontal activation

Note that transmale adolescents are birth-assigned female individuals who identify as male individuals, whereas transfemale adolescents are birth-assigned male individuals who identify as female individuals. —, not applicable.

^a Indicates significant change ($P < .05$).

^b Indicates that a P value was not calculated.

included breast tenderness (57.1%), emotionality (28.6%), hunger (23.8%), fatigue (14.3%), and hot flashes (14.3%).²²

Testosterone

Few side effects were reported with testosterone treatment, with localized injection reactions (5.6%)²⁰ and fatigue (8%)³⁰ all relatively uncommon. However, acne (37.5%) and menorrhagia (25%) were common complaints.³⁰

Bone Mineral Density

GnRHs in Transfemale Adolescents

Lumbar spine bone mineral density (BMD) z scores decreased after treatment with GnRHa monotherapy,^{19,29,31} and this reduction was statistically significant in all^{29,31} but 1 study.¹⁹ When results were stratified by bone age, the mean reduction in z score was only significant (1.32) for individuals with a bone age <15 years.³¹ Absolute lumbar spine BMD did not change over time, and thus the decrease in z scores after GnRHs likely reflects a failure to accrue BMD compared with age-matched peers. In 2 studies, researchers also examined BMD at the hip and femoral regions, which

TABLE 5 Risk of Bias for Studies of Effects of Hormonal Treatments in Transgender Youth

Study	Study Participation (Overall)	Study Attrition (Overall)	Outcome Measures (Overall)
Delemarre-van de Waal and Cohen-Kettenis ²⁹	High	High	Medium
de Vries et al ^{26,27}	High	High	Medium
Klink et al ¹⁹	Medium	High	Medium
Olson et al ²⁰	Medium	High	Medium
Costa et al ²⁵	Medium	Medium	Medium
Staphorsius et al ²⁴	Medium	High	Medium
Burke et al ²³	Medium	Medium	Medium
Schagen et al ²¹	High	High	Medium
Tack et al ³⁰	High	High	Medium
Vlot et al ³¹	Medium	High	Medium
Jarin et al ³²	High	High	Medium
Tack et al ²²	Medium	High	Medium

A modified version of the QUIPS tool was used to assess risk of bias according to 3 domains of bias, with each domain having 3 potential ratings of low, medium, or high.¹⁸ These domains of bias included study participation (study sample adequately represents population of interest), study attrition (available study data adequately represents the study sample), and outcome measurement (outcomes of interest are measured in a similar way for all participants). Use of the QUIPS tool has been described previously.¹⁷

revealed nonsignificant decreases in absolute and *z* scores for BMD.^{19,31} However, the duration of treatment varied significantly in these studies, being unknown in 1 study³¹ and at least 1 year¹⁹ and 2 years²⁹ in the others.

GnRHs in Transmale Adolescents

There was a greater reduction in BMD in transmale adolescents treated with GnRHs than transfemale adolescents. Two studies revealed a significant decrease in absolute and *z* scores for lumbar spine BMD,^{19,31} whereas another study revealed a significant reduction in only *z* scores.²⁹ In 1 study, researchers quantified the reduction in BMD *z* scores as being 0.79 for individuals with a bone age <14 years and 0.56 for individuals with bone ages ≥14 years.³¹ Two studies also revealed statistically significant reductions in BMD *z* scores at the hip and femoral regions in transmale adolescents.^{19,31}

Estrogen

Estrogen monotherapy was associated with significant increases in both absolute BMD and *z* scores in the lumbar spine,^{29,31} but not the hip,³¹ of transfemale adolescents previously treated with GnRHs. Furthermore, their *z* scores after 2

years of estrogen were still below that of age- and birth-assigned sex-matched norms.³¹ Specifically, *z* scores in the spine were −1.10 and −0.66 in those with younger (<15 years) and older (≥15 years) bone ages, respectively.

Testosterone

Testosterone monotherapy led to a significant increase in both absolute BMD and *z* scores in the lumbar spine^{29,31} and hip³¹ of transmale adolescents, who had previously been on GnRHs. However, their *z* scores did not reach that of age- and birth-assigned sex-matched controls, aside from the *z* scores in the hip of individuals with older bone ages. Specifically, *z* scores in the spine and hip were −0.15 and −0.37, respectively, in those with younger (<15 years old) bone ages and −0.06 and 0.02, respectively, in those with older (≥15 years old) bone ages.

Growth and Body Composition

GnRHs

Growth velocity decreased during treatment with GnRHs²⁹ in all transgender youth compared with pubertal-matched peers.²¹ In particular, younger individuals, who had greater growth potential, had significantly lower height

standard deviation scores (SDSs) after treatment.^{21,29} One study revealed significantly lower height standardized values for transfemale adolescents only.¹⁹ No researchers have examined whether individuals given GnRHs achieved their predicted final height after GAHs. After 1 year on GnRHs, individuals had a significant increase in body fat percentage²⁹ and BMI,^{19,21} which was accompanied by a decrease in lean body mass.²⁹

Progestins

Lynestrenol resulted in significant increases in weight and BMI absolute and *z* scores during the first 6 months with a return to baseline after 12 months of treatment.³⁰

Antiandrogens

Cyproterone acetate resulted in a decrease in growth velocity compared with age-matched peers,²² with a final height after 12 months of treatment also being significantly lower than age-matched peers with a mean standardized score of −0.309. There were no clinically significant changes in body weight and BMI after 12 months.

Estrogen

It is unclear whether differences in the pubertal stage and bone age at which estrogen was commenced contributed to the variable outcomes found because these data were not collected.²⁹ Estrogen in combination with cyproterone acetate resulted in reduced growth compared with age-matched peers in 1 study,²² whereas another study revealed no change in growth velocity after estrogen.²⁹ Total BMI was significantly increased after estrogen in 1 study,^{22,32} although another revealed that total BMI did not change after 6 months.³²

Testosterone

Testosterone monotherapy resulted in increased growth velocity compared with age-matched peers in 1 study,²⁹ but the impact on final

height (nor the age and pubertal stage at commencement) was not specified. Testosterone was also associated with weight gain,³⁰ resulting in a significantly raised absolute BMI^{20,30} from an average baseline of 20.7 to 22.4 within 6 months.²⁰ This increase in BMI was less than that of age-matched male adolescents.³²

Other Physical Effects

GnRHs

After 1 year of GnRHa, there were no changes in carbohydrate or lipid metabolism as measured by fasting glucose, insulin, cholesterol, low-density lipoprotein (LDL), and high-density lipoprotein (HDL) levels.²⁹ In 1 study, researchers observed that alkaline phosphatase (ALP) was decreased as a likely secondary result of decreased bone turnover, whereas all other liver enzymes were unchanged.²¹ In this same study, researchers also reported lower levels of creatinine and hypothesized that this might be due to reduced muscle mass but found that there was no correlation between change in muscle mass and creatinine.²¹

Progestin

Progestins were associated with an adverse lipid profile, with a significant decrease in HDL cholesterol by an average of 0.46 mmol/L and an elevation of LDL cholesterol by 0.37 mmol/L after 1 year.³⁰ There were no significant changes in hemoglobin A1c (HbA1c), glucose levels, insulin levels, or homeostasis model assessment (HOMA) index.³⁰ Alanine aminotransferase (ALT) increased after 12 months, but this was not clinically significant.³⁰ Mean hemoglobin (Hb) and hematocrit (Hct) levels increased in the first 6 months and subsequently remained stable.³⁰

Antiandrogens

Cyproterone acetate was associated with a significant reduction in only triglycerides, but total cholesterol, LDL cholesterol, HDL cholesterol, HbA1c, glucose, insulin, and HOMA index were unaffected.²² There was no change in liver enzymes or thyrotropin.²² There was a slight decrease in Hb and Hct after 12 months, but this was not clinically significant.²²

Estrogen

Apart from 1 study in which a significant decrease in HDL after 4 to 6 months was observed,³² estrogen had no effect on carbohydrate and lipid metabolism.^{22,29,32} Similarly, no significant changes in liver enzymes,^{22,32} thyrotropin, or free thyroxine (fT4)²² were noted with estrogen treatment. A significant increase in serum creatinine was seen after 12 months with combined estrogen and cyproterone acetate treatment.²² Hb and Hct were found to have decreased initially but returned to baseline after approximately 6–12 months.³² However, when estrogen was used in combination with a progestin, Hb and Hct levels did not change any further after 12 months.²² Blood pressure (BP) was unchanged after 6 months of estrogen.³²

Testosterone

Testosterone had no significant effect on carbohydrate and lipid metabolism.^{29,30,32} Although in 1 study researchers observed raised liver enzymes (aspartate aminotransferase [AST] and ALT) after a year,³⁰ another study revealed no significant change in AST and a decrease in ALT after 4 to 6 months.³² Testosterone treatment decreased thyrotropin and fT4 to be outside of the normal reference ranges, although these changes were not clinically relevant because there was no clinical or biochemical hypo- or hyperthyroidism in participants.³⁰

Serum creatinine increased after 6 months of testosterone with no subsequent change thereafter and was thought to reflect an increase in muscle mass.³⁰ Hb²⁰ and Hct³⁰ were increased after 6 months but remained stable during the next 6 months within the male reference ranges,^{20,30} whereas another study revealed no significant change in these parameters at any stage.³² Systolic BP was elevated in treated individuals, with an average rise of 5 mm Hg after 6 months.²⁰

PSYCHOSOCIAL EFFECTS

All relevant results are shown in Table 3.

GnRHs

GnRHa treatment was associated with significant improvements in multiple psychological measures, including global functioning,^{25–27} depression,^{26,27} and overall behavioral and/or emotional problems.^{26,27} The effects of GnRHs on anger and anxiety remain unclear with conflicting results.^{26,27} Moreover, GnRHa treatment had no significant effect on symptoms of GD,^{26,27} with researchers in 1 study observing a nonsignificant increase in GD and body image difficulties.²⁶

Progestin, Antiandrogens, Estrogen, and Testosterone

Critically, no researchers have examined the psychosocial effects of these hormonal therapy types in transgender youth.

COGNITIVE EFFECTS

All relevant results are shown in Table 4.

GnRHs

In one study, researchers examined the effect of GnRHs on executive functioning using the Tower of London test, which is used to assess mental planning ability.²⁴

After GnRHa treatment, there was significantly reduced accuracy in transfemale adolescents.²⁴ There was also exaggerated regional brain activation typical of birth-assigned sex on functional magnetic resonance imaging (fMRI).²⁴ However, given the small sample size (8 participants), these results should be interpreted cautiously.

In another study, researchers examined the effect of GnRHa treatment on mental rotation in transmale adolescents,²³ exploring whether rotated pairs of three-dimensional shapes were identical images of each other.^{35,36} Because men significantly perform better on this task compared with women, this result has also previously been suggested as evidence for the classic theory of the organizational and activational effects of sex hormones on the brain.^{37,38} Interestingly, GnRHa suppression in transmale adolescents was associated with male brain activation patterns, with reduced activity in the right frontal area.²³

Progestin, Antiandrogens, and Estrogen

No researchers have examined the cognitive effects of these treatments.

Testosterone

In the same study, researchers also examined the effects of testosterone in transmale adolescents on mental rotation tasks, in which they observed moderate to strong improvements in accuracy and reaction time.²³ Similar to control boys, treated transmale adolescents also demonstrated increased activation of brain regions implicated in mental rotation on fMRI.²³

DISCUSSION

This is the first systematic review of the effects of hormonal treatment in transgender youth; authors of previous systematic reviews in this field, including those commissioned

by the recent Endocrine Society Clinical Practice Guidelines, focused on the use of GAHs in adults.^{8–11,15}

GnRHs successfully suppressed endogenous puberty, consistent with the primary objective of this treatment, although there was only a single study in which researchers actually recorded these data.²⁹ GnRHs were observed to be associated with significant improvements in global functioning,^{25–27} depression,^{26,27} and overall behavioral and/or emotional problems^{26,27} but had no significant effect on symptoms of GD. The latter is probably not surprising, because GnRHs cannot be expected to lessen the dislike of existing physical sex characteristics associated with an individual's birth-assigned sex nor satisfy their desire for the physical sex characteristics of their preferred gender. Like GnRHs, the antiandrogen cyproterone acetate effectively suppressed testosterone in transfemale adolescents,²² but its potential psychosocial benefits remain unclear. Meanwhile, GAHs increased estrogen and testosterone levels and thus induced feminization and masculinization, respectively, of secondary sex characteristics.^{22,29} However, in the case of breast development, the outcomes were subjectively less in size than expected in the majority of recipients,²² and the potential psychosocial benefits of GAHs remain unknown. Finally, although the use of the progestin (lynestrenol) has been studied in transmale adolescents,³⁰ its effects were predominantly examined in the context of potential adverse effects, so the therapeutic impact of progestins for menses suppression and psychosocial outcomes cannot be understood from the current literature.

Overall, hormonal treatments for transgender youth were observed to be relatively safe but not without potential adverse effects. For GnRHs, a significant concern in

clinical practice is their potential effects on BMD accrual; their use was associated with a significant reduction in BMD,^{19,29,31} which appeared to be worse for transmale adolescents^{19,31} and is consistent with previous studies of nontransgender youth^{39,40} and adults⁴¹ who received GnRHs. However, given the relatively short follow-up duration of the studies reviewed here, it will be important for future researchers to better establish if this reduction in bone density is long-lasting or transient, as observed in nontransgender youth after GnRHa cessation.^{39,40} It is notable that BMD increased after estrogen and testosterone, which suggests potential compensation by GAHs. However, for estrogen treatment, the BMD of those who had previously received GnRHs still remained lower than age-matched peers 2 years after estrogen treatment,³¹ so compensation may only be partial. Furthermore, there is a lack of reporting of pubertal stage at treatment commencement, which makes interpretation of some changes difficult, especially BMD.

Clinically, patients who receive GnRHs and still have significant growth potential are counseled about the risk of the treatment affecting their final height. Although researchers in 2 studies have now examined growth and height characteristics in transgender youth receiving GnRHs,^{21,29} their relatively short follow-up times (≤ 3 years) precluded determination of the effects of GnRHs on final height, and future researchers should address this knowledge gap. Another clinical concern in the use of GnRHs is the induction of menopausal-like symptoms due to the withdrawal of sex steroids, especially in postpubertal individuals. GnRHs were commonly observed to cause hot flashes in transmale adolescents in late puberty, but these decreased in frequency over time.²⁹ For

potentially similar reasons, one of the main complaints after cyproterone acetate administration in transmale adolescents was fatigue.

Hormonal treatment of transgender adults is known to be associated with various metabolic and cardiovascular effects.^{10–12} GnRHs significantly increased both body fat percentage²⁹ and BMI^{19,21} while decreasing lean body mass.²⁹ Similarly, testosterone significantly increased both body fat and BMI.^{20,29} Although lynestrenol also increased BMI, this was transient, with BMI returning to baseline after 12 months.³⁰ Cyproterone acetate was not associated with any changes in BMI.²² In terms of lipid metabolism, neither testosterone nor estrogen had any observable impact, but lynestrenol was associated with lower HDL and higher LDL cholesterol after 1 year,³⁰ whereas cyproterone acetate significantly reduced triglycerides.²²

The findings from this review are subject to limitations. Firstly, the current literature has a limited number of studies in which the different hormonal treatments in transgender youth is examined. Secondly, for any given class of hormonal treatments, there is a variety of different agents, formulations, and administration routes that are being used clinically in transgender youth. For example, the physical effects of 1 antiandrogen and 1 progestin have been studied in only 1 study each, with no confirmation of results or further exploration. Thirdly, in existing studies there is a medium to high risk of bias, given small sample sizes, retrospective nature, and lack of

long-term follow-up. In this regard, although randomized controlled trials are often considered gold standard evidence for judging clinical interventions, it should be noted that, in the context of GD in which current guidelines highlight the important role of hormonal treatments,¹⁵ conducting such trials would raise significant ethical and feasibility concerns. Fourthly, authors of existing studies have neglected several key outcomes. These include the following: psychological symptoms related to GD, which is a critical knowledge gap given the high rates of mental health problems observed in transgender youth and justification of these treatments as treating GD⁴²; the impact of hormonal treatments on fertility, which is an integral part of the counseling recommended by current guidelines¹⁵; and potential adverse effects such as arterial hypertension, which was reported in a recent case series in association with GnRHs.⁴³ Finally, there are no known studies to date in which researchers have reported the rates and circumstances under which transgender youth cease their hormonal therapy in an unplanned manner or the risk of subsequent regret, which would be of great clinical utility.

Notwithstanding these limitations, collectively, the studies reviewed provide qualified support for the use of GnRHs, GAHs, cyproterone acetate and, to a lesser extent, lynestrenol in transgender youth. Overall, these hormonal treatments appear to provide some therapeutic benefits in terms of physical effects and are generally well-tolerated on the basis of current evidence.

CONCLUSIONS

Looking ahead, it will be essential for future researchers to reassess and expand on the findings of the existing studies. Large, prospective longitudinal studies, such as have been recently initiated,⁴⁴ with sufficient follow-up time and statistical power and the inclusion of well-matched controls will be important, as will the inclusion of outcome measures that investigate beyond the physical manifestations.

Not social transition status, but peer relations and family functioning predict psychological functioning in a German clinical sample of children with Gender Dysphoria

Abstract

Research provides inconclusive results on whether a social gender transition (e.g. name, pronoun, and clothing changes) benefits transgender children or children with a Gender Dysphoria (GD) diagnosis. This study examined the relationship between social transition status and psychological functioning outcomes in a clinical sample of children with a GD diagnosis. Psychological functioning (Child Behavior Checklist; CBCL), the degree of a social transition, general family functioning (GFF), and poor peer relations (PPR) were assessed via parental reports of 54 children (range 5–11 years) from the Hamburg Gender Identity Service (GIS). A multiple linear regression analysis examined the impact of the social transition status on psychological functioning, controlled for gender, age, socioeconomic status (SES), PPR and GFF. Parents reported significantly higher scores for all CBCL scales in comparison to the German age-equivalent norm population. Peer problems and worse family functioning were significantly associated with impaired psychological functioning, whilst the degree of social transition did not significantly predict the outcome. Therefore, claims that gender affirmation through transitioning socially is beneficial for children with GD could not be supported from the present results. Instead, the study highlights the importance of individual social support provided by peers and family, independent of exploring additional possibilities of gender transition during counseling.

Introduction

Children with a Gender Dysphoria (GD) diagnosis experience an incongruence between their birth-assigned sex and their experienced gender with which they identify (also referred to as Gender Incongruence or Transgender). The clinical condition is referred to as *Gender Dysphoria* in the DSM 5 (American Psychiatric Association, 2013). Gender Identity Services around the world are facing the challenge to provide optimal treatment for individuals and their families to promote psychological well-being. While pubertal transgender adolescents with a GD diagnosis are eligible for puberty suppressing and gender affirming hormonal medication to medically support a gender transition, prepubescent children are not advised to receive any medical treatment before the onset of puberty (Tanner stage 2; Coleman et al., 2012). However, they often transition socially from one gender to another during childhood (Coleman et al., 2012). This reversible non-medical step towards a life in the identified gender may include changing one's name or pronoun, being introduced as the experienced gender in public, as well as gender typical appearance in terms of e.g., hair length and clothing (Steensma et al., 2013; Wong et al., 2019).

Social transition is often the first possibility to align with one's experienced gender and to living in the preferred gender role different from the one assigned at birth in almost all aspects of life (gender affirmation). If the wish to transition persists, this can be followed by medical, surgical and legal procedures during adolescence and adulthood (Coleman et al., 2012; Ehrensaft et al., 2018; Hill et al., 2010). Some clinicians consider a social transition as a necessary precondition for puberty suppressing or gender affirming hormonal therapy, and therefore as a first step towards an affirmation of a child's gender identity (Hill et al., 2010). However, according to the World Professional Association for Transgender Health (WPATH) Standards of Care for the Health of Transsexual, Transgender, and Gender-Nonconforming People (SoC 7; Coleman et al., 2012), vice versa a puberty suppression does not always or inevitably lead to social transition or to gender affirmation.

To this date, the possible benefits or disadvantages of an "early" social transition for a child's future development are among the most controversially discussed topics in Transgender Health Care (Coleman et al., 2012; Giordano, 2019; Steensma & Cohen-Kettenis, 2015; Wong et al., 2019); especially bearing in mind the developmental trajectories of persistence versus desistance into adolescence and adulthood (Ristori & Steensma, 2016). Children with either a GD diagnosis or so-called gender nonconforming or gender variant experiences often do not continue to experience a clinical GD as adolescents and adults (Ristori & Steensma, 2016; Steensma et al., 2013). This developmental pathway is referred to as a desisting GD ("desisters"), in contrast to "persisters," whose GD continues to persist into adolescence and adulthood (Steensma et al., 2011). This research has been criticized for including gender variant children despite not meeting the diagnostic criteria for a GD (Giordano, 2019; Temple Newhook et al., 2018). Furthermore, it has been argued that the number of desisters has been overestimated due to the timing of follow-up (Ehrensaft et al., 2018; Giordano, 2019). In a response to these critiques, Steensma and Cohen-Kettenis (2018) have subsequently described limitations and also highlighted the possibilities for more than these two developmental pathways of either persisting or desisting. Hence, the actual percentages of desistance and persistence remain uncertain, and so does the degree to which clinicians support a social transition in childhood.

In the general population, gender experiences may appear more fluctuating during childhood: according to a Germany study on high-school students, a relatively higher degree of younger adolescents (around the age of 11) presented gender variant experiences compared to older adolescents (around the age of 15), and compared to clearly incongruent gender experiences (Becker et al., 2017). Because of such possible fluctuations in gender experience during childhood and the

assumed relatively lower persistence of GD from childhood into adolescence, many researchers and clinicians have suggested to follow a so-called “supportive watchful-waiting” approach (e.g. Cohen-Kettenis et al., 2008; Steensma et al., 2013). This approach refers to providing a safe place for children to explore their gender, but advises to withhold complete social transitions until puberty. For example, de Vries and Cohen-Kettenis (2012) recommended for young children to not yet make a complete social transition before the very early stages of puberty. In contrast to this clinical management, a more gender affirmative approach freely endorses social transitions when they are perceived as appropriate (Ehrensaft et al., 2018; Giordano, 2019).

There are experts arguing, that an affirmation of the gender status and support of a complete social transition during childhood and adolescence may be associated with better psychosocial health (Durwood et al., 2017; Ehrensaft et al., 2018; Olson et al., 2016). Durwood et al. (2017) and Olson et al. (2016) reported relatively low levels of depression, anxiety and better self-worth in community samples of 63 young adolescents (9–14 years) and of 73 children (3–12 years) who had already undergone a complete social transition, and thus were supported in their experienced gender by parents. These findings were underlined in another community-based sample, where children with a GD diagnosis who had fully completed a social transition scored within the norm range for behavioral and emotional problems (Kuvalanka et al., 2017).

In contrast to the US-American studies from Durwood et al. (2017), Olson et al. (2016) and Wong et al. (2019), most clinical European studies report higher levels of psychological problems in clinical samples of both children and adolescents with a GD diagnosis (e.g. Cohen-Kettenis et al., 2003; de Vries et al., 2016; Steensma et al., 2013, 2014). On average, these populations of children presented more behavioral and emotional problems than their siblings and other control groups on parent- and teacher report questionnaires, assessed via the Child Behavior Checklist (CBCL Achenbach, 1991). These clinical studies indicated that children with GD are more likely to experience internalizing problems, such as anxiety and depression, than externalizing problems (Cohen-Kettenis et al., 2003; Steensma et al., 2014). Similarly, a Canadian community-based sample among gender-nonconforming children aged 6–12 years found impaired psychological functioning comparable to the results reported in clinical studies (Van der Miesen et al., 2018).

At the same time, however, most of this previous clinical research from Europe has not explored the possible role of the social transition status for psychological functioning outcomes. Nowadays, the two main explanations for elevated vulnerability and distress within this group are the state of conflict between one’s self-understanding of one’s gender and physical appearance on the one hand (Aitken et al., 2016), and lacking social support or poor peer relations (PPR) on the other hand (Aitken et al., 2016; Cohen-Kettenis et al., 2003; de Vries et al., 2016; Levitan et al., 2019; Steensma et al., 2014). Considering that gender nonconforming behavior is often evaluated negatively by peers, children with a GD diagnosis often experience a lack of social support from their peers or PPR, which in turn is associated with poorer psychological functioning. Family support or good general family functioning (GFF) levels on the contrary, may act as a protective factor against such health risks in youth with a GD diagnosis (Levitan et al., 2019; Simons et al., 2013). For example, in a population of 66 American adolescent transgender youth, parental support was significantly associated with higher life satisfaction, lower perceived burden related to being transgender and fewer depressive symptoms (Simons et al., 2013).

The aforementioned studies from Durwood et al. (2017) and Olson et al. (2016) indicate that internalizing problems, such as depression, were less present than previously assumed when children with a GD diagnosis had undergone a social transition. These findings suggest a positive association between family support, particularly in terms of affirming one’s child wish to transition, and better psychological functioning outcomes. Yet, the comparison of depression and anxiety measures in the statistical model among participants and controls in the study by Olson et al.

(2016) did not justify the conclusion that a social transition was directly linked to better psychological functioning outcomes. In contrast, the comparison of psychological functioning in socially transitioned children versus cisgendered gender-variant children by Wong et al. (2019) provide evidence for similar levels of behavioral problems regardless of their transition status. This study assessed different online assessed community samples of gender-variant children and highlights the importance of peer relationships for psychological well-being, instead of the social transition status or the degree of parental acceptance towards a child's gender experience. Hence, it remains unsolved whether the results of Durwood et al. (2017) and Olson et al. (2016) can be transferred to other samples, other families with different social transitioning pathways and support, and whether it is social transition status per se that explains the differences in psychological functioning.

Aim of the study and research questions

There is currently a lack of evidence in how far and to which degree a social transition during childhood impacts psychological functioning among children with a GD diagnosis. Previous studies have resulted in inconclusive results regarding the effects of support and the status of transitioning socially on psychological functioning outcomes. Thus, the present study examines two main research objectives: Firstly, psychological functioning of children diagnosed with GD in a clinical sample from Germany will be assessed. Secondly, the impact of transitioning socially on psychological functioning as an outcome will be examined, while controlling for age, gender, SES, PPR, and GFF.

Method

Procedure

The present study was conducted using a cross-sectional, questionnaire-based design. Data collection took place between September 2013 and December 2018 at the Hamburg Gender Identity Service for Children and Adolescents (Hamburg GIS) via parental reports of clinically referred children. All families that attended the Hamburg GIS during the aforementioned period were kindly invited to voluntarily complete a set of self- and parent-report questionnaires during their first appointment (see Figure 1). Hence, all data collection was conducted before undergoing any form of counseling or treatment. The study was granted approval by the local ethical committee. Written informed consent was collected from every study participant according to institutional guidelines.

Clinical protocol at the Hamburg GIS

The Hamburg GIS for Children and Adolescents at the University Medical Center Hamburg-Eppendorf was founded in 2006 (Möller et al., 2014). All treatment performed at the clinic comply to the international guidelines for the SoC 7 released by the World Professional Association for Transgender Health (WPATH) in 2012 by Coleman et al. (2012). Clinicians follow a diagnostic and treatment protocol that was developed and in the past referred to as the "Dutch Model" (Cohen-Kettenis et al., 2011; Delemarre-van de Waal & Cohen-Kettenis, 2006; de Vries & Cohen-Kettenis, 2012). This clinical management approach suggests a watchful-waiting approach which differentiates counseling in contrast to a more gender affirmative treatment approach during adolescence (Cohen-Kettenis et al., 2008; Edwards-Leeper, 2016; Giordano, 2019). Sessions may include clinical diagnostics, counseling, psychotherapy and psychoeducation during childhood, as well as the possibility of referral to an endocrinology specialist for medical interventions after the onset of

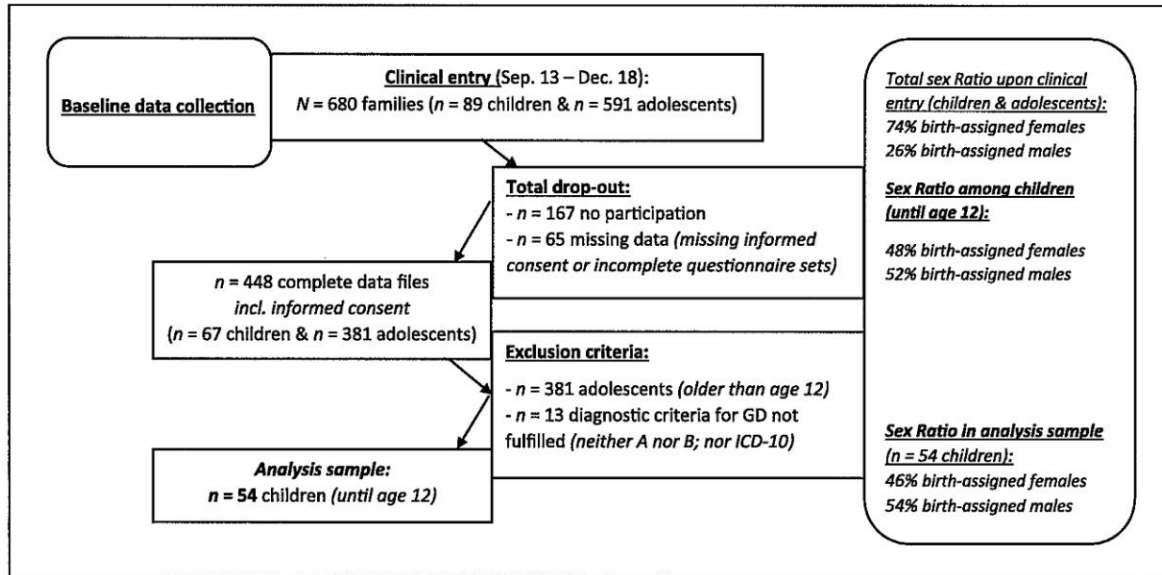

Figure 1. Participants and sex ratios at clinical entry (children and adolescents) and in analysis sample (children only).

puberty. After a comprehensive diagnostic and psychological evaluation over multiple sessions, medical interventions are currently recommended in Hamburg if GD during adolescence is persistent (without strict onset criteria) and accompanied by distress, if adolescents present the ability to consider and anticipate treatment options as well as possible consequences of a life in the preferred gender role. The psychosocial treatment modalities are based on a psychodynamic and developmental perspective and similar to a supportive watchful-waiting approach. This means that steps of social transition during childhood are supported in individual cases, when the family is open to such a step and if a child clearly expresses the desire to proceed to live in their experienced gender. Decisions are never being made by a clinician alone, but in line with current SoC7, where clinicians, children and parents identify the best individual pathway together (informed consent), and in relation to the personal social circumstances (Coleman et al., 2012). Psychotherapy offered include psychodynamic individual and family sessions with a frequency tailored to the child's individual needs.

Participants

This study was targeted towards clinically referred children under the age of 12 living in Germany and fulfilling the diagnostic criteria for GD according to the DSM 5 (American Psychiatric Association, 2013) and/or the ICD-10 (World Health Organization, 1992). During their first appointment, all families with initial visits to the clinic were invited to complete a set of questionnaires (see Figure 1). In total, 680 families and their children aged 5 to 18 visited the clinic during this period, with 74% of them being assigned female at birth (AFAB) and 26% being assigned male at birth (AMAB; cf. Levitan et al., 2019). Information was obtained upon clinical entry from parents, adolescents (aged 11 and above) as well as from clinicians. As this study aims to evaluate the situation of children under the age of 12, adolescent participants (12 years and older) were excluded from the present analysis. Thus, a distinction between children and adolescents was made based on age in this study (rather than on puberty status). In addition, $n = 13$ children had to be excluded because they did not fulfil any diagnostic criteria for GD according to either the DSM 5 or the ICD-10. Therefore,

parental reports of $n = 54$ (46% AFAB and 54% AMAB) children up to and including the age of 11 were included in the present analysis.

Measures

Sociodemographic variables

To describe the sample, the following sociodemographic measures were evaluated: birth-assigned sex, age at clinical entry (age at assessment), nationality, and the socioeconomic status (SES). To measure the SES based on the Winkler-Index (Winkler & Stolzenberg, 1999), education, income, and job position of both parents were included (similar to a previous study; cf. Levitan et al., 2019). Educational background of the parent with the higher status was coded as 1 (no or lower education), 2 (middle or technical school) and 3 (higher education or university). The household income was coded as 1 (less than 2.000€ per month), 2 (2.000–4.000€ per month) and 3 (more than 4.000€ per month). The job position of the parent with the higher status was coded as 1 (lower occupation or unemployed), 2 (skilled occupation or self-employed) and 3 (executive or academic occupation). Eventually, the score for the SES was the sum score of these three 3-point variables, therefore the SES ranged from 3 to 9.

Social transition status

The degree to which a child had transitioned socially was assessed via three items asking whether they lived in their preferred gender role in the following three everyday life areas: at home/with family, with friends/peers, and at school. Taking into consideration that multiple answers were possible, the final variable was summed up and then recoded as 1 (no social transition, yet, and living in birth-assigned gender role); 2 (partial social transition in at least 1 out of 3 life areas or in-between gender roles); 3 (almost complete social transition, living in the new gender role in at least 2 out of 3 life areas); 4 (complete social transition in all life areas). This measure was introduced in a previous study from Levitan et al. (2019) and allows for a more nuanced assessment of possible variance within the steps or the status of transitioning socially in multiple life domains (before undergoing any kind of transition-related medical intervention). In addition, parents were asked on a scale from 1 (not at all) to 5 (completely) in how far they supported their child's current gender role or social transition.

Psychological Functioning

Parents completed the German version of the Child Behavior Checklist (CBCL) for children and adolescents (ranging between 4 to 18 years of age; Achenbach et al., 1991; Döpfner et al., 1998) to measure behavioral and emotional problems. The original version of the CBCL consists of 113 items. Responses are rated on a 3-point scale ranging from 0 (not true) to 2 (very true or often true), with a higher score indicating a greater degree of the interrogated problems.

The CBCL provides a Total Problem Score which reflects the sum of problems and two main scales that allow to separate Internalizing and Externalizing problems. The Internalizing scale consists of items assessing anxiety and depression, somatic complaints and withdrawal problems. The Externalizing scale consists of items assessing externalizing problems, such as aggressive and rule breaking behavior. Scores above the 90th percentile or T -scores above 63 indicate clinically relevant problems. Birth-assigned sex-specific T -scores for all three scales of the German norm

population (aged 4–11; Döpfner et al., 1998) allow to determine whether the scores of the transgender sample lie within the German birth-assigned sex- and age-equivalent norm range.

Four items were not included in the Total Problem Score according to the manual and in order to avoid conflation due to extreme scores: two health-related items (“allergies” and “asthma”), and two items regarding cross-gender identification (item 5: “behaves like the opposite sex”; item 110: “wishes to be the other sex”). Additionally, if the answer given to item 85 (“has strange thoughts or ideas”) had a reference to the child’s gender identity or GD, the item was excluded from the Total Problem Score. In the present sample, Cronbach’s alpha for the Internalizing, Externalizing and Total Problem scales ranged between $\alpha = 0.90$ and 0.98 , respectively.

Poor Peer Relations (PPR)

Three items from the CBCL were used to create an index for problematic social interactions with peers, items 25 (“doesn’t get along with other kids”), 38 (“gets teased a lot”) and 48 (“is not liked by other kids”). This measure has been extensively used in previous research to assess the quality of peer relations of children and adolescents referred for GD (e.g. Aitken et al., 2016; Cohen-Kettenis et al., 2003; de Vries et al., 2016; Kuvalanka et al., 2017; Levitan et al., 2019). The answer range was between 0 and 6, with a greater score indicating higher degrees of peer related problems or more problematic peer interactions. Cronbach’s alpha for the PPR in the present sample was $\alpha = .73$.

General Family Functioning (GFF)

Based on the McMasters’ Model of Family Functioning, the Family Assessment Device (MFAD; Epstein et al., 1983) is an instrument designed to evaluate several aspects of family relationships. The seventh and so-called General Family Functioning Scale (GFF) evaluates family functioning in terms of how far family members feel supported by one another and feel like they can rely on each other. It consists of 12 items on a 4-point Likert-scale with response options from 1 (“strongly agree”) to 4 (“strongly disagree”). The sum of values is divided by the number of items, so that the total score ranges from 1 to 4. A higher score on the GFF reflects higher levels of problematic family functioning or lower perceived family support. The cut-off for problematic family functioning is set at 2.17 (Byles et al., 1988). In the present sample, Cronbach’s alpha for the GFF scale was $\alpha = .68$.

Statistical analysis

Missing values were replaced using the expectation-maximization (EM) algorithm method in cases where less than 20% of the items per scale and per participant were missing at random (Little & Rubin, 2014).

To identify characteristics of the population, *mean scores (M)* and *standard deviations (SD)*, as well as frequencies for the sociodemographic variables were assessed and possible gender group differences between AFAB and AMAB children were explored using independent samples *t*-tests.

To be able to compare psychological functioning scores of our sample with the German-age equivalent population-based norm, *T*-scores provided by Döpfner et al. (1998; $M = 50$, $SD = 10$) were assigned to the raw scores of the CBCL scales (Internalizing, Externalizing and Total Problem Score). Furthermore, *95%-confidence intervals* for the three scales were calculated. If confidence intervals do not include the mean of the norm *T*-distribution ($M = 50$), it can be assumed that they significantly differ from the birth-assigned sex and age equivalent reference group (Cumming & Finch, 2005).

Table 1. Sociodemographic and clinical characteristics.

	AFAB (<i>n</i> =25)		AMAB (<i>n</i> =29)		Total (<i>n</i> =54)		Group comparisons			
	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>	<i>t</i>	<i>df</i>	<i>p</i>	<i>d</i>
Age	9.98	1.53	8.25	2.17	9.05	2.08	3.321	52	.002**	0.93
SES mean score ^a	6.63	1.55	6.51	1.34	6.56	1.43	0.299	52	.766	0.08
Poor peer relations (PPR) ^b	0.94	1.18	1.03	1.50	0.99	1.35	-0.266	52	.791	0.07
General family functioning (GFF) ^c	1.46	0.30	1.48	0.41	1.47	0.36	-0.182	52	.856	0.06
Social transition status ^d	2.58	1.32	2.61	1.26	2.60	1.27	-0.088	52	.930	0.02

Note. AFAB = assigned female at birth; AMAB = assigned male at birth.

^aRange 3–9 (sum score based on parent's educational background, household income, and parental job position; a higher score reflects a higher SES).

^bRange 0–6 (sum score of CBCL items 25, 38, and 48; a higher score reflects higher levels of peer related problems).

^cRange 1 (better family functioning)–4 (higher levels of problematic family functioning).

^dRange 1 (no social transition)–4 (complete social transition in all life areas).

***p* < .01.

The second research question was performed using a multiple linear regression analysis. The raw score of the CBCL Total Problem Score was chosen as an outcome to assess possible predictors for overall psychological functioning. A modified version of the Total Problem score excluded one of the predictors in the model, the PPR scale (items 25, 38, and 48). In the first step of the regression analysis, the sociodemographic variables age, birth-assigned sex and SES were entered into the model as control variables. Afterwards, the variables assessing the degrees of PPR and GFF were included. Subsequently, the effect of social transition status on the outcome was determined by adding this variable into the model. In a multiple regression with *n*=54 cases and six predictors, an average effect (*f* = 0.15) can be tested with a power of 88% (calculated with GPower). In addition, a second and third exploratory data analysis were conducted to assess the impact of the six predictors of the main regression analysis on the Internalizing and Externalizing scales, separately. All data analyses were conducted using SPSS 25.

Results

Results of the clinical and sociodemographic characteristics are provided in Table 1. AFAB were on average older (*M* = 9.98, *SD* = 1.53) at the time of the first clinical referral than AMAB (*M* = 8.25, *SD* = 2.17). This difference was statistically significant, but no other gender differences were found.

Most children came from a family with a middle (50%) or high (48%) socioeconomic background. Around 96% of the sample were German citizens. 70% of the children with GD had undergone a social transition in at least one life area and 39% had undergone a complete social transition (lived in their preferred gender role in all life areas). Parental support of the social transition was generally high (with 87% of parents supporting their child's current gender role or social transition completely). GFF reported by the parents was above the cut-off or within the healthy range for 96% of the sample according to the cut-off provided by Byles et al. (1988); thus only 4% of the sample presented problematic GFF scores. 43% of the parents reported problematic peer interactions for their children in at least one domain of PPR. For both items 25 ("doesn't get along with other kids") and 38 ("gets teased a lot"), more than a third (31 and 32%, respectively) of the parents reported PPR for their children sometimes or often.

Table 2. Psychological Functioning Compared to German Norm.

CBCL scales	T-scores (children with GD with reference to the German norm)		
	M	SD	95% CI of the M
Internalizing scale (31 items)			
AFAB	60.68	10.20	[56.47; 64.89]
AMAB	59.17	12.80	[54.30; 64.04]
Total	59.87	11.59	[56.71; 63.03]
Externalizing scale (33 items)			
AFAB	55.60	14.57	[49.57; 61.61]
AMAB	55.86	9.34	[52.31; 59.42]
Total	55.74	11.93	[52.49; 59.00]
Total problem score (109 items)			
AFAB	59.20	12.26	[54.14; 64.26]
AMAB	59.52	10.68	[55.45; 63.58]
Total	59.37	11.33	[56.28; 62.46]

Note. AFAB = assigned female at birth; AMAB = assigned male at birth.

Age and birth-assigned sex equivalent German norm T-scores with $M = 50$, $SD = 10$ derived from Döpfner et al. (1998).

Psychological functioning in comparison to the German norm

An overview of the raw scores and T-scores for the three CBCL scales is presented in Table 2. Significant deviations from the norm population measured in T-Scores ($M = 50$, $SD = 10$) could be found via non-overlapping 95% confidence intervals for all groups, except for externalizing problems among AFAB.

In general, internalizing problems were more strongly elevated in all groups compared to externalizing problems. Both AFAB and AMAB presented scores for internalizing problems around one standard deviation higher than their age-equivalent German norm group. Internalizing problems within the clinical range (> 90 th percentile; T -scores > 63) were reported by 46% of the sample.

Both AMAB and AFAB also showed elevated scores for externalizing problems (around half a standard deviation above the norm mean), although AFAB were closer to the norm range. 40% of AMAB' parents reported clinically relevant scores, whereas only 28% of AFAB' parents reported the same.

The Total Problem Score for overall psychological functioning was significantly elevated in both groups in comparison to the German norm: 39% of the sample scored above the clinical range. Post-hoc t -tests confirmed the significant results of the non-overlapping 95%-confidence intervals for almost all scales, thus confirming that T-scores in this sample significantly differed from the norm, except for externalizing problems in AFAB.

Predictors of psychological functioning

The results of the regression analysis are reported in Table 3. An overview of the correlations for predictor variables in the regression analyses can be found in Table 4.

The results of the first model indicate that the three control variables birth-assigned sex, age and SES explained in total 11.1% of the variance. The SES significantly predicted psychological functioning, whereas birth-assigned sex and age did not. In the second model, birth-assigned sex, age, SES, PPR, and GFF in total explained 63.2% of the variance. It was found that both PPR and GFF

significantly predicted psychological functioning, but the control variables did not. In the third model, however, the social transition status variable did not significantly explain additional variance, and thus psychological functioning outcomes. The results of the final third model indicate that the six predictors together explained 64.6% of the variance.

The value for the Durbin-Watson statistic was 1.751. With the assumption that a value of 2 is an indicator for perfect independence, no autocorrelations in the residua were expected. The variance inflation factor (VIF) in all three models was not substantially greater than 1 (range between 1.003 and 1.343), therefore no multicollinearity was expected. Furthermore, the histogram of standardized residuals indicated that the data contained approximately normally distributed errors, as did the normal P-P plot of standardized residuals, which showed points that were not completely on the line, but close. Regarding homogeneity of variance and linearity, the scatterplot of standardized residuals showed that the data met these assumptions.

Exploratory data analysis

Exploratory data analysis was conducted to assess the impact of the six predictors of the main regression analysis on the Internalizing and Externalizing CBCL scales as an outcome. For the Internalizing scale, it was found that only SES ($\beta = -.282, p = .037$) and PPR ($\beta = .614, p = .000$) significantly predicted internalizing problems. For the Externalizing scale, it was found that only PPR ($\beta = .500, p = .000$) and GFF ($\beta = .302, p = .012$) significantly predicted externalizing problems.

Additionally, to investigate potential effect modifiers, interaction terms for all 15 possible combinations of the six predictor variables in the regression analysis were entered and excluded one by one the model. Only the interaction term of birth-assigned sex and GFF ($\beta = -.309, p = .032$) significantly predicted psychological functioning. For AMAB, lower GFF was reported when having higher behavioral problems. Interestingly, for AFAB, higher GFF was reported despite the presence of higher behavioral problems.

Discussion

The purpose of the present study was to describe psychological functioning and its association with the status of transitioning socially in clinically referred children with a GD diagnosis in Germany.

A significantly impaired psychological functioning compared to the same-aged German norm population was reported by parents on the CBCL. Especially internalizing problems were elevated in comparison to the German norm, similar to most previous research reporting more internalizing than externalizing problems for youth with GD (Cohen-Kettenis et al., 2003; de Vries et al., 2016; Steensma et al., 2014). Both AMAB and AFAB also showed elevated scores for externalizing problems, although AFAB were closer to the norm range. This finding is not conclusively in line with previous studies on youth with GD: most of them report Internalizing and Externalizing problem scores to be comparable to the problems that are “typically” reported for the sex opposite of the sex-assigned at birth or with the experienced gender (e.g. Levitan et al., 2019; Steensma et al., 2014; van der Miesen et al., 2020).

From the present results, it can be concluded that clinically referred children with a GD diagnosis from Germany show significantly elevated levels of emotional and behavioral problems, especially internalizing problems, similar to most previous research on children with GD from Europe (e.g. Aitken et al., 2016; Cohen-Kettenis et al., 2003; Steensma et al., 2014). These results are contradicting recent findings from North American studies using community based samples (Durwood et al., 2017; Kuvalanka et al., 2017; Olson et al., 2016), though not all of them (Van der Miesen et al., 2018).

The second research question of the present study was to assess the impact of the degree to which a child had already transitioned socially on psychological functioning outcomes among these children. In the present study, the social transition status (living in the preferred gender role in different everyday life areas) was not significantly associated with psychological functioning. Hence, the results are in contrast with the most prominent results so far provided by Olson et al. (2016), who argued that a complete social transition in childhood may lead to improved psychological functioning. Another recent study comparing transgender children who had completely transitioned to gender variant children who had not transitioned found that PPR, but not transition status, predicted psychological functioning (Wong et al., 2019). Likewise, our study found that, social support in general (from family and peers), but not necessarily in terms of affirming one's child gender status, plays a role for the psychological outcomes. This finding is in line with previous studies assessing similar relationships with psychological functioning (e.g. Aitken et al., 2016; de Vries et al., 2016; Levitan et al., 2019; Steensma et al., 2014; Wong et al., 2019).

Therefore, another result relates to the role of the family and support in the present analysis: next to PPR, a higher degree of problematic GFF significantly predicted higher degrees of problematic psychological functioning (especially for externalizing problems). Previous research has shown that, among transgender adolescents, a communicative and satisfactory family climate is associated with less suicidality, self-harm, depression and anxiety and more self-esteem and resilience (Katz-Wise et al., 2018), and less emotional and behavioral problems (Levitan et al., 2019). On the other hand, family support can promote self-esteem (Katz-Wise et al., 2018) and lead to higher quality of life, and less perceived burden of being transgender (Simons et al., 2013). Another recent study on transgender adolescents and their caregivers indicates that family functioning should not be assessed as a general construct, but as a more detailed pattern, as there can be differences in acceptance and rejection towards transgender adolescents between family members (Pariseau et al., 2019).

Limitations

In general, it is not possible to draw causal conclusions from the present results, since this study was conceptualized with a cross-sectional design.

Because of the small sample size, this study does not provide sufficient power for multiple hypothesis testing. However, there are various other factors that may explain the increased psychological vulnerability in children with GD. The intensity of experienced GD may lead to more emotional and behavioral problems, as well as the likelihood to transition socially, and should thus be considered as another potential confounder in future research. However, all children from this sample were referred to the Hamburg GIS for their GD, experienced more or less intense GD and a wish to transition, which is usually why their families reached out to the center.

Furthermore, the present sample was selected based on age (younger than age 12) and not on pubertal status. Onset of puberty may have had an effect on the degree to which individuals already transitioned in the present study and on their psychological functioning, especially in the significantly older sub-sample of AFAB. Future studies should therefore also consider possible relationships between puberty status and the outcome.

In consideration of the age of the children assessed in this study, no self-report was available and parental reports were used for the analyses. Parental ratings are a common method to measure children's behavior. However, parents may be limited in evaluating their children's situation compared to the child itself (Achenbach et al., 1987). Thus, it is possible that parental evaluations regarding their child's emotional and behavior problems in this sample were biased.

Caution is also warranted in generalizing the results to all children with a GD because of the small and relative unique sample. All 54 children in the analysis sample were referred to the clinic for their GD, most of them came from families with a medium or high socio-economic background and the family support of the children's gender identity was generally high. Due to the health care situation in Germany for children and adolescents with a GD diagnosis, some families go to considerable length to get access to treatment which they probably would not do if they did not generally support their child's personal situation. At the same time, the clinical guidelines of the Hamburg GIS are quite liberal and allow for individual treatment pathways. Thus, these findings might not apply to a more diverse sample of transgender children who are not supported in their gender identity or expression by parents or clinicians, or children who identify themselves on a broader gender spectrum.

Conclusion and Future Directions

This study provides additional evidence that children with a GD diagnosis from Germany experience impaired psychological functioning, which is in line with many results for children from other gender clinics worldwide.

At the same time, transitioning socially did not significantly affect the degree of emotional and behavioral problems in this population — contrary to previous studies looking at community based samples carried out by Durwood et al. (2017) and Olson et al. (2016), but in line with recent findings from a comparison of different online assessed community samples by Wong et al. (2019). Instead of social transition status itself, the individual social support was a significant predictor in the present study with regard to psychological functioning among children with GD. While further research is needed to address the possible impact of a “complete” social transition versus the degree of social transition on psychological functioning, the present study highlights the importance of both social interactions with peers and within the family for the psychological functioning in children with GD.

Clinicians can help children to deal with potential emotional and behavioral problems, and should aim to strengthen their resilience towards possible negative interactions, for example by teaching them strategies to cope with experiences of stigmatization and enhancing self-efficacy or self-esteem (Levitan et al., 2019; Steensma et al., 2013). Interventions targeted at reducing stigmatization among

children and adolescents in the general population and at schools are essential, since children with a GD diagnosis often lack peer support (Cohen-Kettenis et al., 2003; Steensma et al., 2014) and transgender adolescents are more likely to be bullied at school (Toomey et al., 2010). Both peers and family should be incorporated in the psychosocial treatment of this population as early as possible, because incorporating parents' needs and feelings in the psychotherapeutic process could improve the child's situation as well. Parents themselves can be affected by their child's GD and may experience parenting stress (Kolbuck et al., 2019).

Although claims that gender affirmation through transitioning socially is beneficial during this early stage could not be supported from the present results, supporting this step may still be considered in individual cases and together with the whole family. A clinical approach that considers children to explore their identity without strict criteria, but with an open mind, may allow for a discussion of all possible outcomes and individual strategies of exploring gender identity during childhood. This may include both persisting and desisting pathways (Giordano, 2019), possibilities of living in another (non-binary) gender, as well as the possibility that there are more than two future developmental pathways (Steensma & Cohen-Kettenis, 2015).

Due to the young age of the children investigated here, it is very likely that the long-term development these children undergo regarding their gender identity and the possible problems they may experience will be largely influenced by their parents' support in terms of access to treatment. Children may be encouraged in taking a lead in discussing possible social transitions and retransitions with their parents (Ehrensaft et al., 2018; Hidalgo et al., 2013; Olson et al., 2019). This is particularly important since transitioning socially should not only be viewed as a form of treatment, but can be understood as a possibility for children to explore their own individual developmental pathways (Giordano, 2019).

The present study highlights the importance of considering every case individually, as well as making decisions about a gender transition together with the whole family, as currently suggested by the SoC 7 of the WPATH (Coleman et al., 2012). Further longitudinal studies are urgently needed to draw more specific conclusions regarding the current clinical management of GD in childhood, advantages and disadvantages of social transition, long-term developmental outcomes from childhood throughout adolescence to young adulthood, and the interactions between children and their social environments — as well as the interactions between all of these aspects.

Acknowledgements

We thank all the families who contributed to this study by providing important personal data on many levels, and the clinicians for their contribution to the data collection in the care unit.

Abstract

Background

In adolescents with severe and persistent gender dysphoria (GD), gonadotropin releasing hormone analogues (GnRHa) are used from early/middle puberty with the aim of delaying irreversible and unwanted pubertal body changes. Evidence of outcomes of pubertal suppression in GD is limited.

Methods

We undertook an uncontrolled prospective observational study of GnRHa as monotherapy in 44 12–15 year olds with persistent and severe GD. Prespecified analyses were limited to key outcomes: bone mineral content (BMC) and bone mineral density (BMD); Child Behaviour Checklist (CBCL) total t-score; Youth Self-Report (YSR) total t-score; CBCL and YSR self-harm indices; at 12, 24 and 36 months. Semistructured interviews were conducted on GnRHa.

Results

44 patients had data at 12 months follow-up, 24 at 24 months and 14 at 36 months. All had normal karyotype and endocrinology consistent with birth-registered sex. All achieved suppression of gonadotropins by 6 months. At the end of the study one ceased GnRHa and 43 (98%) elected to start cross-sex hormones.

There was no change from baseline in spine BMD at 12 months nor in hip BMD at 24 and 36 months, but at 24 months lumbar spine BMC and BMD were higher than at baseline (BMC +6.0 (95% CI: 4.0, 7.9); BMD +0.05 (0.03, 0.07)). There were no changes from baseline to 12 or 24 months in CBCL or YSR total t-scores or for CBCL or YSR self-harm indices, nor for CBCL total t-score or self-harm index at 36 months. Most participants reported

Funding: The author(s) received no specific funding for this work.

Competing interests: The authors have declared that no competing interests exist.

positive or a mixture of positive and negative life changes on GnRHa. Anticipated adverse events were common.

Conclusions

Overall patient experience of changes on GnRHa treatment was positive. We identified no changes in psychological function. Changes in BMD were consistent with suppression of growth. Larger and longer-term prospective studies using a range of designs are needed to more fully quantify the benefits and harms of pubertal suppression in GD.

Introduction

Gender dysphoria (GD) describes the experience of incongruence between an individual's experienced gender and the sex they were assigned at birth. GD [1] in children and young people, also known as Gender Incongruence [2] and previously known as Gender Identity Disorder (GID), is associated with considerable distress or impairment in social, school or other important areas of functioning [3,4]. Interventions include psychosocial support, therapy and medical or surgical interventions to align the body with the identified gender [3,5]. Terminology in this field can be challenging [6]. Here we use birth-registered sex to refer to the sex assigned at birth by clinicians based upon external genitalia [6]. Gender identity refers to a young person's personal sense of their gender. We use the terms 'continuation' and 'discontinuation' to refer to GD across childhood and adolescence.

GD in adolescence is highly likely to continue into adult life where gender dysphoria persists after the onset of puberty [3]. Those with earlier onset or more intense GD and those in whom the development of secondary sexual characteristics in puberty is associated with increasing gender dysphoria or psychological distress are more likely to have persistent GD [3,7]. In adolescents with severe and persistent GD, international [8] and national [9–11] guidelines recommend the use of treatments to suppress the rise in sex hormones (oestradiol or testosterone) in young people during puberty. Gonadotropin releasing hormone analogues (GnRHa) are synthetic peptides that work by stimulating gonadotropin release in a tonic fashion which desensitises the gonadotropin receptors, resulting in reversible suppression of sex hormone production.

In GD, GnRHa can be used from the early/middle stages of puberty with the aim of delaying irreversible and unwanted pubertal body changes and giving young people the opportunity to explore their gender identity during a period when puberty is not advancing [3]. This period also allows clinicians more time to assess the stability of young people's gender identity [6]. Despite this treatment being given in mid-puberty it is also called early puberty suppression, where 'early' refers to earlier than the historic practice of suppression after completion of puberty.

Pubertal suppression is currently practised in the majority of international centres across Europe, the Americas and Australasia, as evidenced by a recently published survey of 25 international centres by the European Society of Paediatric Endocrinology (ESPE) [12]. Pubertal suppression with GnRHa as monotherapy is a time-limited strategy, due to the potential for side effects with long-term use. In the UK, for those commencing under age 15 years, use of GnRHa alone ceases after 16 years when young people face a decision to return to the sex hormones produced by their body or begin cross-sex hormones [5]. There are limited data on the outcomes of pubertal suppression in the treatment of young people with GD [3,13]. A recent

systematic review included data on the physical and mental health outcomes of pubertal suppression using GnRHa in over 500 young people [4]. Longer-term follow-up data on pubertal suppression in GD are limited to individuals from four cohorts [14–19].

In 2011 a study was begun to evaluate the proximal outcomes of mid-pubertal suppression using GnRHa in young people with persistent GD (see <http://gids.nhs.uk/our-early-intervention-study>). Use in the UK began after mid-pubertal suppression had been incorporated into international guidelines [20] and had become available in the USA [21,22], the Netherlands [15], Australia [23] and a number of European countries. The Gender Identity Development Service (GIDS) at the Tavistock and Portman NHS Foundation Trust, London, is a national service for children and young people with GD, drawing from England, Wales and Ireland. Mid-pubertal suppression was offered by the GIDS from 2011 initially only within an ethically approved uncontrolled observational research study with prospective data collection, where all participants received GnRHa. We anticipated that we would recruit 10–15 young people per year for 3 years and follow them up to the end of monotherapy with GnRHa. At the time, a randomised controlled study was not considered feasible due to very small numbers and inability to retain participants in the control arm, as the control treatment would have resulted in progression into near complete puberty and an increasing number of UK families were accessing mid-pubertal suppression internationally. Allocation blinding was also not considered feasible in young people using a product requiring monthly injections.

Here we describe the short-term outcomes of 44 young people with GD from this research cohort, recruited aged 12–15 years and followed to the end of GnRHa monotherapy after age 16 years. This paper describes their medical, psychological and social outcomes during the GnRHa treatment pathway up to the point of decisions about whether or not to undertake further physical treatment. The aims of the study as defined at inception in 2011 were:

1. To evaluate the benefits and risks for physical and mental health and wellbeing of mid-pubertal suppression in adolescents with GD
2. To add to the evidence base regarding the efficacy of GnRHa treatment for young people with GD
3. To evaluate continuation and discontinuation of GD and the continued wish for gender reassignment within this group.

Methods

We undertook an uncontrolled prospective observational study of GnRHa monotherapy in a highly selected group of young people with persistent and severe GD.

Participants

The cohort consisted of 44 sequentially eligible young people, aged 12 to 15 years, who were recruited between April 2011 and April 2014 and who commenced GnRHa treatment between June 2011 and April 2015. They were all recruited from patients referred to the GIDS.

Eligibility criteria were chosen to match those used for a Netherlands cohort [24], namely that the young person:

- A. is aged 12–15 years
- B. Psychological criteria

1. has been seen by the GIDS for at least 6 months and attended at least 4 interviews for assessment and therapeutic exploration of their gender identity development.

2. psychological stability sufficient to withstand the stresses of medical treatment for GID.
3. fulfils the following criteria relating to GID:
 - a. Throughout childhood (defined as over 5 years) the adolescent has demonstrated an intense pattern of cross-gendered behaviours and cross-gender identity.
 - b. The adolescent has gender dysphoria that is significantly increased with the onset of puberty. Following assessment the clinician(s) working with the young person deem that there is a high likelihood of the young person experiencing severe psychological distress consequent on experiencing full pubertal development before pubertal suppression is implemented.
4. The young person and their parents/guardians are actively requesting pubertal suppression.
5. is able to give informed consent.

C. Physical/medical criteria

1. is in established puberty:
 - For birth-registered males Tanner (genital and pubic hair (PH)) stage 3 and above.
 - For birth-registered females Tanner (breast and PH) stage 2 and above.

The rationale for the sex difference was that the pubertal growth spurt which early intervention aims to avoid occurs typically two years earlier in females (Tanner stage 2–3) than in males (Tanner stage 3–4), thus earlier intervention is required in females.
 2. has normal endocrine function and karyotype consistent with birth registered sex.
- Note that the presence of mildly elevated androgens in birth registered females consistent with polycystic ovarian syndrome is not an exclusion criterion.
- Exclusion criteria:
1. Inability to participate with full investigatory protocol e.g. needle phobia, failure to attend for tests and scans.
 2. Body mass index (BMI) <2nd centile for age and birth-registered sex [20].
 3. Serious psychiatric conditions (e.g. psychosis, bipolar condition, anorexia nervosa, severe body-dysmorphic disorder unrelated to GD).
 4. Inability to give informed consent according to the Fraser/Gillick guidelines.
 5. Low spine or hip bone mineral density (BMD) on DXA scan: more than 2 SD below expected BMD for age and birth-registered sex. In exceptional circumstances a low BMD was acceptable if:
 - i. it was felt to be clinically appropriate by the treating clinicians, who felt that on the balance of risks, pubertal suppression was justified despite the later risk of osteoporosis
 - ii. the young person and parents understood the risks of GnRHa treatment for bone density (i.e. potential risks of later osteoporosis)
 - iii. The young person and parents consented to more frequent monitoring of BMD (repeat DXA scans 6 months after starting GnRHa and yearly thereafter while on GnRHa) despite the small DXA radiation dose

- iv. The young person and parents consented to stopping treatment if raw BMD fell whilst on GnRHa.

The treatment

The treatment under study was suppression of puberty using the GnRHa *triptorelin* together with psychosocial support and therapy, from study entry until the end of the GnRHa monotherapy pathway at age 16 years or older. GnRHa monotherapy ceased when young people either started cross-sex hormones (and continued on GnRHa) or stopped GnRHa. Treatment duration was therefore from 1 to 4 or 5 years depending on age at study entry. Consenting young people were given triptorelin 3.75mg by intramuscular injection every 28 days during the treatment period. Two participants who found monthly injections difficult were moved to a ten-weekly preparation of 11.25mg of triptorelin. The aim of treatment was to suppress gonadotropins and sex hormones to near pre-pubertal levels [13]. Continued regular attendance for psychological support and therapy throughout the study was a precondition of GnRHa prescription. In addition local psychological services provided support for co-occurring difficulties for participants as required.

Procedures and pathway

All young people and families attending the GIDS during the study period were provided with an information leaflet about research underway within the unit. Those wishing to find out more about the study discussed it with their GIDS clinicians and those deemed likely to be eligible were given detailed written study information. Those wanting to participate were invited to a medical clinic at UCLH for an initial discussion. At the first medical clinic, young people and families were seen by a senior paediatric endocrinology clinician together with a senior GIDS clinician, who discussed with the family the then current state of knowledge and rationale for treatment, eligibility criteria and potential risks and benefits of participation. Risks included the anticipated side-effects of GnRHa treatment including symptoms resulting from the withdrawal of sex steroids (headaches, hot flushes), fatigue, loss of libido and low mood, the potential that treatment could influence the continuation of their GD and the potential for unknown risks. It was emphasised that young people needed to continue with both regular medical and psychosocial follow-up during the study and that treatment would cease if they did not comply with the treatment or monitoring requirements. A full medical history was elicited and the clinicians also reviewed a summary of the psychological history and assessment from the GIDS. In this visit information sheets were re-provided if families had lost them or forgotten details of the study. If young people and families remained interested in participation, medical investigations were organised and families were invited for a repeat discussion and a formal evaluation of eligibility at a second medical clinic visit approximately 3 months later. Families were asked to think about the issues raised in the meeting and to discuss with their GIDS clinicians if necessary, in order to discuss further at the second visit.

At the second medical clinic visit, the same clinicians repeated the discussion of risks and benefits and explored understanding with the young person and family. A chaperoned medical examination was undertaken including pubertal assessment and the results of medical investigations were reviewed. Endocrine and GIDS clinicians jointly reviewed eligibility and offered participation in the study to those deemed eligible.

The implications of treatment for fertility were discussed at the first and second medical visits and all young people were urged to consider storing gametes before starting GnRHa. Access to storage depended on regional availability within the NHS. Note that counselling on fertility

continued across the study, and clinicians periodically checked with young people who had decided against storage whether they wished to revisit their decision.

Informed consent was obtained in writing from both the young person and a parent or carer holding parental responsibility. The ability of the young person and parents to give informed consent was assessed jointly by the senior adolescent endocrine and GIDS clinicians, informed by written notes from the GIDS team. The consent forms were read with the young person and the parent by the clinicians to be sure they fully understood the information on the forms before signing.

48 young people and families attended the medical clinics for discussion of participation in the trial, of whom 44 wished to participate. Eight young people (7 birth assigned males) were not eligible for participation at the second medical visit as they were not yet sufficiently advanced in puberty. They were followed up every 3–6 months and entered the study subsequently when sufficiently advanced in puberty (median waiting time 7 months).

The date of signing the consent form was taken as the start of study treatment, although it frequently took one to three months for GnRHa treatment to start due to administrative requirements. Participants were followed up in the endocrine clinic, 3–6 monthly in the first 18 months and 12-monthly thereafter, till the end of the treatment pathway, defined as the date on or after the 16th birthday when a decision was made to either cease GnRHa or start cross-sex hormones. The final participant completed the pathway in February 2019.

Outcomes

The following data were collected:

A. Baseline explanatory variables

1. Sex and gender: Young people were classified by their sex assigned at birth (birth-registered sex) and self-identified gender.
2. Ethnicity: Ethnicity was obtained from clinic records. For analysis, ethnicity was grouped as white, South Asian, black or mixed.
3. Puberty: Pubertal status at baseline was classified using information on genital/breast and pubic hair Tanner stages as appropriate. This was summarized into a single pubertal stage, with the breast/genital stage taking precedence if there was discrepancy between breast/genital and pubic hair stage.
4. Clinical data: These consisted of a) identification of normal phenotype on physical examination for birth-registered sex; b) venepuncture assessment of endocrinology (gonadotropins, prolactin, oestrogen or testosterone, adrenal androgens, thyroid function; and a short synacthen test in birth-registered females only), karyotype, full blood count, renal and liver function, calcium and vitamin D; and c) imaging including wrist bone age and (in birth-registered females only) pelvic ultrasound scan. Medical assessment at baseline and follow-up was consistent with Endocrine Society guidelines [8,20].

B. Study outcomes

Study outcomes concerned domains including response to treatment, bone health, safety indicators and adverse events, psychological function; participant experience and satisfaction; and decisions regarding treatment following GnRHa. Outcome data were collected at routine clinic visits to GIDS or medical clinics at UCLH and timings therefore varied. For the purposes of these analyses, data for each participant were assigned to baseline (before treatment) and to the closest of the following outcome periods: 12, 24, 36 and 48 months on treatment. For safety and response to pubertal suppression outcomes, data were also examined at 6 months.

1. Response to pubertal suppression

Gonadotropins (LH, FSH), testosterone (in birth-registered males) and oestrogen (birth-registered females) were measured after venepuncture. Height, weight and blood pressure were recorded by trained clinic staff. BMI z-score for age and birth-registered sex was calculated [25]. Menarcheal status and presence/absence of menstrual periods was obtained by report from birth-registered females.

2. Bone health

Bone mineral content (BMC) and bone mineral density (BMD) in the lumbar (L1 to L4) spine and hip (total hip) were measured by dual energy X-ray absorptiometry (DEXA) scans using a Hologic Discovery QDR series model 010–1549 (Hologic Inc, Bedford, MA, USA). BMD z-scores for age and birth-registered sex appropriate to this machine were calculated [26]. BMD z-scores for spine and hip were further adjusted for height (height-adjusted z-scores) using published formulae [27].

3. Safety indicators and adverse events

Blood samples were collected by venepuncture for liver and renal function, full blood count, calcium and vitamin D, prolactin, adrenal androgens and thyroid function. Participants were routinely questioned about adverse events at medical clinic visits, including anticipated events such as headaches, hot flushes or fatigue plus any other unanticipated events.

4. Psychological function

Psychological outcomes included a clinical outcome routinely collected after GIDS appointments and a range of outcomes assessed using questionnaires. A standardised set of psychological questionnaires used in the GIDS clinic was completed at the time young people were deemed potentially eligible and referred to the medical clinic. Questionnaires were completed at home by the young person and parent between GIDS clinical meetings, and a research assistant followed up families to ensure their completion. Questionnaires were repeated approximately every 12 months on treatment.

i. General psychological functioning

The Child Behaviour Checklist (CBCL) (parent report) and Youth Self Report (YSR) (self-report) are general measures of psychological functioning and part of the Achenbach System of Empirically Based Assessment (ASEBA; www.aseba.org). The CBCL consists of 113 questions and is validated for children aged 6–18 years in international population samples [28]. The YSR consists of 112 questions and is validated in international populations of young people aged 11–18 years [29]. Questions in both are scored on a three-point Likert scale (0 = absent, 1 = occurs sometimes, 2 = occurs often), with the time frame for item responses being the past six months. Scoring for both instruments provides a total problems score, an internalizing problems score (items which assess anxious/depressed, withdrawn-depressed, and somatic complaints) and an externalizing score (focusing on rule-breaking and aggressive behaviours). Each questionnaire was scored with Assessment Data Manager Software using ASEBA standard norms and t-scores were generated based on reference data for birth-registered sex and broad age-ranges (here 12–18 years). Higher scores indicate greater morbidity. To account for normative change within our age-range, we used international reference data [29] to transform YSR raw scores into z-scores for year of age. As reference data from the UK were not available, reference data from both Australia and the Netherlands were used.

ii. Self-harm index

Self-harm actions and thoughts were assessed through two questions in each of the CBCL (parent report) and YSR (self-report): Item 18 (I deliberately try to hurt or kill myself) and Item 91 (I think about killing myself). Possible responses for each question were 0 = not true, 1 = somewhat or sometimes true, or 2 = very true or often true. We followed previous studies in calculating a self-harm index score to avoid multiple statistical comparisons across

correlated categorical-response variables. The index was calculated as the sum of the two items in each scale to create an index from 0 to 4 for each of the CBCL and YSR [30–32], a higher score indicating greater self-harm thoughts and behaviour.

iii. Health related quality of life (HRQoL)

This was assessed through separate young person and parent Kidscreen-52 questionnaires, each consisting of 52 items which assess HRQoL across ten dimensions: physical well-being; psychological well-being; moods and emotions; self-perception; autonomy; relations with parents and home life; social support and peers; school environment; social acceptance (bullying); and financial resources. All items use five-point Likert-style scales to assess either the frequency (never-seldom-sometimes-often-always) of certain behaviours/feelings or the intensity of an attitude (not at all-slightly-moderately-very-extremely). The measure was developed for young people aged 8–18 years, with the recall period of one week. The questionnaires provide scores in the form of continuous t-scores for the ten subscales derived from a multinational European sample [33]. Lower scores indicate lower HRQoL, i.e. greater morbidity.

iv. Body image

The Body Image Scale (BIS) is a self-report measure of 30 items used to assess body image satisfaction or dissatisfaction validated for age 12+. The instrument considers 30 body features which the respondent is asked to rate in terms of satisfaction on a five-point scale (1 = very satisfied, 2 = satisfied, 3 = neutral, 4 = dissatisfied, and 5 = very dissatisfied). The BIS provides a total score in the form of a continuous score for the total scale as well as for three subscales assessing primary sexual characteristics, secondary sexual characteristics and 'neutral' characteristics (i.e. non-sexual characteristics, e.g. nose) [34]. Higher scores represent higher degrees of body dissatisfaction.

v. Gender dysphoria

The Utrecht Gender Dysphoria Scale (UGDS) is a self-report measure used to assess the intensity of GD validated for age 12+. It comprises of 12 statements with agreement on a five-point scale (1 = agree completely, 2 = agree somewhat, 3 = neutral, 4 = disagree somewhat, and 5 = disagree completely). There are separate versions for birth-registered males and females. Items are summed to give a single total score, with higher scores indicating greater GD.

vi. Clinical outcomes

The Children's Global Assessment Scale (CGAS) is a rating of functioning in children and young people aged 6–17 years, extensively used as a routine clinical measure in child and adolescent mental health services in the UK. Treating clinicians assign young people a single score between 1 and 100, based on a clinician's assessment of a range of aspects related to a child's psychological and social functioning, with the time period being the previous month. Higher scores indicate better functioning, with categories ranging from 'extremely impaired' (1–10) to 'doing very well' (91–100) [35].

5. Participant experience and satisfaction with GnRHa

Young people were invited to participate in semi-structured qualitative interviews at 6–15 months and 15–24 months after starting GnRHa. Interviews were conducted in person or by telephone with a research assistant. If young people were unavailable, questions were posted to be completed and returned. The interview consisted of 12 questions related to changes young people had experienced in ten domains since starting on GnRHa: life overall, memory, focus, sense of direction, mood, energy levels, relationships with friends, relationships with family, gender role and sexuality. For each domain, young people were asked first about the general direction of change in that domain (whether changes were positive, neutral, negative or mixed positive and negative) and then asked for examples of changes experienced and why they assigned the chosen change rating. At the end of the interview two further questions were asked about change in any other experiences (i.e. allowing open ended responses) and whether

young people wished to continue on GnRHa treatment. Note there was no interview conducted before young people started GnRHa. Interviews were recorded in contemporaneous written notes by the researcher. The questionnaire is provided in the [S1 Appendix](#).

6. Further treatment decisions

Decisions made at the end of the GnRHa pathway were recorded in terms of which if any further treatment for GD young people chose.

Note that other measures of gender dysphoria (Gender Identity Interview; Recalled Childhood Gender Identity Scale) were specified in our original protocol, however they were discontinued during the study as: a) they were historical instruments with poor construct validity and the binary references to male and female roles were challenging for some participants; and b) repeated questioning about gender dysphoria resulted in some distress to respondents. Our protocol had originally included the ASEBA Teacher Report Form (TRF), however we were unable to obtain data from teachers so this outcome was dropped. The Social Responsiveness Scale (SRS) was a baseline only assessment of autistic traits; these data will be analysed in the future.

Analysis plan

Analyses were conducted according to the Statistical Analysis and Dissemination Plan, lodged with the ethics committee that approved the study before the analysis started (see [S2 Appendix: Statistical Analysis Plan](#)). The analysis plan was designed to report data on all outcomes but to minimise the likelihood of chance findings due to the large number of outcomes and small sample size. Sample sizes necessarily varied across follow-up as young people were recruited at different ages (12–15 years) but left the study soon after their 16th birthday. All 44 participants had data at 12 months follow-up. As participants necessarily left the study soon after their 16th birthday, numbers reduced after 12 months follow-up as participants could no longer remain in the study. Note this does not represent drop-out. There were 24 left at 24 months, 14 at 36 months and 4 at 48 months. In view of this, outcome reporting was restricted to change from baseline to 12, 24 and 36 months. We made no attempt to account for missing data due to the small sample size and the likelihood of the data missing not at random.

We restricted analyses to primarily descriptive statistics, with formal statistical testing of change across the study restricted to six pre-specified outcomes, i.e.:

1. Overall psychological functioning
 - a. parent report: CBCL total t-score
 - b. young person self-report: YSR total t-score
2. Self-harm index
 - a. parent report: CBCL self-harm index
 - b. young person self-report: YSR self-harm index
3. Bone health
 - a. BMD and BMC for lumbar spine
 - b. BMD and BMC for hip

Assessment of change was through paired t-tests for normally distributed data and the Wilcoxon matched-pairs sign-rank test for non-normal data. The number of formal statistical tests conducted in the study was 16; with overall significance at $p = 0.05$ and a Bonferroni correction, the appropriate threshold for statistical significance is about $p = 0.003$.

In our results and conclusions we refer to change in outcomes only for those that were formally tested. Reporting for other continuous outcomes was restricted to mean and 95% confidence intervals (95%CI) or median and interquartile range (IQR). For categorical outcomes, simple proportions were reported. We reported laboratory tests as normal or abnormal based upon laboratory reference data for age, with the exception of gonadotropins. We did not report data where the sample size was less than 8.

Analysis of potential predictors of outcome was confined a priori to two factors, birth-registered sex and pubertal stage at baseline. Three pre-specified continuous outcomes were examined at 12 months, namely:

1. BMD for lumbar spine
2. YSR total t-score
3. CGAS score

Associations were examined using linear regression of follow-up score on baseline score, adding each baseline factor separately to the model and considering the interaction of predictor with baseline score. All analyses were conducted using Stata 16 (Statacorp, College Station TX).

Responses to the semi-structured interview questionnaires were analysed simply for thematic content in terms of the direction and amount of change that young people experienced in each domain. This involved coding responses about experiences since starting GnRHa into categories; i.e. either positive/improving, negative/deteriorating, both positive and negative, no change or not known. The question on change in sexuality was coded as yes change, no change or not known. Wishes to continue with GnRHa were coded as yes, no or don't know.

To compare our findings with the literature, we drew upon recent reviews [3,4,6,13] and updated a recent review [4] from 1 June 2017 to 31 December 2019 using the same search terms in Medline (see [S1 Appendix](#)).

Ethics

Ethical approval for the study was obtained from the National Research Ethics Service (NRES: reference 10/H0713/79) in February 2011. Study consent allowed the use of routinely collected clinical data (medical and psychological) as part of clinical treatment for the study. Study procedures including consent were reviewed by the UK Health Research Authority.

Data sharing. These are highly sensitive data from a small group of vulnerable young people treated in a single service and the risk of identification and disclosure is high. Research ethics permissions at the time the study was undertaken did not include permission to share data. After discussions with the Health Research Authority, UK, an anonymised dataset modified to remove sensitive data and minimise disclosure risk of personal information has been deposited with the UK Data Service.

Results

Participants received psychosocial assessment and support within the GIDS before entering the study for a median of 2.0 years (IQR 1.4 to 3.2; range 0.7 to 6.6). The median time between first medical assessment at UCLH and starting treatment was 3.9 months (IQR 3.0 to 8.4; range 1.6 to 25.7). Median time in the study was 31 months (IQR 20 to 42, range 12 to 59).

Baseline characteristics of the participants by birth-registered sex are shown in [Table 1](#). Median age at consent was 13.6 years (IQR 12.8 to 14.6, range 12.0 to 15.3). A total of 25 (57%) were birth-registered as male and 19 (43%) as female. At study entry, birth-registered males

Table 1. Participant characteristics at baseline.

		Total sample	Birth-registered sex	
		n = 44	male n = 25	female n = 19
Age at consent (years)	Median (IQR)	13.6 (12.8, 14.6)	13.4 (12.7, 14.1)	13.9 (13.5, 14.7)
Ethnic group n (%)	white	39 (89)	24 (96)	15 (79)
	South Asian	1 (2)	1 (4)	0
	black	2 (5)	0	2 (11)
	Mixed ethnicity	2 (5)	0	2 (11)
Pubertal status n (%)	Stage 2	0	0	0
	Stage 3	19 (43)	17 (68)	2 (10)
	Stage 4	16 (36)	5 (20)	11 (58)
	Stage 5	9 (21)	3 (12)	6 (32)
Menarcheal status n (%)	Premenarcheal	-	-	4 (21)
	Post-menarcheal	-	-	15 (79)
Time in study (months)	Median (IQR)	31 (20, 42)	37 (24, 43)	29 (17, 36)
Age at end of pathway (years)	Median (IQR)	16.1 (16.0, 16.4)	16.1 (16.0, 16.5)	16.1 (16.0, 16.3)

At baseline, all participants had normal endocrinology, karyotype, imaging and clinical phenotype on physical examination for birth-registered sex and normal full blood count and liver and renal function. No participants had evidence of disorders of sexual differentiation. Eight participants (18%) had vitamin D insufficiency at baseline and were given vitamin D supplements.

<https://doi.org/10.1371/journal.pone.0243894.t001>

were predominantly in stage 3 puberty (68%) whilst birth-registered females were predominantly in stages 4 (58%) or 5 (32%) with 79% (15/19) post-menarcheal. 89% of participants were of white ethnicity. Birth-registered females were on average 6 months older than birth-registered males at study entry.

Response to treatment

All participants achieved adequate suppression of gonadotropins and sex hormones by 6 months (mean LH 0.5IU/L; mean FSH 1.4IU/L) and maintained it throughout the study (see Table 2). Liver function, basic haematology and biochemistry were normal in all participants at 3–6 months. All post-menarcheal birth-registered females reported amenorrhoea in the 3 months after starting GnRHa treatment and remained so throughout treatment. No participants reported progression in pubertal development. Height and weight were normal at baseline. Height growth continued through the study but more slowly than expected for age, thus

Table 2. Growth and gonadotropin levels at baseline, 12, 24 and 36 months.

Growth		Baseline		12 months		24 months		36 months	
		n	Mean (95% CI)	n	Mean (95% CI)	n	Mean (95% CI)	n	Mean (95% CI)
Height	z-score	44	0.4 (0.1, 0.7)	44	0.2 (-0.1, 0.4)	24	0.0 (-0.4, 0.4)	14	0.0 (-0.5, 0.5)
Weight	z-score	44	0.8 (0.4, 1.3)	44	0.8 (0.3, 1.3)	24	0.6 (-0.1, 1.3)	14	1.0 (0.1, 1.9)
BMI	z-score	44	0.7 (0.2, 1.1)	44	0.7 (0.2, 1.2)	24	0.6 (-0.1, 1.3)	14	1.1 (0.3, 1.9)
Gonadotropins									
LH	IU/L	42*	4.2 (2.8, 5.6)	44	0.60 (0.42, 0.68)	17	0.40 (0.22, 0.60)	7	0.30 (0.14, 0.46)
FSH	IU/L	42*	3.9 (3.2, 4.5)	44	1.3 (1.0, 1.7)	17	1.0 (0.6, 1.5)	7	1.4 (0.7, 2.2)

*In two participants data recorded as normal at baseline were not available.

<https://doi.org/10.1371/journal.pone.0243894.t002>

height z-score fell over time (Table 2). Weight and BMI z-scores were stable from baseline to 24 months but increased at 36 months.

Three participants had brief periods off GnRHa prior to their 16th birthday. In one, treatment was withdrawn by clinicians due to non-attendance at clinics and restarted 4 months later. Another requested a period off GnRHa to think further about treatment in view of other things happening in their life; they restarted 4 months later. A third, birth-registered male, stopped GnRHa for 9 months to attempt to store sperm, contrary to their earlier decision not to, and restarted afterwards.

Median age at the end of the GnRHa pathway was 16.1 years (Table 1). A quarter of participants made their decision more than six months later, either because they wished to delay due to school exams or other events or because clinicians felt they were not yet ready to make the decision. One young person decided to stop GnRHa and not start cross-sex hormones, due to continued uncertainty and some concerns about side-effects of cross-sex hormones. The remaining 43 (98%) elected to start cross-sex hormones.

Bone mineral density. BMD was available on 44 participants at baseline, 43 at 12 months, 24 at 24 months and 12 at 36 months (Table 3). Numbers were lower for hip than for spine as some hip scans were not done for technical reasons. The table shows mean values at baseline and 12, 24 and 36 months, along with mean baseline values corresponding to the paired samples at each time point. There was no change from baseline in spine or hip at 12 months nor in hip at 24 and 36 months, but at 24 months lumbar spine BMC and BMD were higher than at baseline, as was lumbar BMC at 36 months. Lumbar and hip BMD age-adjusted z-scores were in the normal range at baseline but point-estimates fell at 12 and 24 months but not at 36 months. Point-estimates for height-adjusted z-scores for lumbar and hip BMD also fell at 12 and 24 months but not at 36 months.

Psychological outcomes. For the standardised questionnaires, baseline assessments were conducted at a median of 0.5 (IQR 0.4, 0.8) years before starting treatment, and were available for all 44 participants by self-report and 43 by parental report. Data on the CBCL, YSR, Kidscreen-52, BIS and CGAS were normally distributed whilst those for UGDS and the CBCL and YSR self-harm indices were skewed.

The first psychological follow-up was at a median of 13 (IQR 12, 14) months after start of treatment, with ASEBA data available for 41 participants (parent and self-report). ASEBA data at 24 months (median 25 (21, 28)) were available on 20 young people by parent report and 15 by self-report, and at 36 months (median 36 (29, 39)) on 11 by parent report and 6 by self-report.

Formal testing was undertaken only for key ASEBA outcomes (Table 4). For the CBCL total t-scores, there was no change from baseline to 12, 24 or 36 months. Similarly for the YSR total t-score, there was no change from baseline to 12 or 24 months; YSR data at 36 months ($n = 6$) were not analysed. There were no significant changes in parent-report CBCL self-harm index scores from baseline to 12, 24 or 36 months, nor for self-report YSR self-harm index scores.

Other psychological outcomes are described in Table 5. Point-estimates of scores on the Kidscreen-52, BIS, UGDS and CGAS showed little change over time."

The pre-specified outcomes of BMD at lumbar spine, YSR total t-score and CGAS score at 12 months, adjusted separately for birth-registered sex and baseline pubertal status, along with the baseline level of the outcome, are shown in Table 6. None of the outcomes were associated with birth-registered sex or pubertal status, and there were no important interactions.

Participant experience, satisfaction and side effects. 41 participants completed interviews at 6–15 months (median 9) and 29 at 15–24 months (median 21); 3 missed both. Fig 1 shows proportions with positive or negative changes for life overall, mood and friendships, with summary data for all questions shown in S1 Appendix (S1 and S2 Tables).

Most participants reported positive or a mix of positive-negative changes in their life at both time points. At 6–15 months 46% reported only positive changes, including feeling happier, relieved, less facial hair or stopping periods. A further 37% reported both positive and negative changes such as feeling happier but also experiencing hot flushes and headaches. In addition 12% reported overall negative changes namely hot flushes, tiredness, and feeling more emotional, while 5% reported no change. At 15–24 months, 55% reported solely positive changes such as feeling happier, no longer experiencing side effects and feeling more

comfortable with puberty suspended. A further 17% reported both positive and negative changes including less body hair but continued growth in height, or having clearer skin but also experiencing more hunger, weight gain and tiredness. 17% reported largely negative changes such as mood swings, tiredness and hot flushes whilst 10% reported no change.

Reports of change in mood were mixed. At 6–15 months, the majority reported mood to be improved (49%), mixed changes (such as both feeling happier but experiencing some mood swings; 15%) or no change (7%), however 24% reported negative changes in mood such as

experiencing more mood swings or feeling low. Findings at 15–24 months were similar. The most common negative change was reduced energy levels, reported by 29% at 6–15m and 38% at 15–24m.

Young people's reports of change in family and peer relationships were predominantly positive or neutral at both time points. Positive changes included feeling closer to the family,

feeling more accepted and having fewer arguments. Those reporting both positive and negative change reported feeling closer to some family members but not others. At 6–15 months, negative family changes were largely from family members not accepting their trans status or having more arguments. But by 15–24 months only one young person reported this. Improved relationships with peers related to feeling more sociable or confident and widening their circle of friends; negative changes related to bullying or disagreements at school. Again, at 15–24 months only one young person reported negative change, related to feelings of not trusting friends.

At 6–15 months, changes in gender role were reported by 66% as positive, including feeling more feminine/masculine, living in their preferred gender identity in more (or all) areas of life and feeling more secure in their gender identity, with no negative change reported. At 15–24 months, most reported no change although 41% reported positive changes including experimenting more with physical appearance and changing their details on legal documents.

All young people affirmed at each interview that they wished to continue with GnRHa treatment. Note that this was also the case when asked routinely at medical clinics (excepting those who briefly ceased GnRHa as noted above).

Adverse events. Adverse events are shown in Table 7. All adverse events were minor and anticipated, i.e. they were previously described in study participant information and/or noted in the triptorelin medication package inserts. Anticipated adverse events were common in the first two years, particularly mild headaches or hot flushes which were reported in 25% at 0–6m, 23% at 7–12m and 22% at 13–24m. Moderate or severe headaches and/or hot flushes were uncommon. Birth-registered females with distressing headaches or hot flushes were offered ‘add-back’ oestrogen therapy, and two accepted treatment briefly with very small doses of oestradiol, which was effective in reducing symptoms. Mild fatigue was reported by 5–8% over the first two years and no participants reported moderate or severe fatigue. Sleep problems, mood swings and weight gain were reported by very small numbers and in each case symptoms were mild. Adverse events were less common after 12 months of treatment.

Discussion

We report the short and medium-term outcomes of a prospective cohort of 44 young people with persistent and severe GD treated with GnRHa resulting in pubertal suppression from mid-puberty for 1–4 years. Young people were considered for recruitment after lengthy

assessment, spending an average of 2 years and up to 6 years within the GIDS psychological service before being referred to the endocrine clinic for assessment to enter the study. Medical assessment found no endocrine abnormalities at baseline. GnRHa treatment started in the majority of participants in later stages of puberty, with 57% in puberty stages 4 and 5 and 79% of birth-registered females being post-menarcheal. After starting GnRHa all quickly achieved and maintained suppression of pubertal hormones and none experienced pubertal progression. At the end of the study, 43 (98%) chose to start cross-sex hormones whilst one young person chose to stop GnRHa and continue with puberty consistent with their birth-registered sex.

As anticipated, pubertal suppression reduced growth that was dependent on puberty hormones, i.e. height and BMD. Height growth continued for those not yet at final height, but more slowly than for their peers so height z-score fell. Similarly for bone strength, BMD and BMC increased in the lumbar spine indicating greater bone strength, but more slowly than in peers so BMD z-score fell. These anticipated changes had been discussed with all participants before recruitment to the study. Young people experienced little change in mean weight or BMI z-score in the first two years. The rise in weight and BMI z-score at 36 months may represent a trend towards greater adiposity in those on GnRHa for a prolonged period, or reflect a higher baseline in this group.

Information on side-effects was available through routine reporting in medical clinics and in the participant experience interviews. Anticipated side effects of treatment were common, particularly mild symptoms directly related to suppression of sex hormones. Severe symptoms were uncommon. Fatigue or low energy was reported rarely in medical clinic assessments but frequently at interview (38% at 15–24m). The relationship of symptoms such as headaches, fatigue and sleep disturbance to GnRHa treatment is unclear as they are all very common in early adolescence [36,37], although a conservative perspective would regard them as side-effects of treatment.

Young people experienced little change in psychological functioning across the study. We found no differences between baseline and later outcomes for overall psychological distress as rated by parents and young people, nor for self-harm. Outcomes that were not formally tested also showed little change.

Participant experience of treatment as reported in interviews was positive for the majority, particularly relating to feeling happier, feeling more comfortable, better relationships with family and peers and positive changes in gender role. Smaller numbers reported having mixed positive and negative changes. A minority (12% at 6–15 months and 17% at 15–24 months) reported only negative changes, which were largely related to anticipated side effects. None wanted to stop treatment due to side effects or negative changes. We are not aware of comparative patient experience data from other cohorts.

The median age at consent in our study was very similar to that in the earliest published outcome study of mid-pubertal suppression using GnRHa treatment in Dutch young people (13.6 years) [24]. Similarly to this Dutch cohort, all but one of our participants elected to start cross-sex hormones after completing the GnRHa pathway. However they spent an average of 31 months on GnRHa compared with 23 months in the Dutch cohort [24]. In our study, the successful suppression of puberty and cessation of menses with GnRHa, the impact on height growth [4,16,38] and BMD [4,16] and the normality of liver and renal function through treatment were each consistent with previous reports [4,16].

Our findings that BMD increased over time in the lumbar spine but more slowly than in same age peers, resulting in a fall in z-score, are similar to others [4,14,39,40]. The fall in height-adjusted BMD z-score was consistent with but larger than the fall in height z-score. We found that birth-registered sex and pubertal status at baseline were not associated with later BMD. There is evidence that accretion of bone mass resumes and that BMD increases with the

start of cross-sex hormone therapy [4,14,39,41]. Future research needs to examine longer-term change in BMD in young people treated with mid-pubertal suppression.

We reported a range of adverse events previously described to be associated with pubertal suppression [42], with the exception of mild sleep disturbance although this is a known association with triptorelin use. As anticipated, the withdrawal of sex hormones produces symptoms such as headaches and lack of energy, although in the great majority (11 of 13 at 0–6 months; 10 of 14 at 7–12 months; 8 of 9 at 13–24 months) the symptoms were minor. Symptoms diminished over time as has previously been noted [4], and no young people chose to cease treatment due to the side-effects.

Our finding that 1 participant ceased pubertal suppression and did not commence cross-sex hormones is somewhat similar to the experience of one US cohort and a second Dutch cohort; Kuper et al. described that 2 of approximately 57 young people aged 10–15 years who commenced pubertal suppression treatment stopped this treatment without commencing cross-sex hormones [17]. Brik et al. reported that in a cohort of 137 young people who began GnRHa between 10 and 18 years and were followed until eligible to commence cross-sex hormones, 5 (3.6%) ceased treatment and did not later commence cross-sex hormones [19].

Three longitudinal studies from the Netherlands and the USA have examined psychological function over time in cohorts of young people treated with GnRHa and then cross-sex hormones [17,18,24], although the two US cohorts were of limited size. Our study adopted the same psychological outcome measures as the Dutch cohort, to facilitate comparison [24]. Mean baseline YSR scores in our cohort were similar to those previously reported in 141 young people aged 12–18 years from the London GIDS [43], and baseline CBCL and YSR scores were close to those at baseline from the original Dutch cohort [24]. A number of other studies have shown that young people with GD have higher scores on the CBCL or YSR than same-age population peers, and that they are similar to young people referred to clinical services for a range of mental health problems [44–46]. Population-based studies in America support higher baseline levels of mental health problems amongst young people with GD, with the prevalence of self-harm notably higher than for male or female peers [47,48]. Young people in our study had baseline YSR scores 0.7–1.0 SD higher than norms for age in comparable countries [29,46].

We found no evidence of change in psychological function with GnRHa treatment as indicated by parent report (CBCL) or self-report (YSR) of overall problems, internalising or externalising problems or self-harm. This is in contrast to the Dutch study which reported improved psychological function across total problems, externalising and internalising scores for both CBCL and YSR and small improvements in CGAS [24]. It also contrasts with a previous study from the UK GIDS of change in psychological function with GnRHa treatment in 101 older adolescents with GD (beginning > 15.5 years) which reported moderate improvements in CGAS score over 12 months of GnRHa treatment [49]. CGAS scores in this previous study increased from 61 to 67 with GnRHa treatment, similar to those (63 at baseline, 66 at 24 months) in our study. Follow-up of the Kuper et al. cohort found non-significant changes in depression and anxiety scores in those ($n = 25$) who had only pubertal suppression treatment, although improvements were seen in the whole sample combining these with those receiving cross-sex hormones [17]. A second US cohort reported that in 23 young people who had received pubertal suppression (using GnRHa or anti-androgens in birth-registered males and either GnRHa or medroxyprogesterone in birth-registered females), there was a reduction in depression scores in birth-registered males but not females.

A recent large US survey found that those who received pubertal suppression in early or mid adolescence had lower odds of lifetime suicidal ideation when studied in adulthood compared with those who did not, regardless of whether they later received cross-sex hormones

and after adjustment for a range of confounding factors [50]. This implies an enduring benefit of pubertal suppression on psychological function, however the cross-sectional design and retrospective exposure classification means the findings require replication. Data are also available from other conditions in which GnRHa is used to suppress puberty during adolescence. A trial of GnRHa suppression of puberty during early adolescence in young people born small-for-gestational-age (SGA) who were also treated with human growth hormone (GH) reported that those treated with GnRHa had similar cognitive and psychological function in adult life to those treated only with GH [51].

The differences between our findings and the previous GIDS study re change in psychological function may relate simply to sample size. But why our findings differ from those of the Dutch study is unclear. They may relate to the timing of assessments; we assessed young people multiple times whereas in the Dutch study the second assessment was shortly before starting cross-sex hormone treatment. Alternatively, there may have been baseline differences in the two cohorts. Whilst some aspects of psychological function were similar, as noted above, the baseline CGAS scores were notably higher in the Dutch group (indicating better function). A previous international comparison study has found that young people aged 12–18 years with GD from the UK have higher scores indicating greater problems on the CBCL and YSR than those from the Netherlands, Belgium and Switzerland [52].

Psychological distress and self-harm are known to increase across early adolescence. Normative data show rising YSR total problems scores with age from age 11 to 16 years in non-clinical samples from a range of countries [29]. Self-harm rates in the general population in the UK and elsewhere increase markedly with age from early to mid-adolescence, being very low in 10 year olds and peaking around age 16–17 years [53–56]. Our finding that psychological function and self-harm did not change significantly during the study is consistent with two main alternative explanations. The first is that there was no change, and that GnRHa treatment brought no measurable benefit nor harm to psychological function in these young people with GD. This is consonant with the action of GnRHa, which only stops further pubertal development and does not change the body to be more congruent with a young person's gender identity. The second possibility is that the lack of change in an outcome that normally worsens in early adolescence may reflect a beneficial change in trajectory for that outcome, i.e. that GnRHa treatment reduced this normative worsening of problems. In the absence of a control group, we cannot distinguish between these possibilities. We aimed to use normative reference data to examine this issue. However age- and gender-standardised t-scores for ASEBA and other outcomes cannot answer this question as they cover a very broad age range (e.g. 12–18 years). We had anticipated that z-scores on the YSR available by calendar year for two comparable countries (Netherlands; Australia) might be informative however confidence intervals were too wide to draw reliable inferences.

Gender dysphoria and body image changed little across the study. This is consistent with some previous reports [24] and was anticipated, given that GnRHa does not change the body in the desired direction, but only temporarily prevents further masculinization or feminization. Other studies suggest that changes in body image or satisfaction in GD are largely confined to gender affirming treatments such as cross-sex hormones or surgery [57]. We found that birth-registered sex and baseline pubertal status were not associated with later psychological functioning on GnRHa, consistent with previous reports [24,49].

These data correct reports from a recent letter by Biggs [58] which used preliminary data from our study which were uncleaned and incomplete data used for internal reporting. In addition there were many statistical comparisons which inflated the risk of type 1 error. Our statistical analysis plan restricted testing all outcomes for differences by sex due to the type 1

error risk. Contrary to Biggs's letter, we found no evidence of reductions over time in any psychological outcomes, and no material differences by sex.

Strengths and limitations

Our study provides comprehensive data on this cohort during follow-up, with an anonymised dataset containing standardised scores deposited to allow other researchers to replicate our findings where data-sharing allows. The study size and uncontrolled design were key limitations. The small sample size limited our ability to identify small changes in outcomes. This was an uncontrolled observational study and thus cannot infer causality. Further, many of the outcomes studied here, including psychological function, self-harm and BMD, undergo normative changes by age and developmental stage during puberty that could confound any observed effect of GnRHa treatment in an uncontrolled study. The analysis plan aimed to take these issues into account as far as possible, however this particularly limits the potential for the study to show benefits or harms from treatment. However, some conclusions can be drawn. It is unlikely that the reported adverse events such as headaches do not relate directly to GnRHa treatment. Equally, given that there were no changes in psychological function and differences in point estimates were minimal for nearly all outcomes, it is unlikely that the treatment resulted in psychological harm. Observational studies are important sources of data on harms of treatment [59–61].

Our data are subject to a number of other limitations. This was an unfunded study undertaken within a clinical service and we were dependent on the clinical service for data collection. There were varying sample sizes for differing tests as some participants did not attend certain investigations and some follow-up medical tests were processed locally to patients; these data are reported as normal or otherwise. Missing items on psychological questionnaires resulted in some unusable data. Some young people found repeated completion of questionnaires about gender issues intrusive and refused to complete them at later follow-ups, as has been reported in other studies [62]. This questionnaire fatigue also affected parent responses. Scoring of psychological questionnaire data was rechecked at the completion of the study however this was not possible in very small numbers of participants in whom only scale scores rather than individual item data were preserved during data migration in hospital clinical information systems. In sensitivity analyses, repeat analysis of ASEBA psychological outcomes restricted to those with rescored data showed highly similar findings to the full sample (see S3 Table in S1 Appendix).

A more detailed qualitative evaluation of participant experience was not possible due to lack of interviewer time, and reporting of interview data was restricted to perceptions of positive or negative change and the giving of examples.

Implications and conclusions

Treatment of young people with persistent and severe GD aged 12–15 years with GnRHa was efficacious in suppressing pubertal progression. Anticipated effects of withdrawal of sex hormones on symptoms were common and there were no unexpected adverse events. BMD increased with treatment in the lumbar spine and was stable at the hip, and BMD z-score fell consistent with delay of puberty. Overall participant experience of changes on GnRHa treatment was positive. We identified no changes in psychological function, quality of life or degree of gender dysphoria.

The great majority of this cohort went on to start cross-sex hormones, as was hypothesized given the severity and continuation of their GD. However one young person did not, providing some evidence that development of gender identity continues on GnRHa treatment and

confirming the importance of continuing supportive psychological therapy to allow further exploration of gender identity and a range of future pathways whilst on GnRHa.

This cohort will be followed up longer term to examine physical and mental health outcomes into early adulthood. However larger and longer-term prospective studies using a range of designs are needed to more fully quantify the harms and benefits of pubertal suppression in GD and better understand factors influencing outcomes [3]. These are beginning to be funded in a number of countries [63]. (<https://logicstudy.uk>) Given that pubertal suppression may be both a treatment in its own right and also an intermediate step in a longer treatment pathway, it is essential for such studies to examine benefits and harms across the longer pathway including pubertal suppression and initiation of cross-sex hormones.

Abstract

Puberty is characterized by hormonal, physical and psychological transformation. The human brain undergoes significant changes between childhood and adulthood, but little is known about how puberty influences its structural development. Using a longitudinal sample of 711 magnetic resonance imaging scans from 275 individuals aged 7–20 years, we examined how subcortical brain regions change in relation to puberty. Our regions of interest included the amygdala, hippocampus and corpus striatum including the nucleus accumbens (NA), caudate, putamen and globus pallidus (GP). Pubertal development was significantly related to structural volume in all six regions in both sexes. Pubertal development and age had both independent and interactive influences on volume for the amygdala, hippocampus and putamen in both sexes, and the caudate in females. There was an interactive puberty-by-age effect on volume for the NA and GP in both sexes, and the caudate in males. These findings suggest a significant role for puberty in structural brain development.

Abbreviations: NA, Nucleus Accumbens; GP, Globus Pallidus**Keywords:** Puberty, Adolescence, MRI, Subcortex

Introduction

The past 15 years have seen a major expansion in research on the structural development of the human adolescent brain, based largely on the results of cross-sectional and longitudinal magnetic resonance imaging (MRI) studies ([Brain Development Cooperative Group, 2012](#); [Giedd et al., 1996](#); [Lenroot et al., 2007](#); [Østby et al., 2009](#); [Raznahan et al., 2011](#); [Sowell et al., 2002](#)). Studies of brain growth trajectories over adolescence to date have predominantly considered growth in relation to chronological age, with few exceptions ([Paus et al., 2010](#); [Raznahan et al., 2010](#)). However, this approach ignores the cascade of developmental processes during adolescence that are related to puberty, including sexual maturation, linear (height) growth, body fat re-distribution and maturation of many other physiological systems ([Patton and Viner, 2007](#); [Wheeler, 1991](#)). Since there is a normal variation of 4–5 years in the timing of onset of puberty in healthy humans ([Parent et al., 2003](#)), pubertal development is partially dissociable from chronological age. Examining brain development in relation to pubertal maturation may provide additional information regarding the mechanisms associated with adolescent brain development. In this study, we investigated how the developmental trajectories of subcortical regions that are linked to stereotypical behaviours are associated with pubertal development ([Forbes and Dahl, 2010](#); [Steinberg, 2008](#)): the amygdala and hippocampus, which play an important role in emotion and mood regulation ([Davidson et al., 2002](#)); and the corpus striatum including the nucleus accumbens (NA), caudate, putamen and globus pallidus (GP), which are involved in decision-making and reward-seeking behaviours ([Gottfried, 2011](#)).

It has been hypothesised that the brain restructuring and development seen in adolescence may be specifically related to the hormonal influences that control the onset of and progression through puberty ([Giedd et al., 1999](#); [Lenroot et al., 2007](#); [Peper et al., 2011](#); [Sowell et al., 2002](#)). Sex steroids such as testosterone (an androgen) and oestradiol (an oestrogen) have been shown to be capable of inducing both synaptogenesis and synaptic pruning in rats and nonhuman primates ([Ahmed et al., 2008](#); [Hajszan et al., 2008](#); [Sato et al., 2008](#)) with differential effects of androgens and oestrogens on different brain areas, which may be related to hormone receptor distribution ([Clark et al., 1988](#); [Sholl and Kim, 1989](#)). These differential effects across brain areas may provide an explanation for the diverging growth trajectories of particular brain structures between males and females documented across studies, and the resultant increasing sexual dimorphism in adolescence reported in some regions ([Brain Development Cooperative Group, 2012](#); [Lenroot et al., 2007](#); [Neufang et al., 2009](#); [Sowell et al., 2002](#)).

Cross-sectional studies have reported that puberty is associated with aspects of brain development in adolescence. A study focussing on the association between brain volumes and both pubertal stage and testosterone concentration found that males and females in later stages of puberty, and with higher circulating testosterone concentration, had larger amygdala volumes and smaller hippocampal volumes than their less well developed peers (Neufang et al., 2009). In contrast, a second study investigating puberty and pubertal hormone correlations with grey matter volume replicated the positive association between amygdala volume and pubertal stage in boys, but showed decreasing amygdala volume with increasing testosterone levels in girls (Bramen et al., 2011). These studies have limited power due to their relatively small sample sizes and cross-sectional methods. To date, no longitudinal studies incorporating pubertal measures have been published. Longitudinal analysis allows comparison of brain volumes both between-subjects and also within each subject over time, and therefore can provide a measure not just of brain volume at a particular time-point, but also of developmental trajectories for each of these subcortical brain regions by following what happens to each participant. This is particularly advantageous when looking at brain volumes, which vary substantially between individuals (Brain Development Cooperative Group, 2012; Giedd et al., 1999; Tamnes et al., 2013).

Using a large sample of scans from 275 individuals scanned longitudinally, we examined how subcortical brain regions change in relation to puberty as measured by Tanner stage (Tanner and Whitehouse, 1976), and compared developmental trajectories in females and males. We used a large dataset containing information on pubertal stage and chronological age to examine growth trajectories over adolescence in each of these subcortical regions. Based on previous cross-sectional findings, we predicted that the volume of the amygdala and hippocampus would increase between 7 and 20 years (Giedd et al., 1999; Østby et al., 2009), whilst the volumes of the corpus striatum – the NA, caudate, putamen and GP – would decrease (Brain Development Cooperative Group, 2012; Østby et al., 2009; Sowell et al., 2002). We hypothesized that volume change for all structures of interest would be related to pubertal development as measured by Tanner stage, and that puberty and age would have independent effects on volume in these regions. Therefore, we hypothesized that models incorporating both Tanner stage and chronological age as explanatory variables for volume change would provide a significant fit for the developmental data from the structures examined.

Experimental procedures

Participants

The sample used for the analysis was taken from the NIMH Child Psychiatry Branch Section on Brain Imaging longitudinal dataset of structural MRI scans (Giedd et al., 1996). This large dataset consists of more than 6500 scans from more than 3000 participants of which approximately half are typically developing and half are from various diagnostic groups. Inclusion and exclusion criteria for the overall dataset can be found on the NIMH website (http://clinicalstudies.info.nih.gov/cgi/detail.cgi?A_1989-M-0006.html). For each participant, the outcomes of interest that were measured included ethnicity, socioeconomic status (using Hollingshead scales), IQ (estimated using age-appropriate Wechsler Intelligence Scales) and handedness (using Physical and Neurological Examination of Soft Signs inventory (Denckla, 1985)), each of which was collected at the time of the first scan, and pubertal status, ascertained at the time of each scan using Tanner stage diagrams (Taylor et al., 2001). Tanner staging is the most widely used technique for assessing physical puberty stage. For each participant at each time-point, a single combined Tanner stage score was assigned based on the overall stage that the participant felt best described themselves from looking at the separate breast/genital and pubic hair scores.

The subgroup used for the current analysis consisted of 275 unrelated individuals (117 females), and incorporated the scans of all individuals who met the following criteria:

1. Healthy individuals at the time of scanning. Participants were screened for neurological or psychiatric illness using a telephone screening interview and completion of a parent-report screening questionnaire (CBCL) at each time-point, and only healthy participants were included in the analysis as established by standardized scoring (Achenbach, 1991). All participants included had an IQ of greater than 80.
2. Two or more MRI scans between the ages of 7.0 and 20.0 years. This age range was estimated using two large US population-based studies on pubertal timing (Herman-Giddens et al., 1997; Sun et al., 2002), and incorporating ages from two 2 SD below the mean age of being in Tanner stage 2 (6.3–7.8 years for females and 6.9–9.7 years for males depending on the measure (breast/pubic hair/gonadal development) used), to 2 SD above the mean age of being in Tanner stage 5 (20.5–21.0 years for females, 19.6–20.1 years for males depending on the measure used). This range was refined based on our dataset to 7.0 to 20.0 years, as this incorporated the ages at which there was variation in Tanner stage between individuals.
3. Complete data for age and self-reported Tanner stage for each MRI scan. Individuals who reported regression of puberty during adolescence (as indicated by reducing Tanner score) were excluded from the analysis ($N = 1$; female), since pubertal regression is essentially biologically implausible and likely represents error. Pubertal arrest, which may be perceived as regression, is associated with significant systemic illness or malnutrition.
4. Only one individual per family. The original dataset incorporates a high number (> 400 individuals) of monozygous and dizygous twin pairs, as well as siblings. The heritability of brain structure and development is still not well-understood, but there are likely to be both genetic and environmental effects on structural brain volume and developmental trajectory, as well as pubertal timing, which are not independent between family members, and therefore might bias the analysis. Where data were available for more than one family member, only one individual was included in the analysis; the family member included was determined by the participant with a higher number of high quality scans, more complete demographic data, or, if these were equal, by random selection.

Of the 275 participants whose data were included in the study, 87.3% were right-handed (7.3% left-handed, 5.4% mixed). The majority (89.5%) were Caucasian (5.1% African-American; 2.2% Hispanic; 0.7% Asian; 2.5% other). Details of socioeconomic status, IQ, puberty status and number of scans can be seen in Table 1.

Participants were recruited from the community through local advertisement and reimbursed for their participation in the study. The study research protocol was approved by the Institutional Review Board of the National Institutes of Health and written informed consent and assent to participate in the study were obtained from parents/adult participants and children respectively.

Image acquisition

All MRI scans were T-1 weighted images with contiguous 1.5 mm axial slices and 2.0 mm coronal slices, obtained on the same 1.5-T General Electric Signa scanner (Milwaukee, WI) using a 3D spoiled gradient recalled echo sequence with the following parameters: echo time: 5 ms; repetition time: 24 ms; flip angle: 45°; acquisition matrix: 256 × 192; field of view: 24 cm. The same scanner, hardware and software were used throughout the scanning period. All scans were assessed by a clinical neuroradiologist for gross abnormalities. All scans performed as part of the NIH project have been rated for motion-related quality by trained technicians. Only scans given a high-quality rating were included in the analysis.

Image processing

Subcortical volume estimation was performed with the Freesurfer 5.1 image analysis suite using the programme's automated segmentation procedure (<http://surfer.nmr.mgh.harvard.edu/>). This procedure has been described in detail previously (Fischl et al., 2002), and is summarized here. An optimal linear transform is computed that maximises the likelihood of the input image, given an atlas constructed from manually labelled images. A nonlinear transform is then initialized with the linear one, and the image is allowed to further deform to better match the atlas. Finally, a Bayesian segmentation procedure is carried out, and the maximum a posteriori estimate of the labelling is computed. The segmentation uses three pieces of information to disambiguate labels: (1) the prior probability of a given tissue class occurring at a specific atlas location; (2) the likelihood of the image given that tissue class; and (3) the probability of the local spatial configuration of labels given the tissue class. The automated segmentations have been found to be statistically indistinguishable from manual labelling (Fischl et al., 2002), and correlations between Freesurfer segmentation and manual labelling of hippocampal volume by trained researchers reached 0.85 in a study by Tae et al. (2008).

Our analysis focussed on the following subcortical brain regions, based on a priori hypotheses regarding changes in volume over adolescence and pubertal effects: the amygdala, hippocampus, NA, caudate, putamen and GP. Each of these regions is defined by the automated Freesurfer segmentation procedure based on location, likelihood of tissue class and spatial configuration. An example of T1W scans showing both the raw data and with Freesurfer's automated segmentation can be seen in the Supplementary information (Fig. S1).

Statistical analysis

We conducted our analysis using the average volume across hemispheres, to produce one value for each ROI. Previous studies have demonstrated no evidence of developmental difference between hemisphere in these regions (Brain Development Cooperative Group, 2012; Østby et al., 2009), and our own dataset shows high correlations between hemispheres for all volumes ($r = 0.5-0.9$, $p < 0.001$). We analysed raw volumes for each region and percentage change for each volume over time. Mixed effects modelling was used (R version 3.1-102; nlme package (Pinheiro et al., 2011)) to analyse the data, thereby allowing an estimation of the fixed effects of measured variables on volume change, whilst incorporating the longitudinal nature of the data by including within-person variation as nested random effects. Age was centred on 7 years, which represented the minimum age included in the sample. Tanner stage was treated as a continuous variable for this analysis, allowing the model to incorporate changing Tanner stage and changing brain volume for each individual.

For each structure, volume was first modelled against Tanner stage (Tanner-only model), and linear, quadratic or cubic developmental trajectories were modelled. Males and females were modelled separately, to allow for different trajectories of growth through adolescence (Lenroot et al., 2007). Tanner stage was treated as a continuous variable to allow the model to account for movement of individuals between stages and to maintain the ordinal nature of the data. The equations for volume growth of a structure in relation to Tanner stage are:

$$\text{Linear model: Volume} = \text{Intercept} + \beta_1 \text{Tanner} \quad \text{Quadratic model: Volume} = \text{Intercept} + \beta_1 \text{Tanner} + \beta_2 \text{Tanner}^2 \quad \text{Cubic model: Volume} = \text{Intercept} + \beta_1 \text{Tanner} + \beta_2 \text{Tanner}^2 + \beta_3 \text{Tanner}^3$$

where β_1 , β_2 and β_3 represent the constant terms defining the effects of each fixed term. To determine whether a cubic, quadratic or linear growth model with Tanner stage best fit the sample, an F test was performed on models where the marginal p-value of the highest order variable was significant ($p < 0.05$).

Given that pubertal development is a developmental process, Tanner stage is necessarily highly correlated with chronological age, and this was found to be the case in our sample ($r = 0.89$ for males and $r = 0.88$ for females). It was therefore necessary to consider the effects of age on the developmental trajectories of the subcortical volumes, to see whether this could explain all of the puberty-related effects, and to establish whether models including age with puberty were a better fit than puberty models alone. Therefore, age was incorporated into the model to ascertain whether there were (i) dissociable main effects of Tanner stage and age, and/or (ii) a Tanner stage by age interactive effect. The model including the main effects of both Tanner stage and age and the tanner by age interaction is referred to as the *combined model* ($\text{Volume} = \text{Intercept} + \beta_1 (\text{Tanner}) + \beta_2 (\text{Age}) + \beta_3 (\text{Tanner} * \text{Age})$), whilst the model including only the Tanner stage by age interaction is referred to as the *interaction-only model* ($\text{Volume} = \beta_1 (\text{Tanner} * \text{Age})$). Lastly, an age-only model was estimated (using linear, quadratic and cubic growth options as above).

Comparison of Tanner-only, combined, interaction-only and age-only models was undertaken using likelihood ratio tests where possible. Where LR tests could not be performed, i.e. if the models were not nested, Akaike Information Criterion (AIC) values were used to compare models. Models were considered to be a significantly improved fit if the difference between AIC values was 5.9 or greater, equating to an Akaike weight of the poorer model of less than 0.05. If the difference exceeded this, the inferior model was discarded, leaving only the models that were equally valid based on relative likelihood (Wagenmakers and Farrell, 2004).

Results

Demographic details for all participants are included in [Table 1](#) and [Fig. 1](#). The raw data for each sex and each structure are displayed in Fig. S2 (Supporting Information).

Models using Tanner stage as an explanatory variable for subcortical volume change

Pubertal development, as measured by Tanner stage, was significantly related to the structural development of all six subcortical regions in both males and females (See [Table 2](#) and [Fig. 2](#)). In both sexes, amygdala and hippocampus volume increased across puberty, whilst the other structural volumes (NA, caudate, putamen and GP) decreased (See [Fig. 2](#)). In females, the growth trajectories were either linear (NA, GP) or quadratic (amygdala, hippocampus, caudate and putamen), whilst in males the trajectories were linear (hippocampus, GP), quadratic (putamen) or cubic (amygdala, NA, caudate) (See [Table 2](#)). The proportional volume change over puberty varied between structures from a 7.5% increase in male amygdala volume, to a 9.9% reduction in female GP volume, with some regions showing more modest volume changes e.g. caudate 2.3% reduction in males. See [Table 2](#) and [Fig. 2](#) for full results.

Models using Tanner stage and chronological age as explanatory variables for subcortical volume change

For the amygdala, hippocampus and putamen in both sexes, as well as the caudate in females, a combined model (including Tanner stage and age as main effects, and a Tanner stage by age interaction) provided a significantly better fit than the Tanner-only model (See [Table 3](#)). For each of these structures, individuals in later stages of puberty (i.e. higher Tanner stage score) than their age-matched peers had volumes that are further along the developmental trajectory than peers in earlier stages of puberty. For females, individuals who were more pubertally mature than their age-matched peers had a larger volume in these structures in late childhood and early adolescence, an earlier peak volume and then a smaller volume until the end of puberty than their less mature, age-matched peers (see [Fig. 3](#)). In males, for the amygdala and hippocampus, individuals in later stages of puberty (i.e. higher Tanner stage score than age-matched peers) had larger structural volumes throughout our studied age range (7–20 years) than age-matched peers in earlier stages of puberty (see [Fig. 3](#)). In contrast, for the putamen in males, individuals in later stages of puberty had smaller structural volumes throughout our studied age range than age-matched peers in earlier stages of puberty (see [Fig. 3](#)).

For the NA and GP in both sexes, and for the caudate in males, an interaction-only model provided a significant fit to the data, but the model was no improvement over the Tanner stage only model (See [Table 3](#)). Based on this interaction model, individuals in a later stage of puberty than their age-matched peers had a smaller NA or GP (both sexes) or caudate (males only) volume throughout the age range investigated (7–20 years) ([Fig. 3](#)).

Models using chronological age as an explanatory variable for subcortical volume change

For some structures in males, the hippocampus and the GP, age-only models gave a significantly better fit of the data than models incorporating Tanner stage (hippocampus LR test compared to interactive model = 4.69, $p = 0.030$; GP LR test compared to interactive model = 9.29, $p = 0.002$). There was no statistically significant age-only model for volume change in the caudate in males over our age range. For the remaining structures in males (amygdala, NA and putamen) and all the six investigated structures in females, an age-only model did not improve the model fit over the models incorporating puberty measures.

Discussion

In the current study, we examined the relationship between puberty and growth trajectories of subcortical regions during adolescence using a large longitudinal dataset. Each of the regions studied showed significant longitudinal associations with puberty ([Fig. 2](#)). For many of the structures (Females: amygdala, hippocampus, caudate, putamen; Males: amygdala, putamen), models including both age and Tanner stage modelled development better than Tanner-only models. This suggests that both variables are important factors when modelling volume change over adolescent development. Some structures in males (hippocampus, GP) were best modelled using only age as an explanatory variable, whilst the caudate in males was best modelled using only Tanner stage.

Despite the close proximity of the subcortical structures explored, there were clear differences in their structural development during adolescence. In both males and females, the amygdala and hippocampus continued to increase in volume during puberty, whilst the other structures examined decreased in volume, with structures changing between 2.3% and 9.9% across adolescence ([Fig. 2](#)). These results may reflect the different mechanisms that influence macroscopic volume changes between structures. Alternatively, the regions may undergo similar growth patterns, but do so at different chronological time-points, resulting in different growth patterns within our restricted age and developmental range.

Observation of pubertal development during adolescence provides an indirect marker of an individual's systemic sex steroid hormone exposure. The principal hormones involved are testosterone and dehydroepiandrosterone (DHEA), both androgens, and oestradiol, an oestrogen. Rising hormone levels, triggered by re-activation of the hypothalamic-pituitary-gonadal axis, leads to the series of physical changes classically associated with puberty. Androgens signal the development of adult-type body hair and skin changes in both females and males, in addition to gonadal development in males, whilst oestradiol primarily affects females, and causes breast and gonadal development. Tanner staging categorises pubertal maturation by describing five stages of development from pre-pubertal to full maturation for each of pubic hair development, genital development and breast development. An individual's puberty stage is related both to how long they have been exposed to the sex steroid hormones, and to their current level of hormones ([Dorn and Biro, 2011](#); [Shirtcliff et al., 2009](#)). Our results, showing that growth trajectories of subcortical structures were related to pubertal development, suggest that these same pubertal hormones influence structural brain growth.

Systemic pubertal hormones cross the blood-brain barrier in small concentrations ([Marynick et al., 1976](#)), and systemic concentrations of testosterone have been shown to be related to amygdala volume in both males and females ([Neufang et al., 2009](#)). Both androgens and oestrogens induce synaptogenesis and synaptic pruning in rat and non-human primates ([Ahmed et al., 2008](#); [Hajszan et al., 2008](#); [Sato et al., 2008](#)) and it is likely that this process also occurs in humans, modulating brain growth across puberty ([Matsumoto, 1991](#)). Sex hormone receptors for both oestrogens and androgens are found throughout the brain in varying concentrations, with high levels in subcortical regions, particularly the hippocampus and amygdala ([Abdelgadir et al., 1999](#); [Clark et al., 1988](#); [Sholl and Kim, 1989](#)). The difference in regional receptor concentrations in the brain potentially helps to explain why different patterns of growth are seen across structures, and the resultant sexual dimorphism reported to emerge during adolescence in some regions ([Brain Development Cooperative Group, 2012](#); [Lenroot et al., 2007](#); [Neufang et al., 2009](#); [Sowell et al., 2002](#)).

We found that both males and females demonstrated pubertal effects related to amygdala growth, with increases in volume over puberty in both sexes. Although the overall volume change was similar between the sexes, the growth trajectories were quite different ([Fig. 2](#)), with females showing a large increase in volume in early puberty before peaking and decreasing, and males showing an increasing volume until the end of puberty. This is consistent with the different patterns of testosterone concentration in puberty, with males showing larger increases in concentration and a longer period of increase, and females showing a much smaller rise and earlier plateau of testosterone concentration ([Ankarberg and Norjavaara, 1999](#)). The smaller increase and earlier peak in testosterone concentration in females compared with males might explain the differences in trajectories between the two sexes, where the changes in neural structure that are seen are being modulated by systemic testosterone concentrations ([Zuloaga et al., 2008](#)). This connection might reflect a direct effect of testosterone on amygdala volume, via the testosterone receptors found in high concentrations in the amygdala, or indirect effects e.g. via aromatisation and effects on oestrogen receptors ([Schwarz and McCarthy, 2008](#)), or through interaction with growth hormone ([Meinhardt and Ho, 2006](#)) and its receptors present in the brain. Previous cross-sectional studies investigating changes in amygdala volume with puberty have reported volume increases with increasing pubertal stage (and testosterone level) in males ([Bramen et al., 2011](#); [Neufang et al., 2009](#)), but have had conflicting results in females, where both increases ([Neufang et al., 2009](#)) and decreases ([Bramen et al., 2011](#)) in amygdala volume have been reported. The different findings between these two papers may result from the relatively small sample sizes or the differing age ranges of the two studies ([Neufang et al., 2009](#): $n = 46$, 23 male, age 8–15 years; [Bramen et al., 2011](#): $n = 80$, 32 male, ages 10.7–14.0 years). As our sample shows, there is large variation in brain volumes between participants, and small samples may not be able to reflect the variation in the population, and within each group (early vs late puberty or Tanner stages 1–5). Our results indicate that both age and puberty impact on the structural development of the amygdala in males and females, and differences in the findings of these two previous studies may reflect that they were sampling participants of different ages.

In the hippocampus, the best model to explain growth in females was the combined model incorporating puberty and age, whilst in males the age-only model provided a better fit. This is consistent with an oestrogen-modulated growth pattern. During puberty, oestrogen concentrations in females increase by 4–9 times ([Ikegami et al., 2001](#)), and oestrogens are dominant in many pubertal changes. In contrast among males, relatively minor rises in oestrogens are seen during puberty due to aromatization of testosterone. The hippocampus in non-human primates has high levels of oestrogen receptors ([Sholl and Kim, 1989](#)), and the increasing concentration of oestrogen that occurs predominantly in females coincides with the growth trajectories seen in the hippocampus in this study.

In our analysis, both males and females showed a decrease in NA volume with puberty (see [Fig. 2](#)), and both sexes show on-going development throughout adolescence. Both androgens and oestrogens modulate the function of the NA, changing levels of dopamine release ([Thompson and Moss, 1994](#)), and these results are consistent with the existence of macroscopic structural effects of both hormones on NA volume. For the NA, there was no statistical difference between the amount of volume change explained by the model based on puberty status alone, the model based on chronological age alone, or the model incorporating the interactive effects of both puberty and age. This may relate to the high correlation between age and pubertal stage. Note that such collinearity reduces the precision of the estimates of coefficients but does not affect estimates of model fit. Importantly, all the models appear to show on-going structural changes across adolescence in the NA.

The caudate, putamen, and GP lie in close proximity to one another, and have related functions. Growth trajectories of these three regions across puberty are similar, with decreases in volume seen with greater pubertal development. The relative changes in volume for the caudate and putamen are the smallest of all the structures over the course of puberty ([Fig. 2](#)). The caudate in males was the only structure analysed that showed no significant relationship with age, emphasizing the importance of considering alternative variables that influence development over this age range. Previous cross-sectional studies of the caudate have shown similar findings, with weak or no age-related changes ([Brain Development Cooperative Group, 2012](#); [Østby et al., 2009](#); [Sowell et al., 2002](#)); our results using a longitudinal dataset support this. Less is known about the sex hormone receptor concentrations in the caudate, putamen and GP. Sex hormones have been shown to impact upon receptor densities in these regions ([Sumner and Fink, 1998](#)), giving one potential indirect mechanism for the changes in structure seen, but further work exploring how sex hormones influence macroscopic structural changes is needed to help ascertain this.

One of the major strengths of this study is the longitudinal nature of the dataset, which enabled us to model growth trajectories based on the trajectories of real individuals instead of using cross-sectional points. There is wide variability in structural volumes in the brain between individuals, and repeated measurements of the same individual will therefore produce more accurate trajectories than assuming that cross-sectional data can be extrapolated to define trajectories, making the analysis more powerful to detect small but significant changes in brain volume. The structural development of the brain is likely to be affected by a number of variables and the use of a large longitudinal dataset maximises our ability to characterise the relationships of different variables with changing structural volume. The longitudinal nature of the data, the replication of previous cross-sectional findings and the presence of plausible biological mechanisms allow us to hypothesize that puberty may have causal effects on brain development. However our study does not allow us to address whether the effects of puberty on structural brain growth are direct, via hormonal action on the brain tissue, or indirect, with the brain structure being shaped by how young people undergoing puberty may be treated differently in society than their less well-developed peers, or how they might perceive themselves differently (Blakemore et al., 2010). To our knowledge, previous research has not tackled this subject, and further work exploring how pubertal hormones influence brain structural development in both animal and human studies, and combining hormonal and pubertal stage variables, may help to establish how this relationship is modulated.

Our data are subject to a number of limitations. Self-reported Tanner stage, whilst the most widely used and clinically validated measure of pubertal development, is nevertheless a relatively crude measure which subjectively categorises puberty into broad developmental stages. It is therefore limited in its capacity to document accurately small developmental changes, and has significantly poorer resolution than age as an explanatory variable. This may mean that our puberty-related effects on growth trajectories are in fact underestimates, and further studies may help to validate our results and explore further their implications. Despite the large sample size, and longitudinal nature of the current dataset, there are limited numbers of participants at the extreme ages for each Tanner stage. This would be expected because our dataset is representative of a normal population undergoing typical development, with a normal distribution of ages for each puberty stage, and therefore relatively small numbers of individuals at the extreme ends of normal puberty timing. These smaller numbers may reduce the accuracy of the model at these extreme ages and further research targeting narrower age ranges, and focusing on these extremes of normal pubertal development, and using different methods to measure pubertal maturation, would help to validate and further expand on our findings. Polynomial models, as used in this study, have been shown to be susceptible to the age range and age-centring used (Fjell et al., 2010) when performing age-based analyses of development. For this reason, we developed a clear a priori method for our analysis, based on our primary aim to explore the relationship between puberty and structural development of subcortical regions. Our age range was clearly defined, based on the largest available recent US-population based studies of pubertal timing (see page 6) to incorporate the reasonable ages associated with pubertal development. We included the full range of pubertal variation, our primary variable of interest, in the analysis, which should reduce any impact on the reliability of the model fit. A further limitation is our use of automated segmentation software to extract structural volumes for our six regions of interest. This method was chosen in view of the large number of scans (711) included in the study, and is widely accepted to be appropriate for very large scale-studies where manual tracing techniques are prohibitively time-consuming and resource intensive. Correlations between amygdala and hippocampus volumes for Freesurfer vs. manual tracing are high (Fischl et al., 2002; Morey et al., 2009; Tae et al., 2008).

Conclusion

We have shown that the structural development of subcortical brain regions is related to pubertal development during adolescence. This relationship likely reflects the effects of systemic sex hormones on structural brain development. Examining brain development in relation to pubertal development may provide additional information regarding the control mechanisms behind adolescent brain development, and in particular may shed light on how many of the behaviours classically associated with puberty come to arise. It may also help explain the development of a marked sexual dimorphism in psychiatric disorders around the time of puberty (Zahn-Waxler et al., 2008), as there is emerging evidence of associations between volumes of subcortical structures and psychiatric diagnoses (Karchemskiy et al., 2011; Rigucci et al., 2010).

Acknowledgments

The authors gratefully acknowledge the continued participation of all families and individuals involved in this longitudinal study. We thank F Lalonde for his valuable contribution in processing the imaging data for this analysis. The authors of this study are funded by grants from the MRC (AG: Clinical Training Research Fellowship), the Royal Society (SJB: University Research Fellowship) and the National Institutes of Health (JNG: Intramural Research Program; KLM: Graduate Partnership Program).

Fig. 1

Showing the age and Tanner stage of each participant at each study time-point. Males are shown in turquoise, and females are shown in orange.

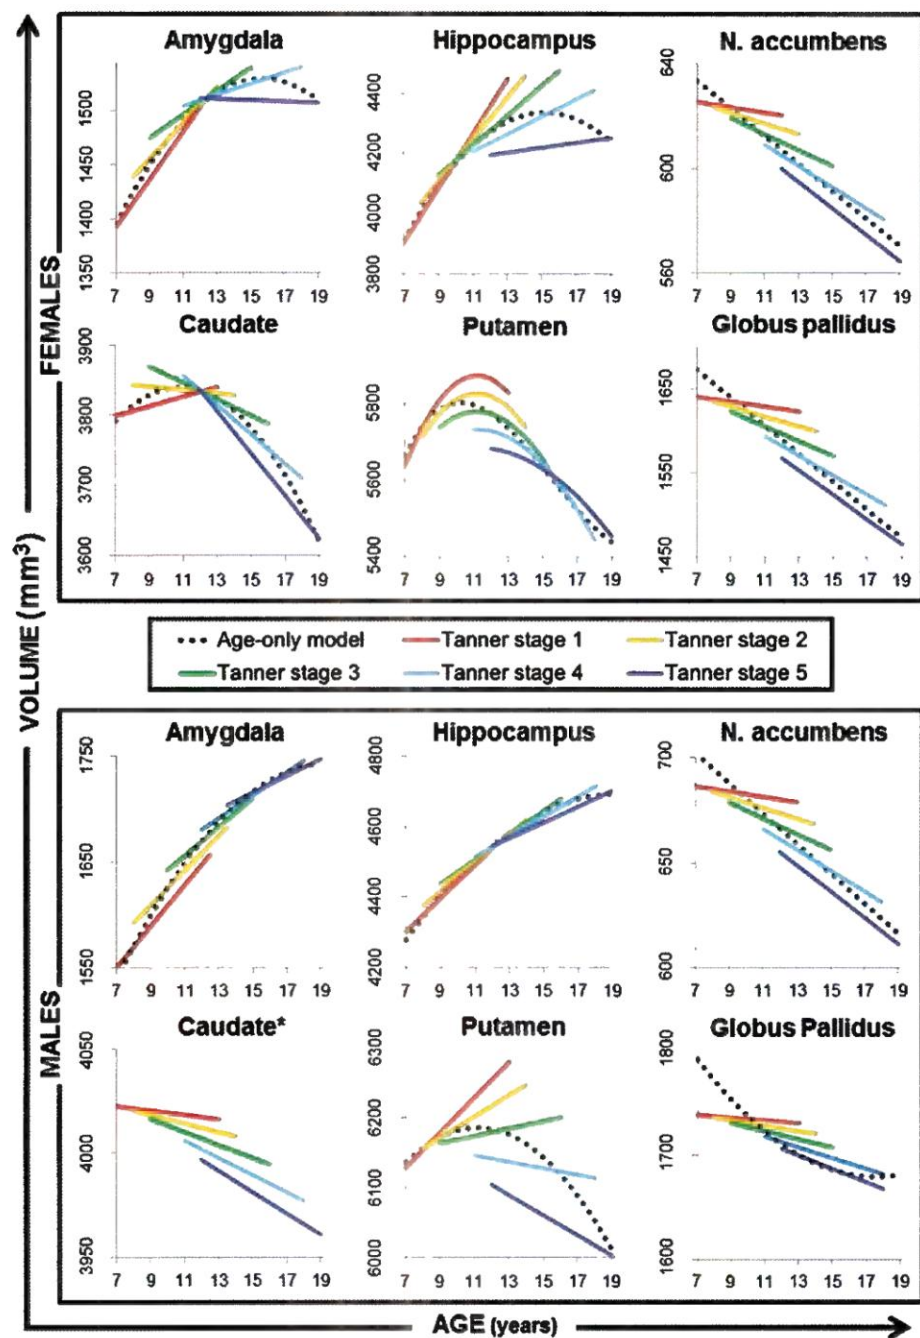

Fig. 2A

Showing the growth trajectories for each subcortical region modelled against Tanner stage in females and males. For both sexes, the amygdala and hippocampus increase in volume over puberty, whilst the NA, caudate, putamen and GP decrease in volume. Shows the models for each region separately. Pink lines represent females and blue lines represent males. The solid line represents the best model fit, with 95% confidence intervals shown by the dashed lines.

Fig. 2B. Showing the growth trajectories for each subcortical region modelled against Tanner stage in females and males. For both sexes, the amygdala and hippocampus increase in volume over puberty, whilst the NA, caudate, putamen and GP decrease in volume. Shows the models in terms of % volume change to allow comparison between structures. For each structure, the percentage volume was calculated for each pubertal stage as a proportion of prepubertal volume (at Tanner stage 1).

Fig. 3

Showing how subcortical volumes change with age and puberty stage in (A) females and (B) males using the best-fit combined or interactive model for each structure.

Age is presented on the x-axis, whilst puberty stage is indicated by the coloured lines (Red — Tanner stage 1, Yellow — Tanner stage 2, Green — Tanner stage 3, Blue — Tanner stage 4, Purple — Tanner stage 5). Data for each graph were extracted from the combined models by calculating Intercept + (coefficient for main effect of Tanner x Tanner stage) + (coefficient for main effect of Age-centred x Age-centred) + (coefficient for interactive effect of Tanner-by-age x Tanner stage x Age). Age ranges for each Tanner stage line were decided using the ages and pubertal variation in our sample (see Fig. 1 for range). The age-only model for each structure is included (black dotted line) to aid interpretation.

*For the caudate in males, there is no significant model that explains the developmental trajectory.

Table 1

Showing participants' demographics.

*This shows the number of participants who underwent an MRI scan at each Tanner stage, and the total number of scans collected of participants at each Tanner stage. Since some participants had more than one scan at a single Tanner stage, there are more scans than participants.

Females	Total sample	Tanner stage				
		1	2	3	4	5
N subjects/scans	117/296	36/41	37/42	57/72	79/105	30/36
	Mean (SD)					
Age (years)	12.8 (3.3)	8.6 (1.3)	9.8 (1.1)	11.5 (1.5)	14.6 (1.5)	18.1 (1.4)
Height (metres)	1.52 (0.14)	1.30 (0.09)	1.40 (0.09)	1.47 (0.09)	1.63 (0.06)	1.65 (0.06)
Weight (kilograms)	46.7 (14.8)	28.1 (5.5)	35.4 (7.9)	42.2 (9.2)	57.2 (10.3)	61.7 (10.2)
IQ	113 (12.0)	117 (12.9)	112 (10.3)	111 (12.5)	113 (11.5)	112 (12.7)

Table 2

Showing the Tanner-only best fit model for each of the six subcortical regions in females and males with the F test and p-value of the highest order variable. For each region, volume change across puberty is given in absolute (mm³) and relative (% change for the structure compared to initial volume) terms.

Absolute (mm ³)	Best-fitting model	Volume change across puberty		Significance of highest order variable	p-value
	% change				
Females					
Amygdala	Quadratic	80	5.3%	$F_{(1,177)} = 6.38$	0.012
Hippocampus	Quadratic	191	5.1%	$F_{(1,177)} = 6.26$	0.013
Nucleus accumbens	Linear	-50	-8.6%	$F_{(1,178)} = 18.73$	< 0.0001
Caudate	Quadratic	-131	-3.6%	$F_{(1,177)} = 10.78$	0.001
Putamen	Quadratic	-282	-5.5%	$F_{(1,177)} = 16.15$	0.0001
Globus pallidus	Linear	-149	-9.9%	$F_{(1,178)} = 45.02$	< 0.0001
Males					
Amygdala	Cubic	130	7.5%	$F_{(1,254)} = 7.40$	0.007
Hippocampus	Linear	296	6.3%	$F_{(1,256)} = 69.01$	< 0.0001
Nucleus accumbens	Cubic	-55	-8.7%	$F_{(1,254)} = 4.44$	0.036
Caudate	Cubic	-92	-2.3%	$F_{(1,254)} = 4.21$	0.041
Putamen	Quadratic	-159	-2.6%	$F_{(1,255)} = 7.91$	0.005
Globus pallidus	Linear	-79	-4.7%	$F_{(1,256)} = 19.22$	< 0.0001

Table 3

Showing best fit models using a combination of Tanner stage and chronological age variables, with likelihood ratios and differences in AIC. **Structures in BOLD** show structures where the mixed Tanner stage and age model is a significantly better fit than the Tanner stage only model.

a: Combined model refers to a model incorporating independent effects of Tanner stage and chronological age as well as an interactive Tanner stage by age effect. Interactive model refers to a model using only an interactive Tanner stage by age effect.

b: In females, the best fit model for the putamen was a combined model including independent effects of Tanner stage, linear and quadratic chronological age as well as an interactive Tanner stage by age effect.

* For these structures, a likelihood ratio test is not valid as the models are not nested and have the same number of degrees of freedom. Therefore, significance of the models has been judged using AIC differences. If AIC difference ≥ 5.9 , the model is a significantly better fit (equivalent to Akaike weight of < 0.05).

Structure	Best-fitting Tanner and age model ^a	Likelihood ratio test compared to Tanner only model	p-value	Difference between AIC
Females				
Amygdala	Combined	7.67	0.006	
Hippocampus	Combined	23.96	< 0.0001	
Nucleus accumbens	Interactive	3.21*	*	3.21
Caudate	Combined	14.16	0.0002	
Putamen	Combined^b	28.13	< 0.0001

Commentary: The Signal and the Noise—questioning the benefits of puberty blockers for youth with gender dysphoria—a commentary on Rew et al. (2021)

In less than a decade, there has been a sharp rise in the numbers of young people presenting with gender dysphoria (GD). Today, the majority are adolescents, many with post-puberty adolescent-onset transgender histories, and suffering from mental health and neurodevelopmental comorbidities (De Vries, 2020; Zucker, 2019). Furthermore, there is controversy and heated debate in the literature on this topic (Dubicka, 2021). This lack of scientific consensus highlights the need for any published literature on the topic of GD to be carefully evaluated.

In this commentary, we critically examine a systematic review of the evidence for puberty blockers for GD youth that was recently published in this journal (Rew, Young, Monge, & Bogucka, 2021). Our aim is to highlight problems with this review that compromise its findings and conclusions.

Brief description of Rew et al.'s (2021) study

Rew et al. described undertaking a "critical" and "systematic" literature review on the topic of puberty blockers for GD youth. They identified nine studies for review and, on the basis of these, concluded that puberty blockers have "few serious adverse outcomes," and "several potential positive ones." Rew et al.'s abstract highlighted two key conclusions: the "potentially life-saving benefits" of puberty blockers; and a need for rigorous research. Their "implications," "conclusion," and "key practitioner message" sections appeared to claim that the literature supports the use of puberty blockers for the early puberty subgroup of GD youth.

Overview of our concerns

We agree with Rew et al.'s conclusion that more rigorous research is required in the area of management of GD in youth. However, in our view, their review suffers from methodological oversights, including the omission of relevant studies and suboptimal analysis of the quality of the included studies. As a result, the authors overstate the certainty of the potential positive outcomes and minimize the potential adverse outcomes of puberty blockers. Importantly, their statement, that a "positive

outcome" of puberty blockers is "decreased suicidality in adulthood," is a misinterpretation of a single cross-sectional study. This study's design was incapable of determining causation, and adult suicidality was not one of the measured outcomes (Turban, King, Carswell, & Keuroghlian, 2020).

Contrast Rew et al.'s (2021) conclusions with another recently completed systematic review of puberty blockers for GD youth, commissioned by England's NHS and conducted by The National Institute for Health and Care Excellence (NICE) (2020). The NICE review concluded that studies investigating the benefits or adverse effects of GnRH analogs (puberty blockers) were of "very low certainty using modified GRADE." They noted that any outcome differences that were found could have represented changes of "questionable clinical value," or, as the studies themselves were "not reliable," could have been "due to confounding, bias or chance." They suggest that if controlled studies are not possible, then reliable comparative studies are required.

These findings came just after NHS England suspended the use of puberty blockers for new patients under the age of 16, following the High Court's judgment that children so young could not consent to the unknown risks of these drugs. The Karolinska Institute in Sweden suspended the use of puberty blockers as treatment for GD youth outside of clinical trials following this review, citing multiple physical risks, including to bone development (Nainggolan, 2021). Finland also sharply curtailed the use of these drugs after their systematic review arrived at similar conclusions about the uncertain risk/benefit profile (COHERE, 2020).

We are concerned that Rew et al.'s review will mislead clinicians unfamiliar with the literature into prescribing puberty blockers to GD youth with confidence, when the only clinical stance supported by the evidence is that of extreme caution. This is also underscored by the fact that the research literature in this field is rapidly evolving. For example, a recently published study, that attempted to demonstrate the benefits of the Dutch puberty suppression protocol in the UK setting, failed to show any psychological benefit (Carmichael et al., 2021).

Limitations in study selection strategy

The review published by Rew et al. has important limitations that compromise its usefulness for clinical decision-making. Rew et al. identified only 151 potentially eligible studies, while the NICE review found 525 studies. One possible explanation for this could be their limited study search strategy. Another possible explanation is that Rew et al. did not conduct a comprehensive search so that, in omitting one of the largest electronic databases—EMBASE, they may have overlooked relevant evidence.

Notably, the final set of nine studies reviewed by Rew et al. is missing at least one key study on puberty blockers and psychosocial functioning (Costa et al., 2015), and two other studies examining the risks of puberty blockers on bone density (Joseph, Ting, & Butler, 2019; Klink, Caris, Heijboer, van Trotsenburg, & Rotteveel, 2015). It is unclear to us whether these studies were omitted due to the limited database search or whether the evaluators decided to exclude these studies, and if so for what reason. These three studies were all included in the NICE (2020) review. Although it has to be kept in mind that all the NICE reviewed studies' findings were assessed as "very low certainty," the Costa et al. study provided comparative evidence and found no significant difference in psychosocial functioning between a group of adolescents receiving puberty blockers plus psychosocial support, and a group receiving only psychosocial support, at eighteen months (the study end period) (Biggs, 2019). In addition, the Costa study was cited by the Finnish gender identity services in their policy change, which now recommends psychotherapy alone as first-line treatment.

Failure to adequately assess certainty of the study findings

It is our contention that the reviewers did not adequately assess the certainty of the reviewed studies' findings. For example, they used the Joanna Briggs Institute checklist to assess Turban et al. (2020), the study from which their message that puberty blockers reduce adult suicidality and have "potentially life-saving benefits" derives. This checklist can overemphasize whether studies report information and underemphasize the assessment of study validity. Below, we show how Rew et al. applied this tool to Turban et al. (2020), and the important study limitations it overlooked.

Was the exposure measured in a valid and reliable way? (Q3) Rew et al. answered "yes" to this question. We believe it should be "no." The exposure to puberty blockers was based on a self-report, with 73% of those respondents, who answered yes, claiming they began to use puberty blockers after the age of 18. It was noted that the respondents likely confused puberty blockers with other hormonal interventions (Biggs, 2020; D'Angelo et al., 2020). Although Turban et al. attempted to reduce the effects of this confusion by excluding certain participants from the sample, no adequate correction was possible. This introduced a significant risk of bias.

Were confounding factors identified and strategies to deal with them stated? (Q5, Q6) Rew et al. answered "yes" to both questions. We believe the answer to the latter question should be "no." For example, while one key confounding factor—prior mental health status—was indeed correctly identified by Turban et al., no strategy

was articulated to deal with it. When discussing their finding that puberty suppression is associated with lower lifetime suicidality, they acknowledged that "reverse causation cannot be ruled out: it is plausible that those without suicidal ideation had better mental health when seeking care and thus were more likely to be considered eligible for pubertal suppression" (Turban et al., 2020). This is one of the most serious limitations of the study, introducing a high risk of bias, and reducing the certainty of the findings.

In addition, while two questions ask about the subject selection criteria and whether the subjects and the setting were described in detail (Q1, Q2), these questions do not attempt to assess the impact of the sample composition. Affirmative ("yes") and "not applicable" answers to these questions, respectively, masked the fact that the study participants were not required to have a diagnosis of GD, and that the participant demographics were markedly different from the US population of transgender adults (D'Angelo et al., 2020), which negatively impacts the study's applicability/generalizability.

Rew et al. aggregated the answers to the checklist questions, with the Turban et al.'s study earning an 86% mark and a "good quality" rating. Even if we sideline the issue of any scoring inaccuracy, using such a simplistic scoring category is misleading since it implies that all questions are equally important, which is clearly not the case.

We also note, what appears to be, at least one error in Rew et al.'s assessment and reporting of study outcomes. In Table 2, they reported that Turban et al.'s positive outcome findings included decreased past-month psychological distress, past-month binge drinking, and lifetime illicit drug use. However, Turban et al.'s univariate analysis showed only one of these three outcomes, past-month psychological distress, showed any significant difference, and this significance disappeared once demographic variables were controlled for in the multivariable analysis.

A more rigorous tool to assess Turban et al.'s study would be ROBINS-I (The Risk of Bias of Non-randomized Studies of Interventions) (Sterne et al., 2016). This tool focuses on confounding, selection bias, classification and deviations from intervention, measurement of outcome, missing data, and selective reporting, and the extent to which the study design minimized biases and yielded trustworthy results. Given this, applying the ROBINS-I tool would find that the Turban et al.'s study is at a critical risk of bias.

Misleading statements regarding puberty blockers and suicidality

We are concerned that Rew et al.'s discussion of evidence about suicidality is unbalanced and misleading. Reading that puberty blockers had "positive outcomes [of] decreased suicidality in adulthood" will likely be understood as indicating causation. However, Turban et al. (2020), where this claim originates, noted that their study design did not allow for determination of causation, and "reverse causation" (individuals without suicidal ideation had better mental health and were more likely to be considered eligible for puberty blockers) was a plausible alternative explanation.

Further, there is a critical difference in meaning between "lifetime," and "adulthood." Not only does the

latter erroneously imply a pre-post effect (i.e., access to puberty blockers in childhood reduces suicidality in adults), which was not detectable in the study, but a measure of "adulthood suicidality," which Rew et al. claim was impacted, was never included in the original study (Turban et al., 2020).

There is also unclear use of the term suicidality, which exaggerates the implication of Turban et al.'s findings. Suicidality is a broad term, which is comprised of suicide attempts, plans, and ideation, and indeed this was the manner it was used by Turban et al. It is also important to note that Turban et al. made no assessment of completed suicides. Turban et al. assessed six areas of suicidality (including recent and lifetime suicide attempts, recent ideation with plans, recent and lifetime ideation) and found no association between puberty blockers and suicidality measures on five of the six areas. The only association was with "lifetime suicidal ideation." Of course, any suicidal ideation is concerning, but suicide attempts are generally considered of higher concern, in terms of suicide risk assessment, than suicidal ideation (Ryan & Oquendo, 2020).

Rew et al.'s inaccurate language further intensifies in the final sentence of their abstract, which described puberty blockers as "potentially life-saving." This exaggerated claim is misleading, since there is no evidence to support it.

Absence of an appropriate process for making clinical recommendations

Finally, the authors appear to recommend the use of puberty blockers in the "key practitioner messages" box and in the "implications" section of their paper. Making recommendations requires not only evidence about benefits and harms on all health outcomes that are important for decision-making (which this review provides in a suboptimal way), but also considerations about patients' values and preferences, ethics, acceptability, resources, costs, etc. (Andrews et al., 2013). All these considerations are balanced by making value judgments, which should be documented and reported explicitly and transparently. Rew et al. failed to do this, which, in our view, further undermines the credibility of their clinical practice recommendations.

Clinician reflections on the state of the GD literature

Rew et al.'s review illustrates a concerning trend, that we have observed in the GD literature, to overstate the evidence underpinning clinical practice recommendations for youth with GD. New publications reference prior ones with increasing and unwarranted confidence, and with the risk of misleading clinicians regarding the state of evidence. There is also a marked asymmetry in outcomes reporting: findings of positive outcomes of medical interventions are trumpeted in abstracts, while their profound limitations remain behind the paywall, thus, below the radar of busy clinicians.

Rew et al.'s paper demonstrates these types of issues. To start, the Turban et al.'s paper described a noncausal association between puberty blockers and "lifetime suicidal ideation," carefully avoiding making a causal claim (although, arguably, implying it). Then, Rew et al., whose findings on suicidality are based solely on this Turban et al.' study, rewrite this finding to create the strong

impression of causality—that puberty blockers reduce adult suicidality and are "potentially life-saving." Subsequently, a recent Commentary and Editorial in the *Lancet* both directly state that puberty blockers reduce suicidality, and the latter adds the extraordinary claim that "removing these treatments is to deny life." The only reference provided for these claims is the Rew et al. (2021) paper (Baams, 2021; *Lancet* editorial, 2021).

This resembles the game of "Telephone," in which a message is whispered from person to person distorting the original meaning of the message. However, this is not a game, and these types of errors can cause harm. Clinicians relying on Rew et al.'s review are likely to misinform patients and families about the risk/benefit profile of puberty blockers. Can such patients really be considered as giving informed consent?

The clear signals emerging from the various reviews of the available evidence of the use of puberty blockers for GD youth are that there is very low certainty of the benefits of puberty blockers, an unknown risk of harm and there is need for more rigorous research. The clinically prudent thing to do, if we aim to "first, do no harm," is proceed with extreme caution, especially given the rapidly rising case numbers and novel GD presentations. We must also, collectively, raise the bar on the quality of publications, in order to accurately educate clinicians and help patients make truly informed decisions that may impact for the rest of their lives.

Acknowledgements

The study received no external funding. Open Access fees were provided by the Society for Evidence-Based Gender Medicine. We would also like to thank the Society for Evidence-based Gender Medicine (SEGM) for providing access to several experts who helped shape this commentary and ensure its accuracy. Specifically, we would like to thank Dr. Romina Brignardello Peteresen for contributing her methodological expertise; Dr. Michael Biggs for reviewing the accuracy of the claims relating to puberty blockers and suicidality made in this review, as well as relating to the developments in the United Kingdom; and to Ema Syrnulik for her help with the preparation of this manuscript. The authors have declared that they have no competing or potential conflicts of interest.

ABSTRACT

Purpose: To assess how adolescent development progresses and psychiatric symptoms develop among transsexual adolescents after starting cross-sex hormone treatment.

Materials and methods: Retrospective chart review among 52 adolescents who came into gender identity assessment before age 18, were diagnosed with transsexualism and started hormonal gender reassignment. The subjects were followed over the so-called real-life phase of gender reassignment.

Results: Those who did well in terms of psychiatric symptoms and functioning before cross-sex hormones mainly did well during real-life. Those who had psychiatric treatment needs or problems in school, peer relationships and managing everyday matters outside of home continued to have problems during real-life.

Conclusion: Medical gender reassignment is not enough to improve functioning and relieve psychiatric comorbidities among adolescents with gender dysphoria. Appropriate interventions are warranted for psychiatric comorbidities and problems in adolescent development.

cross-sex hormones

Introduction

Adolescence starts from puberty and ends approximately ten years later with the consolidation of adulthood personality structures [1,2]. The upsurge of steroid hormones in puberty initiates the maturation of the reproductive system and secondary sexual characteristics, and also vast structural and functional developments in the brain [3]. These biological changes are accompanied by extensive cognitive, emotional and social changes characteristic of adolescent development. The psychosocial developmental tasks of adolescence comprise sexual maturation (including adopting to the sexually maturing body and becoming capable of mutually satisfying, reciprocal romantic and sexual relationships), achieving independence from parents, and assuming an identity and responsible social role [1,4–6].

Gender Dysphoria (GD) refers to a marked discrepancy between the experienced gender and biological sex, causing clinically significant distress or impairment in functioning (DSM-5) [7]. Individuals with GD often wish to obtain hormonal and surgical treatments to align their body with the experiences gender. In ICD-10 the corresponding diagnosis is Transsexualism (ICD-10) [8].

Favourably progressing adolescent development manifests in the adolescent's functioning in relation to her/his own sexually maturing body, parents, peers, romance and sexuality, and school/future career [4,9,10]. The literature exploring adolescent development and functioning among adolescents

with gender dysphoria and/or transgender identity is scarce and scattered. The sexually maturing body is a core challenge for adolescents suffering from gender dysphoria. A recent review suggested that adolescent gender dysphoria/transgender identity is associated with both negative (rejection, bullying) and positive (closer relationship, inclusion, attention) features in parent and peer relationships, both delayed and advanced for age or risky sexual behaviours, and with school-related challenges that are primarily assumed to relate to prejudice and peer rejection [10].

Psychiatric comorbidities, particularly depression, anxiety disorders and autism spectrum disorders as well as suicidality and self-harming behaviours are common among adolescents seeking gender reassignment [10]. Psychiatric comorbidities cannot automatically be assumed to be secondary to gender dysphoria [11] and do not necessarily remit due to sex reassignment [12].

During the past ten years the number of adolescents contacting gender identity services in order to seek for medical gender reassignment has increased across Western countries [13–16]. The reasons for this are not known [10].

Medical approaches to adolescent gender dysphoria may comprise halting/delaying the physical maturation (puberty blocking), and cross-sex hormonal treatments. Surgical treatments are mainly available for legal adults [17,18]. Medical gender reassignment is expected to alleviate gender dysphoria, psychiatric comorbidities and related

psychosocial problems. Initial studies have suggested that puberty blocking with GnRH analogues may reduce psychiatric symptoms and improve functioning in gender dysphoric adolescents [19,20], but follow-up studies assessing the effectiveness and safety of hormonal interventions initiated during the developmental years are, however, scarce and biased by methodological problems to the extent that a recent meta-analysis concluded that they must be considered experimental [21,22]. There is an urgent need for follow-up studies on the outcomes of gender identity based hormonal interventions initiated during adolescent development.

The aim of this study was to evaluate the adolescent development of young people diagnosed with transsexualism and offered cross-sex hormonal interventions in one of the two gender identity units for minors in the period 2011–2017. We set out to evaluate the psychosocial functioning and need for psychiatric treatment of this patient group during the gender identity diagnostic phase and after about a year on cross-sex hormone treatment. We expected to see improvements in psychosocial functioning and a decrease in need for psychiatric treatment after starting the hormonal treatment that results in the desired changes in secondary sexual characteristics, which expectedly alleviates gender dysphoria.

Materials and methods

In Finland, the gender identity assessments required in order to proceed to medical sex reassignment interventions are centralized to two of the five university hospitals in the country. After the diagnostic assessments, legal sex change can take place after a period of about a year on cross-sex hormonal treatments, the so-called real-life phase of living in the desired role. Diagnostic assessments in Finnish health care take place according to ICD-10 [8]. Legal sex change and surgical treatments require the patient to have achieved legal majority (18 years). To proceed to legal sex change, the patient has to obtain a certificate from the gender identity unit that carried out the primary diagnostic assessments and from the other gender identity service (second opinion). Gender identity assessments for minors were initiated in 2011.

The study comprises a retrospective chart review of adolescents referred to one of the two gender identity service facilities for minors in Finland (Tampere University Hospital, Department of Adolescent Psychiatry) before age 18, who had been diagnosed with transsexualism and proceeded to cross-sex hormonal treatments and who had completed a follow-up of approximately a year after starting on cross-sex hormones (real-life phase).

The assessments conducted by the gender identity team comprise structured and free format assessments and interviews by a multi-disciplinary team and an evaluation of the adolescent's existing psychiatric and medical files [11]. Two of the authors (RK, MT) were involved in the clinical assessments of all the gender-referred adolescents during the study period. The research data was collected retrospectively

from the case files by a junior researcher (EH) trained and supervised by the first author. All information available after the clinical evaluations was used and the data was collected with help of a structured data collection form until the referral for the second opinion in the other adolescent gender identity unit was written. The study received approval from the ethics committee of Tampere University Hospital.

Between 2011 and 2017, 57 adolescents had been diagnosed with F64.0, transsexualism, and had been offered an opportunity to start hormonal sex reassignment. One of them did not want any treatment, two withdrew and two had started hormonal treatments but had not yet completed the real-life phase at the end of 2017. Thus, 52 patients were included in the study. Of these 11 were birth assigned males (transfemales) and 41 birth assigned females (transmales). They had a mean (sd) age of 18.1 (1.1) years at diagnosis, range 15.2–19.9 years (no difference between sexes).

Measures

Indicators of adolescent development

Adolescent development was evaluated in terms of age-appropriate living arrangements, peer relationships, school/work participation, romantic involvement, competence in managing everyday matters and need for psychiatric treatment.

Living arrangements were classified as (1) living with at least one parent/guardian, (2) living in a boarding school, with an adult relative, in some form of supported accommodation or the like, where supervision and guidance by a responsible adult is provided, (3) independently alone or in a shared household with a peer, (4) with a romantic partner. In the analyses dichotomized living arrangements (a) during gender identity assessment and (b) during the real-life phase living with (a) parent(s)/guardian(s) vs. in other arrangements. In Finnish culture, minors younger than 18 years usually live in the parental home, but leaving the parental home takes place earlier than in the majority of EU countries. Of young people aged 20–24, about a fourth are living in the parental home in Finland [23,24].

Peer relationships were classified as follows: (1) socializes with friends in leisure time, outside of activities supervised by adults, (2) socializes with peers only at school or in the context of rehabilitative activity, (3) spends time close to peers, for example in school or rehabilitative activity, but does not connect with them, (4) does not meet peers at all. In the analyses, peer relationships during (a) gender identity assessment and (b) the real-life phase were dichotomized to age-appropriate (normative) [1] vs. restricted or lacking [2–4].

School/work participation was classified as (1) age appropriate participation in mainstream curriculum, progresses without difficulties, (2) participates in mainstream curriculum with difficulty, (3) participates in rehabilitative educational or work activity, (4) not involved in education and working life. Age-appropriate participation during [1] was recorded if the adolescent attended mainstream secondary education or upper secondary education at a regular rate (a class per year in comprehensive school; has not changed more than once

between tracks in upper secondary education) or had proceeded to work life after completing vocational education. Participation with difficulty [2] was recorded if the adolescent was enrolled in mainstream education but had to repeat a class, studied with special arrangements (for example, in a special small group), or followed some form of adjusted curriculum. In the analyses, school/work life during (a) gender identity assessment and (b) real-life phase was dichotomized to normative [1] vs. any other (2, 3 or 4).

Romantic involvement was recorded (1) has or has had a dating or steady relationship, not only online, (2) has had a romantic relationship only online, (3) has not had dating or steady relationships. In the analyses we compared has or has had [1] vs. has not had [2,3] a dating or steady relationship during (a) gender identity assessment and (b) real-life phase. Sexual history was recorded in more detail in case histories during gender identity assessment, and for this period we also collected the experiences of (French) kissing (yes/no), intercourse (yes/no) and experience of any genitally intimate contact with a partner (petting under clothes or naked, intercourse, oral sex) (yes/no).

In recording age-appropriate competence in managing everyday matters we expected that early adolescents (up to 14 years) would be able, for example, to do shopping and travel alone on local public transport, and to help with household duties assigned by their parents. Middle adolescents (15–17 years) were further assumed, for example, to be able make telephone calls in matters important to them (for example, when seeking a summer job), to deal with school-related issues with school personnel without parental participation, to select and start new hobbies independently and to fulfil their role in summer jobs and in similar responsibilities of young people. Late adolescents (18+ years), legally adults, were expected to have, in addition to the above, competence to talk to authorities such as professionals in health and social services, employment or educational institutions, to deal with banks or health insurance, to manage their financial issues and to manage their housekeeping if they chose to move to live independently of parents/guardians. Competence in managing everyday matters was recorded as follows: (1) the adolescent is able to cope age-appropriately outside home, (2) the adolescent needs support in age-appropriate matters outside home but functions age-appropriately in the home (manages her/his own hygiene, clothing and nutrition, participates in (younger subjects) or takes responsibility for (older subjects) housekeeping) and (3) the adolescent's functioning is inadequate both at home and outside home. In the analyses we focused in being age-appropriately able cope with matters outside of the home [1] vs. not [2,3].

Psychiatric disorders (depression, anxiety, suicidality/self-harm, conduct problems, substance abuse problems, psychoses, ADHD, autism, eating disorders) were recorded a) if they had required specialist level psychiatric treatment during or before the gender identity assessment, (i.e. the adolescent was in treatment, or treatment had been recommended but the adolescent refused it) and b) if they required specialist level psychiatric treatment during the real-life phase (i.e. the

adolescent was in treatment or the psychiatrist in the gender identity unit recorded that treatment was recommended or made a referral to psychiatric treatment irrespective of whether or not the adolescent complied with the recommendation).

Statistical analyses

Distributions of variables illustrating adolescent development are given for (a) the time of the gender identity assessment and (b) the real-life phase. Differences in proportions displaying age-appropriate functioning were compared using chi-square statistics/Fisher's exact test as appropriate. Cross-tabulations with chi-square statistics/Fisher's exact test as appropriate were used to explore functioning on a domain during the real-life phase according to functioning therein during assessment (i.e. school/work during real-life phase according to school/work during assessment etc.).

Need for specialist level psychiatric treatment before or during the gender identity assessment and during the real-life phase was compared using cross-tabulations with chi square statistics. Similarly, need for treatment according to the nine disorder dimensions recorded was compared between the two time periods. The associations between need for specialist level psychiatric treatment a) before or during the gender identity assessment, and b) during the real life-phase and functioning in the domains studied were explored using cross-tabulation with chi-square statistics/Fisher's exact test where appropriate.

The role of sex/gender and age were analysed by logistic regression. Functioning in peer relationships, school/work, managing everyday matters and dating/going steady were entered each in turn as the dependent variable with age and sex/gender as independent variables. Odds Ratios (OR) with 95% confidence intervals (CI) were calculated.

Results

Adolescent development and need for treatment during assessment and during real-life phase

During the gender identity assessment, three quarters of the adolescents lived with their parents. About three out of five displayed age-appropriate progress in school/work, four out of five functioned age-appropriately in dealing with matters outside home, and almost all had normative peer contacts. About three out of five had experienced dating/steady relationships before the end of the gender identity assessment (Table 1). In more detail about sexual development, 83% (43/52) had been in love/had a crush on someone, 56% (29/52) had experienced kissing, 8% (4/52) intercourse and 64% (33/52) any genitally intimate sexual contact with a partner by the end of the gender identity assessment.

During and before the gender identity assessment, half of the adolescents required specialist level psychiatric treatment, most commonly because of depression, anxiety, and suicidality/self-harm (Table 2).

In the end of the real-life phase, a majority had moved on to live independently of parents/guardians. The shares of

Table 1. Functioning in different domains of adolescent development during gender identity assessment and real-life phase among 52 young people diagnosed with transsexualism after starting gender identity assessments before age 18 [% (n/N)].

	During gender identity assessment	During real life phase	p Value
Living with parent(s)/guardians	73% (38/52)	40% (21/50)	0.001
Normative peer contacts	89% (46/52)	81% (42/52)	<0.001
Progresses normatively in school/ work	64% (33/52)	60% (31/52)	0.69
Has had dating or steady relationships	62% (32/50)	58% (30/52)	0.51
Is age-appropriately able to deal with matters outside of the home	81% (42/52)	81% (42/52)	1.0

Table 2. Need for specialist level psychiatric treatment, and disorder/symptom dimensions requiring this treatment during and before gender identity assessment, and during real life phase [% (n/N)].

	During and before gender identity assessment	During real life phase	p Value
Need for psychiatric treatment	50% (26/52)	46% (24/51)	0.77
Need for treatment due to ...			
depression	54% (28/52)	15% (8/52)	<0.001
anxiety	48% (25/52)	15% (8/52)	<0.001
suicidality/self-harm	35% (18/52)	4% (2/52)	<0.001
conduct problems/antisocial	14% (7/52)	6% (3/52)	0.18
psychotic symptoms/psychosis	2% (1/52)	4% (2/52)	0.56
substance abuse	4% (2/52)	2% (1/52)	0.56
autism	12% (6/52)	6% (3/52)	0.30
ADHD	10% (5/52)	2% (1/52)	0.09
eating disorder	2% (1/52)	2% (1/52)	1.0

those progressing age-appropriately in school/work, dealing age-appropriately with matters outside of home and being involved in dating/steady relationships did not change from the assessment phase to the end of the real-life phase. The proportion of those functioning age-appropriately in peer relationships decreased from the assessment period to the real-life phase (Table 1). The share of those requiring specialist level psychiatric treatment during real-life due to any reason was similar to that during and before the assessment, but treatment needs due to depression, anxiety and suicidality/self-harm had diminished (Table 2).

Changes within different domains of functioning

Of those adolescents with age appropriate peer contacts during assessment (46/52), 91% (42/46) continued to have age-appropriate peer contacts during the real-life phase while 9% (4/46) no longer had these. Of those with difficulties in peer contacts (6/52), all continued to have difficulties in this field. ($p < 0.001$)

Of those who progressed age-appropriately at school (working life) during assessment (33/52), 85% (28/33) continued to do so during the real-life phase, but 15% (5/33) did not. Of those with problems at school (work) (19/52), 84% (16/19) continued to have problems, but 16% (3/19) ceased to have problems in this field. ($p < 0.001$)

Of those who had had age-appropriate skills in dealing with matters outside home (42/52), 88% (37/42) continued to be able to do so but 12% (5/42) functioned below the age-appropriate level during the real-life phase. Of those who

had had difficulties in dealing with matters outside home (10/52), half (5/10) continued to do so, but half (5/10) no longer had problems in this field ($p = 0.02$).

Of those who had experiences of dating/steady relationships during the assessment (32/50), 66% (21/32) had dating/steady relationships during the real-life phase, and 34% (11/32) did not. Of those who had not had any dating/steady relationships by the end of the gender identity assessment, 44% (8/18) had and 56% (10/18) did not have these during the real-life phase. ($p = 0.12$)

Of those not needing psychiatric treatment before or during the assessment (26/52), 73% (19/26) did not need any during the real-life phase but in 27% (7/26), a need had emerged. Of those who had needed (25/51) psychiatric treatment during or before the assessment, 68% (17/25) still needed it during the follow-up but 32% (8/25) did not. ($p = 0.004$)

The role of psychiatric comorbidities for functioning during real life

Need for psychiatric treatment before or during the real-life phase was not associated with functioning in peer relationships or romantic relationships during the real-life phase. Those needing psychiatric treatment before or during gender identity assessment were more likely to not function age-appropriately in school/work (47% (15/32) vs. 82% (14/17) functioned well, $p = 0.02$), and borderline significantly less likely to cope well with managing everyday matters outside home (72% (23/32) vs. 94% (16/17) managed well, $p = 0.06$) during the real-life phase.

Concurrent need for psychiatric treatment during the real-life phase was associated with a smaller proportion functioning well at school/work [42% (10/24) vs. 74% (20/27), $p = 0.02$] and in taking care of everyday matters [67% (16/24) vs. 93% (25/27), $p = 0.02$].

No associations were found between age and sex (gender) and functional outcomes.

Discussion

The aim of this study was to assess the adolescent development of those adolescents who were diagnosed with transsexualism and offered cross-sex hormonal interventions during the subsequent real-life phase, when the cross-sex hormonal treatment was initiated and started to produce the desired changes in physical appearance. Moving to live independently, relationships with peers, romantic involvement, ability to take care of everyday issues age-appropriately outside home and need for psychiatric treatment were assessed as proxies for adolescent development. Earlier empirical research on outcomes of medical sex reassignment interventions initiated during developmental years was scarce and offered little advice on the impact of treatments on adolescent development [10,21,22].

We observed that the majority of the adolescents diagnosed with transsexualism and offered cross-sex hormonal treatments displayed age-appropriate functioning in the

domains studied during the gender identity assessment, as is to be expected given that severe psychopathology and markedly lowered functioning may complicate the possibilities to assess identity achievement and may constitute a contraindication for medical treatment. Nevertheless, a considerable share also had difficulties in different domains of functioning. What is more, even if the majority also functioned well in the domains studied during the first year on cross-sex hormones, no statistically significant improvements in functioning were observed in the group as a whole, and in the domain of peer relationships the share of those with normative contacts decreased. This is in disagreement with earlier studies suggesting improved functioning and reduced psychiatric symptoms in adolescent onset hormonal treatment of gender dysphoria [19,20], and likely due to older age, more difficult psychopathology and different intervention (cross-sex hormones vs. GnRH analogues) in our sample. Our subjects were all post-pubertal and halting of development was thus not possible.

The majority of the adolescents diagnosed with transsexualism were still living in the parental home during the gender identity assessment, which is to be expected and culturally normal as they were in the age range of 15.2–19.9 years. During the subsequent real-life phase, the share of those living in the parental home decreased. This concurs with progression of adolescent development. Given the knowledge of normative timing of leaving the parental home in Finland [21,22], the increasing proportion of those no longer living with their parents likely indicates positive progress in adolescent development instead of, for example, negative parental reactions to sex reassignment, which has also been reported in the literature [25], particularly as most of those leaving the parental home went to live with romantic partners (data not shown). Due to excellent social security benefits, moving to live independently does not necessitate regular income from employment and is therefore not a proxy for good functioning in other domains of life.

The difficulties in peer relationships commonly reported among adolescents with transgender identities have been associated with prejudice and discrimination [10,26]. Anxiety disorders, particularly social anxiety, could relate both to victimization and distress created by not being able to satisfactorily present oneself according to one's perceived gender. With the appearance of the desired physical characteristics, passing in the desired role is expected to be facilitated and self-confidence to increase. Positive changes in connection with peers could be expected. However, of those who had difficulties in peer relationships during the gender identity assessment, all continued to have them in the follow-up, and almost one in ten of those functioning well in this domain during the assessment developed difficulties in follow-up. This was contrary to our expectations and suggests that difficulties in peer relationships cannot be attributed to difficulties in passing in the desired role.

About two out of five of the adolescents diagnosed with transsexualism had experienced dating or steady relationships by the end of the gender identity assessments, and an equal share during the real-life phase. For comparison, recent

Finnish data on 15-year-old adolescents reveals that about a half of them have experienced dating/steady relationships (unpublished observation). Steady relationships in adolescence may be short and not dating/going steady exactly during the real-life phase cannot be taken as an indicator of delayed development. Earlier studies have shown that clinically referred adolescents with gender dysphoria display normative emotional development in regard to romance and dating but show slight delays in behavioural level sexual development [27,28]. Compared to earlier findings on all gender-referred adolescents, the adolescents now studied had experienced falling in love and dating/steady relationships about equally frequently but had slightly less often engaged in sexually intimate behaviours than both all gender-referred adolescents and same aged adolescents in general population (Kaltiala-Heino et al. [28]). These observations do not suggest remarkable delays in sexual development. During the real-life phase, a considerable share also gained their first experiences of dating/steady relationships, which suggests favourable progression of adolescent development.

If the adolescents diagnosed with transsexualism had had difficulties at school/work as during the gender identity assessment, they mainly continued to have difficulties during the real-life phase. Only a minority moved from progressing with difficulties to progressing normatively, and equally many deteriorated during follow-up. Improved functioning as a consequence of alleviating gender dysphoria and passing better in the desired role is commonly assumed but has not previously been researched in relation to education/work. Our findings suggest that treatment of gender dysphoria does not suffice to improve functioning in education and working life. Difficulties in school adjustment and learning are common among gender-referred adolescents and often not properly addressed, on the assumption that treatment of gender dysphoria would relieve an array of problems [11,29]. Educational difficulties need to be fully addressed during adolescence regardless of gender identity.

On their developmental path towards emotional, social and economic independence from parents, adolescents gain competence in taking care of increasingly demanding matters outside home. Delays in this could be associated with gender dysphoria through psychiatric symptoms secondary to gender dysphoria and lack of self-confidence related to challenges in self-presentation. Such problems could be expected to be alleviated with gender affirming hormonal treatments. In taking care of matters at an age-appropriate level, a greater share had improved than had declined during the real-life phase. Thus, favourable progression of adolescent development was seen in the group studied, even if a fifth of the subjects continued to function on a lower than age-appropriate level during the real-life phase.

Need for treatment due to depression, anxiety and suicidality/self-harm was recorded less frequently during the real-life phase than before it. This is in line with the conclusion of a relatively recent meta-analysis [30] that in adults with gender dysphoria, cross-sex hormonal treatment alleviates anxiety, and may also reduce depression or depressive symptoms. However, need for psychiatric treatment overall did

not decrease from the level before and during the gender identity assessment to the real-life phase. New needs had also emerged about as frequently as need for treatment diminished. Cross-sex hormonal treatment is not enough to alleviate psychiatric comorbidities which in adolescents with gender dysphoria may also precede gender identity concerns [11] and will likely have equally many and complex underpinnings as they have in any population. A large-scale register study among adults likewise found that psychiatric needs were not alleviated with gender reassignment [12]. Depression, anxiety and suicidality/self-harm are often assumed to be secondary to gender dysphoria, and our findings may be interpreted as lending some support to that assumption among adolescents, similarly as earlier research seems to imply for adults [30].

Both earlier and concurrent need for psychiatric treatment were associated with not progressing age-appropriately at school/work and in taking care of matters outside home during the real-life phase, even though need for psychiatric treatment was, somewhat unexpectedly, not associated with functioning in peer relationships and romantic relationships. This further underlines the need to actively address psychiatric comorbidities among adolescents with gender dysphoria.

The study was based on file information on all adolescents diagnosed with transsexualism and proceeding to cross-sex hormone treatment after entering gender identity earlier than age 18 in one of the two centralized gender identity service facilities for minors in Finland. The two gender identity units for minors operate on similar principles, receive equal numbers of referrals and during the study period prescribed cross-sex hormones to similar numbers of adolescents. The follow-up period was approximately only a year, which inhibits drawing conclusions on long-term outcomes. However, as during adolescence, both physical, cognitive, emotional and social aspects of development are in a constant state of change [3], one year is a very relevant period.

Collected from medical files, the data is as accurate as clinical documentation can be. Because gender identity assessments and medical gender reassignments in minors involve numerous controversies (Kaltiala-Heino et al. [10]), the documentation is likely to be done particularly meticulously. The study unit operates within the field of adolescent psychiatry, and particular attention is always paid to adolescent development illustrated in age-appropriate functioning. Data collection was carried out in a structured way, which adds to the reliability of the study. Most of the recorded issues are clear-cut and concrete (living arrangements; progressing one class per year at school or having a job; socializing with peers in leisure time; being in (an offline) steady relationship). Age-appropriate capacity taking care of matters outside home may be somewhat more abstract and difficult to quantify. Ambiguous details were discussed between the authors and rated in consensus.

The disorders that were the reason for need for psychiatric treatment were recorded as they appeared in the documentation produced by the gender identity team or were

recorded in case files obtained by the gender identity team from the adolescent's local services and classified on a robust level. They were not always systematically recorded with ICD-codes, and we were not able to ascertain the accuracy of the diagnostic work. However, the diagnoses mentioned in this paper represent problem categories that are the basis for treatment offered. A better understanding of psychiatric comorbidities could have been obtained by using structured diagnostic interviews.

Conclusion

Among adolescents diagnosed with transsexualism, difficulties in adolescent development and functioning in life domains appropriate to late adolescence do not disappear with cross-sex hormone treatment. Cross-sex hormone treatment may alleviate depression and anxiety but does not have a positive impact on psychiatric comorbidities at large. Even deterioration as regards psychiatric treatment needs and functioning occurs during the first year of cross-sex hormone treatment. Not all psychiatric and psychosocial problems in adolescents displaying gender dysphoria are secondary to gender identity issues and will not be relieved by medical gender reassignment. An adolescent's gender identity concerns must not become a reason for failure to address all her/his other relevant problems in the usual way.

ABSTRACT

Background

Gender dysphoria is described as a mismatch between an individual's experienced or expressed gender and their assigned gender, based on primary or secondary sexual characteristics. Gender dysphoria can be associated with clinically significant psychological distress and may result in a desire to change sexual characteristics. The process of adapting a person's sexual characteristics to their desired sex is called 'transition.'

Current guidelines suggest hormonal and, if needed, surgical intervention to aid transition in transgender women, i.e. persons who aim to transition from male to female. In adults, hormone therapy aims to reverse the body's male attributes and to support the development of female attributes. It usually includes estradiol, antiandrogens, or a combination of both. Many individuals first receive hormone therapy alone, without surgical interventions. However, this is not always sufficient to change such attributes as facial bone structure, breasts, and genitalia, as desired. For these transgender women, surgery may then be used to support transition.

Objectives

We aimed to assess the efficacy and safety of hormone therapy with antiandrogens, estradiol, or both, compared to each other or placebo, in transgender women in transition.

Search methods

We searched MEDLINE, the Cochrane Central Register of Controlled Trials (CENTRAL), Embase, Biosis Previews, PsycINFO, and PSYDEX. We carried out our final searches on 19 December 2019.

Selection criteria

We aimed to include randomised controlled trials (RCTs), quasi-RCTs, and cohort studies that enrolled transgender women, age 16 years and over, in transition from male to female. Eligible studies investigated antiandrogen and estradiol hormone therapies alone or in combination, in comparison to another form of the active intervention, or placebo control.

Data collection and analysis

We used standard methodological procedures expected by Cochrane to establish study eligibility.

Main results

Our database searches identified 1057 references, and after removing duplicates we screened 787 of these. We checked 13 studies for eligibility at the full text screening stage. We excluded 12 studies and identified one as an ongoing study. We did not identify any completed studies that met our inclusion criteria. The single ongoing study is an RCT conducted in Thailand, comparing estradiol valerate plus cyproterone treatment with estradiol valerate plus spironolactone treatment. The primary outcome will be testosterone level at three month follow-up.

Authors' conclusions

We found insufficient evidence to determine the efficacy or safety of hormonal treatment approaches for transgender women in transition. This lack of studies shows a gap between current clinical practice and clinical research. Robust RCTs and controlled cohort studies are needed to assess the benefits and harms of hormone therapy (used alone or in combination) for transgender women in transition. Studies should specifically focus on short-, medium-, and long-term adverse effects, quality of life, and participant satisfaction with the change in male to female body characteristics of antiandrogen and estradiol therapy alone, and in combination. They should also focus on the relative effects of these hormones when administered orally, transdermally, and intramuscularly. We will include non-controlled cohort studies in the next iteration of this review, as our review has shown that such studies provide the highest quality evidence currently available in the field. We will take into account methodological limitations when doing so.

PLAIN LANGUAGE SUMMARY

Does hormone therapy help transgender women undergoing gender reassignment to transition?

Background

Transgender women may feel that they have been born in a body with the wrong sexual characteristics. This may result in significant psychological distress (gender dysphoria) and the desire to adapt their male physical and sexual characteristics to be more consistent with their experienced female gender. This is a process called transition. If measures to aid transition are not taken, this can result in greater psychological distress. One of the medical treatments given to help transgender women with male bodies to achieve transition is synthetic female hormones. These hormones can be taken by mouth, absorbed through the skin or injected into muscle.

Study characteristics

We looked for randomised controlled trials (RCTs) that included transgender women (age 16 and over) in transition from male to female. RCTs are a type of research study that can reduce the possibility of several types of bias. To be included in this review, studies needed to compare different hormone treatments used to support transgender women to transition (oestrogen alone, testosterone blockers alone, or oestrogen in combination with testosterone blockers), or compare these hormone treatments to placebos (fake or dummy treatments that appear to be the same as the actual treatment, but have no medical effects). We wanted to see whether hormone treatments help transgender women to make a transition that they are happy with. We also wanted to look at whether there were any health risks of the treatment.

Key results

We searched for studies up to 19 December 2019. We were unable to find any relevant completed studies that we could include. We did find one ongoing study that aimed to recruit all of the people taking part in the study by the end of 2020. This study is comparing the effects of estradiol valerate plus cyproterone treatment with estradiol valerate plus spironolactone treatment in transitioning transgender women in Thailand.

Quality of evidence

Our review found no RCTs that looked at whether hormone therapies are effective and safe when used to help transgender women to transition. Therefore, high-quality RCTs are needed to research these questions.

BACKGROUND

Description of the condition

There is a growing trend towards de-psychopathologisation of transgenderism (Drescher 2014; ATME 2015). There is an emerging consensus that transgenderism is not a psychiatric disorder (WPATH 2011). For instance, the 11th Revision of the International Classification of Diseases (ICD-11) (WHO 2018) no longer classifies transgenderism as a behavioural and personality disorder, but has instead drafted the term "gender incongruence" to describe gender dysphoria.

In contrast, the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) (DSM-5 2013) describes gender dysphoria as a "marked incongruence between one's experienced/expressed gender and assigned gender, of at least six months duration, as manifested by at least two of the following" characteristics:

- A marked incongruence between one's experienced/expressed gender and primary and/or secondary sex characteristics (or, in young adolescents, the anticipated secondary sex characteristics);
- A strong desire to be rid of one's primary and/or secondary sex characteristics because of a marked incongruence with one's experienced/expressed gender (or, in young adolescents, a desire to prevent the development of the anticipated secondary sex characteristics);
- A strong desire for the primary and/or secondary sex characteristics of the other gender;
- A strong desire to be of the other gender (or some alternative gender different from one's assigned gender);
- A strong desire to be treated as the other gender (or some alternative gender different from one's assigned gender);
- A strong conviction that one has the typical feelings and reactions of the other gender (or some alternative gender different from one's assigned gender).

Gender dysphoria has been defined as associated with "clinically significant distress or impairment in social, occupational or other important areas of functioning" (Zucker 2016), which may lead to substantial suffering in affected people (Deutsch 2016a; Soll 2018). Gender dysphoria may result in the desire to modify one's physical and sexual characteristics to be consistent with those of the experienced gender. This process of adaptation is called transition.

The treatments applied in transition differ from those used for maintenance of the new sexual characteristics. Currently, there is uncertainty about the value of hormone therapy as a sole intervention, or when combined with surgery, for transition from male to female. This Cochrane Review specifically focuses on 'transgender women in transition from male to female,' a definition that includes biological males aiming to adapt their sexual characteristics to be consonant with those of females.

A meta-analysis that analyzed 21 studies on the prevalence of gender dysphoria (of which 12 studies contained evaluable data) estimated an overall prevalence of transgender women with gender dysphoria at 6.8 per 100,000 individuals (Arcelus 2015).

Description of the intervention

Current guidelines suggest hormonal and, if needed, surgical treatment of gender dysphoria in transgender women (WPATH 2011). Hormone therapy aims to suppress the development of, or to reverse, male attributes that have already developed. At the same time, hormones aim to develop female attributes. However, where male characteristics have already developed in adult males, such as in the bone structure of the face, hormones are not effective. Other treatments, such as surgery, would be required to change these (WPATH 2011).

The guidelines of the Endocrine Society working group suggest treatment with both oestrogens and antiandrogens (Hembree 2017). Oestrogens can be administered as either oral oestrogen, absorbed through transdermal estradiol patches, or by injection of estradiol valerate or estradiol cypionate. The application frequency differs depending on the patient's reaction to the agent and the administration regimen; it could be multiple times per day or once every two weeks. Meanwhile, antiandrogens such as spironolactone or cyproterone acetate (CPA) are commonly taken orally. Additionally, it is possible to block male puberty by treatment with gonadotropin-releasing hormone (GnRH) agonist injections (Hembree 2017).

While not every transgender woman undergoes hormone therapy in her transition, this intervention is still widely used (Hembree 2017). We know of no studies identifying the ratio of patients who undergo hormone therapy, nor do we know of studies investigating how much time passes between the start of transition (the decision to transition) and the start of hormone therapy. We are not aware of any studies on how often antiandrogens are being prescribed in addition to or instead of 17-beta-estradiol, how often they are being taken, or which kinds of androgens are in use besides CPA and spironolactone.

How the intervention might work

Several hormonal substances and combinations are used clinically for hormone therapy in transitioning women. CPA is a progestin, steroidal anti-androgen and anti-gonadotropin that blocks the receptors for testosterone (T) and dihydrotestosterone (DHT), and thereby prevents these steroidal hormones from exerting their androgenic effects. Hence, it stops processes like body hair growth, hair loss on the head, male body fat distribution and others (Figg 2010; WPATH 2011). According to the World Professional Association for Transgender Health (WPATH) guidelines, it is possible to suppress puberty with GnRH analogues or progestins such as medroxyprogesterone (WPATH 2011).

Spironolactone acts as a weak androgen receptor antagonist (Wenqing 2005). It also causes an increase in oestradiol levels (Thompson 1993), so that further virilisation is prevented and feminisation occurs (WPATH 2011).

17-beta-estradiol is used to feminise the external appearance (WPATH 2011). It binds to oestrogen receptors and thus ensures gene expression, which in turn feminises appearance (Hye-Rim 2012). In addition, estradiol suppresses gonadal testosterone production via the control systems of the hypothalamus (Hayes 2000).

Feminisation therapy aims to adapt the physical appearance and experience of the male body to that of a female body, by

inducing breast growth, softening facial features, and inducing other physical changes commonly considered to comprise a feminine appearance (WPATH 2011). For this purpose, oral or transdermal oestrogen is recommended, and therapy with oestrogen in combination with antiandrogens is most common. Co-treatment with antiandrogens minimises the required dose of oestrogen, and thereby reduces the potential risks of oestrogen identified in previous studies (Schürmeyer 1986; Prior 1989). Some antiandrogens are approved by WPATH, such as spironolactone, cyproterone acetate, GnRH analogues like goserelin, and 5-alpha-reductase inhibitors like finasteride (WPATH 2011).

Why it is important to do this review

Antiandrogens like CPA and spironolactone are prescribed to transgender women in transition by clinicians, including gynaecologists and endocrinologists (Schnelder 2006; Flütsch 2015), and they are commonly considered to be valuable drugs to support transition (WPATH 2011; Hembree 2017). However, clinical evidence suggests that taking these drugs can result in adverse events; for example, CPA has significant potential for causing depression and for worsening depressive symptoms (Seal 2012). There is also some concern that CPA can lead to other psychiatric, neurological, and metabolic disorders (Grlard 1978; Ramsay 1990; Oberhammer 1996; Giltay 2000; Calderón 2009; Bessone 2015). The most common adverse effects of spironolactone are hyperkalaemia, dehydration and hyponatraemia (Greenblatt 1973). Furthermore, spironolactone might have an influence on feelings of anxiety (Fox 2016).

Other studies from the 1980s and 90s reported that there were adverse effects from high-dose estradiol, but these studies used ethinyl estradiol or equine premarin (equine estradiol) instead of bioidentical 17-beta-estradiol; and used progestins, instead of bioidentical progesterone. This may have contributed to the adverse effect profile of these specific treatments (Prior 1989). Unlike the bioidentical alternatives used today (hormone preparations made from plant sources that are similar or identical to human hormones), substances administered in the past (e.g. equine oestrogens, ethinyl estradiol) were associated with more diverse adverse effects like thrombophilia, cardiovascular problems, breast and prostate cancer, as well as liver, adrenal gland and neural dysfunction (Grlard 1978; Calderón 2009; Asscheman 2011). The health risks attributed to estradiol doses high enough to suppress androgens have not been found in the parenteral or transdermal application of bioidentical estradiol (Hembree 2017). Thus, it is unclear why those estradiol doses should be kept low in order to make the addition of androgen antagonists like CPA or spironolactone necessary.

In light of discussions among experts (Seal 2012; Wierckx 2014), and current recommendations for hormonal gender affirmation treatment (WPATH 2011) (which are strongly based on the values and preferences of health consumers), it is necessary to review the evidence from trials that show results for outcomes such as feminisation, satisfactory sexual function, reduced gender dysphoria, and improved quality of life (e.g. Murad 2010).

In 2017, the overall quality of evidence relating to these outcomes was classified as low (Hembree 2017). In 2011, WPATH summarised the situation as follows: "There is a need for further research on the effects of hormone therapy without surgery, and without the goal of maximum physical feminisation or masculinisation" (WPATH

2011). It is necessary to determine whether subsequent trials have provided additional evidence for efficacy, or whether there is still a lack of evidence for these desired outcomes.

OBJECTIVES

We aimed to assess the efficacy and safety of hormone therapy with antiandrogens, estradiol, or both, compared to each other or placebo, in transgender women in transition.

METHODS

Criteria for considering studies for this review

Types of studies

We aimed to include randomised controlled trials (RCTs), quasi-RCTs and controlled cohort studies.

We chose to include quasi-RCTs and cohort studies due to the low prevalence of the condition and the consequent current scarcity of RCTs (WPATH 2011).

Types of participants

We aimed to include studies that enrolled transgender women, age 16 years and over, in transition from male to female. Transitioning is defined as the process of changing one's gender profile or sexual characteristics (or both) to accord with one's sense of gender identity (WPATH 2011). Transition as a concept thus encompasses several aspects, e.g. social, psychological, or physical aspects, or a combination of these. There is consistency in the literature on when the transition begins: namely, with the decision to change a person's gender assignment (Brown 1996). However, we did not differentiate among any supposed phases of the respective types of transitions. Depending on the personal situation, the process of transition (which may include the decision to transition, gathering of information, gathering of experience, medical treatment and change of social role), can take very different periods of time, usually several months to years. Therefore, it is difficult to distinguish certain 'phases' of this process. When focusing on hormone therapy, the transition term can be more precisely defined. The transition process lasts as long as patients are in the process of changing their sexual characteristics (WPATH 2011).

We aimed to include studies with participants age 16 years and older because, according to currently applied guidelines, this is the age when patients start being treated with hormone therapy. Patients below this age are usually being treated with puberty blockers, which are outside the scope of this review (WPATH 2011).

Types of interventions

We considered studies evaluating hormone-based interventions only, excluding those that examined combined hormonal and either psychological or surgical treatments. We aimed to include studies reporting treatment with the following experimental interventions.

- Antiandrogens (cyproterone acetate or spironolactone) and estradiol
- Antiandrogens (cyproterone acetate or spironolactone) alone
- Estradiol alone

For the above interventions, we considered all types of administration: oral, sublingual, transdermal, subdermal and intramuscular. For estradiol, we also considered bioidentical 17-beta-estradiol, as well as synthetic derivatives.

We aimed to include the following comparator interventions.

- Any of the active interventions listed above
- Placebo

Although we consider placebo-controlled studies to be unethical (Bostick 2008), we made them eligible for inclusion in this review so that we could consider the evidence in its entirety. We did not consider interventions consisting purely of psychological treatment, spiritual support, or conversion therapy.

Types of outcome measures

For studies with repeated follow-up (i.e. reporting of outcomes at multiple time points), we regarded follow-up at three to six months as short term, six months to two years as medium term, and more than two years as long term (WPATH 2011).

We intended to include in the descriptive section of the review all studies that met the criteria for type of study, participants, intervention and comparator, regardless of outcomes reported or missing data.

Primary outcomes

- Quality of life (QoL) as measured by validated generic instruments, e.g. Quality of Life Inventory (QOLI) (Frisch 2005); or specific instruments, e.g. for body image, the Body Image Quality of Life Inventory (BIQLI) (Cash 2004); or for sexual life the Sexual Satisfaction Scale for Women (SSS-W) (Meston 2005).
- Satisfaction with change of male to female body characteristics, as measured with validated instruments
- Adverse events specific to hormone therapy, including serious adverse events

Secondary outcomes

- Severity of gender dysphoria/gender incongruence, e.g. as measured with the Utrecht Gender Dysphoria Scale (UGDS) (Schneider 2016)
- Measures of specific body changes, including:
 - * breast size, e.g. by measurement of bust girth;
 - * skin thickness, e.g. by echographic measurement (Laurent 2007);
 - * skin sebum production, e.g. as measured by three-hour sebum collection with absorbent paper (Downing 1981; Giltay 2008; Ezerskaia 2016); and
 - * hair growth, including hair density, diameter, growth rate and anagen/telogen ratio (Giltay 2000; Hoffmann 2013).
- Incidence or severity of depression.

We did not include surrogate outcomes, such as serum hormone levels (e.g. 17-beta-estradiol or testosterone). While these measures can help with monitoring the progress of hormone therapy, they are of little interest of themselves, especially since individuals require varying levels of these hormones to achieve a certain level of feminisation (Gooren 2017).

Search methods for identification of studies

Electronic searches

We searched the following electronic databases for relevant trials up to 19 December 2019 with no restrictions based on language of publication, date of publication, or publication status:

- MEDLINE via PubMed
- Cochrane Central Register of Controlled Trials (CENTRAL)
- Embase
- Biosis Preview
- PsycINFO
- PSYNDEX

Our search strategy is outlined in Appendix 1. We have successfully tested the screening methods for abstracts and titles.

Searching other resources

Had we identified any eligible studies through the electronic searches above we would have searched the reference lists of these in order to find additional relevant studies. We also searched the scientific abstracts of the last two meetings of each of the following organisations:

- American Association of Clinical Endocrinologists
- American Society of Andrology
- Berufsverband der deutschen Endokrinologen (Professional Association of the German Endocrinologists)
- Berufsverband der Frauenärzte e.V. (Professional Association of the Gynaecologists)
- Dachverband Reproduktionsbiologie und Medizin e.V. (Federal Association Reproductive Biology and Medicine)
- Deutsche Gesellschaft für Endokrinologie (German Society for Endocrinology)
- Deutsche Gesellschaft für Gynäkologie und Geburtshilfe (German Society for Gynaecology and Obstetrics)
- Endocrine Society
- European Society of Gynaecological Oncology
- European Thyroid Association
- Nordrhein-Westfälische Gesellschaft für Endokrinologie und Diabetologie (North Rhine-Westphalian Society for Endocrinology and Diabetology)
- Royal College of Obstetricians and Gynaecologists
- Society for Endocrinology
- Society for Gynaecologic Investigation

We also searched the following grey literature databases:

- The New York Academy of Medicine Grey Literature Report (www.greylit.org/)
- OAlster (www.oclc.org/oalster/en.html)
- OpenGrey (www.opengrey.eu/)

Finally, in order to identify completed but unpublished or ongoing studies, we searched the following trial registries.

- ClinicalTrials.gov (www.clinicaltrials.gov/)
- metaRegister of Controlled Trials (mRCT; www.controlledtrials.com/mrct/)

- World Health Organization (WHO) International Clinical Trials Registry Platform (ICTRP) Search Portal (www.who.int/trialsearch/)
- Drugs@FDA (www.accessdata.fda.gov/scripts/cder/drugsatfda/)
- European Public Assessment Reports (EPAR; www.ema.europa.eu/ema/index.jsp?curi=pages/medicines/landing/epar_search.jsp)

We contacted fifteen manufacturers of hormonal agents and experts in the field to identify unpublished or ongoing trials.

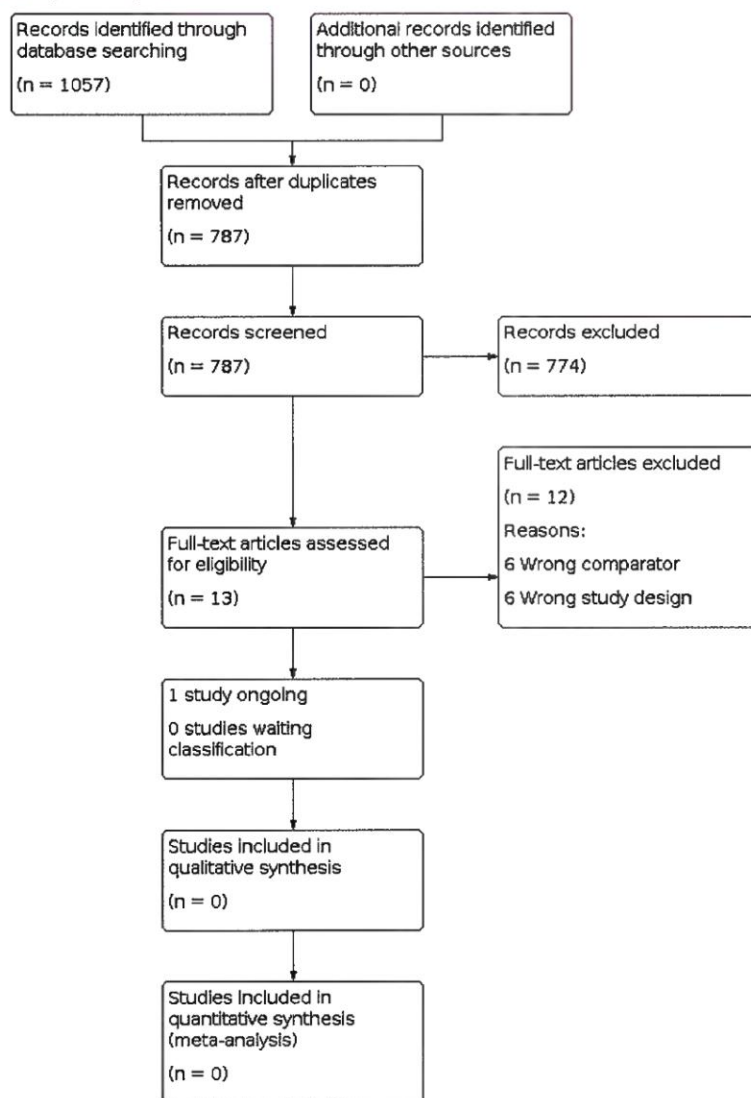

Data collection and analysis

Selection of studies

We used the reference management tool Covidence to identify and remove potential duplicate records of relevant studies (www.covidence.org). Two review authors (AKU and MHE)

independently scanned titles and abstracts of the remaining records to compile a list of potential papers to potentially be included in the review. After this, the same review authors investigated the references in detail (as full text articles or matched records to studies), and categorised these as 'included studies,' 'excluded studies,' 'studies awaiting classification' and 'ongoing studies.' We executed this task in accordance with the criteria provided in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011a). If there had been discrepancies or if a consensus could not be reached, a third review author would have adjudicated (CHA). There were no disagreements that could not be thus resolved. Had this been the case, we would have designated the study as 'awaiting classification' and contacted the study authors for clarification. We listed studies excluded during the full text review stage, and documented the reasons for exclusion in *Characteristics of excluded studies*. We included an adapted PRISMA flow diagram outlining the study selection process (Moher 2009) (Figure 1).

Figure 1. Study Flow Diagram

Data extraction and management

If we had found relevant studies, two review authors (AKU and MHE) would have extracted data from all studies deemed eligible for inclusion independently, with the help of a standardized data extraction form that would have been pilot tested according to Chapter 7 of the *Cochrane Handbook* (Higgins 2011a). We have used Google Spreadsheets to manage all data gathered.

We would have collected data on the following items:

- General information on the study: first author, date of publication, study dates, publication type (full text article, abstract, unpublished), citation.
- Study methods: study design (e.g. parallel, factorial), number of study arms, study setting (single institution, multi-centre national, multi-centre international), study location, and length of follow-up.
- Participant characteristics: study inclusion/exclusion criteria, age (mean/median with range), ethnic distribution, number of participants randomised and included in analysis, participants lost to follow-up.
- Interventions: type of hormonal agents (for example CPA, estradiol, progesterone, spironolactone), dose, administration route, dosing schedule and any other associated therapies. We would have extracted data on the sample size for each intervention group.
- Outcomes: definition and method of assessment for each outcome (including the adverse event classification system used in individual studies), as well as any relevant subgroups. We would have extracted the number of events and participants per treatment group for dichotomous outcomes. We would also extract the mean, standard deviation or median and range, and number of participants per treatment group for continuous outcomes.
- Study funding sources.
- Declarations of potential conflicts of interest reported by study authors.

For each included study, we would have extracted the outcome data relevant for this review, and which would be required for the calculation of summary statistics and measures of variance. If there had been disagreements, we would have resolved them by discussion. If necessary, we would have consulted a third review author (CHA). We provided key information about potentially relevant ongoing studies, including trial identifiers, in the table of *Characteristics of ongoing studies*. We would have attempted to contact authors of included studies to obtain missing key data if needed.

Assessment of risk of bias in included studies

If relevant studies had been found, two review authors (AKU and MHE) would have examined all included studies to assess risk of bias (assessment of methodological quality) independently. We would have used the Cochrane 'Risk of bias' tool for assessing risk of bias in RCTs, as described in the *Cochrane Handbook* (Higgins 2011b). We would have resolved disagreements by consensus or by consulting a third review author (CHA). Our summary judgement would have included a rating (low, high or unclear risk of bias) for each domain (Higgins 2011b). We would have assessed the risk of bias for the following domains:

- Random sequence generation
- Allocation concealment
- Blinding of participants and personnel
- Blinding of outcome assessment
- Incomplete outcome data
- Selective reporting
- Other bias

We would have evaluated the risks of performance bias (blinding of participants and personnel) and detection bias (blinding of outcome assessment) separately for each outcome.

For any relevant cohort studies we would have used the ROBINS-I tool to assess risk of bias (Sterne 2016). We would have assessed each individual study in accordance with the guidance, documenting the results using a spreadsheet and providing details in 'Risk of bias' tables. We would have documented the reasons for our judgements, and would have included relevant quotations from the full-text articles or from information about the study provided by authors in the notes section of the 'Risk of bias' tables. We would have summarised the risk of bias across domains for each primary outcome in every included study, as well as across studies and domains for each primary outcome.

Measures of treatment effect

Dichotomous data

We planned to summarise dichotomous data using risk ratios (RRs), reported with 95% confidence intervals (CIs).

Continuous data

For continuous outcomes with a standard measure, we would have summarised the obtained data as mean differences (MDs) with 95% CIs. For continuous outcomes without a standard measure, we would have summarised data as standardized mean differences (SMDs) with 95% CIs. Alternatively, if the mean value and variance were missing, we would have estimated them using the methods described in Hozo 2005, which allows estimations for mean value and variance of a sample when only the median, range and size of the sample are known. We would also have considered the guidance in the *Cochrane Handbook* where appropriate (Higgins 2011c).

Unit of analysis issues

We planned to treat recurring events in individual participants as single events occurring in one participant (e.g. three episodes of major depressive disorder in one participant would have been recorded as one participant with major depressive disorder). We did not expect to include studies with interventions delivered at the cluster level.

Dealing with missing data

For studies with missing data, we would have followed the recommendations of the *Cochrane Handbook* (Higgins 2011d). We would have collected dropout rates for each study group and would have reported these in the 'Risk of bias' table. Our preferred option would have been to contact study authors in cases of missing data or statistics that were not due to participant dropout (e.g. missing statistics such as standard deviation (SD)). If missing outcome data were not provided, then we would have attempted to impute

data where possible and appropriate, and conduct sensitivity analyses to assess the effect of this on the analysis. However, where imputation is not appropriate, we would not have included the study in the respective meta-analysis, and would have discussed the potential impact of this in the text of the review. In the case of participants lost to follow-up, we would have performed meta-analyses on an intention-to-treat basis. We would have performed sensitivity analyses, excluding studies with missing outcome data, to evaluate the impact of missing data. We would have discussed the potential impact of missing data on review findings in the 'Discussion' section of the full review, using a summary table if appropriate.

Assessment of heterogeneity

We would have compared the characteristics of included studies to identify heterogeneity of content or methodology, and to determine the feasibility of performing a meta-analysis. We would have deemed meta-analyses unsuitable in cases where there was substantial content-related or methodological heterogeneity across studies. Instead, we would have used a narrative approach to data synthesis. Had meta-analyses been deemed appropriate, we would have assessed statistical heterogeneity by visually inspecting the scatter of individual study effect estimates on forest plots and by calculating the I^2 statistic (Higgins 2011c), which gives the percentage of variability in effect estimations that can be attributed to heterogeneity rather than to chance. We would have considered an I^2 of more than 50% to represent substantial heterogeneity. In the case of statistical heterogeneity, we would have conducted the prespecified subgroup and sensitivity analyses described below to investigate the source.

Assessment of reporting biases

If we had included 10 or more studies that investigated the same outcome, we would have used funnel plots to assess small-study effects and publication bias. Given that several explanations are possible for funnel plot asymmetry, we would have interpreted results carefully (Sterne 2011).

Data synthesis

Had we identified any eligible studies, we would have provided a narrative summary of the included studies. We would also have conducted meta-analyses of RCTs for all relevant outcomes, where possible, using data from studies that 1) compared the actual hormone therapy-relevant agents or combinations of agents to placebo, and 2) compared the actual hormone therapy-relevant agents or combinations of agents to other hormone therapy-agents or combinations of agents. Studies comparing two variations on the intervention would have been pooled separately to studies comparing the intervention to placebo. However, if there had been significant variability in the definition of outcomes across trials, we would have decided not to pool data.

Had we conducted meta-analyses, we would have used the Mantel-Haenszel approach to combine dichotomous data and calculate RRs with 95% CIs (Higgins 2011c). For continuous outcomes (e.g. quality of life) we would have calculated MDs or SMDs, with 95% CIs, using the inverse variance approach. Had studies reported the same outcome measure but some studies had reported data on the change from baseline (e.g. mean values and standard deviations) and others for final measurements of outcomes, they would have been placed in subgroups in the meta-analysis and

pooled according to guidance in the *Cochrane Handbook* (Higgins 2011c).

For meta-analyses, we would have used a random-effects model, expecting the true effects to be related, but not the same, across all studies. We would have interpreted random-effects meta-analyses with due consideration of the whole distribution of effects, ideally by presenting a prediction interval (Higgins 2009). A prediction interval specifies a predicted range for the true treatment effect in an individual study (Riley 2011). In addition, we would have performed statistical analyses according to the statistical guidelines contained in the *Cochrane Handbook* (Higgins 2011c).

We would have summarised outcome data from cohort studies (e.g. change scores) narratively.

Subgroup analysis and investigation of heterogeneity

Wherever possible, we would have considered subgroup analyses that are structured by the following characteristics.

- Type of application of intervention (oral, transdermal, intramuscular, subcutaneous)
- Orchiectomy before or during hormone therapy

The justification for these analyses is as follows. Pharmacokinetic mechanisms lead to significant differences in the absorption and metabolism of an active substance depending on the type of application. Therefore, we would, if possible, have formed appropriate subgroups based on the application method of the intervention. Also, patients who have undergone an orchiectomy could have different outcomes than those patients without orchiectomy (Defreyne 2017).

Sensitivity analysis

We would have conducted sensitivity analyses to investigate any potential effect of removing studies judged to be at high risk of bias from meta-analyses. We would have classified studies as being at high risk of bias overall if one or more domains were judged to be at high risk. If appropriate, we would also have conducted sensitivity analyses excluding studies with missing outcome data, or where missing data have been imputed by the review author team. We would also have conducted a sensitivity analysis to compare a fixed-effect model to a random effects model where the studies in a meta-analysis appear more homogeneous than expected.

Summary of findings and assessment of the certainty of the evidence

Following standard Cochrane methodology, had we identified any included studies, we would have created a 'Summary of findings' table for all three primary outcomes. Also following standard Cochrane methodology, we would have used the five GRADE considerations (risk of bias, consistency of effect, imprecision, indirectness and publication bias) to assess the quality of the body of evidence for each outcome, and to draw conclusions about the quality of evidence within the text of the review.

RESULTS

Description of studies

Results of the search

We conducted our searches on 18 January 2019 and updated them on 19 December 2019. Through the database searches, we identified a total of 1057 references. After removing duplicates, we screened the titles and abstracts of 787 references. Through this screening, we identified 13 studies to assess as full text articles. We fully inspected these articles, and excluded 12 studies. The remaining study was still ongoing. Therefore, we did not include any studies in this review (Figure 1).

Of the manufacturers and experts in the field whom we contacted, 15 responded but did not report any additional studies.

Included studies

None of the reports retrieved met the inclusion criteria for this review. Suggestions for future studies are given in Table 1

Excluded studies

We excluded all 12 of the full-text articles that we had assessed for eligibility, either because they used an ineligible comparator or because they used an ineligible study design. See [Characteristics of excluded studies](#) for further details.

Ongoing studies

We identified one ongoing RCT in Thailand, comparing spironolactone with CPA (Krusean 2019). This study started in April 2019. We describe this study in [Characteristics of ongoing studies](#).

Risk of bias in included studies

As no studies met the inclusion criteria, it was not possible to assess risk of bias.

Effects of interventions

As no studies met the inclusion criteria, we were unable to calculate any effects of the interventions.

DISCUSSION

Summary of main results

No study met the inclusion criteria for this review. A total of 13 potentially eligible studies were identified, but ultimately all but one was excluded after we assessed the full text articles. The one remaining RCT is ongoing, and we are awaiting its publication (Krusean 2019). We conducted a comprehensive search to identify eligible studies for inclusion in this review. Despite more than four decades of ongoing efforts to improve the quality of hormone therapy for women in transition, we found that no RCTs or suitable cohort studies have yet been conducted to investigate the efficacy and safety of hormonal treatment approaches for transgender women in transition.

Overall completeness and applicability of evidence

The evidence is incomplete because no studies met the inclusion criteria for the review. This lack of studies shows a gap between current clinical practice and clinical research, which has

been repeatedly emphasised (Hembree 2009; Hembree 2017). If hormone therapy is highly valued in the treatment of gender dysphoria (Hembree 2009; WPATH 2011; Hembree 2017), then this raises the question: why are there no RCTs or appropriate cohort studies for this clinical condition? There is also an ethical need for research into the efficacy and safety of hormone therapy, particularly comparing combination therapy with CPA/estradiol and spironolactone/estradiol to monotherapy with estradiol alone. In view of the reported but rather alarming side-effect profiles of CPA and spironolactone in other populations (De Bastos 2014; Khan 2016; PG12 2019), long-term clinical studies that aim to achieve adequate outcomes are urgently needed for the population of transgender women in transition. The lack of reliable data on hormone therapy for transitioning transgender women should encourage the development of well-planned RCTs and cohort studies to evaluate widespread empirical practice in the treatment of gender dysphoria.

The most common reason for the exclusion of studies from this review was the lack of a control group. We excluded some studies because they did not meet the eligibility requirements for study design (e.g. case series or case-control studies). Further, interventions were not clearly defined.

Among guideline developers in the field of transgender medicine, it has been discussed in recent years why the available evidence remains limited (Deutsch 2016a Reilly 2019). Deutsch 2016a has identified three main reasons, which they believe have hindered the development of evidence based healthcare guidelines. Firstly, a lack of research funding and institutional stigma means that the evidence currently centres around less robust study designs, such as retrospective studies, case series, and individual case reports (Bockting 2016 Reisner 2016a); secondly variation in the collection of gender identity data in observational data sets makes it difficult to identify relevant populations and monitor their health outcomes (Deutsch 2013 Bauer 2009); and finally, academic programmes focused on transgender medicine are in their infancy and few exist (Reisner 2016b), meaning there is a general lack of research and training on this topic.

Against this background, methodological problems such as inconsistent and missing comparison groups, uncontrolled confounding factors, small sample size, short follow-up time and difficulties in recording and evaluating a broad spectrum of health outcomes (physical and mental health, social functioning and QoL) have become apparent in hormone therapy (Deutsch 2016b). The performance of RCTs is controversial, especially with regard to placebo studies, and ethical and methodological objections have been raised (e.g. violation of the principle of equipoise, Miller 2003). However, the positive research potential of active-controlled RCTs is acknowledged, in order to compare different types, dosages and methods of administration of active treatments. Overall, there is a trend in the discussion to favour not only RCTs and quasi-RCTs, but also high-quality cohort studies conducted in a network of health centres, hospitals and practices (Deutsch 2016a; Deutsch 2016b).

Quality of the evidence

We could not appraise the quality of the evidence because no studies met our review's inclusion criteria.

Potential biases in the review process

We consider our search to have been consistent and comprehensive (including the fifteen contacts with manufacturers and experts in the field). At each stage, the review authors independently applied the inclusion criteria before comparing their judgements. Reliability testing was performed in the screening phase. Even though we were unable to test for publication bias, we think it is unlikely that there are studies that have been conducted but remained unpublished. The experts in the field we interviewed believed that there was a general lack of research activity by treatment manufacturers, and considered it very likely that no phase IV studies have ever been conducted in this population. For example, one expert stated that there was probably "nothing to be kept secret."

Agreements and disagreements with other studies or reviews

There are currently no systematic reviews in the Cochrane Library that evaluate the effectiveness of hormone therapy for transgender women in transition, nor are there systematic reviews that evaluate the clinical and economic impact of hormone therapy on transgender women in transition. The Endocrine Society's 2009 and 2017 guidelines addressed endocrine treatment of gender-dysphoric/gender-incongruent persons (Hembree 2009; Hembree 2017). The literature search included in these guidelines did not identify any RCTs of hormone therapy in transitioning transgender women. In the context of the preparation of UK National Health Service (NHS) guidelines (PG12 2019), the NHS Guideline Panel also found no RCTs. However, PG12 2019 includes a recommendation for the prescription of hormone therapy for transitioning transgender women.

Of the potentially relevant studies we excluded, some reported on relevant questions. Asscheman 2011 focused on the important outcome of mortality. Fisher 2016 investigated the important relationship between hormone therapy-related body changes and psychobiological well-being. Giltay 2000 focused on body related outcomes such as hormone therapy's effects on the skin (hair growth rate, density, and shaft diameter by image analysis; and sebum production). Toorians 2003 focused on the outcomes of different interventions (estradiol alone compared with combination therapy estradiol and antiandrogens). Miles 2006 was based on a cross-over design with the intention of comparing groups of individuals on and off oestrogen. Due to the reported deficits, we excluded these studies, although they addressed important questions.

AUTHORS' CONCLUSIONS

Implications for practice

We found insufficient evidence to determine the efficacy or safety of hormonal treatment approaches (estradiol alone or

in combination with cyproterone acetate or spironolactone) for transgender women in transition. The evidence is very incomplete, demonstrating a gap between current clinical practice and clinical research.

Implications for research

This systematic review has shown that well-designed, sufficiently robust randomised controlled trials (RCTs) and controlled-cohort studies do not exist, and are needed, to assess the benefits and harms of hormone therapies (used alone or in combination) for transgender women in transition. The following questions should be addressed via RCTs and cohort studies:

1. What are the short-, medium-, and long-term effects (including adverse effects, benefits, and prognoses) of estradiol therapy alone, as opposed to combination therapy using estradiol together with cyproterone acetate or spironolactone?
2. What is the short-, medium-, and long-term clinical efficacy of hormone therapy when applied orally, transdermally, and intramuscularly?

Table 1 presents design components that we suggest could be used in future studies. Studies should be structured and reported according to the CONSORT Statement or the STROBE Statement in order to improve the quality of reporting on efficacy and to obtain better reports on harms in clinical research (von Elm 2007; Schulz 2010). There is an urgent need for research in this area, not least for ethical reasons.

We will include non-controlled cohort studies in the next iteration of this review, as this review has demonstrated that this is the highest quality evidence currently available in the field. We will take methodological limitations into account when doing so.

ACKNOWLEDGEMENTS

We would like to acknowledge the support of Dr. Jonathan Livingstone-Banks, Dr. Nicola Lindson, and Dr. Paul Aveyard from the Tobacco Addiction Group, as well as Dr. Erik von Elm from Cochrane Switzerland, whom we consulted in preparing this review.

We greatly appreciate Dr. Alissa Jones Nelson's support in reviewing the spelling and grammar of this review. We also gratefully acknowledge peer review comments from Igor Grabovac, Department of Social and Preventive Medicine, Centre for Public Health, Medical University of Vienna, Vienna, Austria and Dr. Barbara Nussbaumer-Streit, Cochrane Austria, Department for Evidence-based Medicine and Evaluation, Danube-University Krems, Krems, Austria, and consumer review comments from Sarah Stephenson-Hunter.

CHARACTERISTICS OF STUDIES

Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion
Asscheman 2011	Mortality rates in transgender people receiving long-term cross-sex hormones. A cohort study. Adequate controls are missing. Interventions are not clearly defined
Colizzi 2015	Increased prevalence of metabolic syndrome among individuals with gender dysphoria treated by cross-sex hormonal treatment. Study without adequate comparator group.
Figuera 2018	Hormone therapy has been associated with changes in bone and lean/fat mass. This study assessed bone mineral density, appendicular lean mass, and total fat mass in transwomen undergoing cross-sex hormone therapy. Study without adequate comparator group.
Fisher 2014	This study aimed to assess differences in body uneasiness and psychiatric symptoms between gender dysphoria clients taking hormone therapy and those not taking hormones (no hormone therapy). A second aim was to assess whether length of hormone treatment and daily dose provided an explanation for levels of body uneasiness and psychiatric symptoms. Cross-sectional design.
Fisher 2016	The objective of the study was to assess whether hormone therapy-related body changes affect psychobiological well-being in gender dysphoria. Study without adequate comparator group.
Giltay 2000	Hormone therapy effects on the skin (hair growth rate, density, and shaft diameter by image analysis; and sebum production) of transsexual patients receiving cross-sex hormones. It is a case series, adequate controls are missing.
Haraldsen 2005	Hormone therapy effects on cognitive performance. Study without adequate comparator group.
Haraldsen 2007	The effects of cross-sex hormones on bone metabolism (bone mineral density, total body fat, total lean body mass) in patients with early onset gender identity disorder. Study without adequate comparator group.
Miles 2006	The study was designed to examine associations between oestrogen and cognition (memory, including visual, spatial, object and location memory, other cognitive abilities that show reliable sex

Study	Reason for exclusion
	differences, including verbal and visual-spatial abilities, and mood variables). The cross-over design used was comparative, but did not used randomization or quasi-randomisation.
Schlatterer 1998	This follow-up study was carried out to validate the effectiveness of cross-gender hormone therapy embedded in a multistep treatment concept for transgender patients. Study without adequate comparator group. This study lacks adequate controls.
Toorians 2003	To find an explanation for the different thrombotic risks of oral ethinyl estradiol and transdermal 17-beta-estradiol use, the researchers compared the effects of treatment of male-to-female transgender people with cyproterone acetate only, and with cyproterone acetate in combination with transdermal 17-beta-estradiol, oral ethinyl estradiol, or oral 17-beta-estradiol on a number of haemostatic variables. There is no adequate control group.
Van Goozen 1995	Effects of sex hormones to the establishment of gender differences in behaviour, a large battery of tests on aggression, sexual motivation and cognitive functioning was administered twice: shortly before and three months after the start of cross-sex hormone treatment. The study does not have an adequate comparator group.

Characteristics of ongoing studies [ordered by study ID]

Krasean 2019

Study name	Anti-androgenic effects comparison between cyproterone acetate and spironolactone in transgender women: a randomised controlled trial (Trial ID: TCTR20190404001)
Methods	Allocation: randomised Study design: randomised controlled trial Control: active Study endpoint classification: efficacy study Intervention model: Parallel Number of arms: 2 Masking: double blind (Masked roles: participant caregiver, investigator) Primary purpose: treatment Study phase: phase 4
Participants	Gender: male Age limit: minimum 18 years: maximum 40 years Condition: Gender dysphoria patients diagnosed from DSM V Male to female transgender Not undergone orchidectomy No psychological disease or mental disability
Interventions	Arm 1: Intervention name: cyproterone acetate Type: active comparator

Krasean 2019 (Continued)

Classification: drug

Descriptions: participants (gender dysphoria patients) will receive estradiol valerate (4 mg daily) combined with cyproterone acetate (25 mg daily) for cross-sex hormone treatment.

Arm: 2

Intervention name: spironolactone

Type: experimental

Classification: drug

Descriptions: participants (gender dysphoria patients) will be received estradiol valerate (4 mg daily) combined with spironolactone (100 mg daily) for cross-sex hormone treatment.

Outcomes

Primary outcome(s):

Outcome name: testosterone level

Measurement: Electrochemiluminescent Immunoassay (ECLIA) of total testosterone level

Time point: three months after intervention

Safety issue: no

Key secondary outcomes:

Outcome name: physical and metabolic changes

Measurement: physical examination, metabolic profile parameters

Time point: three months after intervention

Safety Issue: no

Starting date

April 3, 2019 (estimated end date: June 16, 2020)

Review first published: Issue 11, 2020

CONTRIBUTIONS OF AUTHORS

All authors contributed to the Abstract, Background, Methods, Results, Discussion, and Authors' conclusions. Claudia Haupt, Alexia Kutschmar and Miriam Henke conducted the study selection.

DECLARATIONS OF INTEREST

Claudia Haupt declares no competing interest.

Miriam Henke declares no competing interest.

Alexia Kutschmar declares no competing interest.

Birgit Hauser (BH) declares no competing interest. BH is a clinical practitioner in private practice, who also prescribes hormone therapy.

Sandra Baldinger declares no competing interest.

Sarah Rafaela Saenz declares no competing interest.

Gerhard Schreiber declares no competing interest.

None of the review authors' incomes depends on the prescription of drugs. The review authors did not receive any financial support for this project, but paid for all related expenses themselves. They worked voluntarily and free of charge.

Gender dysphoria in children and adolescents: an inventory of the literature

A systematic scoping review

SBU POLICY SUPPORT | EVIDENCE ASSESSMENT TO SUPPORT DECISION MAKERS IN SWEDEN

DECEMBER 2019 | WWW.SBU.SE/307E

Executive summary

This report was commissioned by the Swedish government and is a scoping review of the literature on gender dysphoria in children and adolescents. The report can be a basis for further evaluation of risk of bias and evidence.

Conclusions

- ▶ We have not found any scientific studies which explains the increase in incidence in children and adolescents who seek the health care because of gender dysphoria.
- ▶ We have not found any studies on changes in prevalence of gender dysphoria over calendar time, nor any studies on factors that can affect the societal acceptance of seeking for gender dysphoria.
- ▶ There are few studies on gender affirming surgery in general in children and adolescents and only single studies on gender affirming genital surgery.
- ▶ Studies on long-term effects of gender affirming treatment in children and adolescents are few, especially for the groups that have appeared during the recent decennium.
- ▶ The scientific activity in the field seems high. A large part of the identified studies are published during 2018 and 2019.
- ▶ Almost all identified studies are observational, some with controls and some with evaluation before and after gender affirming treatment. No relevant randomised controlled trials in children and adolescents were found.

- ▶ We have not found any composed national information from Sweden on:
 - the proportion of those who seek health care for gender dysphoria that get a formal diagnosis
 - the proportion starting endocrine treatment to delay puberty
 - the proportion starting gender affirming hormonal treatment
 - the proportion subjected to different gender affirming surgery

Background

The number of persons below age 18 who seeks the health care for gender dysphoria in Sweden has increased during the last decade. There is a debate as to why this happens and how it should be managed.

Aim

To assess the scientific literature for explanations of the increased number of children and adolescents seeking for gender dysphoria and to make an inventory of the literature on management and long-term effects.

Method

The following questions were assessed.

Are there any scientific studies explaining the increase in numbers seeking for gender dysphoria?

Population: Children and adolescents with gender dysphoria up to 18 years of age.

Intervention: Not applicable.

Control: Not applicable.

Outcome: Studies on incidence and prevalence of gender dysphoria and pattern of self-referral or referral.

Are there any scientific studies on long-term effects of treatment for gender dysphoria?

Population: Persons with gender dysphoria.

Intervention: Treatment for gender dysphoria.

Control: Any.

Outcome: Studies reporting long-term effects such as mental health, suicide attempts, suicide, cardiovascular effects, cancer development, bone health and regrets.

What scientific papers on diagnosis and treatment of gender dysphoria has been published after the National Board of Health and Welfare in Sweden issued its national support for managing children and adolescents with gender dysphoria in 2015?

Population: Children and adolescents with gender dysphoria up to 18 years of age.

Intervention: Diagnosis and treatment for gender dysphoria.

Control: Any.

Outcome: Studies on diagnosis and treatment.

This review is limited to peer reviewed papers with primary data and systematic reviews following PRISMA-standards. Case studies, meeting abstracts and editorials were not included. Only studies written in English or Scandinavian languages were eligible.

A structured systematic literature search in the following databases CINAHL (EBSCO), Cochrane Library (Wiley), EMBASE (Embase.com), PsycINFO (EBSCO), PubMed (NLM), Scopus (Elsevier), SocINDEX (EBSCO). The searches were finalised September 19, 2019.

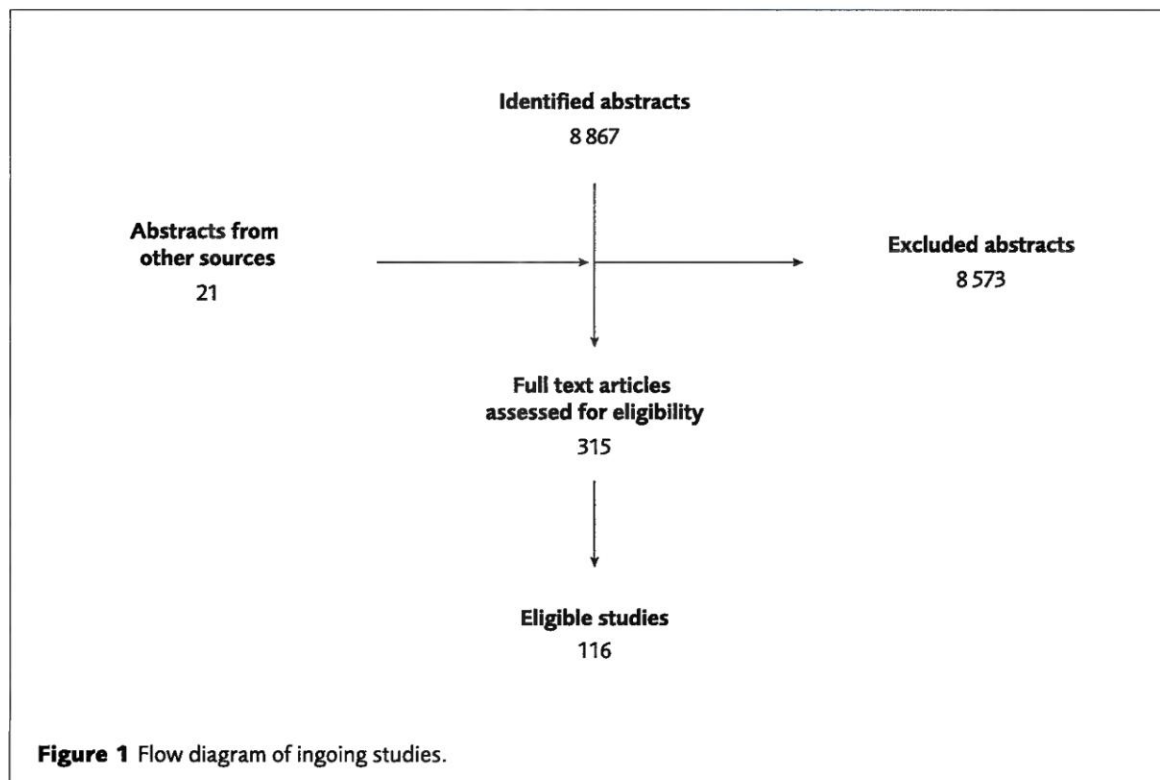

The studies were assessed for their relevance to the questions by two reviewers independently. Assessment of risk of bias, compilation of data or grading of evidence was not done.

Results/discussion

No studies explaining the increase of children and adolescents seeking for gender dysphoria were identified. The literature on management and long-term effects in children and adolescents is sparse, particularly regarding gender affirming surgery. All identified studies are observational, and few are controlled or followed-up over time. Much of the data in the literature are from the University Medical Centre in Amsterdam based on their management tradition. A large part of the literature that was considered relevant was published during 2018 and 2019.

Summary of a recommendation by COHERE 16.6.2020
Finland

Medical treatment methods for dysphoria associated with variations in gender identity in minors – recommendation

In its meeting on 11 June 2020, the Council for Choices in Health Care in Finland (COHERE Finland) adopted a recommendation on medical treatment methods for dysphoria associated with variations in the gender identity of minors

The recommendation clarifies the roles of different healthcare operators in a situation where a minor is uncertain about their gender identity. The recommendation presents the medical treatment methods that fall within the range of public healthcare services when it comes to the medical treatment of gender dysphoria in minors.

In COHERE's view, psychosocial support should be provided in school and student healthcare and in primary healthcare for the treatment of gender dysphoria due to variations in gender identity in minors, and there must be sufficient competency to provide such support. Consultation with a child or youth psychiatrist and the necessary psychiatric treatment and psychotherapy should be arranged locally according to the level of treatment needed. If a child or young person experiencing gender-related anxiety has other simultaneous psychiatric symptoms requiring specialised medical care, treatment according to the nature and severity of the disorder must be arranged within the services of their own region, as no conclusions can be drawn on the stability of gender identity during the period of disorder caused by a psychiatric illness with symptoms that hamper development.

In Finland, the diagnostics of gender identity variation, the assessment of the need for medical treatments and the planning of their implementation are centralised by law in the multi-professional research clinics of Helsinki University Central Hospital (HUS) and Tampere University Hospital (TAYS). The consultation, evaluation periods and treatments provided by the TAYS or HUS working group on the gender identity of minors shall be carried out in accordance with the following principles.

Children who have not started puberty and are experiencing persistent, severe anxiety related to gender conflict and/or identification as the other sex may be sent for a consultation visit to the research group on the gender identity of minors at TAYS or HUS. Any need for support beyond the consultation visit or need for other psychiatric treatment should be addressed by local services according to the nature and severity of the problem.

If a child is diagnosed prior to the onset of puberty with a persistent experience of identifying as the other sex and shows symptoms of gender-related anxiety, which increases in severity in puberty, the child can be guided at the onset of puberty to the research group on the gender identity of minors at TAYS or HUS for an assessment of the need for treatment to suppress puberty. Based on these assessments, puberty suppression treatment may be initiated on a case-by-case basis after careful consideration and appropriate diagnostic examinations if the medical indications for the treatment are present and there are no contraindications. Therapeutic amenorrhea, i.e. prevention of menstruation, is also medically possible.

A young person who has already undergone puberty can be sent to the research clinic on the gender identity of minors at TAYS or HUS for extensive gender identity studies if the variation in gender identity and related dysphoria do not reflect the temporary search for identity typical of the development stage of adolescence and do not subside once the young person has had the opportunity to reflect on their identity but rather their identity and personality development appear to be stable.

Summary of a recommendation by COHERE 16.6.2020
Finland

Based on thorough, case-by-case consideration, the initiation of hormonal interventions that alter sex characteristics may be considered before the person is 18 years of age only if it can be ascertained that their identity as the other sex is of a permanent nature and causes severe dysphoria. In addition, it must be confirmed that the young person is able to understand the significance of irreversible treatments and the benefits and disadvantages associated with lifelong hormone therapy, and that no contraindications are present.

If a young person experiencing gender-related anxiety has experienced or is simultaneously experiencing psychiatric symptoms requiring specialised medical care, a gender identity assessment may be considered if the need for it continues after the other psychiatric symptoms have ceased and adolescent development is progressing normally. In this case, a young person can be sent by the specialised youth psychiatric care in their region for an extensive gender identity study by the TAYS or HUS research group on the gender identity of minors, which will begin the diagnostic studies. Based on the results of the studies, the need for and timeliness of medically justified treatments will be assessed individually.

Surgical treatments are not part of the treatment methods for dysphoria caused by gender-related conflicts in minors. The initiation and monitoring of hormonal treatments must be centralised at the research clinics on gender identity at HUS and TAYS.

Research data on the treatment of dysphoria due to gender identity conflicts in minors is limited. COHERE considers that, moving forward, multi-professional clinics specialising in the diagnostics and treatment of gender identity conflicts at HUS and TAYS should collect extensive information on the diagnostic process and the effects of different treatment methods on the mental wellbeing, social capacity and quality of life of children and youth. There is also a need for more information on the disadvantages of procedures and on people who regret them.

The Council for Choices in Health Care in Finland (COHERE Finland) works in conjunction with the Ministry of Social Affairs and Health, and its task is to issue recommendations on services that should be included in the range of public health services. Further information: www.palveluvalikoima.fi.

Clinical and Ethical Considerations in the Treatment of Gender Dysphoric Children and Adolescents: When Doing Less Is Helping More

David Schwartz, Ph.D.

ABSTRACT

Through an analysis of recently published treatment protocols, research findings and clinical experience, and guided by the principle of “first, do no harm,” the author argues that the use of pharmacological and surgical interventions in the treatment of gender dysphoric youth, especially in light of what is known about the transience of cross-gender identification in children, is mistaken both clinically and ethically. He further argues that psychotherapy, neglected by most of those advocating pharmacological and surgical interventions, is the best treatment option for these patients. The author elaborates some of the modifications of psychotherapeutic technique with both patients and their parents that he has found to be most effective with this population.

I imagine that it is safe to say that the frequency with which you will encounter the word “gender” or “gender identity” – colloquially, in mass media, in clinical literature – has dramatically increased of late. When that happens, when previously uncommonly used terms proliferate rapidly across disciplines and media, as “gender” and “gender identity” have, you can bet that misunderstandings of the terms will soon be fueling controversy about them. This is no surprise: the more widely and frequently any term is used, the more likely it is for the occurrence of errors, or for the recruitment of the term for unintended or inappropriate purposes. It’s like a giant game of telephone. So I want to introduce what I have to say about gender *dysphoria* today, by defining “gender identity.” I am hoping to start fresh, so to speak, with a sense of what gender *is*, apart from the ways it has become entangled in cultural developments and controversies. I think a clear understanding of what gender and gender identity *are*, may go some distance toward establishing a best clinical approach to it. And I am concerned that the spread of a particular misunderstanding about what gender identity is, may be having significant negative consequences for clinical practice.

So what is gender identity? This is from William Byne (2010), an expert in the field, chief editor of a journal that focuses on the health issues of minority communities, and an eminent researcher: “*Gender identity* refers to the persistent sense of belonging to a particular gender category. In the majority of cases, this reduces to one’s sense of belonging to the male gender category (comprising boys and men) or the female gender category (comprising girls and women). **It is a sense of belonging.**” In other words, *gender identity* is psychological, made up of expectations and self-perceptions. Gender does not exist in the body or in any bodily structure or process. This is in contrast to *sex*, which is determined exclusively by bodily data: genitals and chromosomes. Gender exists in the mind, happily or dysphorically. Gender identity, like many high level psychological phenomena such as attachment and affection, has no known specific, demarcated correlate in the nervous system. It is experienced by the individual and by observers of an individual, mentally, as a subjectivity. Gender is an opinion about oneself that others may learn by observation. To put it starkly: if a person is not moving, speaking or clothed, it is not possible to **know** its gender. But, if she *acts* like a female, which is to say, like our cultural notion of a female, her gender is female. The philosopher, Judith Butler (1990) has put this succinctly: gender is a performance. And I will add: a performance that signifies a psychological condition, an intrapsychic condition. My emphasis on the psychological nature of gender should not be taken to diminish the well-known power of gender to influence a person’s experience and behavior, as any state of mind can do. But I underline the psychological nature of gender because the recent use of physical interventions in response to gender *dysphoria* – hormones, surgery, alterations of secondary sex characteristics – may have subtly altered our sense of what gender is. Those physical procedures may or may not help a person’s unhappiness with their sex or their gender, but they do not directly affect their gender. They can’t, because as with any other aspect of identity, i.e. a person’s sense of him or her self, the person has ultimate power over it. This principle of the autonomy of identity, of the individual’s power over their own sense of themselves, applies to gender, and is fundamental to all psychotherapeutic work and human growth.

So I ask you to keep in mind the purely psychological nature of gender and gender identity. I think the importance of this axiom will become plainer later, after I acquaint you with my intellectual and clinical journey into the treatment of gender dysphoria. To that I now turn.

About nine years ago Jack Drescher, a psychiatrist and psychoanalyst, and William Byne, the neuroanatomist mentioned above, were editing a volume on the treatment protocols of various leading clinical groups around the world that were providing services to, trans and gender dysphoric kids. They wanted multi-disciplinary commentaries on these treatment protocols – from philosophy, anthropology and, among other disciplines, from psychoanalysis. They asked me to comment from the perspective of psychoanalysis, and since I have long been concerned with the ways that gender affects human psychology for better and for worse, and I believe deeply in the psychoanalytic approach to mental health treatment, I agreed. I read the protocols and as much as possible, using videos and other material on the internet, familiarized myself with what was going on in the community of children who identified as transgender or who complained of gender dysphoria. Coincidentally, I was treating an eighteen year-old young woman who identified as *trans*, in her words. I was disturbed, provoked and stimulated by all of the material – the protocols, all but one of which were enthusiastic about encouraging the use of hormones, puberty blockers and surgery to facilitate early transitioning of kids with gender trouble, the videos of the kids and their parents, which were intriguing and very ambiguous, (how to interpret filmed performances that were made to persuade and provoke) and sometimes by my patient. I wrote a paper which reflected how troubling I found most of the treatment protocols to be. I was disturbed by what seemed to be a rush to surgical and pharmacological interventions with children and adolescents. I also noticed that in most of these treatment protocols, psychological treatment, i.e. psychotherapy, was very much neglected. After much stimulating dialogue with the editors, my paper (Schwartz, 2012) was published in the anachronistically titled *Journal of Homosexuality*. So I looked forward to getting a free copy of the journal and thought that was the end of it. Who was going to read this, in the *Journal of Homosexuality*, of all places, I naively thought. I thought maybe some, trans activists would call to read me the riot act because I was critical of the use of cross-sex hormones and surgery. Was I ever wrong. Apparently my commentary was picked up by various blogs and I started getting phone calls and e-

mails from literally all over the country; but *not from, trans activists*. Instead the calls came principally from parents of kids with gender trouble, and from therapists. These calls repeated a similar story: my kid thinks she's a boy, or says she's thinks she's, trans and she read on the internet, or talked to a school counselor who told her yes, you're probably trans, and so for her birthday she wants help getting T (testosterone) and a double mastectomy. Or, Someone gave us your paper or told us about it. Can you help us? With great reluctance (back then treating adolescents was not a specialty for me) I started to see the kids who lived nearby and their parents, and for some kids farther away, I used electronic media. What I seemed to have discovered, I suppose unsurprisingly, was that the treatment protocols on which I had commented in my article, which touted the value of hormones and surgery, were what parents of, trans kids were being offered as *standard treatment* much of the time. Clinics and some individual therapists, were describing themselves as "gender specialists," performing assessments that varied widely, but could be quite brief, sometimes a single session, and then declaring that a given child was indeed "trans," and urging parents to accept this and cooperate with the administration of hormones and plan on surgery. The parents who called me exhibited varying degrees of desperation. Apparently there wasn't much out there to resonate with their understandable reluctance to sign on with these recommendations. (My own informal polling of colleagues tells me that the average therapist thinks of themselves as "not knowing much about this," and are inclined to pass such patients on in one way or another.) The parents were often being encouraged to feel guilty for regarding these clinical suggestions with antipathy and dread. Their anxieties were often dismissed as "transphobia." Frequently school psychologists and pediatricians were accepting a simple, but for parents, disturbing, narrative: if a kid says they're, trans and they are not obviously psychotic, "affirm" it and they'll probably need surgery and hormones. Tell the parents that they have to adjust. These parents were very upset, had no place to turn, but knew, from what I had written, that I might present an alternative.

For me, these calls were an opportunity to go beyond theory and have a direct window into the community of children and young adolescents with gender trouble and their parents – an opportunity to know some of them first-hand and to see how the ideas I'd written about played out in the lives of actual families. Actually put my money where my mouth had been. I was also struck by the terrible dilemma these parents were facing: they were being offered a prescription by putative experts for the welfare of their children that went against their deepest instincts. So that's how I began this – but before telling you how it then went, I want to outline my central purpose for today. It is to make a few narrow, clinical points. They are narrow, first, in the sense of having to do exclusively with treatment: I am deliberately side-stepping any theoretical and political issues that the question of transgender experience in children raises. (For examples, what causes, trans phenomena, is it wrong to think of transgendered aspirations as pathological, and is there a "right" to hormones and surgery for those who want them?) Second, I am speaking only of *children and adolescents*, people whom we do not regard as capable of making treatment decisions for themselves, whom we consider to be at risk of suffering the consequences of poor judgments, judgments about themselves and about the world. We are their stewards, not their mouthpieces. We protect them and help them to grow, quite apart from their opinions, though not in disregard of them. Nothing I say today is meant to apply to adults. Adults are free to struggle with gender as they see fit whether that be in a radical manipulation of their bodies or simply in what they say. They are responsible for the consequences of their chosen methods of struggle, and for that, we must respect them. And perhaps I need to add, on the question of struggling with gender: nothing I say today should be construed as favoring gender conformity in either children or adults. (Later, I will take a strong position against certain interventions that some see as embodying gender flexibility. It is the specific interventions with children, not the flexibility, that I oppose.) Children are not free; we adults are responsible for the consequences of the choices they are *allowed* and encouraged to make. This may seem obvious, but as my story unfolds, and you hear the subtle ways that some would alter the appropriate asymmetry between adult and child freedoms, you may agree that it needs re-stating.

A second sense in which my argument is narrow, is that its central clinical recommendation is offered in service to one apparently unambitious, but bedrock principle of all clinical practice: First, do no harm. I define "harm" as physical or mental damage, which I would elaborate slightly to include a diminishing of known functionality. A further word about the principle of "do no harm." We will apply it best if we grasp this principle in its depth. To me, what lies behind the cryptic aphorism of *do no harm*, is an implicit injunction in favor of the humility that the limits of our knowledge mandates. We must be wary of the possibility of doing harm precisely because often, and especially often when we administer chemical agents, we don't know the real consequences of what we are doing. Consider the possibility of harm, because chemicals can be powerful and without carefully controlled longitudinal studies, we really don't know what we are instigating. To do no harm, enter an area of ignorance at a sharply reduced speed, with your hands in your pockets and your eyes open. And to do no harm, be frank with yourself and with your patient, with respect to what you know and don't know, and what cannot be known.

So my narrow purpose today is to persuade you that in the treatment of children and adolescents, no matter what the diagnosis, encouraging mastectomy, ovariectomy, uterine extirpation, penile disablement, tracheal shave, the prescription of hormones which are out of line with the genetic make-up of the child, or puberty blockers, are all clinical practices which run an unacceptably high risk of doing harm. I want to briefly highlight the use of puberty blockers, which I include in my list of high-risk treatments. Puberty blockers are pharmacological agents given to children that interfere with the action of testosterone and estrogen so that the emergence of secondary sex characteristics that usually accompanies the onset of puberty does not happen. Virtually all of those who promote physical interventions for gender dysphoric children point to the use of puberty blockers as a safe way for an uncertain child to have time to consider whether they want to go ahead with more irreversible procedures. They describe puberty blockers as providing a respite from the stress of puberty and a pause. This is mistaken on two counts: First, we do not have certainty about the harmful effects of puberty blockers as we do have for cross-sex hormone administration, because we do not have good longitudinal data on their effects in general. But we do know that puberty blockers adversely affect bone density, can instigate excessive height and adversely affect fertility. (Mahfouda et al., 2017). It is false to say that we know them to be physiologically benign. And second, what about the psychological consequences of this maneuver? The claim of providing a respite, or pause, suggests that puberty suppression is a benign, non-prejudicial move in the life of a gender dysphoric child. It seems to me that this is extremely misleading. Consider: what is the implicit message we give a child when we offer puberty blockers? We are validating the idea that the advent of puberty is a fearsome thing that calls for a prophylactic *medical* intervention. That is the last message I want to send to a gender dysphoric child. Advocates of the use of blockers argue that for some gender dysphoric children the onset of puberty with its incontrovertible news as to the sex of the subject, is so traumatic that the child *needs* such an intervention. They are taking the subjective narrative of the dysphoric child literally, and feeding it back to the child as a medicalized truth, reifying it and likely exacerbating his or her preoccupation with gender. And what about the social situation of the child who has undergone puberty suppression? Here is a child, side-by-side with other children of his or her own age who are showing secondary sex traits and behaving sexually, while he or she is not. To my knowledge no one has studied the ramifications of this psycho-social situation, but to me it hardly reads as a respite, with its potential to magnify difference and stigma, albeit in a suppressed form.

Puberty is challenging for all children, and for the child with conflict about gender it may be especially challenging. But it is not *intrinsically* traumatic to any child and I want to communicate to the child that, as with all inexorable developmental phenomena, it is manageable: you can do it, I'll help. Encourage ego strength; don't amplify fantasized vulnerability and anxiety. The encouragement of puberty blockers as an alleged pause, is ultimately the encouragement of hormones and surgery, just not openly. In fact, the clinical articles in Drescher and Byne's volume (2013), assert that most adolescents

who undergo puberty suppression do tend to proceed to transition away from their natal sex (Stein, 2013), in contrast to the fact that the large majority of gender dysphoric children in general do not (Singh et al., 2021). It would seem that the use of puberty blockers promotes transition.

You have no doubt noticed that I have gone out of my way to name the procedures that hormonal and surgical transitioning entails. I do this deliberately to avoid the obfuscating euphemisms which tend to hamper a clear view of what we are talking about. I recently reviewed a research paper by a group employing these procedures wherein, unsatisfied with the term “sex re-assignment surgery,” (what they were literally doing) they insisted on calling their procedures “gender-affirming surgery.” Unsurprisingly their research report was as misleading and prejudicial as their terminology. The proliferation of euphemisms in this area is noteworthy: mastectomy is “top surgery.” However you may regard the value of these procedures in a cost/benefit analysis, there can be no disputing what they are: removing healthy tissue, disabling functional organs, impeding the development and operation of inborn neuro-chemical systems and by consequence, turning previously fertile individuals into sterile, post-surgical, chronically medicated ones.

Besides the obvious losses, costs and risks of these procedures, there are problems that are less immediately apparent and insufficiently emphasized in the literature of those who promote them: the surgeries are not uncomplicated. I am not aware of any tabulation of the frequency of serious complications, including fatalities; but I am aware of at least one documented fatality from my incomplete reading of the literature (de Vries et al., 2014). Testosterone is associated with significant acne (Braun et al., 2021; Thoreson et al., 2021; Turrión-Merino et al., 2015) and much more ominously, may exacerbate preexisting affective illness (Elboga & Sayiner, 2018) (a not uncommon condition in the relevant population), both of which I have observed clinically, sometimes with serious consequences; and estrogen administration to genetic males significantly increases their chances of getting breast cancer (de Blok et al., 2019).

What is the other side of this story? Or perhaps a better question would be, what should the other side of this story be? What clinical situation could offset the serious downside of surgery and drugs? Surely it could not be that these children simply *want* these procedures, that they find the *anticipated* results appealing. Children want all sorts of things from time to time that we deny them out of concern for their welfare and we endure their frustration and protests. It would have to be that the clinicians who recommend these procedures believe that some children *need* them. They would have to argue that without these procedures, these children are likely doomed to lives of unremitting misery, and that these procedures are known to be the only reliable and enduring antidote to that misery. And that is indeed what some clinicians claim. Implicitly, as evidenced by their recommendations, and explicitly.

Well, there is research that is pertinent to the validity of the first half of that claim. We have longitudinal studies of what happens to children who complain of gender dysphoria or experience themselves as having a cross-sex identification, and do not receive such interventions. There are five such papers. These are Green (1987), Drummond et al. (2008), Singh et al. (2010), Wallien and Cohen-Kettenis (2008), and Zucker (2008), and Singh et al. (2021).

Here is the conclusion of those studies: the great majority of the children, (80% is the summary figure usually given) simply stop having the complaint or making the identification by late adolescence, and a large proportion of *them* become gay and lesbian adults. This giving up of the transgender complaint has become known as “desisting” in the literature. Its frequency varies from study to study, but never sinks below a majority (from as much as 96% to as few as 50%). Let me clarify what “desisting” means. It does *not* mean that a gender non-conforming child starts to conform, that a little boy, for example, starts conforming to male gender norms that he had previously resisted. It does mean that children who previously insisted they were a different gender from what their parents saw at birth, no longer make that insistence. The little boy stops insisting that he is in fact a little girl, or that he cannot be happy unless something is done to make him one. It means that children who were previously so uncomfortable in their own skins, that they were willing to consider exotic medical procedures and drugs, were no longer so uncomfortable. Operationally, they stopped meeting criteria for GID or gender dysphoria. In simplest terms: they got better. Gender dysphoria in pre-adolescent children is a condition that ameliorates by itself *in most cases* if you are just patient. I have to tell you that when I read that finding I was taken by surprise, because it was mentioned so infrequently in what I was reading in most of the protocols. But what it said did not surprise me at all. Middle school children are among the most unreliable people on earth. They should be. They are going through the work of establishing identities, consolidating their values and struggling with burgeoning desiring systems while around them the world is judging, pressuring and tempting. Of late this pressuring that children in middle childhood endure, has intensified, due principally to the media revolution: it is arguable that the ten year old's of today have access to a wealth of unmodulated information unimaginable thirty years ago, and this has powerfully affected them, cognitively and emotionally. Are they thus in a better or worse position to make life-altering decisions about themselves? Their enhanced vocabularies and expanded knowledge bases can be impressive, but also misleading: I recently sat with a sixteen year old whose command of post-modern theory startled me, but whose life experience of course remained that of a child. Should he be permitted to make irreversible decisions about his reproductive possibilities, among other things? There is no easy answer, but to return to my point here, of course such a person is likely to change his mind about many things of which he was recently certain. What is surprising is that some adults could not foresee that these children's outlandish claims and self diagnoses would likely alter and adjust with time. But that many adults failed to anticipate this changeability also does not surprise those of us who have worked with transgender kids: the earnest emotionality with which these claims are made, sometimes accompanied by threats and dramatizations, especially in the hands of a very intelligent and/or creative child, will move even the most detached adults, not to mention the parents, to a state of very intense distress, possibly impairing their usual ability to anticipate. If only we could be patient. But more on that shortly. Certainly for *these* children, who will likely change their minds while still young, surgery and hormone administration cannot be justified.

But what about the others, those who will persist, who at the age of eighteen will continue to find the body and social expectations into which they were born intolerable? Should they not have been given a chance to avail themselves of surgery and hormones? To begin to answer that question permit me to offer the following anecdote. A few years ago I attended a presentation by a psychologist who is a prolific contributor to the transgender literature. Her work emphasizes what she sees as the particular value of listening to and validating young children's literal accounts of their experience of gender. At the end of her presentation, which stressed interventions that followed the lead of the child with respect to both medical and social gender transitioning, I pressed her on the question of how to modify those interventions in light of the fact that most gender dysphoric children are likely to have no significant gender trouble by late adolescence. She said you should only promote transition if that is where the child is headed. So I asked her how do we know “where the child is headed,” i.e. which children will desist and which will persist? Her reply was: “I know.” This bold but uninformative response highlights the very difficult truth of the matter. Neither she, nor we, know. There is no way to know. We do not have reliable correlates of future persistence when they would matter the most, i.e. early on (Singh et al., 2021). I believe this leaves us with my earlier injunction: First, do no harm.

But wait, just because we can't *know*, doesn't mean we can't think about it. And we should think about it. Right? We're clinicians. We are capable, and obliged to think of what variables might increase the likelihood of a child desisting. We want the child to desist, right? Well you would certainly think so. And that brings us to something very interesting and important: Remember what desisting is: the child becomes *comfortable* in his or her skin. The child stops insisting that he or she *is* really another gender, or that she or he cannot be happy unless she or he is in the body of another gender. The child is at relative peace with the body he or she has. By what logic could the child's acquisition of peace and comfort not be a desirable outcome? Perhaps if the desistance were an unreliable compliance with external pressure, a coerced submission. In this situation the acquisition of peace would be transient and

misleading. But if you have any direct familiarity with, trans kids, you know how unlikely that scenario is. In my experience, trans kids do not comply. Their insistence on self-definition is impressive. So I think we must conclude that desistance, when it happens, is desirable. And therefore, my view is that we should think of every, trans aspiring child as a potential desister. I believe this is more accurate than thinking that he or she will need surgery and/or hormones. This way of thinking would also have the effect of engendering more optimism and less panic in the parents of any given, trans child.

But here is the interesting and important part: I have noticed a disturbing pattern in the literature of the clinical groups that employ surgical and hormonal interventions. Desistance is touched on almost not at all. In a recent paper (Tishelman et al., 2015) by a group out of Boston Children's Hospital that calls itself "the gender multi-specialty service" their sole reference to desistance is as follows: in the context of noting the absence of evidence-based clinical precedent in the field of transgender health generally, they note that some other workers in the field have raised the question of "whether early intervention with gender variant youth can encourage desistance, and whether that [encouraging desistance] is an appropriate practice." I want to repeat that: they are asking *whether encouraging desistance is appropriate*. So their only reference to desistance is not to note its high frequency, nor to explore how it might be promoted, but rather to suggest that an intervention that encourages desistance might *not* be appropriate, that it may be somehow unethical. How can any clinician fail to encourage the desisting child? Why would they actively exclude it from their interventions? For certainly the child who is no longer preoccupied with the idea that his or her welfare depends on a non-medical surgery and the ingestion of hormones should be encouraged. He or she has overcome an inhibiting and unhappy preoccupation. In fact we clinicians should try to figure out the mechanism through which desistance happens and to promote it. Which may turn out to be less mysterious than initially thought. To that I will turn in a moment.

But first, an additional moment of thought on this erasure of one of the most significant and established data points in the whole transgender story, that most, trans kids will get over it. How can this be left out or minimized in the clinical protocols of those who proffer surgery and hormones? Well it is said that to someone with a hammer, everything looks like a nail, and perhaps to the physician who just bought a cat scan, everyone's brain needs examining. Is this a case of technology and a new "discipline" (gender medicine) driving theory and practice? I fear that it may well be. Certainly the less invasive, technology-free options are given very short shrift by these protocols including that of the Boston group, and without explanation. They certainly cannot say that psychotherapy won't work: they don't try it. The authors repeatedly make it clear that psychotherapy is offered as an adjunct to medical intervention, part of the effort to smooth the path of what they call medical treatment, never as a primary intervention. Indeed, they say that for the child close to puberty three to six months of psychotherapy prior to medical intervention (rather short-term) "*is recommended*," but (quoting them) that if the child feels a compelling sense of urgency, "*this can be modified*." They are saying that the child's increased sense of urgency means less need for psychotherapy. I think this is backwards. A child's sense of urgency is a symptom, not a mandate. That child's need for psychotherapy is *greater*, not less. The child's sense of urgency leads to a modification of the need for psychotherapy? Is the child dictating the treatment, or is it that psychotherapy is not seen as treatment at all, it is there to promote the real treatments, surgery and hormones? The authors' opinion is clear, if not clearly stated. Now in my perhaps overheated critique of those who are emphasizing hormones, puberty blockers and surgery, it may seem that I am defensively angry at those clinicians (That is what occurred to me when I read this over.) Well perhaps I am a bit. But here is my real point and perhaps the source of my anger: do not be intimidated into drinking the proffered kool-aid of "gender science." Psychotherapy has much to offer these children, as it does to all children, (gender dysphoric children are not "different") and it will certainly "do no harm."

And now, to create the right mind-set for my discussion of psychotherapy, permit me to suggest a useful thought experiment: what if there were no hormones or surgery? After all, not too long ago this was in fact the case. What would the clinical situation for gender dysphoric children look like then? I am trying to bring your consciousness to a heightened awareness of the likely role of technology that is in play here, so that you can entertain the following speculation: Is it possible that the extraordinary increase in the frequency of youngsters feeling that they are in the wrong body, may have been fostered by the spreading awareness that technologies for changing bodies exists? Is it possible that the internet disseminated knowledge that there is a scientifically validated path to bodily metamorphosis, has encouraged some young people to claim that path, which they might not have even imagined otherwise? I am not suggesting that *all* gender dysphoria is simply the product of an internet contagion. But we are seeing a veritable explosion of cases, for which we really have no explanation. And so what I *will* insist on as you hear my approach to psychotherapy with these youngsters, is that we appreciate the role of contemporary culture in the dynamics of their psychology and their lives and consider how that culture may be distorting their self-narrations. These children and adolescents, perhaps more than any generation before them, because of the information revolution, are deeply enmeshed in the changing tropes of our culture. To reach them we must keep that fact and the contemporary content of our culture at the forefront of *our* consciousness.

So, I am recommending psychotherapy, a decidedly low-tech treatment option. How can we clinicians help children to become comfortable in their own skin, children, who, one way or another have become preoccupied with something wrong with their bodies and with their place in the gendered world. I confronted this clinical problem under significant pressure: parents, urgently wanted to know what to do with very distressed children, and were themselves under intense cultural pressure and inner pressure concerning the welfare of their children, while their children were depressed and anxious, and under myriad pressures themselves. All of these would in some way be my patients. Years of psychoanalytic supervision told me I was in a dangerous countertransference situation, the kind of interpersonal situation where the temptation to give answers, to imagine a quick fix, was terribly alive. Help them (as you wrote about, as they are expecting) or you are a failure, my thinly veiled superego said to me. At clinical moments like that, experience has taught me not to fear depth, but rather to assume a depth approach is what is needed, and that it is the surface that will distract. So I turned to two bodies of depth theory for guidance: social constructivism and psychoanalytic theory. Social constructivist theory (offered by the philosopher, Judith Butler, in particular, but also by various feminist psychoanalytic writers) tells us that gender is a social psychological construction, a soft assembly, a useful fiction, in the words of one writer (Goldner, 1991). Gender is a performance that must vary with the dynamics of the individual and the cultural situation in which a person is transiently located. The *experience* of gender emerges out of a dynamically learned performance, is structured by the actions and consequences of the performance, and the performance in turn reacts to the created gender experience, in a continuous balletic feedback loop. The real boy and the real girl do not exist, they are ideals: but children (as well as the rest of us) live alternately tormented and rewarded by the shadows of these inflated imagoes, the genders.

Psychoanalytic theory tells us that manifest symptomatology conceals an unspoken story, the true outlines of which are only hinted at, or symbolized by the story the patient at *first* tells – the old iceberg problem. To discover the real story and the conflict it may represent, the psychotherapist must make a relationship with the patient, a relationship in which the patient is encouraged to play freely, but mindfully, and the therapist adopts a stance of maximal attention and empathy. The ship will be steered by the patient while the therapist will describe what he or she sees on the journey in a spirit of such complete acceptance and appreciation that the patient feels safe enough to reveal the story that holds the keys to greater freedom, the unconscious story.

These two theoretical frameworks – social constructivism and psychoanalysis – mate well with each other; and here is how I put them together to evolve a *psychological* treatment. I began by recognizing that the preoccupation with gender that these children and their parents were manifesting was only that, a preoccupation, and often, an obsessional preoccupation, which means that the patient felt compelled to return to it, anticipating intense anxiety if he or she didn't, unconsciously anticipating relief when they did. Gender, an ideational configuration only, was being centralized and reified (with cultural

cooperation) to function as a defense against other, unspoken fears. This means that in each case the preoccupation with gender conceals something different, something idiosyncratic. **There is no common underlying meaning to gender dysphoria.** The therapeutic move I had to make was to open a space of relatedness outside of gender. In my interactions with patients I would never bring gender up, nor would I talk about it more than absolutely necessary. If the patient wanted to talk about gender I would welcome it, listen and respond enough so I didn't seem to be evasive, but spend very little time with it in my own mind, thinking all the while of what might really be going on for that patient. In addition I actually made an effort to experience the patient as having no gender, which I guess really meant trying to effect a kind of gender neutralizing in the way I paid attention. This is, of course, impossible, but turns out to be an excellent way of paying better attention to the aspects of a, trans child that he or she is neglecting in his or her hypercathexis of gender: intelligence, creativity, unspoken emotions, friendships. I became deeply involved with all the details of each child's interests – TV shows, movies, songs, other kids, etc. Interestingly, the unanticipated material that has come up has at times been marked by a high frequency of body preoccupations: a young woman is distressed at the feeling of her breasts tugged by gravity when she lies on her side; another is disturbed by the feel of her thighs touching one another while walking; a young woman hates her vagina and feels the face she sees in the mirror does not belong to her. My speculation about the role of obsessiveness is receiving confirmation: I am repeatedly seeing significant obsessive-compulsive symptoms in these patients, e.g., needing to sit perfectly centered on a couch. Parenthetically, it is my impression that greater than once weekly frequency of sessions has been helpful in solidifying my empathic connection to these patients. And I would add the importance of never imposing my conversational agenda on the session. The patient says she doesn't want to talk about difficult things today. I say fine, or more likely, I joke about it. My emphasis is not interpretation, though dynamic meanings are always on my mind – e.g., I am acutely aware that this girl experiences her mother as needing her to be a girl. But rather I emphasize relating, connecting, showing that I don't need her to be anything. Her every new move makes me happy, which I do not conceal.

To the parents, with whom I meet when they feel the need, and which I always encourage, I gave the emphatic advice to give intense and plentiful attention to their child, but not speak about gender at all. Listen to whatever your child has to say on the subject if they bring it up, be interested, but make no contribution of your own and never initiate it. (I am telling them to be like me.) They have found this surprisingly hard to do. I was somewhat surprised to learn how preoccupied with gender some of these parents were – wanting to bombard their children with e-mails about the negative effects of surgery and hormones, among other things. I would receive late night phone calls begging my permission to send such destructive missives. On the question of pronouns and names, my advice was to avoid them as much as possible. There is rarely a need for the noun of address when the child is in the room, and artful dodging can elide gendered pronouns more often than you think. I do not favor explicitly agreeing to a, trans child's requests to modify language and naming. Such agreements are usually infested with dishonesty – parents have not really agreed to a name or gender change, they are just succumbing to pressure – and the unconscious meanings behind the linguistic surrender are very hard to disentangle. Punting and honesty are usually better.

In presentations of this sort, where I specifically and strongly argue against a current, controversial practice, I am reluctant to offer much in the way of clinical examples: it is too easy to re-call and shape examples to support a given cherished imperative. But shared experience can be valuable, and I have been struck by some patterns that have emerged in my almost ten years of experience with transgendered and gender dysphoric youth. So here are some observations, not in any particular order:

A very high proportion of the gender troubled youth with whom I have worked are in families where there is some issue of immigration or national identity. In almost every case at least one parent was born outside the US and speaks accented English. Moreover, the significance of ethnic identity figures in the family psychology: the way experience in the country of origin has distorted the orientation of the non-American parent or parents, is a theme, though not necessarily a source of devaluing. I engage with issues of ethnicity with great eagerness.

The theme of the uncertainty of future life has emerged prominently for many of these kids. They tend to be acutely aware of the troubled condition of our planet and our nation. In some cases this is associated with a denial of the future, the child who lives obsessively in the present and will not plan, the obsessive video gamer, for example; in other cases a depressive, but not unproductive emphasis on the deprivations and injustices that youth in particular, are likely to suffer in our troubled world and nation, is pre-occupying. These are politicized kids, educated through the internet and deeply engaged with the social questions of our time. Now it is certainly true that this sort of anxiety is present for many adolescents, not just for those who are gender dysphoric. But I believe that what I am observing is that often the, trans experience functions, in part for some kids, as a personalization of their perception of the political situation. It makes their participation as political actors more real, urgent and validated. Once again, I jump into discussing politics with both feet, sharing my views and eagerly asking for the details of their thinking.

A final clinical note: The complaint of gender dysphoria, and the claim of transgender identity, are vivid, graphic and captivating. Because of this, they (the complaint and the claim) can function to conceal what might otherwise be obvious. Parents and clinicians alike can be distracted and misled when they are present. So: In a significant number of cases where young people were brought to me with gender as the only designated problem, other, more serious psychiatric conditions were present and not mentioned by any of the parties involved – previous clinicians, school officials, parents or the child in question. I do not have to tell you how calamitous the consequences of ignoring an incipient schizophrenia or affective disorder can be. I have seen both tragic errors, including a case where a young woman succeeded in persuading a surgeon to perform a mastectomy while she was in a manic state, and a case where a fatally suicidal youth persuaded a divorced parent that he would be alright so long as his chosen gender was affirmed. Much has been made of the frequency of suicidality among transgender youth as part of an effort to advance nondiscriminatory practices, an obviously valid concern, but also as part of efforts to justify surgical and hormonal transitioning. The argument in the latter case is that transgender individuals may be driven to suicide if they are denied these options. This is an especially pernicious and dangerous line of reasoning. If I am right in my observation that a fair amount of severe psychopathology may be hidden behind a presentation of gender trouble, that might explain some of the increased suicidality seen in transgender youth. The solution is not to therefore hasten the provision of surgery and hormones, but rather to examine gender dysphoric youth more carefully for the psychopathologies that are known correlates of suicide: schizophrenia and affective illness. I offer this last note in part because of how deeply shaken I was by the two examples I referenced: terrible outcomes that I could not help but imagine could have been averted; but also because of how frequently I am encountering clinicians, who, confronted with a transgendered or gender dysphoric child and their freaked out family, start to doubt themselves, lose track of their established tools of empathic, psychodynamically informed listening and reasoning, and imagine themselves to be in *terra incognita* where the usual rules of safety and value no longer apply and extraordinary measures must be taken. I am here to tell you that the psychotherapeutic relationship is still the safest and best of methods even with these seemingly unusual children. The times indeed are a'changin.' But humans, not so much.

DISORDERS OF SEX DEVELOPMENT

Selma Feldman Witchel, MD

Division of Pediatric Endocrinology, Children's Hospital of Pittsburgh of UPMC, University of Pittsburgh, 4401 Penn Avenue, Pittsburgh, PA 15224

Abstract

Normal sex development depends on the precise spatio-temporal sequence and coordination of mutually antagonistic activating and repressing factors. These factors regulate the commitment of the unipotential gonad into the binary pathways governing normal sex development. Typically, the presence of the SRY gene on the Y chromosome triggers the cascade of molecular events leading to male sex development. Disorders of sex development comprise a heterogeneous group of congenital conditions associated with atypical development of internal and external genitalia. These disorders are generally attributed to deviations from the typical progression of sex development. Disorders of sex development can be classified into several categories including chromosomal, gonadal, and anatomic abnormalities. Genetic tools such as microarray analyses and next-generation sequencing techniques have identified novel genetic variants among patients with DSD. Most importantly, patient management needs to be individualized especially for decisions related to sex of rearing, surgical interventions, hormone treatment, and potential for fertility preservation.

Keywords

Disorders of sex development; Ambiguous genitalia; congenital adrenal hyperplasia; urogenital anomalies

INTRODUCTION

Disorders of sexual development (DSD) encompass a group of congenital conditions associated with atypical development of internal and external genital structures. These conditions can be associated with variations in genes, developmental programming, and hormones. Affected individuals may be recognized at birth due to ambiguity of the external genitalia. Others may present later with postnatal virilization, delayed/absent puberty, or infertility. The estimated frequency of genital ambiguity is reported to be in the range of

CONFLICT OF INTEREST: NONE

1:2000-1:4500 [1]. According to the Danish Cytogenetic Central Registry, the prevalence of XY females is 6.4 per 100,000 live born females. In this registry, the prevalence of androgen insensitivity was 4.1 per 100,000 live born with median age at diagnosis of 7.5 years. The prevalence of XY gonadal dysgenesis was 1.5 per 100,000 live born females with median age at diagnosis of 17 years [2]. The incidence of DSD varies among ethnic groups with the highest incidence in the southern African population.

International stakeholders representing multiple disciplines continue to modify the terminology used to categorize specific DSDs to emphasize the underlying genetic etiologies [3]. Ongoing development and use of novel molecular cytogenetic techniques have enriched understanding regarding the genomic alterations associated with DSDs. In addition, analyses regarding these genomic alterations have illuminated novel genetic regulatory mechanisms associated with DSDs [4].

When presented with a child with ambiguous genitalia, unique decision-making challenges can occur regarding sex of rearing, parent and patient education, and medical management [5]. It is important to note that sex does not indicate gender; sex refers to the biology of the internal and external genital structures that is traditionally considered to be a binary categorization. Gender identity is the self-defined experience of one's gender. Tales from Greco-Roman cultures, e.g. Hermaphrodite and Daphne, have documented and celebrated transformations and fluidity in sex and gender identity [5].

EMBRYOLOGY

Sexually dimorphic development of the reproductive tracts is influenced by multiple factors. Normal sex development is dependent on the synergistic orchestration of activating and repressing factors interacting in a precise spatio-temporal pattern [6]. Sex determination is governed by the sex chromosomes. The Sex Determining Region on the Y chromosome (SRY) gene located on the short arm of the Y chromosome is the binary switch that initiates the male developmental program [7]. The pivotal experiments performed by Dr. Alfred Jost established the relevance of testosterone for male sexual differentiation [8].

The urogenital ridges develop by 4-6 weeks of gestation as outgrowths of the coelomic epithelium. Subsequently, the urogenital ridges develop into the kidneys, adrenal cortices, gonads, and reproductive tracts. SRY functions as a transcription factor to trigger the developmental trajectory that directs differentiation of the bipotential gonad into a testis during the 6th week of human gestation. SRY induces SOX9 expression; SOX9 activates and maintains the male gonadal differentiation pathway. With differentiation of the Sertoli cells, the developing testis becomes organized into two compartments. One compartment consists of the testis cords that are aggregates of the germ cells surrounded by Sertoli cells and encased by the peritubular myoid cells. The other compartment is the testis interstitium, which contains the Leydig cells and testis vasculature.

Initially, both Wolffian and Müllerian ducts develop. The Wolffian ducts originate as the excretory ducts of the mesonephros. Testosterone, secreted by the fetal Leydig cells, stabilizes the Wolffian ducts resulting in the development of the epididymis, vas deferens,

ejaculatory duct, and seminal vesicle. Another hormone secreted by the testis, insulin-like factor 3 (INSL3), mediates testicular descent from the original perinephric location through the abdomen. Testosterone promotes testicular descent into the scrotum. Testicular descent is generally completed by 32 weeks' gestation. Sertoli cells secrete Anti-Müllerian Hormone (AMH), which induces regression of the Müllerian ducts.

Ovarian differentiation occurs slightly later than testicular differentiation. In the absence of SRY in the female fetus, the ovary specific transcription factors, Forkhead transcription factor 2 (FOXL2), Wingless type MMTV integration site family, member 4 (WNT4), R-spondin 1 (RSPO1), and the activated β -catenin pathway, initiate and maintain ovarian differentiation [9]. In the absence of testosterone and dihydrotestosterone (DHT), the external genital structures develop into the clitoris, vagina, and labia. Both the urethra and the vagina open onto the perineum.

In peripheral target tissues, testosterone is converted to DHT. DHT promotes fusion of the urethral folds to form the corpus spongiosum and penile urethra. DHT also promotes development of the genital tubercle into the corpora cavernosa of the penis and fusion of the labioscrotal folds to form the scrotum.

Primordial germ cells migrate from the allantois to the fetal gonads. Differentiation of germ cells to a spermatogenic or an oogenic fate does not depend on their XY or XX karyotype. Rather, the neighboring somatic cells in the gonads influence germ cell differentiation. In the female embryo, germ cells are exposed to high levels of retinoic acid which induce the expression of STRA8 leading to germ cell meiosis and development of oocytes. In the developing testis, the absence of retinoic acid causes the germ cells to develop into gonocytes that differentiate into spermatogonia and proliferate by mitosis; meiosis only starts at puberty in the male gonad.

GENETICS OF SEX DIFFERENTIATION AND DEVELOPMENT

Sex development is achieved by the precise synergistic temporal-spatial expression of numerous activating and repressing factors. Deviations from this established developmental sequence can result in disorders of sex development. Investigations into the molecular basis of DSDs in patients have elucidated many genes and genetic regulatory mechanisms involved in this process. Gene expression reflects tissue specificity, programming, and relative dosages to influence cell fate decisions.

Genes involved in the initial differentiation of the bipotential gonad include empty spiracles homeobox2 (EMX2), chromobox homolog2 (CBX2), Wilms' tumor 1 (WT1), steroidogenic factor 1(NR5A1), LIM homeobox factor 9 (LHX9), sine oculis-related homeobox 1/4 (SIX 1/4), and GATA binding protein 4 (GATA4) [10]. Subsequently, cell fate decisions influence the differentiation of the bipotential genital ridge towards male or female phenotype. This process involves a complex regulatory network in which activation of one pathway, i.e., testicular, leads to repression of the other pathway, ovarian, and vice versa [11].

In the developing testis, SRY promotes SOX9 expression. In conjunction with SRY and NR5A1, SOX9 generates a positive feedback loop for maintaining its expression and to

promote Sertoli cell development. Two paracrine signaling molecules downstream of SOX9, fibroblast growth factor 9 (FGF9) and prostaglandin D2 synthase (PGD2) promote maintenance of testicular development [12]. FGF9 signals from the central region of the gonad to promote SOX9 expression and antagonize WNT4 signaling. Other genes relevant for testicular differentiation include CITED4 and other members of the *SOX* family, i.e. SOX3, SOX10, and SOX13 [13].

Rather than being the “default pathway”, differentiation of the ovary is an active process dependent on the activity of specific factors. WNT4 suppresses SOX9 expression in the pre-granulosa cell of the developing ovary. WNT4 and RSPO1 stabilize β -catenin expression. FOXL2 is another ovarian transcription factor and nuclear protein crucial for differentiation and maintenance of ovarian differentiation [14]. The proteins, WNT4 and RSPO1, promote β -catenin accumulation in the nucleus where it interacts with LEF1 to promote transcription of other genes. FOXL2 and β -catenin also repress SOX9 expression. The WNT4 pathway upregulates follistatin, which inhibits activin B and prevents formation of the testis-specific vasculature [15]. Recent data derived from mouse studies suggest that the orphan nuclear receptor, chicken ovalbumin upstream promoter transcription factor II (COUP-TFII) may play an active role in eliminating the Wolffian ducts in females [16].

CLASSIFICATION OF DSD

DSDs are classified into several categories (Table 1). The category of 46,XX DSD includes virilized females such as girls with a virilizing congenital adrenal hyperplasia and girls with aberrant ovarian development. The category of 46,XY DSD patients includes patients with abnormal testicular differentiation, defects in testosterone biosynthesis, and impaired testosterone action. Sex chromosome DSDs include Turner Syndrome, Klinefelter Syndrome, and 45,X/46,XY gonadal dysgenesis. In general, patients with Turner Syndrome and Klinefelter Syndrome do not present with genital ambiguity. Other DSDs include XX sex reversal, XY sex reversal, and ovotesticular disorder.

A. XX, DSD

The most common form of virilizing congenital adrenal hyperplasia is 21-hydroxylase deficiency due to mutations in the 21-hydroxylase (CYP21A2) gene. Infant girls with classic salt-losing 21-hydroxylase deficiency usually present in the immediate neonatal period due to genital ambiguity. For affected female infants, virilization of the external genitalia ranges from clitoromegaly to perineal hypospadias with chordee to complete fusion of labiourethral and labioscrotal folds. The magnitude of external genital virilization may be so extensive that affected female infants appear to be males with bilateral undescended testes [17]. Unless identified by neonatal screening, infant boys with congenital adrenal hyperplasia typically present at 2 to 3 weeks of age with failure to thrive, poor feeding, lethargy, dehydration, hypotension, hyponatremia, hyperkalemia, and normal male sexual development. Hyperpigmentation of the scrotum may be apparent. When the diagnosis is delayed or missed, congenital adrenal hyperplasia is potentially fatal. Newborn screening programs decrease the morbidity and mortality associated with acute adrenal insufficiency or with assignment of affected female infants to male sex of rearing [18].

Other disorders of steroidogenesis associated with 46,XX DSD include 11-beta hydroxylase deficiency, 3-beta hydroxysteroid dehydrogenase deficiency, P450 oxidoreductase deficiency, and aromatase deficiency due to mutations in CYP11B1, HSD3B2, POR, and CYP19A1, respectively. Paradoxically, male infants with HSD3B2 and POR mutations may present with undervirilization due to impaired testosterone biosynthesis [19]. Maternal hyperandrogenism during gestation can be due to luteomas of pregnancy, androgen secreting tumors, and exposure to exogenous androgen.

Loss of function mutations in the genes coding for ovarian factors are associated with ovarian dysgenesis and/or accelerated loss of primordial follicles resulting in premature ovarian failure. After birth, WNT4 is detected in oocytes and granulosa cells [20]. SERKAL syndrome is characterized by female to male sex reversal associated with renal, adrenal, and lung dysgenesis; this disorder is associated with a homozygous recessive missense mutation in WNT4 [21]. Mutations in FOXL2 are associated with blepharophimosis-ptosis-epicanthis inversus syndrome that can be associated with premature ovarian failure (BPES I). Continued FOXL2 expression in the ovary is essential to maintain an ovarian phenotype because loss of FOXL2 expression in adult mice reprograms granulosa and theca cells into cells that are similar to Sertoli and Leydig cells, respectively [22]. Other genes associated with ovarian dysgenesis and premature ovarian failure include LHX8, MCM8, MCM9, NOBOX, and FSHR [23,24,25].

B. XY, DSD

This category includes patients with abnormal testicular differentiation, defects in testosterone biosynthesis, and impaired testosterone action. The phenotype may be limited to aberrant testicular differentiation or may include other anomalies. Loss of function SOX9 mutations are typically associated with gonadal dysgenesis and campomelic dysplasia. Mutations in GATA4 may also be associated with congenital heart disease in addition to testicular anomalies. Patients with Smith-Lemli-Opitz associated with 7-dehydrocholesterol reductase (DHCR7) mutations typically manifest characteristic facial features, and syndactyly of the second and third toes. Several phenotypes have been described for patients with WT1 mutations including Denys-Drash, Frasier, Meacham, and WAGR syndromes. Other genes associated with XY gonadal dysgenesis include CBX2, DHH, DMRT1, DMRT2, MAP3K1, and SOX8 [26]. In XY individuals, MAP3K1 mutations appear to shift signaling pathways to suppress SOX9 and promote ovarian differentiation [27].

Mutations in the proteins necessary for testosterone biosynthesis are associated with undervirilization. The genes encoding these proteins include SF1 (NR5A1), LH receptor (LHR), steroidogenic acute regulatory peptide (StAR), cholesterol desmolase (CYP11A1), 17 α -hydroxylase/17,20-lyase (CYP17A1), 3 β -hydroxysteroid dehydrogenase type 2 (HSD3B2), 17 β -hydroxysteroid dehydrogenase type 3 (HSD17B3), 3 α -hydroxysteroid dehydrogenase (AKR1C2/4), P450-oxidoreductase (POR), and 5 α -reductase type 2 (SRD5A2) [28,29,30].

Mutations in the androgen receptor gene (AR/NR3C4), which is located on the long arm of the X chromosome at Xq12, interfere with testosterone signaling [31]. The phenotype of patients with AR/NR3C4 mutations ranges from normal female external genitalia, labial

masses, and absence of a uterus to partial forms that may present with male infertility in adulthood.

C. Sex chromosome DSD

Turner syndrome describes the phenotype of patients with aneuploidy or structural rearrangements of the X chromosomes. Structural rearrangements include isochromosome Xq, partial deletions, and ring X chromosome. The reported incidence is 1 in 2500 live-born female birth [32]. Patients with Turner syndrome may be diagnosed in the neonatal period due to low birth weight, short neck, and lymphedema of hands and feet. Other typical presentations include short stature and delayed puberty. Characteristic features include epicanthal folds, downslanting palpebral fissures, low set ears, micrognathia, left-sided cardiac anomalies, and horseshoe kidneys. The cardiac anomalies include coarctation of the aorta, bicuspid aortic valve, and aortic stenosis. Girls suspected of having Turner syndrome should have a standard 20-cell karyotype. If mosaicism for Turner syndrome is suspected, FISH can be performed, additional metaphases can be counted, or a second tissue can be analyzed. Genetic analysis that detects Y chromosomal material warrants further evaluation because these girls may develop virilization and have an increased risk for gonadoblastoma and dysgerminoma. Girls with Turner syndrome have an increased risk to develop other disorders such as Hashimoto's thyroiditis, celiac disease, neurosensory hearing loss, hypertension, and diabetes mellitus. Approximately 50% of girls have congenital heart disease including coarctation of the aorta, bicuspid aortic valve, and increased risk for aortic dissection. The likelihood for development of these co-morbidities is greatest in the girls with 45,X karyotype [33]. Growth hormone therapy improves final height. Estrogen and progesterone hormone therapy are essential to promote development of secondary sexual characteristics and prevent osteopenia [34]. A large series of British women with Turner Syndrome reported a decreased incidence of breast cancer, but an increased risk for gonadoblastoma, corpus uteri cancer, and possibly childhood brain cancers [35].

Klinefelter syndrome is characterized by 47,XXY karyotype. The incidence is approximately 1 in 500 males. Affected boys have normal external genital development. They may present with tall stature, small testes, delayed puberty, infertility, and gynecomastia. Boys with Klinefelter syndrome often manifest dyslexia, behavior difficulties, and defects in executive function [36]. Autism spectrum disorders are more common among boys with Klinefelter syndrome than the general population [37].

D. XX, Sex Reversal, Ovotesticular Disorder, and XY, Sex Reversal Disorder

Patients with XX sex reversal can be classified into two major groups. One group (SRY+) is positive for SRY due to the translocation of the SRY gene to another location, which is usually the X chromosome or, rarely, an autosome. The other group consists of SRY negative XX (SRY-) males.

Ovotesticular disorder is defined by the presence of both ovarian follicles and seminiferous tubules in the same patient. The specific phenotype depends on relative gene expression patterns and the function of the gonads particularly related to hormone secretion. Gonadal histology can include ovarian, testicular, ovotesticular, and dysgenetic patterns. Potential

mechanisms responsible for ovotesticular disorder in the XX (SRY⁻) individual could involve activation of testis specifying genes in the absence of SRY and/or inadequate expression of pro-ovary/anti-testis genes. Duplications involving the SOX9 locus or potential SOX9 regulatory elements have been associated with XX testicular and XX ovotesticular DSD [13]. Genes associated with ovotesticular DSD include NR5A1, SOX3, SOX10, WNT4, and RSPO1 [38]. Considerations regarding sex assignment in the XX patient with ovotesticular disorder are similar to other patients with DSD with the caveat that sufficient ovarian tissue with follicles may be present to allow for pregnancy.

Duplication of a region on the Xp21.2 region of the X chromosome containing the DAX1 gene is associated with XY sex reversal. Deletion of this region in an XY individual is associated with congenital adrenal hypoplasia. However, a microdeletion of this region was associated with XX sex reversal underlining the genetic complexity of this locus [39].

Persistent Müllerian Duct Syndrome (PMDS)—PMDS is a rare autosomal recessive disorder characterized by the persistence of Müllerian structures in a boy. Typically, phallic development and testicular function are normal. This disorder is typically diagnosed during surgery for inguinal hernia and/or cryptorchidism. Often, both testes are on the same side (transverse testicular ectopia) and may be embedded in the broad ligament. Abnormal development of male excretory ducts is common. Although most men are infertile, fertility may be possible if at least one testis is scrotal with intact excretory ducts. Most cases are due to either AMH or AMHR2 mutations [40].

Urogenital anomalies—Some patients initially appear similar to patients with DSDs, but have disorders of urogenital tract development. Examples of malformations include cloacal and bladder exstrophy. The prevalence of uterine malformations has been reported to range from 5.5-9.8% [41]. Uterine developmental anomalies can range from complete aplasia, fusion defects, and septal absorption defects [42]. Associated findings can include renal, spinal, and cardiac anomalies. Uterine anomalies can be associated with MODY 5 diabetes, renal cysts, and HNF1B mutations. Mutations in the HOX genes have been associated with uterine anomalies. The hand-foot-genital syndrome associated with HOXA13 mutations is characterized by limb malformations and urogenital anomalies in both males and females [43]. In addition to HOX genes, other genes associated with uterine anomalies include WNT genes, GATA3, FRAS1, FREM, and other genes associated with syndromic ciliopathies [44].

GENETIC TESTING IN DSD

Genetic testing plays an important role in the evaluation of a patient with a possible DSD because knowing the genetic etiology improves the ability to predict the patient's phenotype, clarifies recurrence risk, and can be utilized in medical decision-making.

Peripheral blood karyotype analyses can be useful to detect the X and Y chromosomes, balanced chromosomal rearrangements, and large structural rearrangements. Fluorescence in situ hybridization (FISH) analysis using X and Y centromere-specific probes can be used to assess for sex chromosome mosaicism. Probes specific for the SRY gene can be used to

ascertain for Yp rearrangements. Unknown marker chromosomes and chromosomal rearrangements should be identified using FISH analyses to discern Y chromosomal material and establish recurrence risk.

Chromosomal microarray analyses such as array CGH or SNP microarrays can detect submicroscopic gene variations. CGH may identify novel candidate genes associated with DSD. The use of customized CGH focused on DSDs can interrogate multiple genes simultaneously which can accelerate the diagnostic process and limit the financial burden associated with testing multiple individual genes [45]. One caveat is that CGH may fail to detect balanced chromosomal translocations and low level mosaicism.

Genome-wide association studies (GWAS) offer a hypothesis free approach for the detection of novel loci associated with DSD. Many loci detected in GWAS are located outside of the coding region of a gene which confounds the interpretation regarding the functional impact of the variant on the phenotype. These variants may influence gene regulatory elements, affect co-factor recruitment, or modulate local chromatin structure. The need to replicate GWAS findings limits its usefulness in DSDs because of phenotypic and genetic heterogeneity and the low incidences for specific disorders.

The use of next generation sequencing (NGS) techniques such as whole exome sequencing (WES) simultaneously targets the coding regions of thousands of genes. Whole genome sequencing (WGS) targets the entire genome. These techniques are useful, but neither technique adequately detects large copy number variants, repetitive sequences, e.g. trinucleotide repeats, aneuploidy, or epigenetic changes.

Variations such as translocations, inversions, duplications, and deletions can modify the normal chromatin structure and alter spatiotemporal relationships with gene regulatory elements [46]. Non-coding genomic changes near *SOX9* have been associated with several phenotypes including XY male to female DSD associated with campomelic dwarfism and XX female to male sex reversal [47]. Genomic rearrangements involving long-range regulatory elements may result in ectopic and/or disrupted spatiotemporal expression of relevant genes. Two examples of *AR* mutations located outside of the coding region and associated with AIS include a mutation located in the 5'-untranslated region associated with reduced protein levels and an intronic mutation that created a novel 5'-splice site resulting in aberrant splicing and decreased *AR* protein levels [48,49]. A synonymous *AR* mutation, p.S510S, changed the exon 1 donor splice site generating a premature stop codon and truncated protein [50]. In some instances, no *AR* mutations have been detected suggesting that other proteins located beyond *AR* influence testosterone signaling [51].

ETHICS OF GENETIC TESTING

WES and WGS are powerful tools that are being used to identify the molecular basis of many diseases. However, these tests can detect genetic variants unrelated to sexual differentiation. Hence, counseling and informed consent need to precede these genetic studies; parents and patients should be alerted and counseled about the possibility of incidental findings with the potential for significant medical impact. Additional existing

limitations of NGS include the inability to completely characterize the functional significance of all variants and false assignment of causality detected by these tools [52].

GONADAL TUMORS

The decision to pursue gonadectomy needs to be individualized with active participation of a multidisciplinary team and, if possible, knowledge of the specific molecular etiology [53]. Considerations include risk of malignant degeneration, fertility potential, and ability to bring the gonads into a location for repeated physical examinations. The presence of a Y chromosome in a dysgenetic gonad is associated with high risk for neoplastic transformation into gonadoblastoma or dysgerminoma. Germ cell neoplasia in situ (GCNIS) in the testis represents a pre-malignant change. The neoplastic cells in these lesions are derived from primordial germ cells that arrested at an early stage of development and typically express OCT3/4.

Removal of testes in patients with complete androgen insensitivity is controversial. Most recent data indicate that the risk for tumor development is low until early adult years [54,55]. For patients with CAIS, the risks of neoplastic changes, risks of the surgical procedure, and need for long term hormone replacement should be discussed. Hence, many women with CAIS elect to keep gonads *in situ*. Laparoscopic gonadopexy to situate the gonads in a fixed position near the anterior abdominal wall with gonadal biopsy, molecular screening with SNP and micro-RNA testing, and ultrasound surveillance may be an option for patients wishing to avoid gonadectomy [56,57]. Delayed surgery promotes shared decision making with the patient, family, and healthcare providers [58].

SURGERY IN DSD

No uniform consensus regarding the indications, timing, and extent of the operation is applicable for individuals with DSD. Each patient warrants individual contemplation and attention by a multidisciplinary team at experienced centers. Considerations include future fertility, risk for gonadal tumors, propensity for urinary tract infections, avoiding stigmatization related to atypical genital anatomy, and ensuring functional genital anatomy to allow future penetrative intercourse [59]. For girls with CAH, favorable outcome was reported with early genital surgery [60,61]. Available outcome reports are largely small clinical series with diagnostic heterogeneity. Importantly, data regarding outcome for non-treated DSD are even more limited.

FERTILITY POTENTIAL AND PRESERVATION

Fertility preservation via embryo, oocyte, or sperm banking has become an option for those who face a loss of fertility due to a chronic illness such as cancer. Experimental protocols are being developed for preservation of fertility for prepubertal children with cancer. Apart from individuals with virilizing congenital adrenal hyperplasias, most individuals with DSDs have traditionally been considered to be infertile. Finlayson and colleagues propose a paradigm shift to this traditional notion because they detected germ cells in the gonads of patients with CAIS, ovotesticular disorder, Denys-Drash syndrome, and other disorders

associated with DSD [62]. Limitations of their report include small sample size and incomplete knowledge regarding the functional competence of these germ cells. Currently, most protocols for cryopreservation of immature gonadal tissues are experimental. Ethical considerations include false hope, potential transmission of genetic disorders to future offspring, financial burden, and provision of consent/assent for a minor child [63]. Nevertheless, optimism regarding potential assisted reproductive technologies may be justified following a report of a live birth following a uterine allograft transplantation in a female with uterine agenesis and successful intracytoplasmic sperm injection (ICSI) procedure with a subsequent live birth after testicular sperm extraction from a 46,XX/46,XY azoospermic male [64,65]. The multidisciplinary team involved in the care of children with DSDs should discuss fertility potential and possible role of assisted reproductive techniques [66].

APPROACH TO THE PATIENT

The birth of a child with a DSD is generally not a medical emergency. Rather, the birth of a baby with ambiguous genitalia is bewildering, alarming, and is considered to be a social emergency. Everyone wants to know if the baby is a boy or a girl. In many instances, the parents have been told the sex of the infant based on prenatal ultrasound findings. Until the sex of rearing has been established, the infant should be referred to as “your baby”.

Following review of the pregnancy and family histories and a thorough physical examination, it is appropriate to congratulate the parents on the birth of their child, show them the physical findings on their baby, and review that the gonadal structures are bipotential. Most importantly, “guessing” whether the child is a boy or a girl is inappropriate. A multidisciplinary team comprised of pediatric endocrinologists, pediatric urologists/surgeons/ob-gyn specialists, geneticists, pediatric radiologists, neonatologists, pediatric nurse educators, and behavioral health professionals should be involved in the care of infants, children, and adolescents with DSDs [67]. It is important to include the parents in discussions regarding sex of rearing and be cognizant of their level of understanding and cultural/religious perspectives and traditions [68,69].

The infant needs to be carefully examined for evidence of other anomalies [70]. The symmetry of the external genitalia, presence of palpable gonads, genital pigmentation, and extent of labioscrotal fusion should be assessed. The length and diameter of the phallus should be measured. The location of the urethral meatus and number of perineal openings need to be noted. The presence of posterior labial fusion and estimation of the ano-genital ratio can be helpful. For normal girls, the distance from the base of the phallus to the posterior forchette should be approximately 2/3 of the distance from the base of the phallus to the anus [71].

Individualized laboratory evaluations provide optimal information to ascertain the likely etiology and select the initial management recommendations. Bloodwork may include electrolytes, 17-hydroxyprogesterone, testosterone, LH, FSH, AMH, plasma renin activity, androstenedione, and DHT. Karyotype analysis and additional genetic testing are essential. Determination of urinary steroids and/or stimulation tests may be use to clarify the specific

diagnosis [72]. Ultrasound studies to assess for the presence of a uterus can be helpful. Ovaries are often too small to be accurately visualized on ultrasound; the lack of visualization of ovaries does not indicate absence of ovaries. Renal anomalies can be assessed by renal ultrasound.

The infant's history and physical examination can direct the course of the laboratory investigations. Significant virilization of the external genitalia with bilateral non-palpable gonads offers a clue that the infant is a virilized female with a virilizing form of congenital adrenal hyperplasia. Apparently normal symmetric female external genitalia with labial masses suggest the possibility of complete androgen insensitivity syndrome. Asymmetric external genital development can be associated with gonadal dysgenesis and ovotesticular disorder.

Upon completion of all studies, this information can be shared with the parents. The tone of this encounter should be positive and optimistic to promote bonding between the parents and their infant. During this discussion, sex of rearing, medical management plans, gonadal development, results of genetic testing, recurrence risks, and follow-up plans can be discussed. As the child transitions to an adolescent and young adult, specific details regarding their medical condition, karyotype, and potential for fertility need to be openly discussed.

For the older child or adolescent patient, an evaluation for delayed puberty, primary amenorrhea, or virilization can lead to the diagnosis of a DSD. A thorough evaluation including linear growth patterns, presence and sequence of secondary sexual characteristics, and family history is essential. On physical examination, the external genital appearance, pubertal features typical of estrogen effect such as breast development, and characteristics of androgen effect such as pubic hair and virilization should be noted. In this instance, the patient and parents play active roles in the diagnostic evaluation and decision-making process. Confidentiality and privacy are essential because the diagnosis of a DSD can be devastating to the patient and family. Discussion regarding karyotype and likely infertility are essential aspects of medical care for these patients.

SUMMARY

Disorders of sex development are variations in reproductive tract development. Novel genetic techniques have introduced a new era of the diagnosis of DSDs and elucidation of the molecular factors involved in sex development. Thoughtful respectful care is critical for the management of infants, children, adolescents, and their families to ensure positive and meaningful quality of life. Goals for individuals with DSDs include psychosocial well-being, sexual satisfaction, and fertility options [73].

PRACTICE POINTS

- Normal sexual development is dependent on the synergistic orchestration of numerous activating and repressing factors interacting in a precise spatio-temporal pattern.
- Disorders of sex development can be classified into several categories and are associated with atypical development of chromosomal, gonadal, or anatomic sex.
- Patients with DSDs can present in infancy with ambiguous genitalia or at older chronological ages with aberrant pubertal development.
- The healthcare team needs to provide patients with comprehensive medical information regarding their specific condition as appropriate for age, developmental stage and cognitive abilities. Patients and their parents benefit from review of this information as they pass from childhood to adolescence to adulthood.
- Karyotype analyses, microarray analyses, and next generation sequencing techniques are helpful in the diagnostic and genetic evaluation of patients; these techniques may identify novel genes involved in sex development.
- The benefits and potential risks of surgical interventions need to be carefully reviewed and assessed with parents and patients.
- Multidisciplinary individualized health care is essential for all patients with DSDs. Goals include fostering the individual's healthy sexual and gender identity development while minimizing risks for deleterious physical and psychosocial consequences.
- Shared decision making and open communication are vital for optimal health and quality of life. This approach needs to respect the wishes, beliefs, and cultural traditions of patients and their families.

RESEARCH AGENDA

- Current evidence-based data remain inadequate to address assignment of male or female sex for some infants.
- Elucidation of the factors and processes involved in gender identity development is needed because our current knowledge of the structures and functions of the CNS underlying gender identity is extremely limited.
- Evidence-based data to address issues related to timing, techniques and consent for surgical interventions.
- Exploration of fertility preservation

Highlights

- Normal sex development depends on the precise spatio-temporal sequence and coordination of mutually antagonistic activating and repressing factors.
- Disorders of sex development can be classified into several categories including chromosomal, gonadal, and anatomic abnormalities.
- Genetic tools such as microarray analyses and next-generation sequencing techniques have identified novel genetic variants among patients with DSD.
- Patient management needs to be individualized especially for decisions related to sex of rearing, surgical interventions, hormone treatment, and potential for fertility preservation.

Article Guidance**Article Text**

Gender Dysphoria (GD) is defined by the Diagnostic and Statistical Manual of Mental Disorders - Fifth Edition, DSM-5™ as a condition characterized by the "distress that may accompany the incongruence between one's experienced or expressed gender and one's assigned gender" also known as "natal gender", which is the individual's sex determined at birth. Individuals with gender dysphoria experience confusion in their biological gender during their childhood, adolescence or adulthood. These individuals demonstrate clinically significant distress or impairment in social, occupational, or other important areas of functioning.

GD is characterized by the desire to have the anatomy of the other sex, and the desire to be regarded by others as a member of the other sex. Individuals with GD may develop social isolation, emotional distress, poor self-image, depression and anxiety. The diagnosis of GD is not made if the individual has a congruent physical intersex condition such as congenital adrenal hyperplasia.

Gender Reassignment Therapy

GD cannot be treated by psychotherapy or through medical intervention alone. Integrated therapeutic approaches are used to treat GD, including psychological interventions and gender reassignment therapy. Gender reassignment therapy, either as male-to-female transsexuals (transwomen) or as female-to-male transsexuals (transmen), consists of medical and surgical treatment that changes primary or secondary sex characteristics.

Initially, the individual may go through the real-life experience in the desired role, followed by cross-sex hormone therapy and gender reassignment surgery to change the genitalia and other sex characteristics. The difference between cross-sex hormone therapy and gender reassignment surgery is that the surgery is considered an irreversible physical intervention.

Gender reassignment surgical procedures are not without risk for complications; therefore, individuals should undergo an extensive evaluation to explore psychological, family, and social issues prior to and post surgery.

Additionally, certain surgeries may improve gender- appropriate appearance but provide no significant improvement in physiological function. These surgeries are considered cosmetic and are non-covered.

NON-SURGICAL TREATMENT

Initiation of cross-sex hormone therapy may be provided after a psychosocial assessment has been conducted and informed consent has been obtained by a health professional.

The criteria for cross sex hormone therapy are as follows:

1. Persistent, well-documented gender dysphoria;
2. Capacity to make a fully informed decision and to consent for treatment;
3. Member must be at least 18 years of age;
4. If significant medical or mental health concerns are present, they must be reasonably well controlled.

The presence of co-existing mental health concerns does not necessarily preclude access to cross-sex hormones. These concerns should be managed prior to or concurrent with treatment of gender dysphoria.

Cross-sex hormonal interventions are not without risk for complications, including irreversible physical changes. Medical records should indicate that an extensive evaluation was completed to explore psychological, family and social issues prior to and post treatment. Providers should also document that all information has been provided and understood regarding all aspects associated with the use of cross-sex hormone therapy, including both benefits and risks.

READINESS FOR THE TREATMENT OF GENDER DYSPHORIA

Readiness criteria for gender reassignment surgery includes the individual demonstrating progress in consolidating gender identity, and demonstrating progress in dealing with work, family, and interpersonal issues resulting in an improved state of mental health. In order to check the eligibility and readiness criteria for gender reassignment surgery, it is important for the individual to discuss the matter with a professional provider who is well-versed in the relevant medical and psychological aspects of GD. The mental health and medical professional providers responsible for the individual's treatment should work together in making a decision about the use of cross-sex hormones during the months before the gender reassignment surgery. Transsexual individuals should regularly participate in psychotherapy in order to have smooth transitions and adjustments to the new social and physical outcomes.

TRANS-SPECIFIC CANCER SCREENINGS

Professional organizations such as the American Cancer Society, American College of Obstetricians and Gynecologists and the US Preventive Services Task Force provide recommended cancer screening guidelines to facilitate clinical decision-making by professional providers. Some cancer screening protocols are sex/gender specific based on assumptions about the genitalia for a particular gender. There is little data on cancer risk specifically in transsexual individuals.

There is difficulty in recommending sex/gender specific screenings (e.g., breast, cervix, ovaries, penis, prostate, testicles and uterus) for transsexual individuals because of their physiologic changes. For example, transmen who have not undergone a mastectomy have the same risks for breast cancer as natal women. In transwomen, the prostate typically is not removed as part of genital surgery, so individuals who do not take feminizing hormones may be at the same risk for prostate cancer as natal men. Therefore, cancer screenings (e.g., mammograms, prostate screenings) may be indicated based on the individual's original gender.

Gender specific screenings may be medically necessary for transgender persons appropriate to their anatomy. Examples include:

1. Breast cancer screening may be medically necessary for transmen who have not undergone a mastectomy.
2. Prostate cancer screening may be medically necessary for transwomen who have retained their prostate.

Claims for gender reassignment surgery will be reviewed on a case by case basis. Surgical treatment of gender reassignment surgery for gender dysphoria may be eligible when medical necessity and documentation requirements outlined within this article are met.

Surgical treatment for gender dysphoria may be considered medically necessary when **ALL** of the following criteria are met:

- The individual is at least 18 years of age.
- A gender reassignment treatment plan is created specific to an individual beneficiary
- The individual has a documented Diagnostic and Statistical Manual of Mental Disorders -Fifth Edition, DSM-5™ diagnosis of GD:

A. *A marked incongruence between one's experienced/expressed gender and assigned gender, of at least 6 months duration, as manifested by at least two of the following:*

1. A marked incongruence between one's experienced/expressed gender and primary and/or secondary sex characteristics.
2. A strong desire to be rid of one's primary and/or secondary sex characteristics because of a marked incongruence with one's experienced/expressed gender.
3. A strong desire for the primary and/or secondary sex characteristics of the other gender.
4. A strong desire to be of the other gender (or some alternative gender different from one's assigned gender).
5. A strong desire to be treated as the other gender (or some alternative gender different from one's assigned gender).
6. A strong conviction that one has the typical feelings and reactions of the other gender (or some alternative gender different from one's assigned gender).

B. *The condition is associated with clinically significant distress or impairment in social, occupational or other important areas of functioning.*

- One letter from a mental health professional that the patient has had, at minimum, twelve months of psychotherapy sessions attesting to all of the following clinical criteria:
 1. That any co-morbid psychiatric or other medical conditions are stable and that the individual is prepared to undergo surgery.
 2. That the patient has had persistent and chronic gender dysphoria.
 3. That the patient has completed twelve months of continuous, full-time, real-life experience (i.e., the act of fully adopting a new or evolving gender role or gender presentation in everyday life) in the desired gender.
- The individual, if required by the mental health professional provider, has regularly participated in psychotherapy throughout the real-life experience at a frequency determined jointly by the individual and the mental health professional provider.
- Unless medically contraindicated (or the individual is otherwise unable to take cross-sex hormones), there is documentation that the individual has participated in twelve consecutive months of cross-sex hormone therapy of the desired gender continuously and responsibly (e.g., screenings and follow-ups with the professional provider).
- The individual has knowledge of all practical aspects (e.g., required lengths of hospitalizations, likely complications, and post-surgical rehabilitation) of the gender reassignment surgery.

SURGICAL TREATMENTS FOR GENDER REASSIGNMENT

When all of the above criteria are met for gender reassignment surgery, the following genital surgeries may be considered for transwomen (male to female):

- Orchiectomy - removal of testicles
- Penectomy - removal of penis
- Vaginoplasty - creation of vagina
- Clitoroplasty - creation of clitoris
- Labiaplasty - creation of labia
- Mammoplasty - breast augmentation
- Prostatectomy - removal of prostate
- Urethroplasty - creation of urethra

When all of the above criteria are met for gender reassignment surgery, the following genital/breast surgeries may be considered for transmen (female to male):

- Breast reconstruction (e.g., mastectomy) - removal of breast
- Hysterectomy - removal of uterus
- Salpingo-oophorectomy - removal of fallopian tubes and ovaries
- Vaginectomy - removal of vagina
- Vulvectomy - removal of vulva
- Metoidioplasty - creation of micro-penis, using clitoris
- Phalloplasty - creation of penis, with or without urethra
- Urethroplasty - creation of urethra within the penis
- Scrotoplasty - creation of scrotum
- Testicular prostheses - implantation of artificial testes

Services or procedures may not be covered when the criteria and documentation requirements outlined within this article are not met.

Services that are considered cosmetic for the treatment of gender dysphoria are not covered.

This list is not all-inclusive:

- Liposuction: removal of fat
- Rhinoplasty: reshaping of nose
- Rhytidectomy: face lift
- Blepharoplasty: removal of redundant skin of upper and/or lower eyelids and protruding periorbital fat
- Hair removal/ hair transplantation
- Facial feminizing (e.g., facial bone reduction)
- Chin augmentation: reshaping or enhancing the size of the chin
- Collagen injections
- Lip reduction/enhancement: decreasing/enlarging lip size
- Cricothyroid approximation: voice modification that raises the vocal pitch by simulating contractions of the cricothyroid muscle with sutures
- Trachea shave/reduction thyroid chondroplasty: reduction of the thyroid cartilage
- Laryngoplasty: reshaping of laryngeal framework (voice modification surgery)
- Mastopexy: breast lift

For a list of additional services that are considered cosmetic and therefore, non-covered, please refer to LCD L33428-

Cosmetic and Reconstructive Surgery.

Cosmetic surgery or expenses incurred in connection with such surgery is not covered. Cosmetic surgery includes any surgical procedure directed at improving appearance, except when required for the prompt [i.e., as soon as medically feasible] repair of accidental injury or for the improvement of the functioning of a malformed body member.

The individual's medical record must be submitted along with the claim and support the services billed. These medical records may include, but are not limited to: records from the professional provider's office, hospital, nursing home, home health agencies, therapies, and test reports.

When reporting procedure code 55970 (Intersex surgery; male to female), the following staged procedures to remove portions of the male genitalia and form female external genitals are included:

- The penis is dissected, and portions are removed with care to preserve vital nerves and vessels in order to fashion a clitoris-like structure.
- The urethral opening is moved to a position similar to that of a female.
- A vagina is made by dissecting and opening the perineum. This opening is lined using pedicle or split-thickness grafts.
- Labia are created out of skin from the scrotum and adjacent tissue.
- A stent or obturator is usually left in place in the newly created vagina for three weeks or longer.

When reporting CPT® code 55980 (Intersex surgery; female to male), the following staged procedures to form a penis and scrotum using pedicle flap grafts and free skin grafts are included:

- Portions of the clitoris are used, as well as the adjacent skin.
- Prostheses are often placed in the penis to create a sexually functional organ.
- Prosthetic testicles are implanted in the scrotum.
- The vagina is closed or removed.

Coding Information

CPT/HCPCS Codes

Group 1 Paragraph:

Transwoman procedures (male to female)

*NOTE: For Part A services only, the provider should bill the appropriate procedure code(s) for inpatient services.

The following CPT® codes will be considered when applicable criteria have been met:

Group 1 Codes: (14 Codes)

CODE	DESCRIPTION
19325	BREAST AUGMENTATION WITH IMPLANT
54125	AMPUTATION OF PENIS; COMPLETE

CODE	DESCRIPTION
54520	ORCHIECTOMY, SIMPLE (INCLUDING SUBCAPSULAR), WITH OR WITHOUT TESTICULAR PROSTHESIS, SCROTAL OR INGUINAL APPROACH
54690	LAPAROSCOPY, SURGICAL; ORCHIECTOMY
55866	LAPAROSCOPY, SURGICAL PROSTATECTOMY, RETROPUBIC RADICAL, INCLUDING NERVE SPARING, INCLUDES ROBOTIC ASSISTANCE, WHEN PERFORMED
55970	INTERSEX SURGERY; MALE TO FEMALE
56800	PLASTIC REPAIR OF INTROITUS
56805	CLITOROPLASTY FOR INTERSEX STATE
57291	CONSTRUCTION OF ARTIFICIAL VAGINA; WITHOUT GRAFT
57292	CONSTRUCTION OF ARTIFICIAL VAGINA; WITH GRAFT
57295	REVISION (INCLUDING REMOVAL) OF PROSTHETIC VAGINAL GRAFT; VAGINAL APPROACH
57296	REVISION (INCLUDING REMOVAL) OF PROSTHETIC VAGINAL GRAFT; OPEN ABDOMINAL APPROACH
57335	VAGINOPLASTY FOR INTERSEX STATE
57426	REVISION (INCLUDING REMOVAL) OF PROSTHETIC VAGINAL GRAFT, LAPAROSCOPIC APPROACH

Group 2 Paragraph:

Transman procedures (female to male)

*NOTE: For Part A services only, the provider should bill the appropriate procedure code(s) for inpatient services.

The following CPT® codes will be considered when applicable criteria have been met:

Group 2 Codes: (31 Codes)

CODE	DESCRIPTION
19303	MASTECTOMY, SIMPLE, COMPLETE
53420	URETHROPLASTY, 2-STAGE RECONSTRUCTION OR REPAIR OF PROSTATIC OR MEMBRANOUS URETHRA; FIRST STAGE
53425	URETHROPLASTY, 2-STAGE RECONSTRUCTION OR REPAIR OF PROSTATIC OR MEMBRANOUS URETHRA; SECOND STAGE
53430	URETHROPLASTY, RECONSTRUCTION OF FEMALE URETHRA
54660	INSERTION OF TESTICULAR PROSTHESIS (SEPARATE PROCEDURE)
55175	SCROTOPLASTY; SIMPLE
55180	SCROTOPLASTY; COMPLICATED
55980	INTERSEX SURGERY; FEMALE TO MALE

CODE	DESCRIPTION
56625	VULVECTOMY SIMPLE; COMPLETE
57106	VAGINECTOMY, PARTIAL REMOVAL OF VAGINAL WALL;
57110	VAGINECTOMY, COMPLETE REMOVAL OF VAGINAL WALL;
58150	TOTAL ABDOMINAL HYSTERECTOMY (CORPUS AND CERVIX), WITH OR WITHOUT REMOVAL OF TUBE(S), WITH OR WITHOUT REMOVAL OF OVARY(S);
58180	SUPRACERVICAL ABDOMINAL HYSTERECTOMY (SUBTOTAL HYSTERECTOMY), WITH OR WITHOUT REMOVAL OF TUBE(S), WITH OR WITHOUT REMOVAL OF OVARY(S)
58260	VAGINAL HYSTERECTOMY, FOR UTERUS 250 G OR LESS;
58262	VAGINAL HYSTERECTOMY, FOR UTERUS 250 G OR LESS; WITH REMOVAL OF TUBE(S), AND/OR OVARY(S)
58275	VAGINAL HYSTERECTOMY, WITH TOTAL OR PARTIAL VAGINECTOMY;
58290	VAGINAL HYSTERECTOMY, FOR UTERUS GREATER THAN 250 G;
58291	VAGINAL HYSTERECTOMY, FOR UTERUS GREATER THAN 250 G; WITH REMOVAL OF TUBE(S) AND/OR OVARY(S)
58541	LAPAROSCOPY, SURGICAL, SUPRACERVICAL HYSTERECTOMY, FOR UTERUS 250 G OR LESS;
58542	LAPAROSCOPY, SURGICAL, SUPRACERVICAL HYSTERECTOMY, FOR UTERUS 250 G OR LESS; WITH REMOVAL OF TUBE(S) AND/OR OVARY(S)
58543	LAPAROSCOPY, SURGICAL, SUPRACERVICAL HYSTERECTOMY, FOR UTERUS GREATER THAN 250 G;
58544	LAPAROSCOPY, SURGICAL, SUPRACERVICAL HYSTERECTOMY, FOR UTERUS GREATER THAN 250 G; WITH REMOVAL OF TUBE(S) AND/OR OVARY(S)
58550	LAPAROSCOPY, SURGICAL, WITH VAGINAL HYSTERECTOMY, FOR UTERUS 250 G OR LESS;
58552	LAPAROSCOPY, SURGICAL, WITH VAGINAL HYSTERECTOMY, FOR UTERUS 250 G OR LESS; WITH REMOVAL OF TUBE(S) AND/OR OVARY(S)
58553	LAPAROSCOPY, SURGICAL, WITH VAGINAL HYSTERECTOMY, FOR UTERUS GREATER THAN 250 G;
58554	LAPAROSCOPY, SURGICAL, WITH VAGINAL HYSTERECTOMY, FOR UTERUS GREATER THAN 250 G; WITH REMOVAL OF TUBE(S) AND/OR OVARY(S)
58570	LAPAROSCOPY, SURGICAL, WITH TOTAL HYSTERECTOMY, FOR UTERUS 250 G OR LESS;
58571	LAPAROSCOPY, SURGICAL, WITH TOTAL HYSTERECTOMY, FOR UTERUS 250 G OR LESS; WITH REMOVAL OF TUBE(S) AND/OR OVARY(S)
58572	LAPAROSCOPY, SURGICAL, WITH TOTAL HYSTERECTOMY, FOR UTERUS GREATER THAN 250 G;

CODE	DESCRIPTION
58573	LAPAROSCOPY, SURGICAL, WITH TOTAL HYSTERECTOMY, FOR UTERUS GREATER THAN 250 G; WITH REMOVAL OF TUBE(S) AND/OR OVARY(S)
58720	SALPINGO-OOPHORECTOMY, COMPLETE OR PARTIAL, UNILATERAL OR BILATERAL (SEPARATE PROCEDURE)

Group 3 Paragraph:

All unlisted procedure codes will suspend for medical review.

The following CPT® codes are considered cosmetic. When billed with any Covered ICD-10 Codes listed below, the service will not be covered (list may not be all-inclusive):

Group 3 Codes: (50 Codes)

CODE	DESCRIPTION
11950	SUBCUTANEOUS INJECTION OF FILLING MATERIAL (EG, COLLAGEN); 1 CC OR LESS
11951	SUBCUTANEOUS INJECTION OF FILLING MATERIAL (EG, COLLAGEN); 1.1 TO 5.0 CC
11952	SUBCUTANEOUS INJECTION OF FILLING MATERIAL (EG, COLLAGEN); 5.1 TO 10.0 CC
11954	SUBCUTANEOUS INJECTION OF FILLING MATERIAL (EG, COLLAGEN); OVER 10.0 CC
15769	GRAFTING OF AUTOLOGOUS SOFT TISSUE, OTHER, HARVESTED BY DIRECT EXCISION (EG, FAT, DERMIS, FASCIA)
15771	GRAFTING OF AUTOLOGOUS FAT HARVESTED BY LIPOSUCTION TECHNIQUE TO TRUNK, BREASTS, SCALP, ARMS, AND/OR LEGS; 50 CC OR LESS INJECTATE
15772	GRAFTING OF AUTOLOGOUS FAT HARVESTED BY LIPOSUCTION TECHNIQUE TO TRUNK, BREASTS, SCALP, ARMS, AND/OR LEGS; EACH ADDITIONAL 50 CC INJECTATE, OR PART THEREOF (LIST SEPARATELY IN ADDITION TO CODE FOR PRIMARY PROCEDURE)
15773	GRAFTING OF AUTOLOGOUS FAT HARVESTED BY LIPOSUCTION TECHNIQUE TO FACE, EYELIDS, MOUTH, NECK, EARS, ORBITS, GENITALIA, HANDS, AND/OR FEET; 25 CC OR LESS INJECTATE
15774	GRAFTING OF AUTOLOGOUS FAT HARVESTED BY LIPOSUCTION TECHNIQUE TO FACE, EYELIDS, MOUTH, NECK, EARS, ORBITS, GENITALIA, HANDS, AND/OR FEET; EACH ADDITIONAL 25 CC INJECTATE, OR PART THEREOF (LIST SEPARATELY IN ADDITION TO CODE FOR PRIMARY PROCEDURE)
15775	PUNCH GRAFT FOR HAIR TRANSPLANT; 1 TO 15 PUNCH GRAFTS
15776	PUNCH GRAFT FOR HAIR TRANSPLANT; MORE THAN 15 PUNCH GRAFTS
15820	BLEPHAROPLASTY, LOWER EYELID;
15821	BLEPHAROPLASTY, LOWER EYELID; WITH EXTENSIVE HERNIATED FAT PAD
15822	BLEPHAROPLASTY, UPPER EYELID;

CODE	DESCRIPTION
15823	BLEPHAROPLASTY, UPPER EYELID; WITH EXCESSIVE SKIN WEIGHTING DOWN LID
15824	RHYTIDECTOMY; FOREHEAD
15825	RHYTIDECTOMY; NECK WITH PLATYSMAL TIGHTENING (PLATYSMAL FLAP, P-FLAP)
15826	RHYTIDECTOMY; GLABELLAR FROWN LINES
15828	RHYTIDECTOMY; CHEEK, CHIN, AND NECK
15829	RHYTIDECTOMY; SUPERFICIAL MUSCULOAPONEUROTIC SYSTEM (SMAS) FLAP

ICD-10-CM Codes that Support Medical Necessity

Group 1 Paragraph:

The following diagnosis codes are considered covered when applicable criteria have been met:

Group 1 Codes: (5 Codes)

CODE	DESCRIPTION
F64.1	Dual role transvestism
F64.2	Gender identity disorder of childhood
F64.8	Other gender identity disorders
F64.9	Gender identity disorder, unspecified

CODE	DESCRIPTION
Z87.890	Personal history of sex reassignment

ICD-10-CM Codes that DO NOT Support Medical Necessity

Group 1 Paragraph:

All other diagnosis codes will be denied as non-covered.

Group 1 Codes:

N/A

Additional ICD-10 Information

N/A

Bill Type Codes

Contractors may specify Bill Types to help providers identify those Bill Types typically used to report this service. Absence of a Bill Type does not guarantee that the article does not apply to that Bill Type. Complete absence of all Bill Types indicates that coverage is not influenced by Bill Type and the article should be assumed to apply equally to all claims.

N/A

Revenue Codes

Contractors may specify Revenue Codes to help providers identify those Revenue Codes typically used to report this service. In most instances Revenue Codes are purely advisory. Unless specified in the article, services reported under other Revenue Codes are equally subject to this coverage determination. Complete absence of all Revenue Codes indicates that coverage is not influenced by Revenue Code and the article should be assumed to apply equally to all Revenue Codes.

Revision History Information

REVISION HISTORY DATE	REVISION HISTORY NUMBER	REVISION HISTORY EXPLANATION
01/01/2021	R13	Under CPT/HCPCS Codes Group 1: Codes descriptor was revised for 19325. This revision is due to the Q1 2021 CPT/HCPCS Code Update and is retroactive effective for dates of service on or after 1/1/2021.
01/01/2020	R12	Under CPT/HCPCS Codes Group 2: Codes CPT® code 19304 was deleted. CPT® was inserted throughout the article where applicable. Under CPT/HCPCS Codes Group 3: Codes added 15769, 15771, 15772, 15773 and 15774. This revision is due to the 2020 Annual CPT/HCPCS Code Update and is effective on January 1, 2020.
10/03/2019	R11	This article is being revised in order to adhere to CMS requirements per chapter 13, section 13.5.1 of the Program Integrity Manual, to remove all coding from LCDs and incorporate into related Billing and Coding Articles.
11/15/2018	R10	Under Article Text added the verbiage "be submitted along with the claim and" after the verbiage "The individual's medical record must" in the third paragraph from the bottom of the section.
02/26/2018	R9	The Jurisdiction "J" Part A and Part B Contracts for Alabama (10111/10112), Georgia (10211/10212) and Tennessee (10311/10312) are now being serviced by Palmetto GBA. Effective 02/26/18, these 6 contract numbers are being added to this article. No coverage, coding or other substantive changes (beyond the addition of the 6 Part A and B contract numbers) have been completed in this revision.
04/27/2017	R8	Under Article Text – Grammatical and punctuation changes were made throughout text. Revised sentence under B. to read "One letter from a mental health professional that the patient has had, at minimum, twelve months of psychotherapy therapy sessions attesting to all of the following clinical criteria:"
10/01/2016	R7	Under Covered ICD-10 Codes the description was revised for ICD-10 code F64.1. This revision is due to the Annual ICD-10 Code Update and becomes effective 10/01/16.
10/01/2015	R6	Under CPT/HCPCS Codes-Group 3 Paragraph the bolded verbiage was removed for the Group 3 CPT codes.
10/01/2015	R5	Under Article Text in the first sentence of the first paragraph corrected "DSM-V-TR, 2013" to now read "Diagnostic and Statistical Manual of Mental Disorders - Fifth Edition, DSM-5™". Under Non-Surgical Treatment , deleted "also" found in the third sentence of the last paragraph as this was redundant. Under Trans-Specific Cancer Screenings in the third bullet of the fifth paragraph corrected "DSM-IV-TR" to now read "Diagnostic and Statistical Manual of Mental Disorders - Fifth Edition, DSM-5™". Under Surgical Treatments for Gender Reassignment corrected the title of the specific LCD cited in the sixth paragraph. Under CPT/HCPCS Codes-Group 1 Paragraph revised the verbiage in the *Note and deleted the following, "See Article Text for included surgeries." Under CPT/HCPCS Codes-Group 2 Paragraph added the *Note. Under CPT/HCPCS Codes-Group 3 Paragraph the verbiage was revised in the second sentence. Under

REVISION HISTORY DATE	REVISION HISTORY NUMBER	REVISION HISTORY EXPLANATION
		Covered ICD-10 Codes Paragraph added the first sentence. Under Non-Covered ICD-10 Codes corrected the spelling of "diagnosis."
06/11/2015	R4	Per CMS Internet-Only Manual, Pub 100-08, Medicare Program Integrity Manual, Chapter 13, §13.1.3 LCDs consist of only "reasonable and necessary" information. All bill type and revenue codes have been removed from the LCDs. For consistency, they are also being removed from the articles.
10/01/2015	R3	Under Covered ICD-10 codes added ICD-10 codes F64.2, F64.8, F64.9 and Z87.890 per TDL-150320. Under Associated Documents , subheading Statutory Requirements URL(s) added Title XVIII of the Social Security Act §1862(a)(1)(A).
10/01/2015	R2	Under Article Text deleted the following statement and replaced it with the definition of cosmetic surgery as defined by manual instruction: "Cosmetic services may improve an individual's physical appearance but provide no significant improvement in physiologic function. Emotional and/or psychological improvement alone does not constitute improvement in physiologic function."
10/01/2015	R1	Under CPT/HCPCS Codes added the NOTE . Under Covered ICD-10 Codes deleted the paragraph related to Z87.890 and deleted ICD-10 code Z87.890 as this code was redundant with F64.1.

About this report

This interim report represents the work of the independent review of gender identity services for children and young people to date. It reflects a point in time. It does not set out final recommendations; these will be developed over the coming months, informed by our formal research programme.

This Review is forward looking. Its role is to consider how to improve and develop the future clinical approach and service model. However, in order to do this, it is first necessary to understand the current landscape and the reasons why change is needed, so that any future model addresses existing challenges, whilst retaining those features that service users and the professionals supporting them most value.

This report is primarily for the commissioners and providers of services for children and young people needing support around their gender. However, because of the wide interest in this topic, we have included some explanations about how clinical service development routinely takes place in the NHS, which sets the context for some of our interim advice.

The care of this group of children and young people is everyone's business. We therefore encourage the wider clinical community to take note of our work and consider their own roles in providing the best holistic support to this population.

Since the Review began, it has focused on hearing a wide range of perspectives to better understand the challenges within the current system and aspirations for how these could be addressed. This report does not contain all that we have heard during our listening sessions but summarises consistent themes. These conversations will continue throughout the course of the Review and there will be further opportunities for stakeholders to engage and contribute.

It is important to note that the references cited in this report do not constitute a comprehensive literature review and are included only to clarify why specific lines of enquiry are being pursued, and where there are unanswered questions that will be addressed more fully during the life of the Review. A formal literature review is one strand of the Review's commissioned work, and this will be reported in full when complete.

A note about language

There is sometimes no consensus on the best language to use relating to this subject. The language surrounding this area has also changed rapidly and young people have developed varied ways of describing their experiences using different terms and constructs that are relevant to them.

The Review tries as far as possible to use language and terms that are respectful and acknowledge diversity, but that also accurately illustrate the complexity of what we are trying to describe and articulate.

The terms we have used may not always feel right to some; nevertheless, it is important to emphasise that the language used is not an indication of a position being taken by the Review. A glossary of terms is included.

The Review is cognisant of the broader cultural and societal debates relating to the rights of transgender adults. It is not the role of the Review to take any position on the beliefs that underpin these debates. Rather, this Review is strictly focused on the clinical services provided to children and young people who seek help from the NHS to resolve their gender-related distress.

A letter to children and young people

Children and young people accessing the NHS deserve safe, timely and supportive services, and clinical staff with the training and expertise to meet their healthcare needs.

Dr Hilary Cass

I understand that as you read this letter some of you may be anxious because you are waiting to access support from the NHS around your gender identity. Maybe you have tried to get help from your local services, or from the Gender Identity Development Service (GIDS), and because of the long waiting lists they have not yet been able to see you. I hope that some of you have had help – maybe from a supportive GP, a local Child and Adolescent Mental Health Service (CAMHS), or from GIDS.

I have heard that young service users are particularly worried that I will suggest that services should be reduced or stopped. I want to assure you that this is absolutely not the case – the reverse is true. I think that more services are needed for you, closer to where you live. The GIDS staff are working incredibly hard and doing their very best to see you as quickly as possible but providing supportive care is not something that can be rushed – each young person needs enough time and space for their personal needs to be met. So, with the best will in the world, one service is not going to be able to respond to the growing demand in a timely way.

I am advising that more services are made available to support you. But I must be honest; this is not something that can happen overnight, and I can't come up with a solution that will fix the problems immediately. However, we do need to start now.

The other topic that I know is worrying some of you is whether I will suggest that hormone treatments should be stopped. On this issue, I have to share my thoughts as a doctor. We know quite a bit about hormone treatments, but there is still a lot we don't know about the long-term effects.

Independent review of gender identity services for children and young people

Whenever doctors prescribe a treatment, they want to be as certain as possible that the benefits will outweigh any adverse effects so that when you are older you don't end up saying 'Why did no-one tell me that that might happen?' This includes understanding both the risks and benefits of having treatment and not having treatment.

Therefore, what we will be doing over the next few months is trying to make sense of all the information that is available, as well as seeing if we can plug any of the gaps in the research. I am currently emphasising the importance of making decisions about prescribing as safe as possible. This means making sure you have all the information you need – about what we do know and what we don't know.

Finally, some of you may want the chance to talk to me and share your thoughts about how services should look in the future. Over the coming months we will need your help and there will be opportunities to get involved with the Review, so please keep an eye on our website (www.cass.independent-review.uk), where we will provide updates on our work.

A handwritten signature in black ink, appearing to read 'Hilary'.

Dr Hilary Cass, OBE

Introduction from the Chair

Anyone with an interest in the care of gender-questioning children and young people, as well as those with lived experience, may have wondered what qualifies me to take on this Review, and whether I have a pre-existing position on this subject.

I am a paediatrician who was in clinical practice until 2018, my area of specialism being children and young people with disability. I have also held many management and policy roles throughout my career, most notably as President of the Royal College of Paediatrics and Child Health (RCPCH) from 2012-15.

Children's services are often at a disadvantage in healthcare because health services are usually designed around the needs of adults. As President of RCPCH, a key part of my role was to advocate for services to be planned with children and families at their heart.

I have not worked in gender services during my career, but my strong focus on hearing the voice of service users, supporting vulnerable young people, equity of access, and strong clinical standards applies in this area as much as in my other work.

With this in mind, the aim of the Review is to ensure that children and young people who are experiencing gender incongruence or gender-related distress receive a high standard of NHS care that meets their needs and is safe, holistic and effective.

I have previously set out the principles governing this Review process, namely that:

- The welfare of the child and young person will be paramount in all considerations.
- Children and young people must receive a high standard of care that meets their needs.
- There will be extensive and purposeful stakeholder engagement, including ensuring that children and young people can express their own views through a supportive process.
- The Review will be underpinned by research and evidence, including international models of good practice where available.
- There will be transparency in how the Review is conducted and how recommendations are made.
- There are no pre-determined outcomes with regards to the recommendations the Review will make.

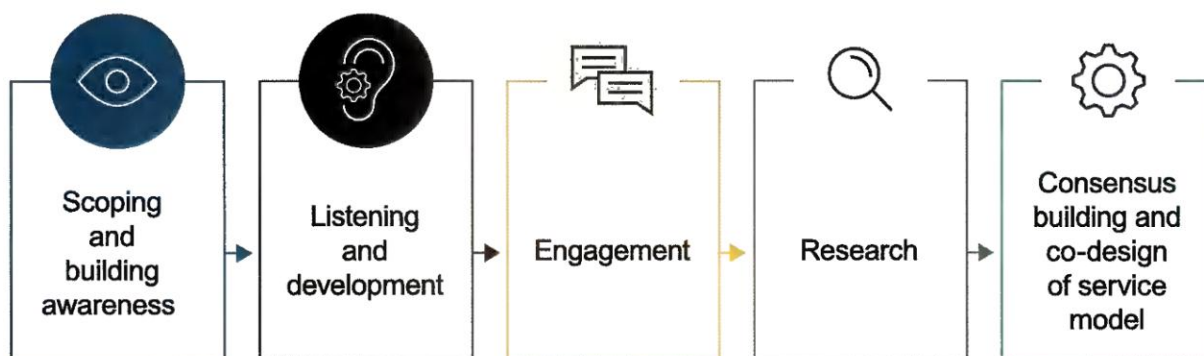

Independent review of gender identity services for children and young people

The Review's terms of reference (**Appendix 1**) are wide ranging in scope, looking at different aspects of gender identity services across the whole pathway through primary, secondary and specialist services, up to the point of transition to adult services. This includes consideration of referral pathways, assessment, appropriate clinical management and workforce recommendations.

I have also been asked to explore the reasons for the considerable increase in the number of referrals, which have had a significant impact on waiting times, as well as the changing case-mix of gender-questioning children and young people presenting to clinical services.

The Review is taking an investigative approach to understanding what the future service model should look like for children and young people. This means that its outcomes are not being developed in isolation or by committee but rather through an ongoing dialogue aimed at building a shared understanding of the current situation and how it can and should be improved.

The key aspects of the approach to the Review are:

My starting point has been to hear from a variety of experts with relevant expertise and those with lived experience to understand as many perspectives as possible. To date, this has included hearing directly from those with lived experience, from professionals and support and advocacy groups. This listening process will continue.

We have been very fortunate in the generosity of all those who have been prepared to talk to the Review and share their experiences. In addition to some divergent opinions, there are also some themes and views which seem to be widely shared. The commitment of professionals at all levels is striking and I genuinely believe that with collective effort we can improve services for the children and young people who are at the heart of this Review.

These discussions have been valuable to get an in-depth sense of the current situation and different viewpoints on how it may be improved. However, it is essential that this initial understanding is underpinned by more detailed data and an enhanced evidence base, which is being delivered through the Review's academic research programme.

Providing this evidence base for the Review is going to take some time. I recognise there is a pressing need to enhance the services currently available for children, young people, their

parents and carers, some of whom are experiencing considerable distress. Clinicians providing their treatment and care are also under pressure and cannot sustain the current workload. As such, I know the time I am taking to complete this Review and make recommendations will be difficult for some, but it is necessary.

I wrote to NHS England in May 2021 (**Appendix 2**) setting out some more immediate considerations whilst awaiting my full recommendations. This report builds on that letter and looks to provide some further interim advice.

Through our research programme, the Review team will continue to examine the literature and, where possible, will fill gaps in the existing evidence base. However, there will be persisting evidence gaps and areas of uncertainty. We need the engagement of service users, support and advocacy groups, and professionals across the wider workforce to work with us in the coming months in a collaborative and open-minded manner in order to reach a shared understanding of the problems and an agreed way forward that is in the best interests of children and young people.

My measure of success for this Review will be that this group of children and young people receive timely, appropriate and excellent care, not just from specialists but from every healthcare professional they encounter as they take the difficult journey from childhood to adulthood.

1. Summary and interim advice

Summary

1.1. In recent years, there has been a significant increase in the number of referrals to the Gender Identity Development Service (GIDS) at the Tavistock and Portman NHS Foundation Trust. This has contributed to long waiting lists and growing concern about how the NHS should most appropriately assess, diagnose and care for this population of children and young people.

1.2. Within the UK, the single specialist service has developed organically, and the clinical approach has not been subjected to some of the usual control measures that are typically applied when new or innovative treatments are introduced. Many of the challenges and knowledge gaps that we face in the UK are echoed internationally,¹ and there are significant gaps in the research and evidence base.

1.3. This Review was commissioned by NHS England to make recommendations on how to improve services provided by the NHS to children and young people who are questioning their gender identity or experiencing gender incongruence and ensure that the best model for safe and effective services is commissioned (**Appendix 1**).

1.4. This interim report represents the Review's work to date. It sets out what we have heard so far and the approach we are taking moving forward. There is still much evidence to be gathered, questions to be answered, and voices to be heard, and our perspective will evolve as more evidence comes to light. However, there is sufficient clarity on several areas for the Review to be able to offer advice at this stage so that action can be taken more quickly.

1.5. The Review is not able to provide definitive advice on the use of puberty blockers and feminising/masculinising hormones at this stage, due to gaps in the evidence base; however, recommendations will be developed as our research programme progresses.

Every gender-questioning child or young person who seeks help from the NHS must receive the support they need to get on the appropriate pathway for them as an individual.

Children and young people with gender incongruence or dysphoria must receive the same standards of clinical care, assessment and treatment as every other child or young person accessing health services.

¹ Vrouwenraets LJ, Fredriks AM, Hannema SE, Cohen-Kettenis PT, de Vries MC (2015). [Early medical treatment of children and adolescents with gender dysphoria: an empirical ethical study](#). J Adolesc Health 57(4): 367-73. DOI: 10.1016/2015.04.004.

Conceptual understanding and consensus about the meaning of gender dysphoria

1.6. In clinical practice, a diagnosis of gender dysphoria is currently based on an operational definition, using the criteria set out in DSM-5 (**Appendix 3**). Some of these criteria are seen by some as outdated in the context of current understanding about the flexibility of gender expression.

1.7. At primary, secondary and specialist level, there is a lack of agreement, and in many instances a lack of open discussion, about the extent to which gender incongruence in childhood and adolescence can be an inherent and immutable phenomenon for which transition is the best option for the individual, or a more fluid and temporal response to a range of developmental, social, and psychological factors. Professionals' experience and position on this spectrum may determine their clinical approach.

1.8. Children and young people can experience this as a 'clinician lottery', and failure to have an open discussion about this issue is impeding the development of clear guidelines about their care.

Service capacity and delivery

1.9. A rapid change in epidemiology and an increase in referrals means that the number of children seeking help from the NHS is now outstripping the capacity of the single national specialist service, the Gender Identity Development Service (GIDS) at The Tavistock and Portman NHS Foundation Trust.

1.10. The mix of young people presenting to the service is more complex than seen previously, with many being neurodiverse and/or having a wide range of psychosocial and mental health needs. The largest group currently comprises birth-registered females first presenting in adolescence with gender-related distress.

1.11. Until very recently, any local professional, including non-health professionals, could refer to GIDS, which has meant that the quality and appropriateness of referrals lacks consistency, and local service provision has remained patchy and scarce.

1.12. The staff working within the specialist service demonstrate a high level of commitment to the population they serve. However, the waiting list pressure and lack of consensus development on the clinical approach, combined with criticism of the service, have all resulted in rapid turnover of staff and inadequate capacity to deal with the increasing workload. Capacity constraints cannot be addressed through financial investment alone; there are some complex workforce (recruitment; retention; and training) and cultural issues to address.

1.13. Our initial work has indicated that many professionals working at primary and secondary level feel that they have the transferable skills and the commitment to offer more robust support to this group of children and young people, but are nervous about doing so, partly because of the lack of formal clinical guidance, and partly due to the broader societal context.

1.14. Primary and secondary care staff have told us that they feel under pressure to adopt an unquestioning affirmative approach and that this is at odds with the standard process of clinical assessment and diagnosis that they have been trained to undertake in all other clinical encounters.

1.15. Children and young people are waiting lengthy periods to access GIDS, during which time some may be at considerable risk. By the time they are seen, their distress may have worsened, and their mental health may have deteriorated.

1.16. Another significant issue raised with us is one of diagnostic overshadowing – many of the children and young people presenting have complex needs, but once they are identified as having gender-related distress, other important healthcare issues that would normally be managed by local services can sometimes be overlooked.

1.17. The current move to adult services at age 17-18 may fall at a critical time in the young person's gender management. In contrast, young people with neurodiversity often remain under children's services until age 19 and some other clinical services continue to mid-20s. Further consideration will be needed regarding the age of transfer to adult services.

Service standards

1.18. The Multi-Professional Review Group (MPRG), set up by NHS England to ensure that procedures for assessment and for informed consent have been properly followed, has stated that the following areas require consideration:

- From the point of entry to GIDS there appears to be predominantly an affirmative, non-exploratory approach, often driven by child and parent expectations and the extent of social transition that has developed due to the delay in service provision.
- From documentation provided to the MPRG, there does not appear to be a standardised approach to assessment or progression through the process, which leads to potential gaps in necessary evidence and a lack of clarity.
- There is limited evidence of mental health or neurodevelopmental assessments being routinely documented, or of a discipline of formal diagnostic or psychological formulation.
- Of 44 submissions received by the MPRG, 31% were not initially assured due to lack of safeguarding information. And in a number of cases there were specific safeguarding concerns. There do not appear to be consistent processes in place to work with other agencies to identify children and young people and families who may be vulnerable, at risk and require safeguarding.

- Appropriate clinical experts need to be involved in informing decision making.

1.19. Many of these issues were also highlighted by the Care Quality Commission (CQC) in 2020.²

International comparisons

1.20. The Netherlands was the first country to provide early endocrine interventions (now known internationally as the Dutch Approach). Although GIDS initially reported its approach to early endocrine intervention as being based on the Dutch Approach,³ there are significant differences in the NHS approach. Within the Dutch Approach, children and young people with neurodiversity and/or complex mental health problems are routinely given therapeutic support in advance of, or when considered appropriate, instead of early hormone intervention. Whereas criteria to have accessed therapeutic support prior to starting hormone blocking treatment do not appear to be integral to the current NHS process.

1.21. NHS endocrinologists do not systematically attend the multi-disciplinary meetings where the complex cases that may be referred to them are discussed, and until very recently did not routinely have

direct contact with the clinical staff member who had assessed the child or young person. This is not consistent with some international approaches for this group of children and young people, or in other multi-disciplinary models of care across paediatrics and adult medicine where challenging decisions about life-changing interventions are made.^{4,5}

1.22. In the NHS, once young people are started on hormone treatment, the frequency of appointments drops off rather than intensifies, and review usually takes place quarterly. Again, this is different to the Dutch Approach.⁶ GIDS staff would recommend more frequent contact during this period, but the fall-off in appointments reflects a lack of service capacity, with the aspiration being for more staff time to remedy this situation.

Existing evidence base

1.23. Evidence on the appropriate management of children and young people with gender incongruence and dysphoria is inconclusive both nationally and internationally.

³ de Vries ALC, Cohen-Kettenis PT (2012). [Clinical management of gender dysphoria in children and adolescents: the Dutch approach](#). J Homosex 59: 301–320. DOI: 10.1080/00918369.2012.653300.

⁴ Ibid.

⁵ Kyriakou A, Nicolaides NC, Skordis N (2020). [Current approach to the clinical care of adolescents with gender dysphoria](#). Acta Biomed 91(1): 165–75. DOI: 10.23750/abm.v91i1.9244.

⁶ de Vries ALC, Cohen-Kettenis PT (2012). [Clinical management of gender dysphoria in children and adolescents: the Dutch approach](#). J Homosex 59: 301–320. DOI: 10.1080/00918369.2012.653300.

1.24. A lack of a conceptual agreement about the meaning of gender dysphoria hampers research, as well as NHS clinical service provision.

1.25. There has not been routine and consistent data collection within GIDS, which means it is not possible to accurately track the outcomes and pathways that children and young people take through the service.

1.26. Internationally as well as nationally, longer-term follow-up data on children and young people who have been seen by gender identity services is limited, including for those who have received physical interventions; who were transferred to adult services and/or accessed private services; or who desisted, experienced regret or detransitioned.

1.27. There has been research on the short-term mental health outcomes and physical side effects of puberty blockers for this cohort, but very limited research on the sexual, cognitive or broader developmental outcomes.⁷

1.28. Much of the existing literature about natural history and treatment outcomes for gender dysphoria in childhood is based on a case-mix of predominantly birth-registered males presenting in early childhood. There is much less data on the more recent case-mix of predominantly

birth-registered females presenting in early teens, particularly in relation to treatment and outcomes.

1.29. Aspects of the literature are open to interpretation in multiple ways, and there is a risk that some authors interpret their data from a particular ideological and/or theoretical standpoint.

The mismatch between service user expectations and clinical standards

1.30. By the time children and young people reach GIDS, they have usually had to experience increasingly long, challenging waits to be seen.⁸ Consequently, some feel they want rapid access to physical interventions and find having a detailed assessment distressing.

1.31. Clinical staff are governed by professional, legal and ethical guidance which demands that certain standards are met before a treatment can be provided. Clinicians carry responsibility for their assessment and recommendations, and any harm that might be caused to a patient under their care. This can create a tension between the aspirations of the young person and the responsibilities of the clinician.

⁷ National Institute for Health and Care Excellence (2020). [Evidence Review: Gonadotrophin Releasing Hormone Analogues for Children and Adolescents with Gender Dysphoria](#).

⁸ Care Quality Commission (2021). [The Tavistock and Portman NHS Foundation Trust Gender Identity Service Inspection Report](#). London: CQC.

Interim advice

1.32. The Review considers that there are some areas where there is sufficient clarity about the way forward and we are therefore offering some specific observations and interim advice. The Review will work with NHS England, providers and the broader stakeholder community to progress action in these areas.

Service model

1.33. It has become increasingly clear that a single specialist provider model is not a safe or viable long-term option in view of concerns about lack of peer review and the ability to respond to the increasing demand.

1.34. Additionally, children and young people with gender-related distress have been inadvertently disadvantaged because local services have not felt adequately equipped to see them. It is essential that they can access the same level of psychological and social support as any other child or young person in distress, from their first encounter with the NHS and at every level within the service.

1.35. A fundamentally different service model is needed which is more in line with other paediatric provision, to provide timely and appropriate care for children and young people needing support around their gender identity. This must include support for any other clinical presentations that they may have.

1.36. The Review supports NHS England's plan to establish regional services, and welcomes the move from a single highly specialist service to regional hubs.

1.37. Expanding the number of providers will have the advantages of:

- creating networks within each area to improve early access and support;
- reducing waiting times for specialist care;
- building capacity and training opportunities within the workforce;
- developing a specialist network to ensure peer review and shared standards of care; and
- providing opportunities to establish a more formalised service improvement strategy.

Service provision

1.38. The primary remit of NHS England's proposed model is for the regional hubs to provide support and advice to referrers and professionals. However, it includes limited provision for direct contact with children and young people and their families.

1: The Review advises that the regional centres should be developed, as soon as feasibly possible, to become direct service providers, assessing and treating children and young people who may need specialist care, as part of a wider pathway. The Review team will work with NHS England and stakeholders to further define the proposed model and workforce implications.

2: Each regional centre will need to develop links and work collaboratively with a range of local services within their geography to ensure that appropriate clinical, psychological and social support is made available to children and young people who are in early stages of experiencing gender distress.

3: Clear criteria will be needed for referral to services along the pathway from primary to tertiary care so that gender-questioning children and young people who seek help from the NHS have equitable access to services.

4: Regional training programmes should be run for clinical practitioners at all levels, alongside the online training modules developed by Health Education England (HEE). In the longer-term, clearer mapping of the required workforce, and a series of competency frameworks will need to be developed in collaboration with relevant professional organisations.

Data, audit and research

1.39. A lack of routine and consistent data collection means that it is not possible to accurately track the outcomes and pathways children and young people take through the service. Standardised data collection is required in order to audit service standards and inform understanding of the epidemiology, assessment and treatment of this group. This, alongside a national network which brings providers together, will help build knowledge and improve outcomes through shared clinical standards and systematic data collection. In the longer-term, formalisation of such a network into a learning health system⁹ with an academic host would mean that there was systematised use of data to produce a continuing research programme with rapid translation into clinical practice and a focus on training.

⁹ Scobie S, Castle-Clarke S (2019). [Implementing learning health systems in the UK NHS: Policy actions to improve collaboration and transparency and support innovation and better use of analytics](#). Learning Health Systems 4(1): e10209. DOI:10.1002/lrh2.10209.

5: The regional services should have regular co-ordinated national provider meetings and operate to shared standards and operating procedures with a view to establishing a formal learning health system.

6: Existing and future services should have standardised data collection in order to audit standards and inform understanding of the epidemiology, assessment and treatment of this group of children and young people.

7: Prospective consent of children and young people should be sought for their data to be used for continuous service development, to track outcomes, and for research purposes. Within this model, children and young people put on hormone treatment should be formally followed up into adult services, ideally as part of an agreed research protocol, to improve outcome data.

Clinical approach

Assessment processes

1.40. We have heard that there are inconsistencies and gaps in the assessment process. Our work to date has also demonstrated that clinical staff have different views about the purpose of assessment and where responsibility lies for different components of the process within the pathway of care. The Review team has commenced discussions with clinical staff across primary, secondary and tertiary care to develop a framework for these processes.

8: There needs to be agreement and guidance about the appropriate clinical assessment processes that should take place at primary, secondary and tertiary level.

9: Assessments should be respectful of the experience of the child or young person and be developmentally informed. Clinicians should remain open and explore the patient's experience and the range of support and treatment options that may best address their needs, including any specific needs of neurodiverse children and young people.

Hormone treatment

1.41. The issues raised by the Multi-Professional Review Group echo several of the problems highlighted by the CQC. It is essential that principles of the General Medical Council's Good Practice in Prescribing and Managing Medicine's and Devices¹⁰ are closely followed, particularly given the gaps in the evidence base regarding hormone treatment. Standards for decision making regarding endocrine treatment should also be consistent with international best practice.^{11,12,13}

10: Any child or young person being considered for hormone treatment should have a formal diagnosis and formulation, which addresses the full range of factors affecting their physical, mental, developmental and psychosocial wellbeing. This formulation should then inform what options for support and intervention might be helpful for that child or young person.

11: Currently paediatric endocrinologists have sole responsibility for treatment, but where a life-changing intervention is given there should also be additional medical responsibility for the differential diagnosis leading up to the treatment decision.

1.42. Paediatric endocrinologists develop a wide range of knowledge within their paediatric training, including safeguarding, child mental health, and adolescent development. Being party to the discussions and deliberations that have led up to the decision for medical intervention supports them in carrying out their legal responsibility for consent to treatment and the prescription of hormones.

12: Paediatric endocrinologists should become active partners in the decision making process leading up to referral for hormone treatment by participating in the multidisciplinary team meeting where children being considered for hormone treatment are discussed.

¹¹ Hembree WC, Cohen-Kettenis PT, Gooren L, Hannema SE, Meyer WJ, Murad MH, et al (2017). [Endocrine treatment of gender-dysphoric/gender-incongruent persons: an Endocrine Society clinical practice guideline](#). J Clin Endocrinol Metab 102(11): 3869–903. DOI: 10.1210/jc.2017-01658.

¹² Cohen-Kettenis PT, Steensma TD, de Vries ALC (2001). [Treatment of adolescents with gender dysphoria in the Netherlands](#). Child Adolesc Psychiatr Clin N Am 20: 689–700. DOI: 10.1016/j.chc.2011.08.001.

¹³ Kyriakou A, Nicolaides NC, Skordis N (2020). [Current approach to the clinical care of adolescents with gender dysphoria](#). Acta Biomed 91(1): 165–75. DOI: 10.23750/abm.v91i1.9244.

1.43. Given the uncertainties regarding puberty blockers, it is particularly important to demonstrate that consent under this circumstance has been fully informed and to follow GMC guidance¹⁴ by keeping an accurate record of the exchange of information leading to a decision in order to inform their future care and to help explain and justify the clinician's decisions and actions.

13: Within clinical notes, the stated purpose of puberty blockers as explained to the child or young person and parent should be made clear. There should be clear documentation of what information has been provided to each child or young person on likely outcomes and side effects of all hormone treatment, as well as uncertainties about longer-term outcomes.

14: In the immediate term the Multi-Professional Review Group (MPRG) established by NHS England should continue to review cases being referred by GIDS to endocrine services.

¹⁴ General Medical Council (2020). [Decision making and consent](#).

2. Context

Transgender, non-binary and gender fluid adults

2.1. NHS clinical services to support transgender adults with hormone treatment and subsequent surgery began in 1966.

2.2. Services were initially established within a mental health model, in conjunction with endocrinology and surgical services.

2.3. Currently, NHS services for transgender adults do not have adequate capacity to cope with demand.¹⁵ In addition, the broader healthcare needs of this group are not well met. This is important in the context of the current generation of gender-questioning children and young people in that there are now two inflows into adult services – individuals transitioning in adulthood, and those moving through from children's services.

2.4. Legal rights and protections for transgender people lagged behind the provision of medical services, with the Gender Recognition Act 2004 coming into force in April 2005. Over the last few years, broader discussions about transgender issues have been played out in public, with discussions becoming increasingly polarised and adversarial. This polarisation is such that it undermines safe debate and creates difficulties in building consensus.

2.5. It is not the role of this Review to take any position on the cultural and societal debates relating to transgender adults. However, in achieving its objectives there is a need to consider the information and support that children and young people access from whatever source, as well as any pressures that they are subject to, before they access clinical services.

Terminology and diagnostic frameworks

2.6. The Office for National Statistics defines sex as “referring to the biological aspects of an individual as determined by their anatomy, which is produced by their chromosomes, hormones and their interactions; generally male or female; something that is assigned at birth”.¹⁶

2.7. The Office for National Statistics defines gender as “a social construction relating to behaviours and attributes based on labels of masculinity and femininity; gender identity is a personal, internal perception of oneself and so the gender category someone identifies with may not match the sex they were assigned at birth”.¹⁷

2.8. Societal attitudes towards gender roles and gender expression are changing. Children, teenagers and younger adults may more commonly see gender as a fluid, multi-faceted phenomenon which

¹⁵ Gender Identity Clinic, The Tavistock and Portman NHS Foundation Trust. [Waiting times](#).

¹⁶ Office for National Statistics (2019). [What is the difference between sex and gender?](#)

¹⁷ Ibid.

does not have to be binary, whereas older generations have tended to see gender as binary and fixed. It is not unusual for young people to explore both their sexuality and gender as they go through adolescence and early adulthood before developing a more settled identity. Many achieve this without experiencing significant distress or requiring support from the NHS, but this is not the case for all.

2.9. For those who require support from the NHS, there are two widely used frameworks which provide diagnostic criteria. The International Classification of Diseases (ICD), which is the World Health Organization (WHO) mandated health data standard, and the Diagnostic and Statistical Manual of Mental Disorders (DSM), which is the classification system for mental health disorders produced by the American Psychiatric Association. The current editions of these manuals – ICD-11 and DSM-5 – came into effect in January 2022 and 2013 respectively.

2.10. ICD-11¹⁸ has attempted to depathologise gender diversity, removing the term 'gender identity disorders' from its mental health section and creating a new section for gender incongruence and transgender identities in a chapter on sexual health. These changes are part of a much broader societal drive to remove the stigma previously associated with transgender healthcare. ICD-11

defines gender incongruence as being "characterised by a marked incongruence between an individual's experienced/expressed gender and the assigned sex." Gender variant behaviour and preferences alone are not a basis for assigning the diagnosis. The full criteria for gender incongruence of childhood and gender incongruence of adolescence or adulthood are listed in **Appendix 3**.

2.11. DSM-5¹⁹ is currently the framework used to diagnose gender dysphoria. This diagnostic category describes gender dysphoria as "the distress that may accompany the incongruence between one's experienced or expressed gender and one's assigned gender". A diagnosis of gender dysphoria is usually deemed necessary before a young person can access hormone treatment, and criteria are listed in **Appendix 3**.

Conceptual understanding of gender incongruence in children and young people

2.12. Children and young people presenting to gender identity services are not a homogeneous group. They vary in their age at presentation, their cultural background, whether they identify as binary, non-binary, or gender fluid, whether they are neurodiverse and in a host of other ways.

¹⁸ World Health Organization (2022). [International Classification of Diseases Eleventh Revision](#).

¹⁹ American Psychiatric Association (2013). [Diagnostic and Statistical Manual of Mental Health Disorders: DSM-5™, 5th ed.](#)

2.13. Some children and young people may thrive during a period of gender-questioning whilst for others it can be accompanied with a level of distress that can have a significant impact on their functioning and development.

2.14. Alongside these very varied presentations, it is highly unlikely that a single cause for gender incongruence will be found. Many authors view gender expression as a result of a complex interaction between biological, cultural, social and psychological factors.

2.15. Despite a high level of agreement about these points, there are widely divergent and, in some instances, quite polarised views among service users, parents, clinical staff and the wider public about how gender incongruence and gender-related distress in children and young people should be interpreted, and this has a bearing on expectations about clinical management.

2.16. These views will be influenced by how each individual weighs the balance of factors that may lead to gender incongruence, and the distress that may accompany it. Beliefs about whether it might be inherent and/or immutable, whether it might be a transient response to adverse experiences, whether it might be highly fluid and/or likely to change in later adolescence/early adulthood, etc will have

a profound influence on expectations about treatment options.²⁰

2.17. All of these views may be overlaid with strongly held concerns about children's and young people's rights, autonomy, and/or protection.

2.18. The disagreement and polarisation is heightened when potentially irreversible treatments are given to children and young people, when the evidence base underlying the treatments is inconclusive, and when there is uncertainty about whether, for any particular child or young person, medical intervention is the best way of resolving gender-related distress.

2.19. As with many other contemporary polarised disagreements, the situation is exacerbated when there is no space to have open, non-judgemental discussions about these differing perspectives. A key aim of this review process will be to encourage such discussions in a safe and respectful manner so that progress can be made in finding solutions.

²⁰ Wren B (2019). Notes on a crisis of meaning in the care of gender-diverse children. In: Hertzmann L, Newbigin J (eds) *Sexuality and Gender Now: Moving Beyond Heteronormativity*. Routledge.

3. Current services

Current service model for gender-questioning children and young people

3.1. Currently there are no locally or regionally commissioned services for children and young people who seek help from the NHS in managing their gender-related distress. Within primary and secondary care, some clinical staff have more interest and expertise in initial management of this group of young people, but such individuals are few and far between.

3.2. The pathway for NHS support around gender identity for children and young people is designated as a highly specialised service.²¹ The Gender Identity Development Service (GIDS) at the Tavistock and Portman NHS Foundation Trust is commissioned by NHS England to provide specialist assessment, support and, where appropriate, hormone intervention for children and young people with gender dysphoria. It is the only NHS provider of specialist gender services for children and young people in England. The Trust runs satellite bases in Leeds and Bristol. Until recently GIDS accepted referrals from multiple sources, for example, GPs, secondary care, social care, schools, and support and advocacy groups, which is unusual for a specialist service.

3.3. Children and young people are assessed by two members of the GIDS team who may be any combination of psychologists, psychotherapists, family therapists, or social workers. If there is uncertainty about the right approach, individual cases may be discussed in a complex case meeting. Those deemed appropriate for physical interventions are referred on to the endocrine team; under the current Standard Operating Procedure (SOP), this decision requires a multi-disciplinary team (MDT) discussion within GIDS. A member of the GIDS team attends new appointments in the endocrine clinic, but they will not routinely be the member of staff who saw the young person for assessment. However, very recently a triage meeting has been piloted to enable endocrinologists to discuss upcoming appointments with the clinician who saw the young person for assessment. The young person then attends an education session prior to their endocrine appointment. The endocrinologist will assess any medical contraindications prior to seeking consent from the patient for any hormone treatments.

3.4. For many years, the GIDS approach was to offer assessment and support, and to only start puberty blockers when children reached sexual maturity at about age 15 (Tanner Stage 5) as the first step in the treatment process to feminise or masculinise the young person, with

²¹ [National Health Service Commissioning Board and Clinical Commissioning Groups \(Responsibilities and Standing Rules\) Regulations 2012.](#)

oestrogen or testosterone given from age 16. Feminising/masculinising hormones are not given at an earlier stage because of the irreversibility of some of their actions in developing secondary sex characteristics of the acquired gender.^{22,23}

3.5. In 1998, a new protocol was published by the Amsterdam gender identity clinic.²⁴ It was subsequently named the Dutch Approach.²⁵ This involved giving puberty blockers much earlier, from the time that children showed the early signs of puberty (Tanner Stage 2), to pause further pubertal changes of the sex at birth. This stage of pubertal development was chosen because it was felt that although many younger children experienced gender incongruence as a transient developmental phenomenon, those who expressed early gender incongruence which continued into puberty were unlikely to desist at that stage.

3.6. It was felt that blocking puberty would buy time for children and young people to fully explore their gender identity and help with the distress caused by the development of their secondary sexual characteristics. The Dutch criteria

for treating children with early puberty blockers were: (i) a presence of gender dysphoria from early childhood; (ii) an increase of the gender dysphoria after the first pubertal changes; (iii) an absence of psychiatric comorbidity that interferes with the diagnostic work-up or treatment; (iv) adequate psychological and social support during treatment; and (v) a demonstration of knowledge and understanding of the effects of gonadotropin-releasing hormones (puberty blockers), feminising/masculinising hormones, surgery, and the social consequences of sex reassignment.²⁶

3.7. Under the Dutch Approach, feminising/masculinising hormones were started at age 16 and surgery was permitted to be undertaken from age 18, as in England.

3.8. From 2011, early administration of puberty blockers was started in England under a research protocol, which partially paralleled the Dutch Approach (the Early Intervention Study). From 2014, this protocol was adopted by GIDS as routine clinical practice. Results of the Early Intervention Study were published in December 2021.²⁷

²² Delemarre-van de Wall HA, Cohen-Kettenis PT (2006). Clinical management of gender identity disorder in adolescents: a protocol on psychological and paediatric endocrinology aspects. Eur J Endocrinol 155 (Suppl 1): S131–7. DOI: 10.1530/eje.1.02231.

²³ de Vries ALC, Cohen-Kettenis PT (2012). Clinical management of gender dysphoria in children and adolescents: the Dutch approach. J Homosex 59: 301–320. DOI: 10.1080/00918369.2012.653300.

3.9. However, the Dutch Approach differs from the GIDS approach in having stricter requirements about provision of psychological interventions. For example, under the Dutch Approach, if young people have gender confusion, aversion towards their sexed body parts, psychiatric comorbidities or Autism Spectrum Disorder (ASD) related diagnostic difficulties, they may receive psychological interventions only, or before, or in combination with medical intervention. Of note, in 2011, the Amsterdam team were reporting that up to 10% of their referral base were young people with ASD.²⁸

Changing epidemiology

3.10. In the last few years, there has been a significant change in the numbers and case-mix of children and young people being referred to GIDS.²⁹ From a baseline of approximately 50 referrals per annum in 2009, there was a steep increase from 2014-15, and at the time of the CQC inspection of the Tavistock and Portman NHS Foundation Trust in October 2020 there were 2,500 children and young people being referred per annum, 4,600 children and young people on the waiting list, and a waiting time of over two years

to first appointment.³⁰ This has severely impacted on the capacity of the existing service to manage referrals in the safe and responsive way that they aspire to and has led to considerable distress for those on the waiting list.

3.11. This increase in referrals has been accompanied by a change in the case-mix from predominantly birth-registered males presenting with gender incongruence from an early age, to predominantly birth-registered females presenting with later onset of reported gender incongruence in early teen years. In addition, approximately one third of children and young people referred to GIDS have autism or other types of neurodiversity. There is also an over-representation percentage wise (compared to the national percentage) of looked after children.³¹

Figure 2: Referrals to GIDS, 2010-11 to 2020-21

Source: Gender Identity Development Service.³³

3.12. In 2019, GIDS reported that about 200 children and young people from a referral base of 2,500 were referred on to the endocrine pathway. There is no published data on how the other children and young people from this referral baseline were managed, for example if: their gender dysphoria was resolved; they were still being assessed or receiving ongoing psychological support and input; they were not eligible for puberty blockers due to age; they were referred to endocrine services at a later stage; they were transferred to adult services; or they accessed private services.

Challenges to the service model and clinical approach

3.13. Over a number of years, in parallel with the increasing numbers of referrals, GIDS faced increasing challenges, both internally and externally. There were different views held within the staff group about the appropriate clinical approach, with some more strongly affirmative and some more cautious and concerned about the use of physical intervention. The complexity of the cases had also increased, so clinical decision making had become more difficult. There was also a high staff

³³ Gender Identity Development Service. [Referrals to GIDS, financial years 2010-11 to 2020-21](#).

turnover, and accounts from staff concerned about the clinical care, which were picked up in both mainstream and social media. This culminated in 2018 with an internal report by a staff governor.

3.14. Following that report, a review was carried out in 2019 by the Trust's medical director. This set out the need for clearer processes for the service's referral management, safeguarding, consent, and clinical approach, and an examination of staff workload and support, and a new Standard Operating Procedure (SOP) was put in place.

NHS England Policy Working Group

3.15. In January 2020, a Policy Working Group (PWG) was established by NHS England to undertake a review of the published evidence on the use of puberty blockers and feminising/masculinising hormones in children and young people with gender dysphoria to inform a policy position on their future use. Given the increasingly evident polarisation among clinical professionals, Dr Cass was asked to chair the group as a senior clinician with no prior involvement or fixed views in this area. The PWG comprised an expert group including endocrinologists, child and adolescent psychiatrists and paediatricians representing their respective Royal

Colleges, an ethicist, a GP, senior clinicians from the NHS GIDS, a transgender adult and parents of gender-questioning young people. The process was supported by a public health consultant and policy, pharmacy and safeguarding staff from NHS England.

3.16. NHS England uses a standardised protocol for developing clinical policies. The first step of this involves defining the PICO (the Population being treated, the Intervention, a Comparator treatment, and the intended Outcomes). This of itself was challenging, with a particular difficulty being definition of the intended outcomes of puberty blockers, and suitable comparators for both hormone interventions. However, agreement was reached on what should be included in the PICO and subsequently the National Institute for Health and Care Excellence (NICE) was commissioned to review the published evidence,^{34,35} again following a standardised protocol which has strict criteria about the quality of studies that can be included.

3.17. Unfortunately, the available evidence was not strong enough to form the basis of a policy position. Some of the challenges and outstanding uncertainties are summarised as follows.

³⁴ National Institute for Health and Care Excellence (2020). [Evidence Review: Gonadotrophin Releasing Hormone Analogues for Children and Adolescents with Gender Dysphoria](#).

³⁵ National Institute for Health and Care Excellence (2020). [Evidence review: gender-affirming hormones for children and adolescents with gender dysphoria](#).

Feminising/masculinising hormones

3.18. Sex hormones have been prescribed for transgender adults for several decades, and the long-term risks and side effects are well understood. These include increased cardiovascular risk, osteoporosis, and hormone-dependent cancers.

3.19. In young people, consideration also needs to be given to the impact on fertility, with the need for fertility counselling and preservation.

3.20. The additional physical risk of starting these treatments at age 16+ rather than age 18+ is unlikely to add significantly to the total lifetime risk, although data on this will not be available for many years. However, as evidenced by take-up of treatment with feminising/masculinising hormones, where there is a high level of certainty that physical transition is the right option, the child or young person may be more accepting of these risks, which can seem remote from the immediate gender distress.

3.21. The most difficult question in relation to feminising/masculinising hormones therefore is not about long-term physical risk which is tangible and easier to understand. Rather, given the irreversible nature of many of the changes, the greatest difficulty centres on the decision to proceed to physical transition; this relies on the effectiveness of the assessment, support and counselling processes, and ultimately the shared decision making between

clinicians and patients. Decisions need to be informed by long-term data on the range of outcomes, from satisfaction with transition, through a range of positive and negative mental health outcomes, through to regret and/or a decision to detransition. The NICE evidence review demonstrates the poor quality of these data, both nationally and internationally.

3.22. Regardless of the nature of the assessment process, some children and young people will remain fluid in their gender identity up to early to mid-20s, so there is a limit as to how much certainty one can achieve in late teens. This is a risk that needs to be understood during the shared decision making process with the young person.

3.23. It is also important to note that any data that are available do not relate to the current predominant cohort of later-presenting birth-registered female teenagers. This is because the rapid increase in this subgroup only began from around 2014-15. Since young people may not reach a settled gender expression until their mid-20s, it is too early to assess the longer-term outcomes of this group.

Puberty blockers

3.24. The administration of puberty blockers is arguably more controversial than administration of the feminising/masculinising hormones, because there are more uncertainties associated with their use.

3.25. There has been considerable discussion about whether the treatment is 'experimental'; strictly speaking an experimental treatment is one that is being given as part of a research protocol, and this is not the case with puberty blockers, because the GIDS research protocol was stopped in 2014. At that time, the treatment was experimental and innovative, because the drug was licensed for use in children, but specifically for children with precocious puberty. This was therefore the first time it was used 'off-label' in the UK for children with gender dysphoria. If a drug is used 'off-label' it means it is being used for a condition that is different from the one for which it was licensed. The many uncertainties around the 'off-label' use were recognised, but given that this was not a new drug, it did not need Medicines and Healthcare products Regulatory Agency (MHRA) approval at that time.

3.26. The important question now, as with any treatment, is whether the evidence for the use and safety of the medication is strong enough as judged by reasonable clinical standards.

3.27. One of the challenges that NHS England's PWG faced in considering this question was the lack of clarity about intended outcomes, several of which have been proposed including:

- providing time/space for the young person to make a decision about continuing with transition;
- reducing or preventing worsening of distress;
- improving mental health; and
- stopping potentially irreversible pubertal changes which might later make it difficult for the young person to 'pass' in their intended gender role.

3.28. Proponents for the use of puberty blockers highlight the distress that young people experience through puberty and the risk of self-harm or suicide.³⁶ However, some clinicians do not feel that distress is actually alleviated until children and young people are able to start feminising/masculinising hormones. The Review will seek to gain a better understanding of suicide data and the impact of puberty blockers through its research programme.

3.29. On the other hand, it has been asserted that starting puberty blockers at an older age provides children and young people with more time to achieve fertility preservation. In the case of birth-registered males, there is an argument that it also

³⁶ Turban JL, King D, Carswell JM, et al (2020). [Pubertal suppression for transgender youth and risk of suicidal ideation](#). *Pediatrics* 145 (2): e20191725. DOI: 10.1542/peds.2019-1725.

allows more time to achieve adequate penile growth for successful vaginoplasty.

3.30. In the short-term, puberty blockers may have a range of side effects such as headaches, hot flushes, weight gain, tiredness, low mood and anxiety, all of which may make day-to-day functioning more difficult for a child or young person who is already experiencing distress. Short-term reduction in bone density is a well-recognised side effect, but data is weak and inconclusive regarding the long-term musculoskeletal impact.³⁷

3.31. The most difficult question is whether puberty blockers do indeed provide valuable time for children and young people to consider their options, or whether they effectively 'lock in' children and young people to a treatment pathway which culminates in progression to feminising/masculinising hormones by impeding the usual process of sexual orientation and gender identity development. Data from both the Netherlands³⁸ and the study conducted by GIDS³⁹ demonstrated that almost all children and young people who are put on puberty blockers go on to sex hormone treatment (96.5% and 98%

respectively). The reasons for this need to be better understood.

3.32. A closely linked concern is the unknown impacts on development, maturation and cognition if a child or young person is not exposed to the physical, psychological, physiological, neurochemical and sexual changes that accompany adolescent hormone surges. It is known that adolescence is a period of significant changes in brain structure, function and connectivity.⁴⁰ During this period, the brain strengthens some connections (myelination) and cuts back on others (synaptic pruning). There is maturation and development of frontal lobe functions which control decision making, emotional regulation, judgement and planning ability. Animal research suggests that this development is partially driven by the pubertal sex hormones, but it is unclear whether the same is true in humans.⁴¹ If pubertal sex hormones are essential to these brain maturation processes, this raises a secondary question of whether there is a critical time window for the processes to take place, or whether catch up is possible when oestrogen or testosterone is introduced later.

3.33. An international interdisciplinary panel⁴² has highlighted the importance of understanding the neurodevelopmental outcomes of pubertal suppression and defined an appropriate approach for investigating this further. However, this work has not yet been undertaken.

Initiation of Cass Review

3.34. Dr Cass' own reflections on the PWG process, the available literature, and the issues it highlighted were as follows:

- Firstly, that hormone treatment is just one possible outcome for gender-questioning children and young people. A much better understanding is needed about: the increasing numbers of children and young people with gender-related distress presenting for help; the appropriate clinical pathway for each individual; their support needs; and the full range of potential treatment options.
- Secondly, there is very limited follow-up of the subset of children and young people who receive hormone treatment, which limits our understanding about the long-term outcomes of these treatments and this lack of follow up data should be corrected.

- Thirdly, the assessment process is inconsistent across the published literature. The outcome of hormone treatment is highly influenced by whether the assessment process accurately selects those children and young people most likely to benefit from medical treatment. This makes it difficult to draw conclusions from published studies.

3.35. In light of the above, NHS England commissioned this independent review to make recommendations on how the clinical management and service provision for children and young people who are experiencing gender incongruence or gender-related distress can be improved.

CQC inspection

3.36. In October and November 2020, the Care Quality Commission (CQC) inspectors carried out an announced, focused inspection of GIDS due to concerns reported to them by healthcare professionals and the Children's Commissioner for England. Concerns related to clinical practice, safeguarding procedures, and assessments of capacity and consent to treatment.

⁴² Chen D, Strang JF, Kolbuck VD, Rosenthal SM, Wallen K, Waber DP, et al (2020). Consensus parameter: research methodologies to evaluate neurodevelopmental effects of pubertal suppression in transgender youth. Transgender Health 5(4). DOI: 10.1089/trgh.2020.0006.

3.37. The CQC report, published in January 2021,⁴³ gave the service an overall rating of inadequate. The report noted the high level of commitment and caring approach of the staff but identified a series of issues that needed improvement. In addition to the growing waiting list pressures, the CQC identified problems in several other areas including: the assessment and management of risk; the variations in clinical approach; the lack of clarity and consistency of care plans; the lack of any clear written rationale for decision making in individual cases; and shortfalls in the multidisciplinary mix required for some patient groups. Recording of capacity, competency and consent had improved since the new SOP in January 2020; however, there remained a culture in which staff reported feeling unable to raise concerns.

3.38. The CQC reported that when it inspected GIDS, there did not appear to be a formalised assessment process, or standard questions to explore at each session, and it was not possible to tell from the notes why an individual child might have been referred to endocrinology whilst another had not. Current GIDS data demonstrate that a majority of children and young people seen by the service do not get referred for endocrine treatment, but there is no clear information about what

other diagnoses they receive, and what help or support they might need.

3.39. Since the CQC report, NHS England and The Tavistock and Portman NHS Foundation Trust management team have been working to address the issues raised. However, whilst some problems require a focused Trust response, the waiting list requires a system-wide response. This was noted in the letter from the Review to NHS England in May 2021 (**Appendix 2**).

Legal background

3.40. This section sets out the chronology of recent case law. In October 2019, a claim for Judicial Review was brought against The Tavistock and Portman NHS Foundation Trust. The claimants' case was summarised by the High Court as follows: "The claimants' case is that children and young persons under 18 are not competent to give consent to the administration of puberty blocking drugs. Further, they contend that the information given to those under 18 by the defendant [GIDS] is misleading and insufficient to ensure such children or young persons are able to give informed consent. They further contend that the absence of procedural safeguards, and the inadequacy of the information provided, results in an infringement of the rights of such children and young persons under Article 8 of the European Convention

⁴³ Care Quality Commission (2021). The Tavistock and Portman NHS Foundation Trust Gender Identity Service Inspection Report. London: CQC.

for the Protection of Human Rights and Fundamental Freedoms.”⁴⁴

3.41. In December 2020, three judges in the High Court of England and Wales handed down judgment in *Bell v Tavistock*.⁴⁵ (Most cases in the High Court are heard by a single judge sitting alone, and when a case is heard by more than one judge in the High Court, it is described as the Divisional Court.) The Divisional Court recognised that the Tavistock’s policies and practices as set out in the service specification were not unlawful. However, the Court made a declaration that set out in detail a series of implications of treatment that a child would need to understand to be *Gillick* competent⁴⁶ to consent to puberty blockers. Specifically, because most children put on puberty blockers go on to have feminising/masculinising hormones, the judgment said a child would need to understand not only the full implications of puberty blocking drugs, but also the implications of the full pathway of medical and surgical transition. The judges concluded that it will be “very doubtful” that 14-15 year-olds have such competence, and “highly unlikely” that children aged 13 or under have competence for that decision. Under the Mental Capacity Act 2005, 16-17 year-olds are presumed to have capacity, and they are effectively treated as adults for consent to medical treatment under the Family Law Reform Act 1969 section 8, but the judges

suggested that it would be appropriate for clinicians to involve the court in any case where there were doubts as to whether the proposed treatment would be in the long term best interests of a 16-17 year-old.

3.42. Following the Divisional Court judgment in *Bell v Tavistock*, a claim was brought against the Tavistock in the High Court Family Division by the mother of a child for a declaration that she and the child’s father had the ability in law to consent on behalf of their child to the administration of puberty blockers (*AB v CD*).⁴⁷ The Court concluded that “the parents’ right to consent to treatment on behalf of the child continues even when the child is *Gillick* competent to make the decision, save where the parents are seeking to override the decision of the child” [para 114] and that there is no “general rule that puberty blockers should be placed in a special category by which parents are unable in law to give consent” [para 128].

⁴⁴ *Bell v Tavistock*. [2020] EWHC 3274 (Admin).

⁴⁵ *Ibid*.

⁴⁶ *Gillick v West Norfolk and Wisbech AHA* [1986] AC 112.

⁴⁷ *AB v CD & Ors* [2021] EWHC 741.

3.43. Subsequently, the Tavistock appealed the Divisional Court's earlier decision in *Bell v Tavistock* and was successful.⁴⁸ The Court of Appeal held that it was not appropriate for the Divisional Court to provide the guidance about the likelihood of having *Gillick* competence at particular ages, or about the need for court approval [para 91]. The Court of Appeal went on to say "The Divisional Court concluded that Tavistock's policies and practices (as expressed in the service specification and the SOP) were not unlawful and rejected the legal criticism of its materials. In those circumstances, the claim for judicial review is dismissed." [para 91]. However, clinicians should "take great care before recommending treatment to a child and be astute to ensure that the consent obtained from both child and parents is properly informed" [para 92].

3.44. The Court of Appeal in *Bell v Tavistock* recognised the lawfulness of treating children for gender dysphoria in this jurisdiction. Recognising the divergences in medical opinion, morality and ethics, it indicated that the question of whether treatment should be made available is a matter of policy "for the National Health Service, the medical profession and its regulators and Government and Parliament" [para 3].

3.45. Following the Divisional Court decision in *Bell v Tavistock*, new referrals for puberty blockers were suspended and a requirement was put in place that children currently on puberty blockers were reviewed with a view to court proceedings for a judge to determine the best interests for children in whom these medications were considered essential. This requirement was changed following *AB v CD*, with the reinstatement of the hormone pathway in March 2021. However, an external panel, the Multi Professional Review Group (MPRG), was established to ensure that procedures for assessment and for informed consent had been properly followed. The outcome of the *Bell* appeal has not changed this requirement, which is contingent not just on the legal processes but on the concerns raised by CQC regarding consent, documentation and clarity about decision making within the service.⁴⁹

⁴⁸ [EWCA \[2021\] Civ 1363](#).

⁴⁹ Care Quality Commission (2021). [The Tavistock and Portman NHS Foundation Trust Gender Identity Service Inspection Report](#). London: CQC.

The Multi-Professional Review Group

3.46. NHS England has established a Multi-Professional Review Group (MPRG) to review whether the agreed process has been followed for a child to be referred into the endocrinology clinic and to be prescribed treatment. The Review has spoken directly to the MPRG, which has reported its observations of current practice.

3.47. The MPRG has stated that its work has been impeded by delays in the provision of clinical information, the lack of structure in the documentation received, and gaps in the necessary evidence. This means that when reviewing the documents provided it is not always easy to determine if the process for referral for endocrine treatment has been fully or safely followed for a particular child or young person.

3.48. The MPRG indicates that there does not appear to be a standardised approach to assessment. They are particularly concerned about safeguarding shortfalls within the assessment process. There is also limited evidence of systematic, formal mental health or neurodevelopmental assessments being routinely documented, or of a discipline of formal diagnostic formulation in relation to co-occurring mental health difficulties. This issue was also highlighted by the Care Quality Commission (CQC).⁵⁰

3.49. Additionally, there is concern that communications to GPs and parents regarding prescribed treatment with puberty blockers sometimes come from non-medical staff.

⁵⁰ Care Quality Commission (2021). The Tavistock and Portman NHS Foundation Trust Gender Identity Service Inspection Report. London: CQC.

4. What the review has heard so far

Listening sessions

4.1. Since its establishment, the Review has met with an extensive range of stakeholders, including professionals, their respective governing organisations and those with lived experience, both directly and through support and advocacy groups, to understand the broad range of views and experiences surrounding the delivery of gender identity services.

What we have heard from service users, their families and support and advocacy groups

Issues for children and young people

4.2. What we understand most clearly from all we have heard is that at the centre of a difficult and complex debate are children, young people and families in great distress. We have heard concerns about children and young people facing the stress of being on a prolonged waiting list with limited support available from statutory services, lack of certainty about when and if they might reach the top of that list and subsequent impacts on mental health. Also, the particular issues that have followed the *Bell v Tavistock* litigation.

4.3. We have heard about the anxiety that birth-registered males face as they come closer to the point where they will grow facial hair and their voice drops, and the fear that it will make it harder for them to pass as a transgender woman in later life. We have also heard about the distress

experienced by birth-registered females as they reach puberty, including the use of painful, and potentially harmful, binding processes to conceal their breasts.

4.4. When children and young people are able to access the service, there is often a sense of frustration with what several describe as the “gatekeeping” medical model and a “clinician lottery”. This can feel like a series of barriers and hurdles designed to add to, rather than alleviate, distress. Most children and young people seeking help do not see themselves as having a medical condition; yet to achieve their desired intervention they need to engage with clinical services and receive a medical diagnosis of gender dysphoria. By the time they are seen in the GIDS clinic, they may feel very certain of their gender identity and be anxious to start hormone treatment as quickly as possible. However, they can then face a period of what can seem like intrusive, repetitive and unnecessary questioning. Some feel that this undermines their autonomy and right to self-determination.

4.5. We have heard that some young people learn through peers and social media what they should and should not say to therapy staff in order to access hormone treatment; for example, that they are advised not to admit to previous abuse or trauma, or uncertainty about their sexual orientation. We have also heard that many of those seeking NHS support identify as non-binary, gender non-conforming, or gender fluid. We understand that some

Independent review of gender identity services for children and young people

young people who identify as non-binary feel their needs are not met by clinical services unless they give a binary narrative about their gender preferences.

Issues for parents

4.6. We have also heard about the distress parents may feel as they try to work out how best to support their children and how tensions and conflict may arise where parents and their children have different views. For example, some parents have highlighted the importance of ensuring that children and young people are able to keep their options fluid until such time as it becomes essential to commit to a hormonal course of action, whilst their children may want more rapid hormone intervention.

4.7. We have heard about families trying to balance the risks of obtaining unregulated and potentially dangerous hormone supplies over the internet or from private providers versus the ongoing trauma of prolonged waits for assessment.

4.8. Parents have also raised concerns about the vulnerability of neurodiverse children and young people and expressed that the communication needs of these children and young people are not adequately reflected during assessment processes or treatment planning.

4.9. GIDS has always required consent/assent from both the child and parents/carers and has sought ways to resolve family conflict, which in the worst-case scenario can lead to family breakdown. It has been highlighted to us that the future

service model should provide more targeted support for parents and carers.

Service issues

4.10. Another significant issue raised with us is one of diagnostic overshadowing – many of the children and young people presenting have complex needs, but once they are identified as having gender-related distress, other important healthcare issues that would normally be managed by local services can sometimes be subsumed by the label of gender dysphoria. This issue is compounded by the waiting list, which means that there can be a significant period of time without appropriate assessment, treatment or care.

4.11. Stakeholders have spoken of the need for appropriate assessment when first accessing NHS services to aid both the exploration of the child or young person's wellbeing and gender distress and any other challenges they may be facing.

Information

4.12. We have also heard about the lack of access to accurate, balanced information upon which children, young people and their families/carers can inform their decisions.

4.13. We have heard that distress may be exacerbated by pressure to identify with societal stereotyping and concerns over the influence of social media, which can be seen to perpetuate unrealistic images of gender and set unhealthy expectations, especially given how long

children and young people are waiting to access services.

Other issues

4.14. Several issues that were raised with us are not explored further in this interim report, but we have taken note of them. These will be considered further during the lifetime of the Review and include:

- The important role of schools and the challenges they face in responding appropriately to gender-questioning children and young people.
- The complex interaction between sexuality and gender identity, and societal responses to both; for example, we have heard from young lesbians who felt pressured to identify as transgender male, and conversely transgender males who felt pressured to come out as lesbian rather than transgender. We have also heard from adults who identified as transgender through childhood, and then reverted to their birth-registered gender in teen years.
- The issues faced by detransitioners highlight the need for better services and pathways for this group, many of whom are living with irreversible effects of transition but for whom there is no clear access to services as they fall outside the responsibility of NHS gender identity services.
- The age at which adult gender identity clinics can receive referrals, with concerns about the inclusion of 17-year-olds. The service offer in adult services

is perceived to be quite different from that of GIDS, and young people presenting later may therefore not be afforded the same level of therapeutic input under the adult service model. There is also concern about the impact on the young person of changing clinicians at a crucial point in their care. The movement of young people with special educational needs between children's and adult services raises particular concerns.

What we have heard from healthcare professionals

Lack of professional consensus

4.15. Clinicians and associated professionals we have spoken to have highlighted the lack of an agreed consensus on the different possible implications of gender-related distress – whether it may be an indication that the child or young person is likely to grow up to be a transgender adult and would benefit from physical intervention, or whether it may be a manifestation of other causes of distress. Following directly from this is a spectrum of opinion about the correct clinical approach, ranging broadly between those who take a more gender-affirmative approach to those who take a more cautious, developmentally-informed approach.

4.16. Speaking to current and ex-GIDS staff, we have heard about the pressure on GIDS clinicians, many of whom feel overwhelmed by the numbers of children and young people being referred and who are demoralised by the media coverage of their service. Although the clinical team attempt to manage risk on the waiting list by engaging with local services, there is limited capacity and/or capability to respond appropriately to the needs of this group in primary and secondary care. The Review has already referred to this issue as the most pressing priority in its letter to NHS England (**Appendix 2**), alongside potential risks relating to safeguarding and/or mental health issues, and diagnostic overshadowing.

4.17. With respect to GIDS, we have been told that although there are forums for staff to discuss difficult cases with senior colleagues, it is still difficult for staff to raise concerns about the clinical approach. Also that many individuals who are more cautious and advocate the need for an exploratory approach have left the service.

Consistency and standards

4.18. GIDS staff have confirmed that judgements are very individual, with some clinicians taking a more gender-affirmative approach and others emphasising the need for caution and for careful exploration of broader issues. The Review has been told that there is considerable variation in the approach taken between the London, Leeds and Bristol teams.

4.19. Speaking to professionals outside GIDS, we have heard widespread concern about the lack of guidance and evidence on how to manage this group of young people.

4.20. Some secondary care providers told us that their training and professional standards dictate that when working with a child or young person they should be taking a mental health approach to formulating a differential diagnosis of the child or young person's problems. However, they are afraid of the consequences of doing so in relation to gender distress because of the pressure to take a purely affirmative approach. Some clinicians feel that they are not supported by their professional body on this matter. Hence the practice of passing referrals straight through to GIDS is not just a reflection of local service capacity problems, but also of professionals' practical concerns about the appropriate clinical management of this group of children and young people.

4.21. GPs have expressed concern about being pressurised to prescribe puberty blockers or feminising/masculinising hormones after these have been initiated by private providers.

4.22. This also links to professional concerns about parents being anxious for hormone treatment to be initiated when the child or young person does not seem ready.

Other issues

4.23. We have also heard that parents and carers play a huge role and are instrumental in helping young people

to keep open their developmental opportunities. In discussion with social workers, we heard concerns about how looked after children are supported in getting the help and support they need.

4.24. Therapists who work with detransitioners and people with regret have highlighted a lack of services and pathways and a need for services to support this population. There is also the need for more research to understand what factors contribute to the decision to detransition.

4.25. The importance of broad holistic interventions to help reduce distress has been emphasised to the Review, with therapists and other clinicians advocating the importance of careful developmentally informed assessment and of showing children and young people a range of different narratives, experiences and outcomes.

4.26. Clinicians have raised concerns about children and young people's NHS numbers being changed inconsistently, as there is no specific guidance for GPs and others as to when this should be done for this population and under what consent. This has implications for safeguarding and clinical management of these children and young people and it also makes it difficult to do research exploring long-term outcomes.

4.27. As with the comments made by service users, their families and support and advocacy groups, we have heard similar views from professionals about the

transition from children's to adult services, and the role of schools.

Structured engagement with primary, secondary and specialist clinicians

4.28. The Review's letter to NHS England (**Appendix 2**) set out some of the immediate issues with the current provision of gender identity services for children and young people and suggested how its work might help with the challenging problem of establishing an infrastructure outside GIDS. This included looking at the capacity, capability and confidence of the wider workforce and how this could be built and sustained, and the establishment of potential assessment frameworks for use in primary and/or secondary care.

Professional panel – primary and secondary care

4.29. In order to understand the challenges and establish a picture of current competency, capacity and confidence among the workforce outside the specialist gender development service, an online professional panel was established to explore issues around gender identity services for children and young people. The role of the panel was aimed at better comprehending how it looks and feels for clinicians and other professionals working with these young people, as well as any broader thoughts about the work, and to start exploring how the care of these

Independent review of gender identity services for children and young people

children and young people can be better managed in the future.

4.30. The project was designed to capture a broad mix of professional views and experiences, recruiting from the professional groups that are most likely to have a role in the care pathway – GPs, paediatricians, child psychiatrists, child psychologists and child psychotherapists, nurses and social workers.

4.31. A total of 102 clinicians and other professionals were involved in the panel. The panel represented a balanced professional mix, and participant ages and gender were broadly representative of the overall sector workforce. Participants were self-selecting and were recruited via healthcare professional networks and Royal Colleges.

4.32. Each week the panel was set an independent activity comprised of two or more tasks. Additionally, a sub-set of the panel was invited to participate in focus groups at the midway and endpoint of the project. Activities were designed to capture an understanding of:

- experiences of working with gender-questioning children and young people and panel members' confidence and competence to manage their care;
- changes they may have experienced in the presentation of children and young people with gender-related distress;
- areas where professionals feel they require more information in order to

support gender-questioning children and young people;

- where professionals currently go to find that information;
- the role of different professions in the care pathway;
- the role of professionals in the assessment framework; and
- what participants felt should be included in an assessment framework across the whole service pathway.

Gender specialist questionnaire

4.33. Having concluded the professional panel exercise, we wanted to triangulate what we had heard with the thoughts and views of professionals working predominantly or exclusively with gender-questioning children and young people.

4.34. To do this in a systematic way, we conducted an online survey which contained some service-specific questions, but also reflected and sought to test some of what we had heard from primary and secondary care professionals.

Findings

4.35. This structured engagement has yielded valuable insights from clinicians and professionals with experience working with gender-questioning children and young people both within and outside the specialist gender service. It has contributed to the thinking of the Review and informed some of the interim advice set out in this report.

4.36. There are a number of consistent messages arising from these activities:

- The current long waiting lists that gender-questioning children and young people and their families/carers face are unacceptable for all parties involved, including professionals.
- Many professionals in our sample said that not only are gender-questioning children and young people having to wait a long time before receiving treatment, but they also do not receive appropriate support during this waiting period.
- Another impact of the long wait that clinicians reported is that when a child or young person is seen at GIDS, they may have a more fixed view of what they need and are looking for action to be taken quickly. This reportedly can lead to frustration with the assessment process.
- When considering the more holistic support that children and young people may need, gender specialists further highlighted the difficulties that children and young people face accessing local support, for example, from CAMHS, whilst being seen at GIDS.
- It is clear from the professionals who took part in these activities that there is a strong professional commitment to provide quality care to gender-questioning children and young people and their families/carers. However, this research indicates that levels of confidence and competence do vary

among primary and secondary care professionals in our sample.

- Concerns were expressed by professionals who took part in this research about the lack of consensus among the clinical community on the right clinical approach to take when working with a gender-questioning child or young person and their families/carers.
- In order to support clinicians and professionals more widely, participants felt there is a need for a robust evidence base, consistent legal framework and clinical guidelines, a stronger assessment process and different pathway options that holistically meet the needs of each gender-questioning child or young person and their families/carers.

4.37. There are also several areas where further discussion and consensus is needed:

- There is not a consistent view among the professionals participating in the panel and questionnaire about the nature of gender dysphoria and therefore the role of assessment for children and young people experiencing gender dysphoria.

Independent review of gender identity services for children and young people

- Some clinicians felt that assessment should be focused on whether medical interventions are an appropriate course of action for the individual. Other clinicians believe that assessment should seek to make a differential diagnosis, ruling out other potential causes of the child or young person's distress.
- There are different perspectives on the roles of primary, secondary and specialist services in the care pathway(s) and what support or action might best be provided at different levels.
- While there was general consensus that diagnostic or psychological formulation needs to form part of the assessment process, there were differing views as to whether a mental state assessment is needed, and should it be, where in the pathway and by whom this should be done.

4.38. It is important to note that the information gathered represents the views and insights of the panel participants and survey respondents at a moment in time and findings should be read in the context of a developing narrative on the subject, where perspectives may evolve. This relates to both the experiences of professionals, but also the extent to which this subject matter is discussed in the public sphere.

4.39. The Review is grateful to all the participants for their time and high level of engagement. The Review will build on the work we have undertaken and, alongside our academic research, will continue with a programme of engagement with professionals, service users and their families, which will help to further develop the evidence base.

The full reports from the professional panel and gender specialist questionnaire are on the Review's website (<https://cass.independent-review.uk/>).

5. Principles of evidence based service development

Evidence based service development

5.1. This chapter integrates the information regarding the development of the current service (see Chapter 3) with the views we have heard to date (see Chapter 4) and sets this in the context of how evidence is routinely used to develop and improve services in the NHS.

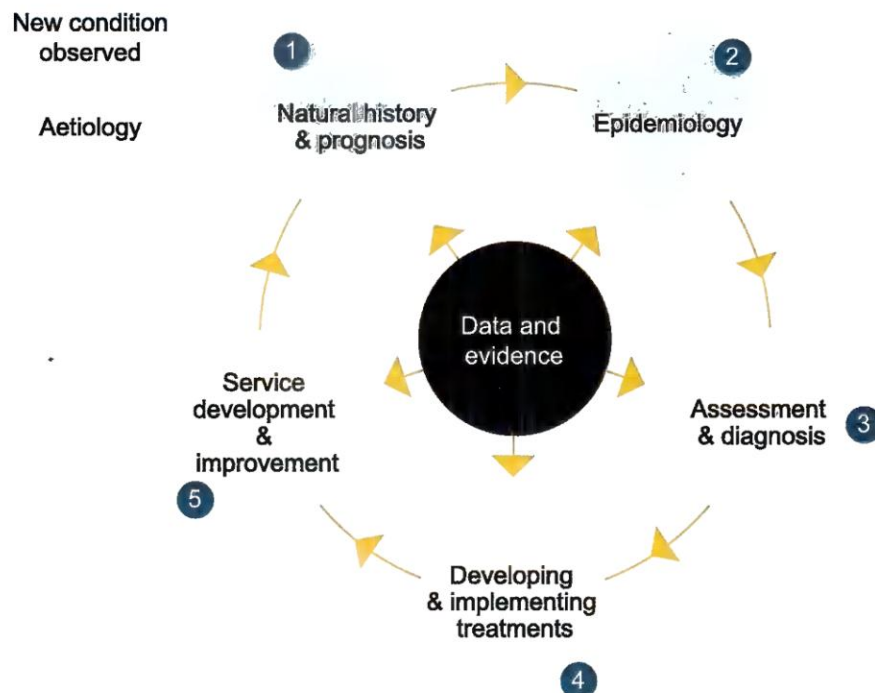

5.2. Some earlier information is necessarily repeated here, but this is with the intention of providing a more accessible explanation of the standards and processes which govern clinical service development. This is essential to an understanding of the rationale for the Review's recommendations.

5.3. Because the specialist service has evolved rapidly and organically in response to demand, the clinical approach and overall service design has not been subjected to some of the normal quality controls that are typically applied when new or innovative treatments are introduced. This Review now affords everyone concerned the opportunity to step back and consider from first principles what this cohort of children and young people now need from NHS services, based on the evidence that exists, or additional evidence that the Review hopes to collect.

5.4. In **Appendix 4** we have described the service development process for three different conditions which may help to illustrate what would be expected to happen at each different stage of developing a clinical service. The steps may proceed in a different sequence for different conditions, but each step is important in the development of evidence based care.

5.5. We recognise that for some of those reading this report it may feel wrong to compare gender incongruence or dysphoria to clinical conditions, and indeed this approach would not be justified if individuals presenting with these conditions did not require clinician intervention. However, where a clinical intervention is given, the same ethical, professional and scientific standards have to be applied as to any other clinical condition.

Key stages of service development

New condition observed: This often begins with a few case reports and then clinicians begin to recognise a recurring pattern and key clinical features, and to develop fuller descriptions of the condition.

Aetiology: Clinicians and scientists try to work out the cause of the condition or the underlying physical or biological basis. Sometimes the answers to this are never found.

Natural history and prognosis: It is important to understand how a condition usually evolves over time, with or without treatment. The latter is important if treatment has limited efficacy and the condition is 'self-limiting' (that is, it resolves without treatment), because otherwise there is a risk that treatments create more difficulties than the condition itself.

5.6. The first UK service for gender-questioning children and young people was established in 1989. At that time there were very few children and young people being

seen by medical services internationally. The most common presentation in the early years of the service was of birth-registered

boys who had demonstrated gender incongruence from an early age.^{51,52,53}

5.7. There is extensive literature discussing the possible aetiology of gender incongruence. Based on the available evidence, many authors would suggest that it is likely that biological, cultural, social and psychological factors all contribute. The examples in **Appendix 4** show that this is not an uncommon situation; many conditions do not have a single clear causation – they are in other words ‘multifactorial’.

5.8. Regardless of aetiology, the more contentious and important question is how fixed or fluid gender incongruence is at different ages and stages of development, and whether, regardless of aetiology, can be an inherent characteristic of the individual concerned. There is a spectrum of academic, clinical and societal opinion on this. At one end are those who believe that gender identity can fluctuate over time and be highly mutable and that, because gender incongruence or gender-related distress may be a response to many psychosocial factors, identity may

sometimes change or the distress may resolve in later adolescence or early adulthood, even in those whose early incongruence or distress was quite marked. At the other end are those who believe that gender incongruence or dysphoria in childhood or adolescence is generally a clear indicator of that child or young person being transgender and question the methodology of some of the desistance studies. Previous literature has indicated that if gender incongruence continues into puberty, desistance is unlikely.^{54,55} However, it should be noted that these older studies were not based on the current changed case-mix or the different socio-cultural climate of recent years, which may have led to different outcomes. Having an open discussion about these questions is essential if a shared understanding of how to provide appropriate assessment and treatment is to be reached.

Complex presentations and complex pathways – exemplars, not comprehensive lists

Epidemiology: Epidemiologists collect data to find out how common a condition is, who is most likely to be affected, what the age distribution is and so on. This allows health service planners to work out how many services are needed, where they should be established, and what staff are needed.

They also report on changes in who is most affected, which may mean that either the disease is changing, or the susceptibility of the population is changing.

5.9. As previously indicated, the epidemiology of gender dysphoria is changing, with an increase in the numbers of birth-registered females presenting in early teens.^{56,57} In addition, the majority of children and young people presenting to GIDS have other complex mental health issues and/or neurodiversity.⁵⁸ There is also an over-representation of looked after children.⁵⁹

5.10. There are several implications arising from the change in epidemiology:

- Firstly, the speed of change in the numbers presenting means that services have not kept pace with demand.
- Secondly, the cohort that the original Dutch Approach was based on is different from the current more complex NHS cohort, and also from the current case-mix internationally, and therefore it is difficult to extrapolate from older literature to this current group.
- Thirdly, different subgroups may have quite different needs and outcomes, and these must be built into any service design, so that it works for all children and young people.

5.11. At present we have the least information for the largest group of patients – birth-registered females first presenting in early teen years. Since the rapid increase in this group began around 2015, they will not reach late 20s for another 5+ years, which would be the best time to assess longer-term wellbeing.

Assessment and diagnosis: Clinicians will usually take a history from (that is, of their symptoms) and examine the patient (that is, for signs and symptoms), and where appropriate undertake a series of investigations or tests, to help them reach an accurate diagnosis.

Sometimes the whole process of making a diagnosis through talking to the patient and asking them to complete formal questionnaires, examining them and/or undertaking investigations is called 'clinical assessment'.

As well as diagnosing and ruling out a particular condition, clinicians often need to consider and exclude other, sometimes more serious, conditions that present in a similar way but may need quite different treatment – this process is called 'differential diagnosis'.

5.12. For children and young people with gender-related distress, many people would dispute the notion that 'making a diagnosis' is a meaningful concept, arguing that gender identity is a personal, internal perception of oneself. However, there are several reasons to why a diagnostic framework is used:

- Firstly, the clinician will seek to determine whether the child or young person has a stable transgender identity, or whether there might be other causes for the gender-related distress.
- Secondly, the clinician will determine whether there are other issues or diagnoses that might be having an impact on the young person's mental health. The Dutch Approach suggesting that these should be addressed prior to or alongside initiation of any medical treatments.
- Thirdly, in any situation where life-altering treatments are being administered, the clinician holds the

responsibility for ensuring that they are being administered based on an appropriate decision making process. Therefore, it is usual practice for a diagnosis of gender dysphoria to be made prior to referring for any physical treatments.

5.13. When the word 'diagnosis' is used, people often associate this with the use of blood tests, X-rays, or other laboratory tests. As set out in the **Appendix 4**, the public is very familiar with diagnosis of Covid-19 and understands that there need to be tests that give a high degree of certainty about whether an individual is Covid-19 positive or not. False positive lateral flow tests are rare, but caused problems for schools, while PCR has been treated as the 'gold standard' test for accuracy.

5.14. When it comes to gender dysphoria, there are no blood tests or other laboratory tests, so assessment and diagnosis in children and young people with gender-related distress is reliant on the judgements of experienced clinicians. Because medical, and subsequently possibly surgical treatments will follow, it may be argued that a highly sensitive and specific assessment process is required. The assessment should be able to accurately identify those children or young people for whom physical intervention is going to be the best course of action, but it is equally important that it identifies those who need an alternative pathway or treatment.

5.15. The formal criteria for diagnosing gender dysphoria (DSM-5) are listed in **Appendix 3**. However, there are two problems associated with the use of these criteria:

- Firstly, several of the criteria are based on gender stereotyping which may not be deemed relevant in current society, although the core criteria remain valid.
- Secondly, and more importantly, these criteria give a basis on which to make a diagnosis that a young person is clinically distressed by the incongruence between their birth-registered and their experienced gender, but they do not help in determining which factors may have led to this distress and how they might best be resolved.

5.16. At present, the assessment process varies considerably, dependent on the perceptions, experience and beliefs of different clinicians. There are some existing measurement tools, but it is suggested that these have substantial limitations.⁶⁰

5.17. The challenges are similar to the early difficulties in diagnosing autism, as set out in **Appendix 4**. As with autism, the framework for assessment needs to become formalised so there are clearer criteria for diagnosis and treatment pathways which are shared more widely. These should incorporate not just whether the child or young person meets DSM-5 criteria for gender dysphoria, but how a broader psychosocial assessment should be conducted and evaluated, and what other factors need to be considered to gain a holistic understanding of the child or young person's experience. Professional judgement and experience will still be important, but if the frameworks and criteria for assessment and diagnosis were more consistent and reproducible, there would be a greater likelihood that two different people seeing the same child or young person would come to the same conclusion. This would also mean that any research on interventions or long-term outcomes would be more reliable because the criteria on which a diagnosis was made, and hence the patients within the sample, would have the same characteristics.

⁶⁰ Bloom TM, Nguyen TP, Lami F, Pace CC, Poulakis Z, Telfer N (2021). [Measurement tools for gender identity, gender expression, and gender dysphoria in transgender and gender-diverse children and adolescents: a systematic review](#). *Lancet Child Adolescent Health*. 5: 582-588. DOI: 10.1016/s2352-4642(21)00098-5.

5.18. As outlined above, it is standard clinical practice to undertake a process called differential diagnosis. This involves summarising the main points of the clinical assessment, the most likely diagnosis, other possible diagnoses and the reasons for including or excluding them, as well as any further assessments that may be required to clarify the diagnosis and the treatment options and plan. This is important when a medical intervention is being provided on the basis of the assessment, so the process

is robust, explicit and reproducible. These considerations need to be applied to the assessment of children and young people presenting with gender-related distress. In mental health services, practitioners may also undertake a diagnostic or psychological formulation, which is a holistic summary of how the patient is feeling and why, and how to make sense of it, and a plan for moving forward with management or treatment.

Developing and implementing new treatments: Clinicians and scientists work on developing treatments. This involves clinical trials and, where there are new treatments, comparing them to any existing treatments. Questions include: What are the intended outcomes or benefits of treatment? What are the complications or side effects? What are the costs? To initiate a new treatment, it must be both safe and effective. Questions of affordability can sometimes become controversial.

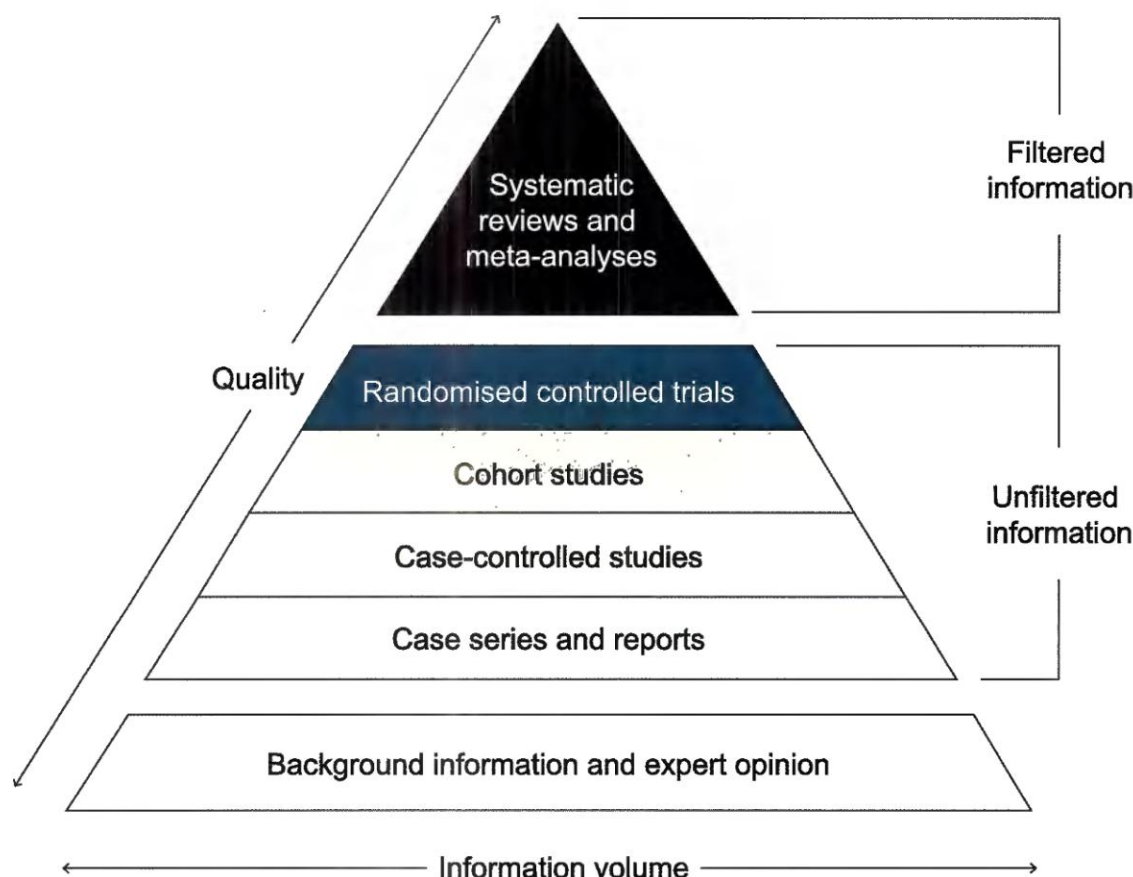

The best type of single study is considered to be the randomised controlled trial (RCT), but sometimes this is not feasible. Even where RCTs are not available, it is usual to at least have data on the outcomes of sufficient cases or cohorts to understand the risk/benefit of the treatment under consideration. As demonstrated in Fig. 4, the highest level of evidence is when the results of several different studies are pooled, but this is only useful if the individual studies themselves are of high quality.

In many instances, evidence is not perfect and difficult decisions have to be made. Where treatments are innovative or life-changing, the whole multi-disciplinary team will usually meet to consider the available options, and how to advise the child or young person and family so that a shared decision can be made. Sometimes an ethics committee is involved. This is one of the most challenging areas of medicine and is underpinned by GMC guidance.^{61,62}

⁶² National Institute for Health and Care Excellence (2021). [Shared decision making](#).

Figure 3: Pyramid of standards of evidence

Source: Levels of evidence pyramid, OpenMD. Reproduced with permission⁶³

5.19. There are three types of intervention or treatment for children and young people with gender-related distress, which may be introduced individually or in combination with one another:

- **Social transition** – this may not be thought of as an intervention or treatment, because it is not something

that happens within health services.

However, it is important to view it as an active intervention because it may have significant effects on the child or young person in terms of their psychological functioning.^{64,65} There are different views on the benefits versus the harms of early social transition. Whatever position one

takes, it is important to acknowledge that it is not a neutral act, and better information is needed about outcomes.

- **Counselling, social or psychological interventions** – these may be offered before, instead of, or alongside physical interventions. Again, they should be viewed as active interventions which require robust evaluation in their own right.
- **Physical treatments** – these comprise puberty blockers and feminising/masculinising hormones (administered by endocrinologists) and surgery. The latter is not considered as part of this Review since it is not available to those under age 18.

5.20. It should also be recognised that 'doing nothing' cannot be considered a neutral act.

5.21. The lack of available high-level evidence was reflected in the recent NICE review into the use of puberty blockers and feminising/masculinising hormones commissioned by NHS England, with the evidence being too inconclusive to form the basis of a policy position.^{66,67} Assessing treatments for gender dysphoria has many of the same problems as assessing treatment for children with autism – it can take many years to get a full appreciation of outcomes and there may be other complicating factors in the child or young

person's life during this period. However, this of itself is not an adequate reason for the major gaps in the international literature.

5.22. It is still common that drugs are not specifically licensed for children because the trials have only taken place on adults. This does not preclude their use or make their use inherently unsafe, particularly if they are used very commonly in children. However, where their use is innovative, patients receiving the drug should ideally do so under trial conditions.

5.23. The same considerations apply to 'off-label' drugs, where the drug is used for a condition different to the one for which it was licensed. This is the case for puberty blockers, which are licensed for use in precocious puberty, but not for puberty suppression in gender dysphoria. Again, it is important that it is not assumed that outcomes for, and side effects in, children treated for precocious puberty will necessarily be the same in children or young people with gender dysphoria.

5.24. As outlined above, in other areas of practice where complex or potentially life-altering treatment is being considered for a child or young person, it is usual for the case to be discussed by an MDT including all professionals involved in their care. In gender services for children and young people in the Netherlands, as well as a number of other countries, there are full

Independent review of gender identity services for children and young people

MDT meetings, including psychiatrists and endocrinologists, to make decisions about suitability for hormone intervention and to review progress.^{68,69}

5.25. Recent legal proceedings have examined the question of the competence and capacity of children and young people to consent to hormone treatment. However, there are some essential components that underpin informed consent; the robustness

of the options offered to the patient, the information provided to them about those options, and their competence and capacity to consider them. The courts have given consideration to competence and capacity, and it is incumbent on this Review to consider the soundness of the decision making which underpins the options offered, and the quality and accuracy of the information provided about those options.

Elements of informed consent

⁶⁸ Kyriakou A, Nicolaides NC, Skordis N (2020). [Current approach to the clinical care of adolescents with gender dysphoria](#). Acta Biomed 91(1): 165–75. DOI: 10.23750/abm.v91i1.9244.

⁶⁹ Cohen-Kettenis PT, Steensma TD, de Vries ALC. [Treatment of adolescents with gender dysphoria in the Netherlands](#). Child Adolesc Psychiatr Clin N Am 20. 689–700. 2001. DOI: 10.1016/j.chc.2011.08.001.

Service development and service improvement: Central to any service improvement is the systematic and consistent collection of data on outcomes of treatment. There is a process of continuous service improvement as new presentations or variations on the original condition are recognised, diagnosis or screening improves and/or trials on new treatments or variations on existing treatments are ongoing.

There should be consistent treatment protocols or guidelines in place, in order to make sense of variations in outcomes. Where possible, these should be compared between and across multiple different centres.

As time passes, services need to be changed or extended based on patient need, and on what resources are needed to deliver the available treatments. They need to be accessible where the prevalence of the condition is highest. The relevant workforce to deliver the service needs to be recruited and trained, contingent on the type of treatments or therapy that is required.

5.26. When a pioneering treatment or specialist service starts, it is often delivered in a single centre. Thereafter, additional centres take on the work as increasing numbers of patients need to access the treatment. Current provision of NHS specialist gender identity services for children and young people has remained concentrated within a single organisation, but demand has grown dramatically.

5.27. The situation has been exacerbated because there are not many local services seeing gender-questioning children at an earlier stage in their journey, which means that GIDS is carrying an unsustainable workload of increasingly complex young people.

5.28. As a condition evolves, rigorous data collection and quantitative research is an essential prerequisite to refining understanding and treatment. Historically, The Tavistock and Portman NHS

Foundation Trust built its international reputation as the home of psychoanalysis, psychotherapy and family therapy, with a strong track record of publishing qualitative rather than quantitative research; consequently its approach to quantitative data collection about this important group of children and young people has been weak.

5.29. A further anomaly is a public perception that The Tavistock and Portman NHS Foundation Trust is the responsible organisation for leading the management of children receiving hormone treatment for their gender dysphoria. In reality, the hormone treatment is delivered by paediatric services in University College London Hospitals NHS Foundation Trust and The Leeds Teaching Hospitals NHS Trust.

Independent review of gender identity services for children and young people

5.30. In practice, it is important that for children and young people who need physical intervention, paediatric and mental health services are seen as equal partners, with seamless joint working and shared responsibility. When there were very small numbers of patients, it was easier for this to be achieved, but cross-site working with a very large caseload has made this more difficult to achieve, despite the best intentions of the staff.

5.31. Over the last two years there have been strong efforts on the part of The Tavistock and Portman NHS Foundation Trust to make practice within GIDS more consistent, with tighter procedures for case management, consent, and safeguarding. However, although this has resulted in better documentation, variations and inconsistencies in clinical decision making remain. In responding to a changing legal framework, some processes have become more cumbersome and complex, and the team are working hard to streamline the process.

5.32. Overall, GIDS faces a daunting task as a single provider in managing risk on the waiting list, seeing new referrals, reviewing and supporting those on hormone treatment, undertaking an ongoing transformation programme, recruiting and training new staff and trying to retain existing staff. This suggests that the current model is not sustainable and that another model is needed.

6. Interim advice, research programme and next steps

Dealing with uncertainty

6.1. As outlined throughout this report, there are major gaps in the research base underpinning the clinical management of children and young people with gender incongruence and gender dysphoria, including the appropriate approaches to assessment and treatment.

6.2. As with any other area of medicine, where there are gaps in the evidence base and uncertainties about the correct clinical approach, three tasks must be undertaken:

- Clinical services must be run as safely and effectively as possible, within the constraints of current knowledge; treatment options must be weighed carefully; and treatment decisions must be made in partnership between the clinicians and the children, young people and their families and carers, based on our current understanding about outcomes.
- Consistent data must be collected by clinical services, for both audit and research purposes so that knowledge gaps can be filled, alongside an active research programme.
- Where there is not an immediate prospect of filling research gaps, professional consensus should be developed on the correct way to proceed pending clearer research evidence, supported by input from service users.

6.3. The additional problem with the current service model is that safety and access are further compromised by the pace at which referrals have grown and outstripped capacity at tertiary level, and the lack of service availability at local level.

6.4. The Review's approach to these tasks is as follows:

- Our **interim advice** focuses on the issues of capacity, safety, and standards around treatment decisions, as well as data and audit.
- Our **research streams** will provide the Review with an independent collation of published evidence relevant to epidemiology, clinical management, models of care, and outcomes, as well as delivering qualitative and quantitative research relevant to the Terms of Reference of the Review. This offers a real opportunity to contribute to the international evidence base for this service area.
- There will be an ongoing and wide-ranging **programme of engagement** to address areas on which we will not be able to obtain definitive evidence during the lifetime of the Review.

Interim advice

6.5. The Review considers that there are some areas where there is sufficient clarity about the way forward and we are therefore offering some specific observations and interim advice. The Review will work with NHS England, providers and the broader stakeholder community to progress action in these areas.

Service model

6.6. It has become increasingly clear that a single specialist provider model is not a safe or viable long-term option in view of concerns about lack of peer review and the ability to respond to the increasing demand.

6.7. Additionally, children and young people with gender-related distress have been inadvertently disadvantaged because local services have not felt adequately equipped to see them. It is essential that they can access the same level of psychological and social support as any other child or young person in distress, from their first encounter with the NHS and at every level within the service.

6.8. A fundamentally different service model is needed which is more in line with other paediatric provision, to provide timely and appropriate care for children and young people needing support around their gender identity. This must include support for any other clinical presentations that they may have.

6.9. The Review supports NHS England's plan to establish regional services, and

welcomes the move from a single highly specialist service to regional hubs.

6.10. Expanding the number of providers will have the advantages of:

- creating networks within each area to improve early access and support;
- reducing waiting times for specialist care;
- building capacity and training opportunities within the workforce;
- developing a specialist network to ensure peer review and shared standards of care; and
- providing opportunities to establish a more formalised service improvement strategy.

Service provision

6.11. The primary remit of NHS England's proposed model is for the regional hubs to provide support and advice to referrers and professionals. However, it includes limited provision for direct contact with children and young people and their families.

- 1:** The Review advises that the regional centres should be developed, as soon as feasibly possible, to become direct service providers, assessing and treating children and young people who may need specialist care, as part of a wider pathway. The Review team will work with NHS England and stakeholders to further define the proposed model and workforce implications.

2: Each regional centre will need to develop links and work collaboratively with a range of local services within their geography to ensure that appropriate clinical, psychological and social support is made available to children and young people who are in early stages of experiencing gender distress.

3: Clear criteria will be needed for referral to services along the pathway from primary to tertiary care so that gender-questioning children and young people who seek help from the NHS have equitable access to services.

4: Regional training programmes should be run for clinical practitioners at all levels, alongside the online training modules developed by Health Education England (HEE). In the longer-term, clearer mapping of the required workforce, and a series of competency frameworks will need to be developed in collaboration with relevant professional organisations.

through the service. Standardised data collection is required in order to audit service standards and inform understanding of the epidemiology, assessment and treatment of this group. This, alongside a national network which brings providers together, will help build knowledge and improve outcomes through shared clinical standards and systematic data collection. In the longer-term, formalisation of such a network into a learning health system⁷⁰ with an academic host would mean that there was systematised use of data to produce a continuing research programme with rapid translation into clinical practice and a focus on training.

5: The regional services should have regular co-ordinated national provider meetings and operate to shared standards and operating procedures with a view to establishing a formal learning health system.

6: Existing and future services should have standardised data collection in order to audit standards and inform understanding of the epidemiology, assessment and treatment of this group of children and young people.

Data, audit and research

6.12. A lack of routine and consistent data collection means that it is not possible to accurately track the outcomes and pathways children and young people take

⁷⁰ Scobie S, Castle-Clarke S (2019). [Implementing learning health systems in the UK NHS: Policy actions to improve collaboration and transparency and support innovation and better use of analytics](#). Learning Health Systems 4(1): e10209. DOI:10.1002/lrh2.10209.

7: Prospective consent of children and young people should be sought for their data to be used for continuous service development, to track outcomes, and for research purposes. Within this model, children and young people put on hormone treatment should be formally followed up into adult services, ideally as part of an agreed research protocol, to improve outcome data.

8: There needs to be agreement and guidance about the appropriate clinical assessment processes that should take place at primary, secondary and tertiary level.

9: Assessments should be respectful of the experience of the child or young person and be developmentally informed. Clinicians should remain open and explore the patient's experience and the range of support and treatment options that may best address their needs, including any specific needs of neurodiverse children and young people.

Clinical approach

Assessment processes

6.13. We have heard that there are inconsistencies and gaps in the assessment process. Our work to date has also demonstrated that clinical staff have different views about the purpose of assessment and where responsibility lies for different components of the process within the pathway of care. The Review team has commenced discussions with clinical staff across primary, secondary and tertiary care to develop a framework for these processes.

Hormone treatment

6.14. The issues raised by the Multi-Professional Review Group echo several of the problems highlighted by the CQC. It is essential that principles of the General Medical Council's Good Practice in Prescribing and Managing Medicine's and Devices⁷¹ are closely followed, particularly given the gaps in the evidence base regarding hormone treatment. Standards for decision making regarding endocrine treatment should also be consistent with international best practice.^{72,73,74}

⁷¹ General Medical Council (2021). [Good practice in prescribing and managing medicines and devices \(76-78\)](#).

⁷² Hembree WC, Cohen-Kettenis PT, Gooren L, Hannema SE, Meyer WJ, Murad MH, et al (2017). [Endocrine treatment of gender-dysphoric/gender-incongruent persons: an Endocrine Society clinical practice guideline](#). J Clin Endocrinol Metab 102(11): 3869–903. DOI: 10.1210/jc.2017-01658.

⁷³ Cohen-Kettenis PT, Steensma TD, de Vries ALC (2001). [Treatment of adolescents with gender dysphoria in the Netherlands](#). Child Adolesc Psychiatr Clin N Am 20: 689–700. DOI: 10.1016/j.chc.2011.08.001.

⁷⁴ Kyriakou A, Nicolaidis NC, Skordis N (2020). [Current approach to the clinical care of adolescents with gender dysphoria](#). Acta Biomed 91(1): 165–75. DOI: 10.23750/abm.v91i1.9244.

10: Any child or young person being considered for hormone treatment should have a formal diagnosis and formulation, which addresses the full range of factors affecting their physical, mental, developmental and psychosocial wellbeing. This formulation should then inform what options for support and intervention might be helpful for that child or young person.

11: Currently paediatric endocrinologists have sole responsibility for treatment, but where a life-changing intervention is given there should also be additional medical responsibility for the differential diagnosis leading up to the treatment decision.

6.15. Paediatric endocrinologists develop a wide range of knowledge within their paediatric training, including safeguarding, child mental health, and adolescent development. Being party to the discussions and deliberations that have led up to the decision for medical intervention supports them in carrying out their legal responsibility for consent to treatment and the prescription of hormones.

12: Paediatric endocrinologists should become active partners in the decision making process leading up to referral for hormone treatment by participating in the multidisciplinary team meeting where children being considered for hormone treatment are discussed.

6.16. Given the uncertainties regarding puberty blockers, it is particularly important to demonstrate that consent under this circumstance has been fully informed and to follow GMC guidance⁷⁵ by keeping an accurate record of the exchange of information leading to a decision in order to inform their future care and to help explain and justify the clinician's decisions and actions.

13: Within clinical notes, the stated purpose of puberty blockers as explained to the child or young person and parent should be made clear. There should be clear documentation of what information has been provided to each child or young person on likely outcomes and side effects of all hormone treatment, as well as uncertainties about longer-term outcomes.

⁷⁵ General Medical Council (2020). [Decision making and consent](#).

14: In the immediate term the Multi-Professional Review Group (MPRG) established by NHS England should continue to review cases being referred by GIDS to endocrine services.

Research programme

6.17. The Review's formal academic research programme, comprising a literature review, quantitative analysis and primary qualitative research, has been based on the identified gaps in the evidence and the feasibility of filling them within the lifetime of the Review.

6.18. Initial work has identified the existing evidence base on epidemiology, natural history, and the treatment and outcomes of children and young people with gender dysphoria/gender-related distress. It has also assessed the feasibility of linking data between local, regional or national datasets in order to assess intermediate and longer-term outcomes.

Literature review

6.19. A literature review is being undertaken, which will interface with evidence gathering from the professional community (see qualitative research section below). Its aim is to systematically identify, collate and synthesise the existing evidence on the changing epidemiology of gender-related distress in children and young people and the appropriate social, clinical,

psychological and medical management of that distress.

6.20. The literature review will capture primary studies of any design, including experimental, observational, survey and qualitative, and is looking to answer the following questions:

1. How has the population of children and young people presenting with gender dysphoria and/or gender-related distress changed over time?
2. What are the appropriate referral, assessment and treatment pathways for children and young people with gender dysphoria and/or gender-related distress?
3. What are the short-, medium- and long-term outcomes for children and young people with gender dysphoria and/or gender-related distress?
4. How do children and young people and their families negotiate distress, present this distress to services, and what are their expectations, following presentation?
5. How do children, young people and their families/carers experience referral, assessment and treatment? And how are these negotiated among children and young people, parents/carers, families and healthcare professionals?

6.21. A separate synthesis for each question will be undertaken. The systematic review has been registered on PROSPERO [ID:289659].

Quantitative research

6.22. The National Institute for Health and Care Excellence (NICE) recently published two evidence reviews.^{76,77} These highlight shortcomings in the follow-up data collected about children and young people, when they are referred to a specialist gender identity service. The quantitative research will therefore focus on the collection and analysis of data to uncover patterns and quantify problems, thereby helping the Review to address some of these shortcomings.

6.23. The aim of the quantitative study is to supplement the material collected by the literature review, further examining the changing epidemiology of gender-related distress in children and young people, in addition to exploring the appropriate social, clinical, psychological and medical management. Its objectives are to:

- a) describe the clinical and demographic characteristics of this population of children and young people and their clinical management in the GIDS service; and

- b) assess the intermediate and longer-term outcomes of this population of children and young people utilising national healthcare data.

6.24. This research will provide an evidence base to facilitate informed decision making among children and young people and their families. It will also provide an evidence base for those responsible for commissioning, delivering and managing services.

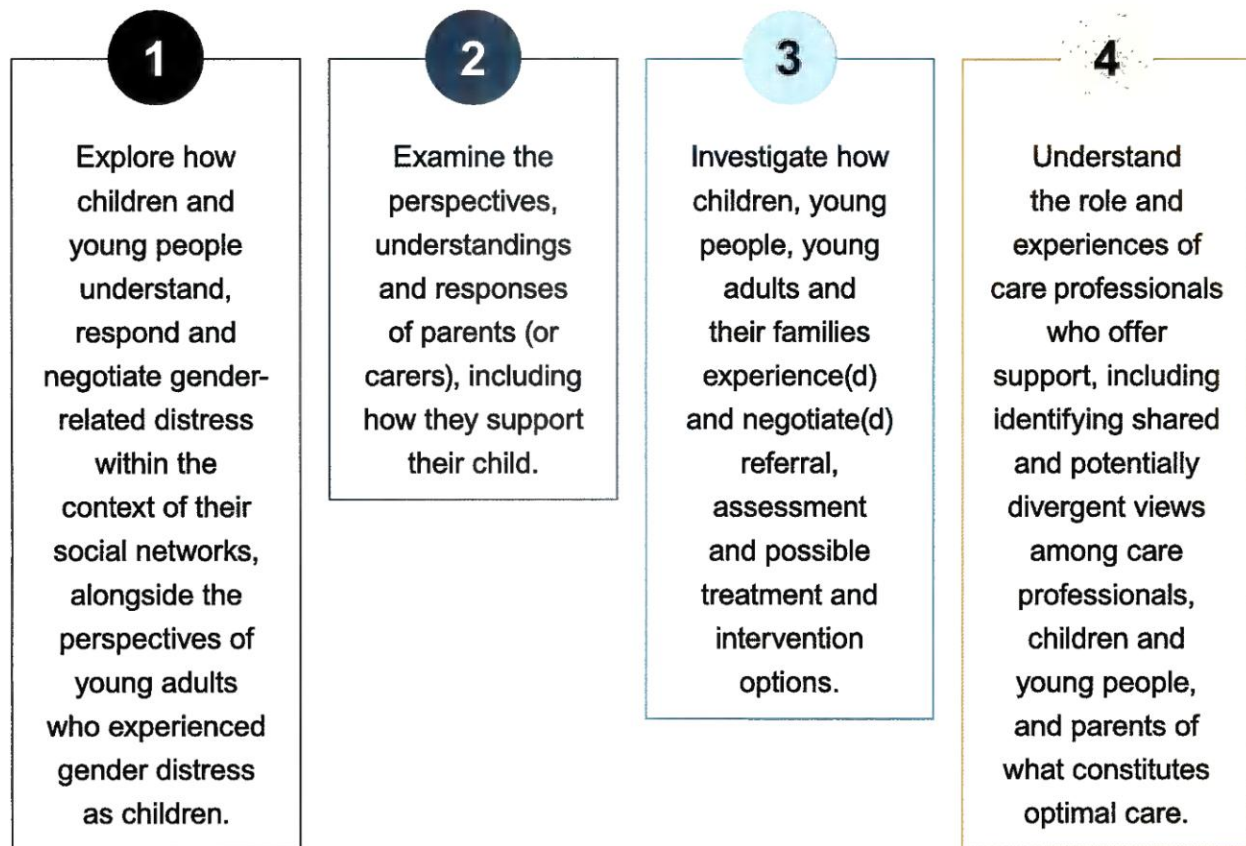

Qualitative research

6.25. The qualitative research will capture a diverse range of trajectories experienced by gender-questioning children and young people, exploring a range of different experiences and outcomes. This will include talking to children and young people and their families/carers who are currently negotiating gender-related distress, young adults who have gone through the process of resolving their distress and care professionals.

⁷⁶ National Institute for Health and Care Excellence (2020). [Evidence Review: Gonadotrophin Releasing Hormone Analogues for Children and Adolescents with Gender Dysphoria](#).

⁷⁷ National Institute for Health and Care Excellence (2020). [Evidence review: gender-affirming hormones for children and adolescents with gender dysphoria](#).

The objectives of the qualitative research are to:

Progress

6.26. The literature review is already underway and is identifying relevant studies. Initial meetings have also taken place with voluntary organisations and other researchers working in the area to ensure there is no duplication and in recognition of research fatigue among this population.

6.27. Children and young people and young adults who have experienced gender-related distress are involved in the research programme. Their advice has been, and will continue to be, sought throughout this work, including in relation to the focus of the research and interpretation

of findings and the design and content of dissemination materials.

6.28. Three research protocols have been produced setting out how the research will be undertaken, and the research team is currently gaining the necessary ethical and governance approvals to progress the study. The systematic review is published on the PROSPERO website and will be published on the Review website in due course, along with the qualitative and quantitative research proposals once ethical and governance approvals have been received.

Independent review of gender identity services for children and young people

6.29. The research findings will be subject to peer review through the publication process and various summaries, aimed at different audiences, will be available on the project website and distributed via support organisations. These summaries will also be made available on the Review website.

Ongoing engagement

6.30. In recognition that not all the published evidence is likely to be of high enough quality to form the sole basis for our recommendations, a consensus development approach will be used to synthesise the published evidence and research outputs of the academic work with stakeholder submissions and expert opinion.

6.31. Over the coming months, the Review will build on its engagement to date and, alongside the academic research programme, will continue informal and structured engagement with service users, their families, support and advocacy groups and professionals to test emerging thinking, provide opportunities for challenge and further develop the evidence base.

6.32. This review is an iterative process and we will share important findings when they become available. For the latest updates, please visit our website: <https://cass.independent-review.uk/>

6.33. We thank those who have participated in the Review to date and welcome engagement with us as work progresses towards final recommendations.

Glossary

Glossary

There is sometimes no consensus on the best language to use relating to this subject. The language surrounding this area has also changed rapidly and young people have developed varied ways of describing their experiences using different terms and constructs that are relevant to them.

The Review tries as far as possible to use language and terms that are respectful and acknowledge diversity, but that also accurately illustrate the complexity of what we are trying to describe and articulate.

The terms we have used may not always feel right to some; nevertheless, it is important to emphasise that the language used is not an indication of a position being taken by the Review. The glossary below sets out a description of some of the terms we have used in the Review.

Term	Description
Affirmative model	A model of gender healthcare that originated in the USA ^{78,79,80,81} which affirms a young person's subjective gender experience while remaining open to fluidity and changes over time. This approach is used in some key child and adolescent clinics across the Western world.
Assent	To agree to or approve of something (idea, plan or request), especially after thoughtful consideration.
Autonomy	Personal autonomy is the ability of a person to make their own decisions. In health this refers specifically to decisions about their care.

Term		Description
Best interests		<p>Clinicians and the courts seek to act in the best interests of children and young people. For the Mental Capacity Act (MCA) 2005, decisions for someone who cannot decide for themselves must be made in their best interests. Under the Children Act 1989, in any decision of the court about a child (under 18), the welfare of the child must be paramount. For these purposes, there is little or no material difference between the welfare and best interests, and we have used “best interests” throughout the report.</p> <p>Although there is no standard definition of “best interests of the child,” the General Medical Council advises that an assessment of best interests will include what is clinically indicated as well as additional factors such as the child or young person’s views, the views of parents and others close to the child or young person and cultural, religious and other beliefs and values of the child or young person.⁸²</p>
		<p>The MCA s4,⁸³ and extensive Court of Protection case law, deals with the approach to best interests under that legislation. Whether in the Court of Protection or the High Court, when the court is asked to make an assessment of a child or young person’s best interests, it will consider their welfare/best interests in the widest sense. This will include not just medical factors but also social and psychological factors.</p>
Case-mix		The mix of patients within a particular group.
Child and adolescent mental health services	CAMHS	NHS children and young people’s mental health services. ⁸⁴

⁸² General Medical Council (2018). [0-18 years – guidance for all doctors](#).

⁸³ Mental Health Law Online. [MCA 2005 s4](#).

⁸⁴ Young Minds. [Guide to CAMHS: a guide for young people](#).

Independent review of gender identity services for children and young people

Term		Description
Child and/or young person		<p>In law, everyone under 18 years of age is a child (Children Act 1989) but we recognise that it may be more appropriate to refer to those approaching the age of 18 as a young person, and that such young people may not recognise themselves as a “child”.</p> <p>In places, we have referred only to “young person”, or only to “child”, for example where treatment in question is only given towards the later stages of childhood, closer to the age of 18, or in reference to the parent/child relationship, in which they remain the parents’ child, regardless of their age.</p> <p>Otherwise, we have used the phrase “child and/or young person” throughout the report for this reason only, and do not intend there to be a material difference between them other than that.</p>
Cognitive		<p>Relating to, or involving, the process of thinking and reasoning.</p>
Consent		<p>Permission for a clinical intervention (such as an examination, test or treatment) to happen. For consent to be ‘informed’, information must be disclosed to the person about relevant risks, benefits and alternatives (including the option to take no action), and efforts made to ensure that the information is understood.</p> <p>In legal terms, consent is seen as needing:</p> <ol style="list-style-type: none"> 1 – capacity (or <i>Gillick</i> competence under 16) to make the relevant decision; 2 – to be fully informed (ie the information provided about the available options, the material risks and benefits of each option, and of doing nothing, “material” meaning (per the Montgomery Supreme Court judgment in 2015) what a reasonable patient would want to know, and what this patient actually wants to know, NOT what a reasonable doctor would tell them); and 3 – to be freely given (that is, without coercion).
Contraindications		<p>A condition or circumstance that suggests or indicates that a particular technique or drug should not be used in the case in question.</p>

Term		Description
Court of Appeal		(England and Wales) The Court of Appeal hears appeals against both civil and criminal judgments from the Crown Courts, High Court and County Court. It is second only to the Supreme Court.
Detransition/ detransitioners		Population of individuals who experienced gender dysphoria, chose to undergo medical and/or surgical transition and then detransitioned by discontinuing medications, having surgery to reverse the effects of transition, or both. ⁸⁵
Diagnostic and Statistical Manual of Mental Disorders Fifth edition	DSM-5	The American diagnostic manual used to diagnose mental health disorders, and commonly used in UK practice. See Appendix 3 .
Diagnostic formulation		The comprehensive assessment that includes a patient's history, results of psychological tests, and diagnosis of mental health difficulties.
Divisional Court		(England and Wales) When the High Court of Justice of England and Wales hears a case with at least two judges sitting, it is referred to as the Divisional Court. This is typically the case for certain judicial review cases (as well as some criminal cases).
Dutch Approach		Protocol published in 1998 by the Amsterdam child and adolescent gender identity clinic. ⁸⁶
Endocrine treatment		In relation to this clinical area, this term is used to describe the use of gonadotropin-releasing hormones (see below) and feminising and masculinising hormones (see below).
Endocrinologist		An endocrinologist is a medical doctor specialising in diagnosing and treating disorders relating to problems with the body's hormones.
Endocrinology		The study of hormones.

⁸⁵ Littman L (2021). [Individuals treated for gender dysphoria with medical and/or surgical transition who subsequently detransitioned: a survey of 100 detransitioners](#). Arch Sex Abuse 50: 3353–69. DOI: 10.1007/s10508-021-02163-w

Independent review of gender identity services for children and young people

Term		Description
Epidemiology		Epidemiology is the study of the distribution and determinants of health-related states or events in specified populations, and the application of this study to the control of health problems. ⁸⁷
Exploratory approaches		Therapeutic approaches that acknowledge the young person's subjective gender experience, whilst also engaging in an open, curious, non-directive exploration of the meaning of a range of experiences that may connect to gender and broader self-identity. ^{88,89,90,91}
Feminising and masculinising hormones (also known as cross-sex hormones, and gender affirming hormones).		Hormones given as part of a medical transition for gender dysphoric individuals, where sex hormones (testosterone for transgender males and oestrogen for transgender females).
Gender dysphoria		Diagnostic term used in DSM-5. ⁹² Gender dysphoria describes "a marked incongruence between one's experienced/expressed gender and assigned gender of at least 6 months duration" which must be manifested by a number of criterion – see Appendix 3 for further detail.
Gender fluid		An experience of gender that is not fixed, but changes between two or more identities.
Gender identity		This term is used to describe an individual's internal sense of being male or female or something else.
Gender identity development		The developmental experience of a child or young person in seeking to understand their gender identity over time.
Gender Identity Development Service	GIDS	The service that NHS England commissions for children and adolescents with gender dysphoria.

⁹² American Psychiatric Association (2013). [Diagnostic and Statistical Manual of Mental Health Disorders: DSM-5™, 5th ed.](#)

Term		Description
Gender incongruence		Diagnostic term used in ICD-11. ⁹³ Gender incongruence is characterised by “a marked and persistent incongruence between an individual’s experienced gender and the assigned sex”. See Appendix 3 for further detail.
Gender-questioning		A broader term that might describe children and young people who are in a process of working out how they want to present in relation to their gender.
Gender-related distress		A way of describing distress that may arise from a broad range of experiences connected to a child or young person’s gender identity development. Often used for young people whereby any formal diagnosis of gender dysphoria has not yet been made.
Gillick competence/ Fraser guidelines		A term derived from <i>Gillick v West Norfolk And Wisbech AHA</i> , 1984 that is used to decide whether a child or young person up to the age of 16 years is able to consent to their own medical treatment, without the need for parental permission or knowledge. A child or young person will be ‘Gillick competent’ for that decision if they have the necessary maturity and understanding to make the decision.
Gonadotropin-releasing hormone analogues (also known as the hormone blocker/s and puberty blocker/s)	GnRH	GnRH analogues competitively block GnRH receptors to prevent the spontaneous release of two gonadotropin hormones, Follicular Stimulating Hormone (FSH) and Luteinising Hormone (LH) from the pituitary gland. This arrests the progress of puberty.
General Practitioner	GP	GPs deal with a whole range of health problems and manage the care of their patients, referring onto specialists as appropriate. ⁹⁴
High Court		The third highest court in the UK. It deals with all high value and high importance civil law (non-criminal) cases and appeals of decisions made in lower courts. When the High Court sits with more than one judge, as required for certain kinds of cases, it is called the Divisional Court.
International Classification of Diseases, Version 11	ICD-11	ICD-11 ⁹⁵ is the World Health Organization (WHO) mandated health data standard used for medical diagnosis.

⁹⁴ NHS. [GP services](#).

⁹⁵ World Health Organization (2022). [International Classification of Diseases Eleventh Revision](#).

Independent review of gender identity services for children and young people

Term		Description
Looked after children		Children who are in the care of their Local Authority who may be living with foster parents or in a residential care setting.
Multi-disciplinary-team	MDT	The identified group of professional staff who provide a clinical service.
Neurodiverse		Displaying or characterised by autistic or other neurologically atypical patterns of thought or behaviour; not neurotypical.
Non-binary		A gender identity that does not fit into the traditional gender binary of male and female. ⁹⁶
Paediatrics		The branch of medicine dealing with children and their medical conditions.
Pass/passing		A person's gender being seen and read in the way they identify.
Precocious puberty		This is when a child's body begins changing into that of an adult (puberty) too soon – before age 8 in girls and before age 9 in boys.
Primary care		Primary care includes general practice, community pharmacy, dental and optometry (eye health) services. This tends to be the first point of access to healthcare.
Psychological formulation		A structured approach to understanding the factors underlying distressing states in a way that informs the changes needed and the therapeutic intervention for these changes to occur.
Psychosocial		Describes the psychological and social factors that encompass broader wellbeing.
Puberty blockers		See gonadotropin-releasing hormone above.
Secondary care		Hospital and community health care services that do not provide specialist care and are usually relatively close to the patient. For children this will include Child and Adolescent Mental Health Services (CAMHS), child development and general paediatric services.
Tanner Stage		Classification of puberty by stage of development. This ranges from Stage 1, before physical signs of puberty appear, to Stage 5 at full maturity.

⁹⁶ Twist J, de Graaf NM (2019). [Gender diversity and non-binary presentations in young people attending the United Kingdom's National Gender Identity Development Service](#). Clin Child Psychol Psychiatry 24(2): 277–90. DOI: 10.1177/1359104518804311.

Term		Description
Tertiary care		Tertiary care is the specialist end of the NHS. These services relate to complex or rare conditions. Services are usually delivered in a number of hospitals/centres.
Transgender	trans	This is an umbrella term that includes a range of people whose gender identity is different from the sex they were registered at birth.
Transition		These are the steps a person may take to live in the gender in which they identify. This may involve different things, such as changing elements of social presentation and role and/or medical intervention for some.

Appendix 1

Terms of reference

TERMS OF REFERENCE FOR REVIEW OF GENDER IDENTITY DEVELOPMENT SERVICE FOR CHILDREN AND ADOLESCENTS

INTRODUCTION

1. NHS England is the responsible commissioner for specialised gender identity services for children and adolescents. The Gender Identity Development Service for children and adolescents is currently managed by the Tavistock and Portman NHS Foundation Trust.
2. In recent years there has been a significant increase in the number of referrals to the Gender Identity Development Service, and this has occurred at a time when the service has moved from a psychosocial and psychotherapeutic model to one that also prescribes medical interventions by way of hormone drugs. This has contributed to growing interest in how the NHS should most appropriately assess, diagnose and care for children and young people who present with gender incongruence and gender identity issues.
3. It is in this context that NHS England and NHS Improvement's Quality and Innovation Committee has asked Dr Hilary Cass to chair an independent review, and to make recommendations on how to improve services for children and young people experiencing issues with their gender identity or gender incongruence, and ensure that the best model/s for safe and effective services are commissioned.

REVIEW SCOPE

The independent review, led by Dr Cass, will be wide ranging in scope and will conduct extensive engagement with all interested stakeholders. The review is expected to set out findings and make recommendations in relation to:

- i. Pathways of care into local services, including clinical management approaches for individuals with less complex expressions of gender incongruence who do not need specialist gender identity services;
- ii. Pathways of care into specialist gender identity services, including referral criteria into a specialist gender identity service; and referral criteria into other appropriate specialist services;
- iii. Clinical models and clinical management approaches at each point of the specialised pathway of care from assessment to discharge, including a description of objectives, expected benefits and expected outcomes for each clinical intervention in the pathway;
- iv. Best clinical approach for individuals with other complex presentations.
- v. The use of gonadotropin-releasing hormone analogues and gender affirming drugs, supported by a review of the available evidence by the National Institute for Health and Care Excellence; any treatment recommendations will include a description of treatment objectives, expected benefits and expected outcomes, and potential risks, harms and effects to the individual;
- vi. Ongoing clinical audit, long term follow-up, data reporting and future research priorities;
- vii. Current and future workforce requirements;
- viii. Exploration of the reasons for the increase in referrals and why the increase has disproportionately been of natal females, and the implications of these matters; and,

Independent review of gender identity services for children and young people

TERMS OF REFERENCE FOR REVIEW OF GENDER IDENTITY DEVELOPMENT SERVICE FOR CHILDREN AND ADOLESCENTS

- ix.** Any other relevant matters that arise during the course of the review
- 4. In addition, and with support from the Royal College of Paediatrics and Child Health and other relevant professional associations, the Chair will review current clinical practice concerning individuals referred to the specialist endocrine service. It is expected that findings and any recommendations on this aspect of the review will be reported early in 2021 with the review's wider findings and recommendations delivered later in 2021.
- 5. The review will not immediately consider issues around informed consent as these are the subject of an ongoing judicial review. However, any implications that might arise from the legal ruling could be considered by the review if appropriate or necessary.

10 May 2021

Dear John

INDEPENDENT REVIEW INTO GENDER IDENTITY SERVICES FOR CHILDREN AND YOUNG PEOPLE

I am writing to update you on my current approach to the work of the independent review into gender identity services for children and young people. However, the most pressing issue is how we augment the immediate support for children and young people currently needing assessment and treatment, some of whom have already been waiting for an extended period for an appointment. I will therefore also make some suggestions about interim arrangements and ways in which the review team could help to support and strengthen these.

Commissioned research programme

As you know, a key principle of the review is that it should be evidence-based, and that final conclusions will be developed through a consensus development process contingent on the synthesised evidence.

I am pleased to see that the National Institute for Health and Care Excellence (NICE) evidence reviews of gonadotrophin releasing hormone analogues and gender affirming hormones for children and adolescents with gender dysphoria have now been published. Although this is a helpful starting point, despite following a standard and robust process the NICE review findings are not conclusive enough to inform policy decisions. As part of my review, I am therefore exploring other methodologies to give increased confidence and clarity about the optimal treatment approaches.

My team is commissioning a broader literature review of the existing evidence base on the epidemiology, management and outcomes of children with gender dysphoria. We are also commissioning qualitative and quantitative research, including considering other approaches which might be employed to understand the intermediate and longer-term outcomes of children with gender dysphoria. We intend to include a review of international models and data in this programme of work.

Addressing the immediate situation

Recognising that the outcome of the review is going to take some time, I have been reflecting on the recent court rulings on puberty blockers and consent and the Care Quality Commission (CQC) report on the Gender Identity Development Service (GIDS) run by the Tavistock and Portman NHS Foundation Trust. These significant developments have changed the context in which the review is taking place, and further added to the service pressures.

I note the proposal to establish an independent multidisciplinary professional review group to confirm decision-making has followed a robust process, which seems an appropriate interim measure pending further clarification of the legal situation.

I know that everyone concerned with the delivery of services – both commissioners and providers – are worried about the increasing number of children on the waiting list for assessment by the GIDS service and the resulting distress for the children and young people and their families. The difficulty in managing risk for those on the waiting list is exacerbated by the staff vacancies at GIDS, the increasing volume of new referrals, and the fact that the support and engagement from local services is highly variable and, in some cases, very limited.

Having a single provider may have been a logical position when the GIDS service was first set up, given that this is a highly specialised service that was seeing a relatively small number of cases each year. As the epidemiology has changed and there has been an exponential increase in numbers of children with gender incongruence or dysphoria, concentration of expertise within a single service has become unsustainable. At the same time, local services have not developed the skills and competencies to provide support for children on the waiting list and those with lesser degrees of gender incongruence who may not wish to pursue specialist medical intervention, and / or to provide help for children with additional complex needs.

I know from discussions we have had that your team is working hard to find some practical alternative arrangements, and that you have been in discussion with relevant professional bodies to come up with creative interim solutions while awaiting the outcome of my review.

The review team has also been in discussion with CQC, with the Tavistock and Portman NHS Foundation Trust and with colleagues within and external to NHS England and NHS Improvement to consider which aspects of this situation we can help with in the short to medium term, whilst keeping our focus on the longer-term questions of the appropriate clinical management and whole care pathway for these children and young people. In the past months I have also met with many groups and individuals with expertise and lived experience relevant to the review, including charities and support groups, Royal Colleges and healthcare professionals.

Recommendations to NHS England and NHS Improvement

I would encourage you to consider the following when developing an interim pathway for children and young people experiencing gender dysphoria:

- **Access and referral:** Children and young people need ready access to services. However, it is unusual for a specialist service to take direct referrals. The risk of having a national service as the first point of access is that assessment and treatment of children and young people who have the greatest need for specialist care is delayed because of the lack of differentiation of those on the waiting list. In addition, many children and

Independent review of gender identity services for children and young people

young people have complex needs, but once they are identified as having gender dysphoria, other important healthcare issues which would normally be managed by local services can sometimes be overlooked.

- **Assessment and management:** All children and young people who are referred to specialist services should have a competent local multi-disciplinary assessment and should remain under active holistic local management until they are seen at a specialist centre.

I recognise that developing capacity and capability outside of the existing GIDS service to provide such initial assessment and support will be difficult to achieve at speed and will be incremental. This means that there will likely be a range of different models and options around the country, dependent on local resources, with some of the work being delivered through existing secondary service teams, and some being delivered at regional level. The support of wider services is vital.

- **Data:** The lack of systematic data collection is a significant issue. Therefore, when employing interim measures, I would suggest that particular attention is paid to the gathering of good quality data, which can then be used to inform the evidence base and future model of provision.

Actions for the review team

I would like to suggest how the review team might help with the challenging problem of growing an infrastructure outside of GIDS. From my conversations to date, I believe there are three barriers to the involvement of local services:

- **Capacity** – the staff most appropriately trained to be involved in initial assessment are those who are already most stretched within Child and Adolescent Mental Health Services (CAMHS) and paediatric services, and this situation has been significantly worsened through the impact of the Covid-19 pandemic on children's mental health. However, I know that there is substantial investment in CAMHS services, so close engagement with the relevant national policy teams at NHS England and NHS Improvement and at Health Education England (HEE) will be crucial.
- **Capability and confidence** – clinical teams outside of GIDS do not feel confident in initial assessment and support of children and young people with gender incongruence and dysphoria, in large part because they have not had the necessary training and experience, but also because of the societal polarisation and tensions surrounding the management of this group.
- **Lack of an explicit assessment framework** – currently expertise in assessment of children and young people presenting to GIDS is held in a small body of clinicians and their assessment processes have not been made explicit. The CQC report drew attention to the lack of structured assessment in the GIDS notes, and this is something that the Tavistock and Portman NHS Foundation Trust is already working to address internally. However, it is equally important to develop an initial assessment approach that can be used by first contact professionals, not just those working in the specialist service.

In the first instance, it is important that we test these assumptions with a range of clinical staff and ascertain whether there are other barriers that are preventing local engagement in this work. Then we would plan to prioritise a series of workshops, in collaboration with relevant professional groups, service users and close engagement with HEE. The purpose of these workshops would be to address identified barriers and develop:

- A framework for initial assessment of children and young people presenting with gender dysphoria.
- An approach to training for professionals at local and regional level.
- Some preliminary workforce recommendations, which will be particularly important in meeting the timelines of the three-year Comprehensive Spending Review.

These workshops will serve multiple purposes – firstly to support NHS England and NHS Improvement in the establishment of local and / or regional teams; secondly as an essential component of the work needed to inform the questions that the review is tackling; and thirdly to form the professional networks that will be needed to underpin future service and research networks.

Timelines

As you will recognise, setting up a complex national review is difficult and time consuming at the best of times. It requires a team to support the work and mechanisms for stakeholders to engage safely and with confidence. Starting a review in the midst of a pandemic is even more challenging.

I have committed to a review approach which is participative, consensus-based, evidence-based, transparent, and informed by lived and professional experience. This requires extensive engagement. Pending the appointment of our research team, the review has now launched its website and I have been proactively engaging with the stakeholder community.

It is critical that we get the approach right, particularly the engagement, the evidence review and the quantitative research given the gaps in the evidence highlighted through the NICE review, and this will take time.

My intention is that an interim report will be delivered in the summer, with a report next year setting out my final recommendations.

Yours sincerely

Dr Hilary Cass
Chair, Independent Review into Gender Identity Services for Children and Young People

Diagnostic criteria for
gender dysphoria

DSM-5 diagnostic criteria for gender dysphoria

Gender Dysphoria in Children

A. A marked incongruence between one's experienced/expressed gender and assigned gender, of at least 6 months' duration, as manifested by at least six of the following (one of which must be Criterion A1):

1. A strong desire to be of the other gender or an insistence that one is the other gender (or some alternative gender different from one's assigned gender).
2. In boys (assigned gender), a strong preference for cross-dressing or simulating female attire; or in girls (assigned gender), a strong preference for wearing only typical masculine clothing and a strong resistance to the wearing of typical feminine clothing.
3. A strong preference for cross-gender roles in make-believe play or fantasy play.
4. A strong preference for the toys, games, or activities stereotypically used or engaged in by the other gender.
5. A strong preference for playmates of the other gender.
6. In boys (assigned gender), a strong rejection of typically masculine toys, games, and activities and a strong avoidance of rough-and-tumble play; or in girls (assigned gender), a strong rejection of typically feminine toys, games, and activities.

7. A strong dislike of one's sexual anatomy.
8. A strong desire for the primary and/or secondary sex characteristics that match one's experienced gender.

B. The condition is associated with clinically significant distress or impairment in social, school, or other important areas of functioning.

Specify if:

With a disorder of sex development (e.g., a congenital adrenogenital disorder such as congenital adrenal hyperplasia or androgen insensitivity syndrome).

Gender Dysphoria in Adolescents and Adults

A. A marked incongruence between one's experienced/expressed gender and assigned gender, of at least 6 months' duration, as manifested by at least two of the following:

1. A marked incongruence between one's experienced/expressed gender and primary and/or secondary sex characteristics (or in young adolescents, the anticipated secondary sex characteristics).
2. A strong desire to be rid of one's primary and/or secondary sex characteristics because of a marked incongruence with one's experienced/expressed gender (or in young adolescents, a desire to prevent the development of the anticipated secondary sex characteristics).

Independent review of gender identity services for children and young people

3. A strong desire for the primary and/or secondary sex characteristics of the other gender.
4. A strong desire to be of the other gender (or some alternative gender different from one's assigned gender).
5. A strong desire to be treated as the other gender (or some alternative gender different from one's assigned gender).
6. A strong conviction that one has the typical feelings and reactions of the other gender (or some alternative gender different from one's assigned gender).

B. The condition is associated with clinically significant distress or impairment in social, occupational, or other important areas of functioning.

Specify if:

With a disorder of sex development (e.g., a congenital adrenogenital disorder such as congenital adrenal hyperplasia or androgen insensitivity syndrome).

Specify if:

Post transition: the individual has transitioned to full-time living in the desired gender (with or without legalization of gender change) and has undergone (or is preparing to have) at least one cross-

sex medical procedure or treatment regimen – namely, regular cross-sex hormone treatment or gender reassignment surgery confirming the desired gender (e.g., penectomy, vaginoplasty in a natal male; mastectomy or phalloplasty in a natal female).

ICD-11: HA60 Gender incongruence of adolescence or adulthood

Gender Incongruence of Adolescence and Adulthood is characterised by a marked and persistent incongruence between an individual's experienced gender and the assigned sex, which often leads to a desire to 'transition', in order to live and be accepted as a person of the experienced gender, through hormonal treatment, surgery or other health care services to make the individual's body align, as much as desired and to the extent possible, with the experienced gender. The diagnosis cannot be assigned prior the onset of puberty. Gender variant behaviour and preferences alone are not a basis for assigning the diagnosis.

Exclusions:

Paraphilic disorders.

ICD-11: HA61 Gender incongruence of childhood

Gender incongruence of childhood is characterised by a marked incongruence between an individual's experienced/expressed gender and the assigned sex in pre-pubertal children. It includes a strong desire to be a different gender than the assigned sex; a strong dislike on the child's part of his or her sexual anatomy or anticipated secondary sex characteristics and/or a strong desire for the primary and/or anticipated secondary sex characteristics that match the experienced gender; and make-believe or fantasy play, toys, games, or activities and playmates that are typical of the experienced gender rather than the assigned sex. The incongruence must have persisted for about 2 years. Gender variant behaviour and preferences alone are not a basis for assigning the diagnosis.

Exclusions:

Paraphilic disorders.

Appendix 4

The standard approach to
clinical service development

The standard approach to clinical service development

The three examples below illustrate the usual process of developing a clinical service: Covid-19 is included because this is a new condition that everyone is familiar with; childhood epilepsy because it is a complex condition with physical manifestations; and autism because it is a condition with neuro-behavioural manifestations.

By comparing these examples of clinical service development, it is possible to demonstrate some of the challenges in developing services for children and young people with gender incongruence or dysphoria, and to identify where there are gaps and questions that need to be addressed for this population, in order to ensure any future service model delivers the highest possible standards of care.

The stages below may proceed in a different sequence for different conditions, but each stage is important in the development of evidence based care.

Stage	Covid-19	Childhood Epilepsy	Autism
New condition is observed This often begins with a few case reports and then clinicians begin to recognise a recurring pattern and key clinical features, and to develop fuller descriptions of the condition.	Covid-19 is an example of a recent new condition that we all recognise, and this started with a few unusual cases of respiratory illness being described in Wuhan.	Childhood epilepsy has been recognised for centuries, but over the last century there has been growing understanding of the many different subtypes.	Individuals with autism have probably also existed for an indefinite period, but it wasn't until 1943 and 1944 that Leo Kanner and Hans Asperger wrote the first scientific accounts about the condition.

Independent review of gender identity services for children and young people

Stage	Covid-19	Childhood Epilepsy	Autism
Aetiology Clinicians and scientists try to work out the cause of the condition or the underlying physical or biological basis. Sometimes the answers to this are never found.	The cause of Covid-19 was identified at a very early stage as being due to a novel coronavirus, although it remains unclear where and how this originated.	It is now known that there are numerous different types of epilepsy, with many different causes – for example, epilepsy can be caused by specific epilepsy genes, by birth trauma, by metabolic conditions, by brain tumours and many other mechanisms. Epilepsies due to a change in the brain structure which occur after birth are called 'symptomatic' – they are a symptom of something else. Epilepsies for which there is no identified cause are called 'idiopathic'.	The first theory about the aetiology of autism was that it was caused by so called 'refrigerator parents'. This was inaccurate and damaging. It has subsequently been shown that there are many complex genetic and physical or chemical brain changes underpinning this condition.
Natural history and prognosis It is important to understand how a condition usually evolves over time, with or without treatment. The latter is important if treatment has limited efficacy and the condition is 'self-limiting' (that is, it resolves without treatment), because otherwise there is a risk that treatments create more difficulties than the condition itself.	Covid-19 is an example of a condition where there are quite polarised views about management based on its prognosis and natural history. A relatively small proportion of people are seriously affected and need treatment, and for the majority the natural history is that it will get better by itself. This has led some people to question the need for lockdowns, vaccinations and other measures which they see as impacting personal freedoms.	In epilepsy the natural history is very important. Some epilepsies get better through puberty and into adulthood, and some can get worse with hormonal changes. This is important to know when monitoring and reviewing drug treatment.	

Stage	Covid-19	Childhood Epilepsy	Autism
<p>Epidemiology</p> <p>Epidemiologists collect data to find out how common a condition is, who is most likely to be affected, what the age distribution is and so on. This allows health service planners to work out how many services are needed, where they should be established, and what staff are needed.</p> <p>They also report on changes in who is most affected, which may mean that either the disease is changing, or the susceptibility of the population is changing.</p>	<p>Epidemiologists have been crucial in supporting the management of Covid-19 because they have extracted and analysed the data on which patients are at greater risk from the virus. This has been fundamental to planning a vaccination strategy and other protective measures.</p>		<p>The epidemiology of autism has changed considerably, with a dramatic increase in the numbers of children diagnosed over the last 20 years. This has had major implications for service provision. There is ongoing debate about the cause of the increase – whether it is because of greater awareness and better diagnosis, or because there are more children with autism. Current opinion favours the first option.</p>

Independent review of gender identity services for children and young people

Stage	Covid-19	Childhood Epilepsy	Autism
<p>Assessment and diagnosis</p> <p>Clinicians will usually take a history from (that is, of their symptoms) and examine the patient (that is, for signs and symptoms), and where appropriate undertake a series of investigations or tests, to help them reach an accurate diagnosis.</p> <p>Sometimes the whole process of making a diagnosis through talking to the patient and asking them to complete formal questionnaires, examining them and/or undertaking investigations is called 'clinical assessment'.</p> <p>As well as diagnosing and ruling out a particular condition, clinicians often need to consider and exclude other, sometimes more serious, conditions that present in a similar way but may need quite different treatment – this process is called 'differential diagnosis'.</p>	<p>PCR has been used as a 'gold standard' test for diagnosis of Covid-19 since the beginning of the pandemic. Lateral flow testing was developed to provide a quicker and cheaper option, but it demonstrates the limitations of testing; it is 99.68% specific, which is a very high specificity. This means there are only a tiny number of false positives. It has lower sensitivity at 76.8%, which means it will miss about a quarter of all cases, so giving many more false negatives, BUT it will only miss 5% of cases with high viral load.</p>	<p>Epilepsy can only be definitively diagnosed by either getting a really clear description of the events from a parent or carer, or seeing the child or young person having a seizure on a video. An EEG (brain wave tracing) and other tests can provide information about the type of epilepsy, but unless a seizure happens during the recording, it does not demonstrate that they actually have seizures – only that they may be susceptible to seizures.</p>	<p>In autism there are no blood tests or X-rays to make the diagnosis. It is a 'clinical' diagnosis, which means it is dependent on taking a standardised history from the parents, and performing standardised assessments on the child or young person to distinguish between autism and other possible diagnoses (for example, language disorder, social anxiety). In the early days, these standardised measures did not exist; the diagnosis was very dependent on experts who were used to diagnosing autism by making a clinical judgement about each child. This made it difficult to teach new people how to do this without a long apprenticeship, and also made it difficult to know whether two different experts would come to the same conclusion about the same child or young person. Standardisation of the questions and process made diagnosis more reliable and consistent, as did an improved evidence base.</p> <p>At the same time, because children with autism all present differently, the assessment had to be flexible enough to accommodate, for example, non-verbal children with severe learning disability, as well as high-functioning children with strong verbal skills.</p>

Stage	Covid-19	Childhood Epilepsy	Autism
Differential diagnosis As well as making a positive diagnosis, clinicians often need to exclude other, sometimes more serious conditions that present in a similar way, but may need quite different treatment.		There are conditions that can be mistaken for epilepsy, so it is important to accurately diagnose whether seizures are happening and exclude other conditions (differential diagnoses) by carrying out relevant tests.	There are many conditions that may be mistaken for autism – for example, children who have language disorders, learning disability, severe social anxiety for other reasons, or ADHD can all appear to have autism. It is important to exclude these other conditions as well as making a positive diagnosis of autism. Sometimes these conditions can exist alongside autism, and management must then be planned to address all the child's difficulties.

Independent review of gender identity services for children and young people

Stage	Covid-19	Childhood Epilepsy	Autism
<p>Developing and implementing new treatments</p> <p>Clinicians and scientists work on developing treatments. This involves clinical trials and, where there are new treatments, comparing them to any existing treatments. Questions include: What are the intended outcomes or benefits of treatment? What are the complications or side effects? What are the costs? To initiate a new treatment, it must be both safe and effective. Questions of affordability can sometimes become controversial.</p> <p>The best type of single study is considered to be the randomised controlled trial (RCT), but sometimes this is not feasible. Even where RCTs are not available, it is usual to at least have data on the outcomes of sufficient cases or cohorts to understand the risk/benefit of the treatment under consideration. As demonstrated in Fig. 3, the highest level of evidence is when the results of several different studies are pooled, but this is only useful if the individual studies themselves are of high quality.</p>	<p>Developing treatments for Covid-19 has been possible at speed because of the large numbers of patients, and the fact that outcomes can be observed on each patient within a matter of days to weeks. Because Covid-19 was a new condition, clinicians also started in a position of 'equipoise' which means that they did not have reason to believe any one treatment might be more effective than another; this made it ethical to have one group having a treatment and another group having a different treatment or a placebo. There are also really clear outcome measures, such as whether or not patients survive or need hospitalisation. This has facilitated a high level of evidence through randomised controlled trials (see diagram below).</p>	<p>Similar considerations apply to the treatment of epilepsy in that there are 'hard' outcome measures (for example, frequency of seizures), but it can take several months to determine whether a new drug is better than an existing one for any one patient, and some side effects may be longer-term, so trials can take several years. In addition, children with epilepsy may have very different conditions causing their seizures which can also make trials more challenging.</p> <p>In the most severe cases of epilepsy, surgery may be the best option for controlling seizures. This can be very radical in certain cases and have lifelong implications for how they function. These options, which have a cost as well as a benefit to the child, will only be offered after a multi-disciplinary team meeting, including the paediatricians, therapists, neuropsychologists, radiologists, neurophysiologists and neurosurgeons have all discussed whether the benefits will outweigh the costs.</p>	<p>Evaluating interventions for autism is the most difficult of these three examples. This is because it can take many years to see developmental outcomes; it is hard to get uniform groups of children; outcomes are extremely sensitive to the social (and historical) response of others; and many other things happen in children's lives (such as changes of school, other medications, new diets). Isolating the effect of the target treatment is therefore challenging.</p>

Stage	Covid-19	Childhood Epilepsy	Autism
<p>In many instances, evidence is not perfect and difficult decisions have to be made. Where treatments are innovative or life-changing, the whole multi-disciplinary team will usually meet to consider the available options, and how to advise the child or young person and family so that a shared decision can be made. Sometimes an ethics committee is involved. This is one of the most challenging areas of medicine and is underpinned by GMC guidance.^{97, 98}</p>	<p>The UK has been internationally recognised for its Recovery Trial, led by Oxford University. This has recruited over 46,000 participants, and resulted in several treatments being approved. A key factor in this success was the willingness of patients to participate in these studies – with over 46,000 being recruited and consented.</p>

Independent review of gender identity services for children and young people

Stage	Covid-19	Childhood Epilepsy	Autism
<p>Service development and service improvement</p> <p>Central to any service improvement is the systematic and consistent collection of data on outcomes of treatment. There is a process of continuous service improvement as new presentations or variations on the original condition are recognised, diagnosis or screening improves and/or trials on new treatments or variations on existing treatments are ongoing.</p> <p>There should be consistent treatment protocols or guidelines in place, in order to make sense of variations in outcomes. Where possible, these should be compared between and across multiple different centres.</p> <p>As time passes, services need to be changed or extended based on patient need, and on what resources are needed to deliver the available treatments. They need to be accessible where the prevalence of the condition is highest. The relevant workforce to deliver the service needs to be recruited and trained, contingent on the type of treatments or therapy that is required.</p>	<p>Service development to manage Covid-19 has been on a scale unlike any normal new service development ever experienced. It has also demonstrated how other non-Covid services have had to evolve alongside, including the need for isolation, and/or PCR testing prior to routine clinical appointments, use of remote consultation and an array of other changes across the NHS. Continuous audit and monitoring of outcomes has resulted in major improvements in survival – for example, changing ventilation approach to include ‘proning’ (putting patients on their front while on the ventilator) and delaying fully intubated ventilation by giving mask ventilation for as long as possible.</p>	<p>Paediatric epilepsy is a good example of how a national approach can be taken to service improvement through the Epilepsy12 programme.⁹⁹ This is a nationally co-ordinated audit which collects a standardised dataset, incorporating NICE standards, and is used to drive up standards of care for children and young people with epilepsy.</p>	<p>Improvement in autism services has been driven by the changing epidemiology, NICE standards, extensive training of the workforce and attempts to improve public understanding. Where previously diagnosis was undertaken in a few specialist centres, the rising waiting times and NICE standards on access, assessment and appropriate multi-professional provision have led to almost every community child development service having an autism assessment clinic or team. Services are able to self-assess against national standards to inform local improvement strategies.</p>

Medicine and gender transidentity in children and adolescents

Press release of the French National Academy of Medicine¹

February 25, 2022

Gender transidentity is the strong sense, for more than 6 months, of identification with a gender different from that assigned at birth. This feeling can cause a significant and prolonged suffering, which can lead to a risk of suicide (a). No genetic predisposition has been found.

The recognition of this disharmony is not new, but a very strong increase in the demand for physicians for this reason has been observed (1, 2) in North America, then in the countries of northern Europe and, more recently, in France, particularly in children and adolescents. For example, a recent study within a dozen high schools in Pittsburgh revealed a prevalence that was much higher than previously estimated in the United States (3): 10% of students declared themselves to be transgender or non-binary or of uncertain gender (b). In 2003, the Royal Children's Hospital in Melbourne had diagnosed gender dysphoria in only one child, while today it treats nearly 200.

Whatever the mechanisms involved in the adolescent – overuse of social networks, greater social acceptability, or example in the entourage - this epidemic-like phenomenon results in the appearance of cases or even clusters in the immediate surroundings (4). This primarily social problem is based, in part, on a questioning of an excessively dichotomous vision of gender identity by some young people.

The medical demand is accompanied by an increasing supply of care, in the form of consultations or treatment in specialized clinics, because of the distress it causes rather than a mental illness per se. Many medical specialties in the field of pediatrics are concerned. First of all psychiatry, then, if the transidentity appears real or if the malaise persists, endocrinology gynecology and finally surgery are concerned.

However, a great medical caution must be taken in children and adolescents, given the vulnerability, particularly psychological, of this population and the many undesirable effects, and even serious complications, that some of the available therapies can cause. In this respect, it is important to recall the recent decision (May 2021) of the Karolinska University Hospital in Stockholm to ban the use of hormone blockers.

Although, in France, the use of hormone blockers or hormones of the opposite sex is possible with parental authorization at any age, the greatest reserve is required in their use, given the

¹ This Press release, adopted by the French Academy of Medicine on February 25, 2022, by 59 votes for, 20 against and 13 abstentions, was approved, in its revised version, by the Board of Directors on February 28, 2022.

side effects such as impact on growth, bone fragility, risk of sterility, emotional and intellectual consequences and, for girls, symptoms reminiscent of menopause.

As for surgical treatments, in particular mastectomy, which is authorized in France from the age of 14, and those involving the external genitalia (vulva, penis), their irreversible nature must be emphasized.

Therefore, faced with a request for care for this reason, it is essential to provide, first of all, a medical and psychological support to these children or adolescents, but also to their parents, especially since there is no test to distinguish a "structural" gender dysphoria from transient dysphoria in adolescence. Moreover, the risk of over-diagnosis is real, as shown by the increasing number of transgender young adults wishing to "detransition". It is therefore advisable to extend as much as possible the psychological support phase.

The National academy of medicine draws the attention of the medical community to the increasing demand for care in the context of gender transidentity in children and adolescents and recommends:

- A psychological support as long as possible for children and adolescents expressing a desire to transition and their parents;
- In the event of a persistent desire for transition, a careful decision about medical treatment with hormone blockers or hormones of the opposite sex within the framework of Multi-disciplinary Consultation Meetings;
- The introduction of an appropriate clinical training in medical studies to inform and guide young people and their families;
- The promotion of clinical and biological as well as ethical research, which is still too rare in France on this subject.
- The vigilance of parents in response to their children's questions on transidentity or their malaise, underlining the addictive character of excessive consultation of social networks which is both harmful to the psychological development of young people and responsible, for a very important part, of the growing sense of gender incongruence.

Glossary:

- a. Gender dysphoria is the medical term used to describe the distress resulting from the incongruence between the felt gender and the gender assigned at birth (5).
- b. A non-binary person is a person whose gender identity is neither male nor female.
- c. A transgender person adopts the appearance and lifestyle of a sex different from that assigned at birth. Whether born male or female, the transgender persons changes, or even rejects, their original gender identity. The sex registered on his or her civil status does not correspond to the appearance he or she sends back. This does not necessarily lead to a therapeutic approach.

Evidence review: Gender-affirming hormones for children and adolescents with gender dysphoria

This document will help inform Dr Hilary Cass' independent review into gender identity services for children and young people. It was commissioned by NHS England and Improvement who commissioned the Cass review. It aims to assess the evidence for the clinical effectiveness, safety and cost-effectiveness of gender-affirming hormones for children and adolescents aged 18 years or under with gender dysphoria.

The document was prepared by NICE in October 2020.

The content of this evidence review was up to date on 21 October 2020. See [summaries of product characteristics](#) (SPCs), [British National Formulary](#) (BNF) or the [Medicines and Healthcare products Regulatory Agency](#) (MHRA) or [NICE](#) websites for up-to-date information.

1. Introduction

This review aims to assess the evidence for the clinical effectiveness, safety and cost-effectiveness of gender-affirming hormones for children and adolescents aged 18 years or under with gender dysphoria. The review follows the NHS England Specialised Commissioning process and template and is based on the criteria outlined in the PICO framework (see [appendix A](#)). This document will help inform Dr Hilary Cass' independent review into gender identity services for children and young people.

Gender dysphoria in children, also known as gender identity disorder or gender incongruence of childhood ([World Health Organisation 2020](#)), refers to discomfort or distress that is caused by a discrepancy between a person's gender identity (how they see themselves¹ regarding their gender) and that person's sex assigned at birth and the associated gender role, and/or primary and secondary sex characteristics ([Diagnostic and Statistical Manual of Mental Disorders 2013](#)).

Gender-affirming hormones are oestradiol for sex assigned at birth males (transfemales) and testosterone for sex assigned at birth females (transmales). The aim of gender-affirming hormones is to induce the development of the physical sex characteristics congruent with the individual's gender expression while aiming to improve mental health and quality of life outcomes.

No oestradiol-containing products are licensed for gender dysphoria and therefore any use for children and adolescents with gender dysphoria is off-label.

The only testosterone-containing product licensed for gender dysphoria is Sustanon 250 mg/ml solution for injection, which is indicated as supportive therapy for transmales, use of all other testosterone-containing products for children and adolescents with gender dysphoria is off-label.

For children and adolescents with gender dysphoria it is recommended that management plans are tailored to the needs of the individual and aim to ameliorate the potentially negative impact of gender dysphoria on general developmental processes, to support young people and their families in managing the uncertainties inherent in gender identity development and to provide ongoing opportunities for exploration of gender identity. The plans may also include psychological support and exploration and, for some individuals, the use of gonadotrophin releasing hormone (GnRH) analogues in adolescence to suppress puberty; this may be followed later with gender-affirming hormones of the desired sex ([NHS England 2013](#)).

Currently NHS England, as part of the Gender Identity Development Service for Children and Adolescents, routinely commissions gender-affirming hormones for young people with continuing gender dysphoria from around their 16th birthday subject to individuals meeting the eligibility and readiness criteria ([Clinical Commissioning Policy 2016](#)).

¹ Gender refers to the roles, behaviours, activities, attributes and opportunities that any society considers appropriate for girls and boys, and women and men ([World Health Organisation, Health Topics: Gender](#)).

2. Executive summary of the review

Ten observational studies were included in the evidence review. Seven studies were retrospective observational studies ([Allen et al. 2019](#), [Kaltiala et al. 2020](#), [Khatchadourian et al. 2014](#), [Klaver et al. 2020](#), [Klink et al. 2015](#), [Stoffers et al. 2019](#), [Vlot et al. 2017](#)) and 3 studies were prospective longitudinal observational studies ([Achille et al. 2020](#), [Kuper et al. 2020](#), [Lopez de Lara et al. 2020](#)). No studies directly compared gender-affirming hormones to a control group (either placebo or active comparator). Follow-up was relatively short across all studies, with an average duration of treatment with gender-affirming hormones between around 1 year and 5.8 years.

The terminology used in this topic area is continually evolving and is different depending on stakeholder perspectives. In this evidence review we have used the phrase 'people's assigned sex at birth' rather than saying natal or biological sex and 'cross sex hormones' are now referred to as 'gender-affirming hormones'. The research studies may use historical terms which are no longer considered appropriate.

In children and adolescents with gender dysphoria, what is the clinical effectiveness of treatment with gender-affirming hormones compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention?

Critical outcomes

The critical outcomes for decision making are impact on gender dysphoria, impact on mental health and quality of life. The quality of evidence for all these outcomes was assessed as very low certainty using modified GRADE.

Impact on gender dysphoria

The study by [Lopez de Lara et al. 2020](#) in 23 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, gender dysphoria (measured using the Utrecht Gender Dysphoria Scale [UGDS]) was statistically significantly reduced (improved) from a mean [\pm SD] score of 57.1 (\pm 4.1) points at baseline to 14.7 (\pm 3.2) points at 12 months, which is below the threshold (40 points) for gender dysphoria ($p < 0.001$).

Impact on mental health

Depression

The study by [Lopez de Lara et al. 2020](#) in 23 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, depression (measured using the Beck Depression Inventory-II [BDI-II]) was statistically significantly reduced from a mean [\pm SD] score of 19.3 (\pm 5.5) points at baseline to 9.7 (\pm 3.9) points at 12 months ($p < 0.001$).

The study by [Achille et al. 2020](#) in 50 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, depression was statistically significantly reduced from baseline to about 12 months follow-up:

- The Center for Epidemiologic Studies Depression (CESD-R) improved from a mean score of 21.4 points at baseline to 13.9 points ($p < 0.001$).
- The Patient Health Questionnaire (PHQ 9) Modified for Teens improved, although absolute scores were not reported numerically ($p < 0.001$).

The study by [Kuper et al. 2020](#) in 148 adolescents with gender dysphoria (of whom 123 received gender-affirming hormones) found that during treatment with gender-affirming hormones for an average of 10.9 months, the impact on depression (measured using the Quick Inventory of Depressive Symptoms [QIDS]) was unclear as no statistical analysis was reported. The mean (\pm SD) self-reported score was 9.6 points (\pm 5.0) at baseline and 7.4 (\pm 4.5) at follow-up. The mean (\pm SD) clinician-reported score was 5.9 points (\pm 4.1) at baseline and 6.0 (\pm 3.8).

The study by [Kaltiala et al. 2020](#) in 52 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, statistically significantly fewer participants needed treatment for depression (54% at initial assessment compared with 15% at 12-month follow-up, $p < 0.001$). No details of the treatments for depression are reported.

Anxiety

The study by [Lopez de Lara et al. 2020](#) in 23 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, state anxiety (measured using the State-Trait Anxiety Inventory [STAI] – State subscale) was statistically significantly reduced from a mean (\pm SD) score of 33.3 points (\pm 9.1) at baseline to 16.8 points (\pm 8.1) at 12 months ($p < 0.001$). Trait anxiety (measured using STAI – Trait subscale) was also statistically significantly reduced from a mean (\pm SD) score of 33.0 (\pm 7.2) points at baseline to 18.5 (\pm 8.4) points at 12 months ($p < 0.001$).

The study by [Kuper et al. 2020](#) in 148 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, small reductions were seen in anxiety, panic, generalised anxiety, social anxiety and separation anxiety symptoms and school avoidance (measured using the Screen for Child Anxiety Related Emotional Disorders [SCARED] questionnaire) from baseline to follow-up (mean duration of treatment 10.9 months). The statistical significance of these findings are unknown as no statistical analyses were reported.

The study by [Kaltiala et al. 2020](#) in 52 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, statistically significantly fewer participants needed treatment for anxiety (48% at initial assessment compared with 15% at 12-month follow-up, $p < 0.001$). No details of treatments for anxiety are reported.

Suicidality and self-injury

The study by [Allen et al. 2019](#) in 47 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, suicide risk (measured using the Ask Suicide-Screening Questions [ASQ]) was statistically significantly reduced from an adjusted mean (\pm SE) score of 1.11 points (\pm 0.22) at baseline to 0.27 points (\pm 0.12) after about 12 months ($p < 0.001$).

The study by [Achille et al. 2020](#) in 50 adolescents with gender dysphoria (of whom 35 received gender-affirming hormones at follow-up) found that during treatment with gender-affirming hormones, the impact on suicidal ideation was unclear (measured using the PHQ 9_Modified for Teens with additional questions for suicidal ideation). At baseline 10% of participants had suicidal ideation and 6% had suicidal ideation after about 12 months, but it is unclear if these participants received gender-affirming hormones. No statistical analyses were reported.

The study by [Kuper et al. 2020](#) in 148 adolescents with gender dysphoria reported the impact on suicidal ideation, suicide attempts and non-suicidal self-injury during treatment with gender-affirming hormones, after mean 10.9 months follow-up. The statistical significance of these findings are unknown as no statistical analyses were reported:

- Suicidal ideation was reported in 25% of participants 1 month before the initial assessment and in 38% of participants during follow-up.
- Suicide attempts were reported in 2% of participants at 3 months before the initial assessment and in 5% during follow-up.
- Self-injury was reported in 10% of participants at 3 months before the initial assessment and in 17% during follow-up.

The study by [Kaltiala et al. 2020](#) in 52 adolescents with gender dysphoria reported that during treatment with gender-affirming hormones, statistically significantly fewer participants needed treatment for suicidal ideation or self-harm (35% at initial assessment compared with 4% at 12-month follow-up, $p<0.001$). No details of treatments for suicidal ideation or self-harm are reported.

Other related symptoms

The study by [Kaltiala et al. 2020](#) in 52 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, there was no statistically significant difference in the number of people needing treatment for either psychotic symptoms or psychosis, conduct problems or antisocial behaviour, substance abuse, autism, attention deficit hyperactivity disorder (ADHD) or eating disorders during the 12-month 'real life' phase compared with before or during the assessment. No details of the treatments received are reported.

Impact on quality of life

The study by [Achille et al. 2020](#) in 50 adolescents with gender dysphoria (of whom 35 were receiving gender-affirming hormones at follow-up) found that during treatment with gender-affirming hormones, quality of life (measured using the Quality of Life Enjoyment and Satisfaction Questionnaire [QLES-Q-SF]) was statistically significantly improved from baseline to about 12 months, but absolute scores were not reported numerically ($p<0.001$).

The study by [Allen et al. 2019](#) in 47 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, quality of life (measured using the General Well-Being Scale [GWBS] of the Paediatric Quality of Life Inventory) was statistically significantly improved from an adjusted mean (\pm SE) score of 61.70 (\pm 2.43) points at baseline to 70.23 (\pm 2.15) points at about 12 months ($p<0.002$).

Important outcomes

The important outcomes for decision making are impact on body image, psychosocial impact, engagement with healthcare services, impact on extent of and satisfaction with surgery and de-transition. The quality of evidence for all these outcomes was assessed as very low certainty using modified GRADE.

Impact on body image

The study by [Kuper et al. 2020](#) in 148 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, the impact on body image is unclear (measured using the Body Image Scale [BIS]). The mean (\pm SD) BIS score was 70.7 points (\pm 15.2) at baseline and 51.4 points (\pm 18.3) at follow-up (mean duration of treatment 10.9 months; no statistical analysis was reported).

Psychosocial impact

The study by [Lopez de Lara et al. 2020](#) in 23 adolescents with gender dysphoria found that during treatment with gender affirming hormones, family functioning is unchanged (measured using the Family Adaptability, Partnership, Growth, Affection and Resolve [APGAR] test). The mean score was 17.9 points at baseline and 18.0 points at 12-month follow-up (no statistical analysis was reported).

The study by [Lopez de Lara et al. 2020](#) in 23 adolescents with gender dysphoria found that during treatment with gender affirming hormones, behavioural problems (measured using the Strengths and Difficulties Questionnaire [SDQ]) were statistically significantly improved from a mean (\pm SD) of 14.7 (\pm 3.3) points at baseline to 10.3 points (\pm 2.9) at 12-month follow-up ($p < 0.001$).

The study by [Kaltiala et al. 2020](#) in 52 adolescents with gender dysphoria found that about 12-months after starting treatment with gender-affirming hormones:

- Statistically significantly fewer participants were living with parents or guardians (73% versus 40%, $p = 0.001$) and statistically significantly fewer participants had normal peer contacts (89% versus 81%, $p < 0.001$).
- There were no statistically significant differences in:
 - progress in school or work (64% versus 60%, $p = 0.69$),
 - the number of participants who had been dating or in steady relationships (62% versus 58%, $p = 0.51$)
 - the ability to cope with matters outside of the home (for example, shopping and travelling alone on local public transport; 81% versus 81%, $p = 1.0$)

Engagement with health care services

No evidence was identified.

Impact on extent of and satisfaction with surgery

No evidence was identified.

De-transition

No evidence was identified.

In children and adolescents with gender dysphoria, what is the short-term and long-term safety of gender-affirming hormones compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention?

Important outcomes

The important outcomes for decision making are short- and long-term safety outcomes and adverse effects. The quality of evidence for all these outcomes was assessed as very low certainty using modified GRADE.

Bone density

The study by [Klink et al. 2015](#) in 34 adolescents with gender dysphoria (who were previously treated with a GnRH analogue) found that gender-affirming hormones may increase lumbar spine and femoral neck bone density. However, not all results are statistically significant (particularly in transfemales). Z-scores suggest the average bone density at the end of follow-up was generally lower than in the equivalent cisgender population (transfemales compared with cis-males and transmales compared with cis-females). From starting gender-affirming hormones to age 22 years:

- There was no statistically significant difference in lumbar spine bone mineral apparent density (BMAD) z-score in transfemales, but this was statistically significantly higher in transmales (z-score [\pm SD]: start of hormones -0.50 [\pm 0.81], age 22 years -0.033 [\pm 0.95], $p=0.002$).
- There was no statistically significant difference in lumbar spine bone mineral density (BMD) z-score in transfemales or transmales.
- Actual lumbar spine BMAD and BMD values were statistically significantly higher in transfemales and transmales.
- There was no statistically significant difference in femoral neck BMD z-score in transfemales, but this was statistically significantly higher in transmales (z-score [SD]: start of hormones -0.35 [0.79], age 22 years -0.35 [0.74], $p=0.006$).
- There was no statistically significant difference in actual femoral neck BMAD values in transfemales, but this was statistically significantly higher in transmales.
- Actual femoral neck BMD values were statistically significantly higher in transfemales and transmales.

The study by [Vlot et al. 2017](#) in 70 adolescents with gender dysphoria (who were previously treated with a GnRH analogue) found that gender-affirming hormones may increase lumbar spine and femoral neck bone density. However, not all results are statistically significant. Z-scores suggest the average bone density at the end of follow-up was generally lower than the equivalent cisgender population (transfemales compared with cis-males and transmales compared with cis-females). From starting gender-affirming hormones to 24-month follow-up:

- The z-score for lumbar spine BMAD was statistically significantly higher in transfemales with a bone age of less than 15 years (z-score [range]: start of hormones -1.52 [-2.36 to 0.42], 24-month follow-up -1.10 [-2.44 to 0.69], $p\leq 0.05$) and 15 years and older (z-score [range]: start of hormones -1.15 [-2.21 to 0.08], 24-month follow-up -0.66 [-1.66 to 0.54], $p\leq 0.05$).
- The z-score for lumbar spine BMAD was statistically significantly higher in transmales with a bone age of less than 14 years (z-score [range]: start of hormones -0.84 [-2.2 to 0.87], 24-month follow-up -0.15 [-1.38 to 0.94], $p\leq 0.01$) and 14 years and older (z-score [range]: start of hormones -0.29 [-2.28 to 0.90], 24-month follow-up -0.06 [-1.75 to 1.61], $p\leq 0.01$).
- Actual lumbar spine BMAD values were statistically significantly higher in transfemales and transmales of all bone ages.
- There was no statistically significant difference in femoral neck BMAD z-score in transfemales (all bone ages).

- The z-score for femoral neck BMAD was statistically significantly higher in transmales with a bone age of less than 14 years (z-score [range]: start of hormones -0.37 [-2.28 to 0.47], 24-month follow-up -0.37 [-2.03 to 0.85], $p \leq 0.01$) and 14 years and older (z-score [range]: start of hormones -0.27 [-1.91 to 1.29], 24-month follow-up 0.02 [-2.1 to 1.35], $p \leq 0.05$).
- There was no statistically significant difference in actual femoral neck BMAD values in transfemales (all bone ages), but this was statistically significantly higher in transmales (all bone ages).

The study by [Stoffers et al. 2019](#) in 62 sex assigned at birth females (transmales) with gender dysphoria (who were previously treated with a GnRH analogue) found that during treatment with gender-affirming hormones there was no statistically significant difference in lumbar spine or femoral neck bone density (measured as BMD z-scores or actual values) from starting gender-affirming hormones to any timepoint (6, 12 and 24 months).

Change in clinical parameters

The study by [Klaver et al. 2020](#) in 192 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, from starting treatment to age 22 years:

- Glucose levels, insulin levels and insulin resistance were largely unchanged in transfemales and transmales.
- Total cholesterol, HDL cholesterol and LDL cholesterol levels were unchanged in transfemales, and there was a statistically significant improvement in triglyceride levels.
- Total cholesterol, HDL cholesterol, LDL cholesterol and triglyceride levels significantly worsened in transmales, but mean levels were within the UK reference range at the end of treatment.
- Diastolic blood pressure was statistically significantly increased in transfemales and transmales. Systolic blood pressure was also statistically significantly increased in transmales, but not in transfemales. The absolute increases in blood pressure were small.
- Body mass index was statistically significantly increased in transfemales and transmales, although most participants were within the healthy weight range (18.5 to 24.9 kg/m).

The study by [Stoffers et al. 2019](#) in 62 sex assigned at birth females (transmales) with gender dysphoria found that during treatment with gender affirming hormones, from starting treatment to 24-month follow-up:

- There was no statistically significant change in glycosylated haemoglobin (HbA1c).
- There was no statistically significant change in aspartate aminotransferase (AST), alanine aminotransferase (ALT) and gamma-glutamyltransferase (GCT).
- There was a statistically significant increase in alkaline phosphatase (ALP) at some timepoints, but the difference was not statistically significant by 24-months.
- There was a statistically significant increase in serum creatinine levels at all timepoints up to 24 months, but these were within the UK reference range. Serum urea levels were unchanged (follow-up duration not reported).

Treatment discontinuation and adverse effects

The study by [Khatchadourian et al. 2014](#) in 63 adolescents (24 transfemales and 39 transmales) with gender dysphoria found that during treatment with gender affirming hormones (duration of treatment not reported):

- No participants permanently discontinued treatment.
- No transfemales temporarily discontinued treatment, but 3 transmales temporarily discontinued treatment due to mental health comorbidities (n=2) and androgenic alopecia (n=1). All 3 participants eventually resumed treatment, although timescales were not reported
- No severe complications were reported.
- No transfemales reported minor complications, but 12 transmales developed minor complications which were: severe acne (n=7), androgenic alopecia (n=1), mild dyslipidaemia (n=3) and significant mood swings (n=1).

In children and adolescents with gender dysphoria, what is the cost-effectiveness of gender-affirming hormones compared to one or a combination of psychological support, social transitioning to the desired gender or no intervention?

No cost-effectiveness evidence was found for gender-affirming hormones for children and adolescents with gender dysphoria.

From the evidence selected, are there particular sub-groups of children and adolescents with gender dysphoria that derive comparatively more (or less) benefit from treatment with gender-affirming hormones than the wider population of children and adolescents with gender dysphoria?

Some studies reported data separately for the following subgroups of children and adolescents with gender dysphoria:

- Sex assigned at birth males (transfemales).
- Sex assigned at birth females (transmales).
- Tanner stage at which GnRH analogue or gender-affirming hormones started.
- Diagnosis of a mental health condition.

Some direct comparisons of transfemales and transmales were included. No evidence was found for other specified subgroups.

Sex assigned at birth males (transfemales)

Impact on mental health

In the study by [Kuper et al. 2020](#) in 33 to 45 (number varies by outcome) sex assigned at birth males (transfemales) with gender dysphoria found that during treatment with gender-affirming hormones changes were seen in depression, anxiety and anxiety-related symptoms from baseline to follow-up (mean duration of treatment 10.9 months). The authors did not report any statistical analyses, so it is unclear if any changes were statistically significant.

The study by [Allen et al. 2019](#) in 47 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, suicide risk (measured using the ASQ) is not statistically significant different in transfemales compared with transmales, between baseline and the final assessment at about 12 months (p=0.79).

The study by [Achille et al. 2020](#) in 17 transfemales with gender dysphoria found that during treatment with gender-affirming hormones, suicidal ideation (measured using the PHQ 9_Modified for Teens with additional questions for suicidal ideation) was reported in 11.8% (2/17) of transfemales at baseline compared with 5.9% (1/17) at about 12-months follow-up (no statistical analysis was reported).

Impact on quality of life

The study by [Allen et al. 2019](#) in 47 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, quality of life (measured using the GWBS of the Paediatric Quality of Life Inventory) was not statistically significant different in transfemales compared with transmales, between baseline and the final assessment at about 12 months ($p=0.32$).

Bone density

The studies by [Klink et al. 2015](#) and [Vlot et al. 2017](#) provided evidence on bone density in transfemales; see above for details.

Change in clinical parameters

The study by [Klaver et al. 2020](#) provided evidence on the following clinical parameters in transfemales:

- Glucose levels, insulin levels and insulin resistance.
- Total cholesterol, HDL cholesterol and LDL cholesterol and triglycerides.
- Blood pressure.
- Body mass index.

See above for details.

Treatment discontinuation and adverse effects

The study by [Khatchadourian et al. 2014](#) provided evidence on treatment discontinuation and adverse effects in transfemales; see above for details.

Sex assigned at birth females (transmales)

Impact on mental health

In the study by [Kuper et al. 2020](#) in 65 to 78 (number varies by outcome) sex assigned at birth females (transmales) with gender dysphoria found that during treatment with gender-affirming hormones, changes were seen in depression, anxiety and anxiety-related symptoms from baseline to 10.9 month follow-up. The authors did not report any statistical analyses, so it is unclear if any changes were statistically significant.

The study by [Allen et al. 2019](#) in 47 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, suicide risk (measured using the ASQ) is not statistically significantly different in transmales compared with transfemales, between baseline and the final assessment ($p=0.79$).

The study by [Achille et al. 2020](#) in 33 transmales with gender dysphoria found that during treatment with gender-affirming hormones, suicidal ideation (measured using the PHQ 9_Modified for Teens with additional questions for suicidal ideation) was reported in 9.1% (3/33) of transmales at baseline compared with 6.1% (2/33) at about 12-months follow-up (no statistical analysis reported).

Impact on quality of life

The study by [Allen et al. 2019](#) in 47 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, quality of life (measured using the GWBS of the Paediatric Quality of Life Inventory) was not statistically significantly different in transmales compared with transfemales, between baseline and the final assessment at about 12 months ($p=0.32$).

Bone density

The studies by [Klink et al. 2015](#), [Stoffers et al. 2019](#) and [Vlot et al. 2017](#) provided evidence on bone density in transmales; see above for details.

Change in clinical parameters

The study by [Klaver et al. 2020](#) provided evidence on the following clinical parameters in transmales:

- Glucose levels, insulin levels and insulin resistance.
- Total cholesterol, HDL cholesterol and LDL cholesterol and triglycerides.
- Blood pressure.
- Body mass index.

See above for details.

The study by [Stoffers et al. 2019](#) provided evidence on HbA1c, liver enzymes and renal function in transmales; see above for details.

Treatment discontinuation and adverse effects

The study by [Khatchadourian et al. 2014](#) provided evidence on treatment discontinuation and adverse effects in transmales; see above for details.

Tanner stage at which GnRH analogues or gender-affirming hormones started

The study by [Kuper et al. 2020](#) stated that the impact of Tanner stage on outcomes was considered, but it is unclear if this refers to Tanner stage at the initial assessment, at the start of GnRH analogue treatment or another timepoint. No results were reported.

Diagnosis of a mental health condition

Impact on mental health

The study by [Achille et al. 2020](#) in 50 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, there was no statistically significant difference in depression (measured using the CESD-R and PHQ 9_Modified for Teens) when the results were adjusted for engagement in counselling and medicines for mental health problems, from baseline to about 12-months follow-up.

Impact on quality of life

The study by [Achille et al. 2020](#) in 50 adolescents with gender dysphoria found that during treatment with gender-affirming hormones, there was no statistically significant difference in quality of life (measured using the QLES-Q-SF) when the results were adjusted for engagement in counselling and medicines for mental health problems, from baseline to about 12-months follow-up.

From the evidence selected,

- (a) **what are the criteria used by the research studies to define gender dysphoria, gender identity disorder and gender incongruence of childhood?**
- (b) **what were the ages at which participants commenced treatment with gender-affirming hormones?**
- (c) **what was the duration of treatment with GnRH analogues?**

The most commonly reported diagnostic criteria for gender dysphoria was the DSM criteria in use at the time (5/10 studies). In 3 studies ([Klaver et al. 2020](#), [Klink et al. 2015](#) and [Vlot et al. 2017](#)) DSM-IV-TR criteria was used. In 2 studies ([Kuper et al. 2020](#) and [Stoffers et al. 2019](#)) DSM-V criteria was used. One study from Finland ([Kaltiala et al. 2020](#)) used the ICD-10 diagnosis of 'transsexualism'. It was not reported how gender dysphoria was defined in the remaining 4 studies.

In the studies, treatment with gender-affirming hormones started at about 16 to 17 years, with a range of about 14 to 19 years. Most studies did not report the duration of treatment with GnRH analogues, but where this was reported there was a wide variation ranging from a few months up to about 5 years ([Klaver et al. 2020](#), [Klink et al. 2015](#) and [Stoffers et al. 2019](#)).

Discussion

The key limitation to identifying the effectiveness and safety of gender-affirming hormones for children and adolescents with gender dysphoria is the lack of reliable comparative studies.

All the studies included in the evidence review are uncontrolled observational studies, which are subject to bias and confounding and were of very low certainty using modified GRADE. A fundamental limitation of all the uncontrolled studies included in this review is that any changes in scores from baseline to follow-up could be attributed to a regression-to-the-mean.

The included studies have relatively short follow-up, with an average duration of treatment with gender-affirming hormones between around 1 year and 5.8 years. Further studies with a longer follow-up are needed to determine the long-term effect of gender-affirming hormones for children and adolescents with gender dysphoria.

Most studies included in this review did not report comorbidities (physical or mental health) and no study reported concomitant treatments in detail. Because of this it is not clear whether any changes seen were due to gender-affirming hormones or other treatments the participants may have received.

There is a degree of indirectness in some studies, with some participants included that fall outside of the population of this evidence review. Furthermore, participant numbers are poorly reported in some studies, with high numbers lost to follow-up or outcomes not reported for some participants. The authors provide no explanation for this incomplete reporting.

Details of the gender-affirming hormone treatment regimen are poorly reported in most of the included studies, with limited information provided about the medicines, doses and routes of administration used. It is not clear whether the interventions used in the studies are reflective of current UK practice for children and adolescents with gender dysphoria.

It is difficult to draw firm conclusions for many of the effectiveness and safety outcomes reported in the included studies because many different scoring tools and methods were used to assess the same outcome, often with conflicting results. In addition to this, most outcomes reported across the included studies do not have an accepted minimal clinically important difference (MCID), making it difficult to determine whether any statistically significant changes seen are clinically meaningful. However, the authors of some studies report thresholds to interpret the results of the scoring tools (for example, by linking scores to symptom severity), so some conclusions can be made.

Conclusion

Any potential benefits of gender-affirming hormones must be weighed against the largely unknown long-term safety profile of these treatments in children and adolescents with gender dysphoria.

Results from 5 uncontrolled, observational studies suggest that, in children and adolescents with gender dysphoria, gender-affirming hormones are likely to improve symptoms of gender dysphoria, and may also improve depression, anxiety, quality of life, suicidality, and psychosocial functioning. The impact of treatment on body image is unclear. All results were of very low certainty using modified GRADE.

Safety outcomes were reported in 5 observational studies. Statistically significant increases in some measures of bone density were seen following treatment with gender-affirming hormones, although results varied by bone region (lumber spine versus femoral neck) and by population (transfemales versus transmales). However, z-scores suggest that bone density remained lower in transfemales and transmales compared with an equivalent cisgender population. Results from 1 study of gender-affirming hormones started during adolescence reported statistically significant increases in blood pressure and body mass index, and worsening of the lipid profile (in transmales) at age 22 years, although longer term studies that report on cardiovascular event rates are required. Adverse events and discontinuation rates associated with gender-affirming hormones were only reported in 1 study, and no conclusions can be made on these outcomes.

This review did not identify sub-groups of patients who may benefit more from gender-affirming hormones.

No cost-effectiveness evidence was found to determine whether gender-affirming hormones are a cost-effective treatment for children and adolescents with gender dysphoria.

3. Methodology

Review questions

The review question(s) for this evidence review are:

1. For children and adolescents with gender dysphoria, what is the clinical effectiveness of treatment with gender-affirming hormones compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention?

2. For children and adolescents with gender dysphoria, what is the short-term and long-term safety of gender-affirming hormones compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention?
3. For children and adolescents with gender dysphoria, what is the cost-effectiveness of gender-affirming hormones compared to one or a combination of psychological support, social transitioning to the desired gender or no intervention?
4. From the evidence selected, are there particular sub-groups of children and adolescents with gender dysphoria that derive comparatively more (or less) benefit from treatment with gender-affirming hormones than the wider population of children and adolescents with gender dysphoria?
5. From the evidence selected,
 - (a) what are the criteria used by the research studies to define gender dysphoria, gender identity disorder and gender incongruence of childhood?
 - (b) what were the ages at which participants commenced treatment with gender-affirming hormones?
 - (c) what was the duration of GnRH analogues treatment?

See [appendix A](#) for the full review protocol.

Review process

The methodology to undertake this review is specified by NHS England in their 'Guidance on conducting evidence reviews for Specialised Services Commissioning Products' (2020).

The searches for evidence were informed by the PICO and were conducted on 21 July 2020.

See [appendix B](#) for details of the search strategy.

Results from the literature searches were screened using their titles and abstracts for relevance against the criteria in the PICO framework. Full text references of potentially relevant evidence were obtained and reviewed to determine whether they met the inclusion criteria for this evidence review.

See [appendix C](#) for evidence selection details and [appendix D](#) for the list of studies excluded from the review and the reasons for their exclusion.

Relevant details and outcomes were extracted from the included studies and were critically appraised using a checklist appropriate to the study design. See [appendix E](#) and [appendix F](#) for individual study and checklist details.

The available evidence was assessed by outcome for certainty using modified GRADE. See [appendix G](#) for GRADE Profiles.

4. Summary of included studies

Ten observational studies were included in the evidence review. Seven studies were retrospective observational studies ([Allen et al. 2019](#), [Kaltiala et al. 2020](#), [Khatchadourian et al. 2014](#), [Klaver et al. 2020](#), [Klink et al. 2015](#), [Stoffers et al. 2019](#), [Vlot et al. 2017](#)) and three studies were prospective longitudinal observational studies ([Achille et al. 2020](#), [Kuper et al. 2020](#), [Lopez de Lara et al. 2020](#)).

The terminology used in this topic area is continually evolving and is different depending on stakeholder perspectives. In this evidence review we have used the phrase 'people's assigned sex at birth' rather than saying natal or biological sex and 'cross sex hormones' are now referred to as 'gender-affirming hormones'. The research studies may use historical terms which are no longer considered appropriate.

Table 1 provides a summary of these included studies and full details are given in [appendix E](#).

Table 1 Summary of included studies

Study	Population	Intervention and comparison	Outcomes reported
Achille et al. 2020 Prospective longitudinal study Single centre, New York, United States	50 children, adolescents and young adults with gender dysphoria; 17 transfemales and 33 transmales Mean age at baseline was 16.2 years (SD 2.2)	Intervention Endocrine interventions (the collective term used for puberty suppression and gender-affirming hormones) were introduced as per Endocrine Society and the World Professional Association for Transgender Health (WPATH) guidelines Puberty suppression was: <ul style="list-style-type: none"> GnRH analogue and/or anti-androgens (transfemales) GnRH analogue or medroxyprogesterone (transmales) Once eligible, gender-affirming hormones were offered, these were: <ul style="list-style-type: none"> Oestradiol (transfemales) 	Critical Outcomes <i>Impact on mental health</i> <ul style="list-style-type: none"> Depression- The Center for Epidemiologic Studies Depression Scale (CESD-R) Depression- The Patient Health Questionnaire Modified for Teens (PHQ 9_Modified for Teens) <i>Impact on quality of life</i> <ul style="list-style-type: none"> Quality of Life Enjoyment and Satisfaction Questionnaire (QLES-Q-SF) Important Outcomes <i>None reported</i>

5. Results

In children and adolescents with gender dysphoria, what is the clinical effectiveness of gender-affirming hormones compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention?

Outcome	Evidence statement
Clinical Effectiveness	

Critical outcomes	
<p>Impact on gender dysphoria</p> <p>Certainty of evidence: very low</p>	<p>This is a critical outcome because gender dysphoria in children and adolescents is associated with significant distress and problems with functioning.</p> <p>One uncontrolled, prospective, observational study (Lopez de Lara et al. 2020) provided evidence relating to the impact on gender dysphoria, measured using the Utrecht Gender Dysphoria Scale (UGDS) score during the first year of treatment with gender-affirming hormones. The UGDS is a validated, screening tool for both adolescents and adults, used to assess gender dysphoria. It consists of 12 items, to be answered on a 1- to 5-point scale, resulting in a sum score between 12 and 60. The authors state that the cut-off point to identify gender dysphoria is 40 points. The higher the UGDS score the greater the gender dysphoria.</p> <p>In this study (n=23), the mean (\pmSD) UGDS score was statistically significantly reduced (improved) from 57.1 (\pm4.1) points at baseline to 14.7 points (\pm3.2) at 12 months ($p < 0.001$). A UGDS score below 40 suggests an absence of gender dysphoria (VERY LOW).</p> <p>This study provides very low certainty evidence that gender-affirming hormones statistically significantly improve gender dysphoria from baseline to 12 months follow-up. The mean UGDS score was below the threshold for gender dysphoria at follow-up.</p>
<p>Impact on mental health: depression</p> <p>Certainty of evidence: very low</p>	<p>This is a critical outcome because depression may impact on social, occupational, or other areas of functioning in children and adolescents.</p> <p>Four observational studies (Achille et al. 2020; Kaltiala et al. 2020; Kuper et al. 2020; Lopez de Lara et al. 2020) provided evidence relating to the impact on depression in children and adolescents with gender dysphoria, with follow-up of around 12 months. Five different outcome measures for depression were reported.</p> <p>Beck Depression Inventory (BDI-II) One uncontrolled, prospective, analytical study (Lopez de Lara et al. 2020) reported the change in BDI-II. The BDI-II is a valid, reliable, and widely used tool for assessing depressive symptoms. There are no specific scores to categorise depression severity, but it is suggested that 0 to 13 is minimal symptoms, 14 to 19 is mild depression, 20 to 28 is moderate depression, and severe depression is 29 to 63.</p> <p>In Lopez de Lara et al. 2020 (n=23) the mean (\pmSD) BDI-II score was statistically significantly reduced (improved) from 19.3 (\pm5.5) points at baseline to 9.7 (\pm3.9) points at 12 months ($p < 0.001$) (VERY LOW).</p> <p>Center for Epidemiologic Studies Depression (CESD-R) One uncontrolled, prospective, longitudinal study (Achille et al. 2020) reported the change in CESD-R scale. The CESD-R is a valid, widely used tool to assess depressive symptoms. Total score ranges from 0 to 60, with higher scores indicating more depressive symptoms. There are no specific scores to categorise depression severity, although the authors of the study suggest that a total CESD-R score less than 16 suggests no clinical depression.</p>

In Achille et al. 2020 (n=50), the mean CESD-R score statistically significantly reduced (improved) from 21.4 points at baseline to 13.9 points at about 12 months follow-up ($p<0.001$; standard deviation not reported) (**VERY LOW**).

Patient Health Questionnaire (PHQ 9) Modified for Teens

One uncontrolled, prospective, longitudinal study ([Achille et al. 2020](#)) reported the change in PHQ 9_Modified for Teens score. The PHQ 9_Modified for Teens is a validated tool to assess depression, dysthymia and suicide risk. The tool consists of 9 questions scored from 0 to 3 (total score 0 to 27), plus an additional 4 questions that are not scored. A score of 0 to 4 suggests no or minimal depressive symptoms, 5 to 9 mild, 10 to 14 moderate, 15 to 19 moderately severe, and 20-27 severe symptoms.

In Achille et al. 2020 (n=50), the mean PHQ 9_Modified for Teens score statistically significantly reduced (improved) from baseline to around 12 months follow-up, although absolute scores were not reported numerically ($p<0.001$). From the visual representation of results, the PHQ-9_Modified for Teens score is about 9 at baseline and about 5 at final follow-up (**VERY LOW**).

Quick Inventory of Depressive Symptoms (QIDS)

One uncontrolled, prospective, longitudinal study ([Kuper et al. 2020](#)) reported the change in QIDS, clinician-reported and self-reported. Both the clinician-reported and self-reported QIDS are validated tools to assess depressive symptoms. The tool consists of 16 items, with the highest score for 9 domains (sleep, weight, psychomotor changes, depressed mood, decreased interest, fatigue, guilt, concentration, and suicidal ideation) added to give a total score ranging from 0 to 27. A score of 0 to 5 suggests no depression, 6 to 10 mild symptoms, 11 to 15 moderate symptoms, 16 to 20 severe symptoms, and 21 to 27 very severe symptoms.

In Kuper et al. 2020 (n=105), the mean (\pm SD) QIDS self-reported score was 9.6 points (± 5.0) at baseline and 7.4 (± 4.5) after 10.9 months of treatment with gender-affirming hormones (no statistical analysis reported). The mean (\pm SD) QIDS clinician-reported score was 5.9 points (± 4.1) at baseline and 6.0 (± 3.8) after 10.9 months of treatment with gender-affirming hormones (no statistical analysis was reported) (**VERY LOW**).

Participants needing treatment for depression

One observational study ([Kaltiala et al. 2020](#)) reported the proportion of participants needing treatment for depression before or during the initial assessment and during the 12-month follow-up period after starting gender-affirming hormones.

In Kaltiala et al. 2020 (n=52), statistically significantly fewer participants needed treatment for depression during the 12-month 'real life' phase (15%, 8/52) compared with before or during the assessment (54%, 28/52; $p<0.001$). No details of what treatments for depression the participants received are reported (**VERY LOW**).

	<p>These studies provide very low certainty evidence that during treatment with gender-affirming hormones depression is reduced from baseline to about 12 months follow-up. However, most participants had mild symptoms at the start of treatment.</p>
<p>Impact on mental health: anxiety</p> <p>Certainty of evidence: very low</p>	<p>This is a critical outcome because anxiety may impact on social, occupational, or other areas of functioning in children and adolescents.</p> <p>Three observational studies (Kaltiala et al. 2020; Kuper et al. 2020; Lopez de Lara et al. 2020) provided evidence relating to the impact on anxiety in children and adolescents with gender dysphoria.</p> <p>State-Trait Anxiety Inventory (STAI) One uncontrolled, prospective, analytical study (Lopez de Lara et al. 2020) reported the change in STAI scores. STAI is a validated and commonly used measure of trait and state anxiety. It has 20 items and can be used in clinical settings to diagnose anxiety and to distinguish it from depressive illness. Higher scores indicate greater anxiety.</p> <p>In Lopez de Lara et al. 2020 (n=23), the mean (\pmSD) STAI-State subscale was statistically significantly reduced (improved) with gender-affirming hormones from 33.3 points (\pm9.1) at baseline to 16.8 points (\pm8.1) at 12 months ($p<0.001$). The mean STAI-Trait subscale scores also statistically significantly reduced (improved) from 33.0 points (\pm7.2) at baseline to 18.5 points (\pm8.4) at 12 months ($p<0.001$) (VERY LOW).</p> <p>Screen for Child Anxiety Related Emotional Disorders (SCARED) One uncontrolled, prospective, longitudinal study (Kuper et al. 2020) reported anxiety symptoms using the SCARED questionnaire. Other anxiety-related symptoms using specific questions from the SCARED questionnaire were also reported: panic, generalised anxiety, social anxiety, separation anxiety and school avoidance. SCARED is a validated, 41-point questionnaire, with each item scored 0 to 2. A total score of 25 or more is suggestive of anxiety disorder, with scores above 30 being more specific. Certain scores for specific questions may indicate the presence of other anxiety-related disorders:</p> <ul style="list-style-type: none"> • A score of 7 or more in questions related to panic disorder or significant somatic symptoms may indicate the presence of these. • A score of 9 or more in questions related to generalised anxiety disorder may indicate the presence of this. • A score of 5 or more in questions related to separation anxiety may indicate the presence of this. • A score of 8 or more in questions related to social anxiety disorder may indicate the presence of this. • A score of 3 or more in questions related to significant school avoidance may indicate the presence of this. <p>In Kuper et al. 2020 (n=80 to 82, varies by outcome), small reductions were seen in anxiety, panic, generalised anxiety, social anxiety and separation anxiety and school avoidance symptoms (measured using the SCARED questionnaire) from baseline to follow-up (mean duration of treatment 10.9 months). The statistical significance of these findings are unknown as no statistical analyses were reported (VERY LOW).</p>

	<p>Participants needing treatment for anxiety</p> <p>One observational study (Kaltiala et al. 2020) reported the proportion of participants needing treatment for anxiety before or during initial assessment and during the 12-month follow-up period after starting gender-affirming hormones.</p> <p>In Kaltiala et al. 2020 (n=52), statistically significantly fewer participants needed treatment for anxiety during the 12-month 'real life' phase (15%, 8/52) compared with before or during the assessment (48%, 25/52; $p<0.001$). No details of what treatments for anxiety the participants received are reported (VERY LOW).</p> <p>These studies provide very low certainty evidence that during treatment with gender-affirming hormones anxiety symptoms may be reduced from baseline to around 12 months follow-up.</p>
<p>Impact on mental health: suicidality and self-injury</p> <p>Certainty of evidence: very low</p>	<p>These are critical outcomes because self-harm and thoughts of suicide have the potential to result in significant physical harm and, for completed suicides, the death of the young person.</p> <p>Four observational studies (Achille et al. 2020; Allen et al. 2019; Kaltiala et al. 2020; Kuper et al. 2020) provided evidence relating to suicidal ideation in children and adolescents with gender dysphoria, with an average follow-up of around 12 months.</p> <p>Ask Suicide-Screening Questions (ASQ)</p> <p>One uncontrolled, retrospective, longitudinal study (Allen et al. 2019) reported the change in ASQ. This is a 4-item dichotomous (yes/no) response measure designed to identify risk of suicide. The authors of Allen et al. 2019 amended 1 question in the ASQ ("Have you ever tried to kill yourself?") by prefacing it with "In the past few weeks . . ." as they were not investigating lifetime incidence. A response of 'no' is scored as 0 and a response of 'yes' is scored as 1; each item is summed to give an overall score for suicidal ideation ranging from 0 to 4. A person is considered to have screened positive if they answer 'yes' to any item with higher scores indicating higher levels of suicidal ideation.</p> <p>In Allen et al. 2019 (n=39), the adjusted mean (\pmSE) ASQ score statistically significantly reduced from 1.11 points (± 0.22) at baseline to 0.27 points (± 0.12) after a mean duration of treatment of about 12 months ($p<0.001$) (VERY LOW).</p> <p>PHQ 9_Modified for Teens (additional questions for suicidal ideation)</p> <p>One uncontrolled, prospective, longitudinal study (Achille et al. 2020) reported the change in suicidal ideation measured using additional questions from the PHQ 9_Modified for Teens. This is a validated tool to assess depression, dysthymia and suicide risk (see above for detailed description). In addition to the 9 scored questions, the PHQ 9_Modified Teens asked 4 additional questions relating to suicidal ideation and difficulty dealing with problems of life. Responses to the PHQ 9_Modified for Teens were used to determine if the participant had suicidal ideation or not, but specific details of how this was determined are not reported.</p>

	<p>In Achille et al. 2020 (n=50), 10% (5/50) of participants had suicidal ideation at baseline and 6% (3/50) had suicidal ideation after about 12 months treatment with gender-affirming hormones (no statistical analysis reported) (VERY LOW).</p> <p>Suicidality and non-suicidal self-injury One uncontrolled, prospective, longitudinal study (Kuper et al. 2020) reported on suicidal ideation, suicide attempts and non-suicidal self-injury, although it was unclear how and when this outcome was measured.</p> <p>In Kuper et al. 2020 (n=130), 25% of participants reported suicidal ideation 1 month before the initial assessment and 38% reported this during the follow-up period (no statistical analysis reported). Suicide attempts were reported in 2% of participants at 3 months before the initial assessment and 5% during follow-up. Self-injury was reported in 10% of participants at 3 months before the initial assessment and 17% during follow-up. No statistical analysis was reported for any outcomes. Mean duration of gender-affirming hormone treatment was 10.9 months (VERY LOW).</p> <p>Participants needing treatment for suicidality or self-harm One observational study (Kaltiala et al. 2020) reported the proportion of participants requiring treatment for suicidality or self-harm before or during initial assessment and during the 12-month follow-up period after starting gender-affirming hormones.</p> <p>In Kaltiala et al. 2020 (n=52) statistically significantly fewer participants needed treatment for suicidality or self-harm during the 12-month 'real life' phase (4%, 2/52) compared with before or during the assessment (35%, 18/52; $p<0.001$). No details of what treatments for suicidal ideation or self-harm the participants received are reported (VERY LOW).</p> <p>These studies provide very low certainty evidence that gender-affirming hormones may reduce suicidality from baseline to about 12 months follow-up. However, results are inconsistent and it is difficult to draw conclusions.</p>
<p>Impact on mental health: other</p> <p>Certainty of evidence: very low</p>	<p>This is a critical outcome because mental health problems may impact on social, occupational, or other areas of functioning in children and adolescents.</p> <p>One observational study (Kaltiala et al. 2020) reported the proportion of participants needing treatment for either psychotic symptoms or psychosis, substance abuse, autism, attention deficit hyperactivity disorder (ADHD) or eating disorders before or during initial assessment and during the 12-month follow-up period after starting gender-affirming hormones.</p> <p>In Kaltiala et al. 2020 (n=52) there was no statistically significant difference in the number of people needing treatment for either psychotic symptoms / psychosis, substance abuse, autism, attention deficit hyperactivity disorder (ADHD) or eating disorders during the 12-month 'real life' phase compared with before or during the assessment.</p>

	<p>No details of which specific treatments the participants received are reported (VERY LOW).</p> <p>This study provides very low certainty evidence on the need for treatment for either psychotic symptoms or psychosis, conduct problems or antisocial behaviour, substance abuse, autism, attention deficit hyperactivity disorder (ADHD) or eating disorders during treatment with gender-affirming hormones. No conclusions could be drawn.</p>
<p>Impact on quality of life score</p> <p>Certainty of evidence: very low</p>	<p>This is a critical outcome because gender dysphoria in children and adolescents may be associated with a significant reduction in health-related quality of life.</p> <p>Two uncontrolled longitudinal studies Achille et al. 2020; Allen et al. 2019) provided evidence relating to quality of life in children and adolescents with gender dysphoria.</p> <p>Quality of Life Enjoyment and Satisfaction Questionnaire (QLES-Q-SF) One uncontrolled, prospective, longitudinal study (Achille et al. 2020) reported the change in QLES-Q-SF scores from baseline to about 12 months of treatment with gender-affirming hormones. QLES-Q-SF is a validated questionnaire, consisting of 15 questions that rate quality of life on a scale of 1 (poor) to 5 (very good).</p> <p>In Achille et al. 2020 (n=50), the mean QLES-Q-SF score was statistically significantly reduced from baseline to about 12 months ($p<0.001$). However, absolute scores are not reported numerically (VERY LOW).</p> <p>General Well-Being Scale (GWBS) of the Paediatric Quality of Life Inventory One uncontrolled, retrospective, longitudinal study (Allen et al. 2019) reported the change in adjusted mean GWBS of the Paediatric Quality of Life Inventory score from baseline to about 12 months of treatment with gender-affirming hormones. The GWBS of the Paediatric Quality of Life Inventory contains 7 items that measure two dimensions: general wellbeing (6 items) and general health (1 item). Each item is scored from 0 to 4, and the total score is linearly transformed to a 0 to 100 scale. Higher scores reflect fewer perceived problems and greater well-being.</p> <p>In Allen et al. 2019 (n=47), the adjusted mean (\pmSE) GWBS of the Paediatric Quality of Life Inventory score was statistically significantly increased (improved) from 61.70 (\pm2.43) points at baseline to 70.23 (\pm2.15) points at about 12 months ($p<0.002$) (VERY LOW).</p> <p>This study provides very low certainty evidence that gender-affirming hormones statistically significantly improve quality of life and well-being from baseline to 12 months follow-up.</p>
Important outcomes	
Impact on body image	<p>This is an important outcome because some children and adolescents with gender dysphoria may want to take steps to suppress features of</p>

<p>Certainty of evidence: very low</p>	<p>their physical appearance associated with their sex assigned at birth or accentuate physical features of their desired gender.</p> <p>One uncontrolled, prospective, longitudinal study (Kuper et al. 2020) provided evidence relating to the impact on body image in children and adolescents with gender dysphoria who started treatment with gender-affirming hormones (median duration 10.9 months; range 1 to 18), measured by the change in Body Image Scale (BIS) score. BIS is a validated 30-item scale covering 3 aspects: primary, secondary and neutral body characteristics. Higher scores represent a higher degree of body dissatisfaction.</p> <p>In Kuper et al. 2020 (n=86), the mean (\pmSD) BIS score was 70.7 points (\pm15.2) at baseline and 51.4 points (\pm18.3) at follow-up (no statistical analysis reported) (VERY LOW).</p> <p>This study provides very low certainty evidence on the effects of gender-affirming hormones on body image during treatment with gender-affirming hormones (mean duration of treatment 10.9 months). No conclusions could be drawn.</p>
<p>Psychosocial impact</p> <p>Certainty of evidence: very low</p>	<p>This is an important outcome because gender dysphoria in children and adolescents is associated with internalising and externalising behaviours, and emotional and behavioural problems which may impact on social and occupational functioning.</p> <p>Two uncontrolled, observational studies (Kaltiala et al. 2020; Lopez de Lara et al. 2020) provided evidence related to psychosocial impact in children and adolescents with gender dysphoria.</p> <p>Family APGAR (Adaptability, Partnership, Growth, Affection and Resolve) test</p> <p>One uncontrolled, prospective, analytical study (Lopez de Lara et al. 2020) reported the Family APGAR test. The Family APGAR test is a 5-item questionnaire, with higher scores indicating better family functioning. The authors reported the following interpretation of the test: functional, 17 to 20 points; mildly dysfunctional, 16 to 13 points; moderately dysfunctional, 12 to 10 points; severely dysfunctional, <9 points.</p> <p>In Lopez de Lara et al. 2020 (n=23), the mean Family APGAR test score was unchanged from baseline (17.9 points) to 12-month follow-up (18.0 points; no statistical analysis or standard deviations reported) (VERY LOW).</p> <p>Strengths and Difficulties Questionnaire (SDQ)</p> <p>One uncontrolled, prospective, analytical study (Lopez de Lara et al. 2020) reported on behaviour using the Strengths and Difficulties Questionnaire (SDQ, Spanish version). The SDQ includes 25-items covering emotional symptoms, conduct problems, hyperactivity/inattention, peer relationship problems and prosocial behaviour. The authors state that a score of more than 20 suggests having a behavioural disorder (normal 0 to 15, borderline 16 to 19, abnormal 20 to 40).</p>

	<p>In Lopez de Lara et al. 2020 (n=23), the mean (\pmSD) SDQ score was statistically significantly reduced (improved) from 14.7 points (\pm3.3) at baseline to 10.3 points (\pm2.9) at 12-month follow-up ($p<0.001$) (VERY LOW).</p> <p>Psychosocial functioning</p> <p>One uncontrolled, retrospective chart review (Kaltiala et al. 2020) reported various markers of functioning in adolescent development, covering living arrangements, peer contacts, school or work progress, relationships, and ability to cope with matters outside the home. These measures were reported during the gender identity assessment and at about 12 months after starting gender-affirming hormones (referred to as the 'real-life phase').</p> <p>In Kaltiala et al. 2020 (n=52), from the gender identity assessment to the 12-month follow-up period:</p> <ul style="list-style-type: none"> • statistically significantly fewer participants were living with parents or guardians (73% versus 40%, $p=0.001$) • statistically significantly fewer participants had normal peer contacts (89% versus 81%, $p<0.001$) • there was no statistically significant difference in progress in school or work (64% versus 60%, $p=0.69$) • there was no statistically significant difference in the number of participants who had been dating or in steady relationships (62% versus 58%, $p=0.51$) • there was no statistically significant difference in the participant's ability to cope with matters outside of the home (81% versus 81%, $p=1.00$) (VERY LOW). <p>These studies provide very low certainty evidence that gender-affirming hormones statistically significantly improve behavioural problems (measured by SDQ score). However, the SDQ score was in the 'normal' range at baseline and at 12-month follow up. There was no significant impact on other measures of psychosocial functioning.</p>
Engagement with health care services	<p>This is an important outcome because patient engagement with health care services will impact on their clinical outcomes.</p> <p>No evidence was identified.</p>
Impact on extent of and satisfaction with surgery	<p>This is an important outcome because some children and adolescents with gender dysphoria may proceed to transitioning surgery.</p> <p>No evidence was identified.</p>
De-transition	<p>This is an important outcome because there is uncertainty about the short- and long-term safety and adverse effects of gender-affirming hormones in children and adolescents with gender dysphoria</p> <p>No evidence was identified.</p>

Abbreviations: APGAR: Adaptability, Partnership, Growth, Affection and Resolve; ASQ: Ask Suicide-Screening Questions; BDI-II: Beck Depression Inventory II; BIS: Body Image Scale; CESD-R: Center for Epidemiologic Studies Depression; GWBS: General Well-Being Scale; p: p-value; PHQ 9_Modified for Teens: Patient Health Questionnaire Modified for Teens; QIDS: Quick Inventory of Depressive Symptoms; QLES-Q-SF: Quality of Life Enjoyment and Satisfaction Questionnaire; SCARED: Screen for Child Anxiety Related Emotional Disorders;

SD: standard deviation; SE: standard error; SDQ: Strengths and Difficulties Questionnaire; STAI: State-Trait Anxiety Inventory; UGDS: Utrecht Gender Dysphoria Scale.

In children and adolescents with gender dysphoria, what is the short-term and long-term safety of gender-affirming hormones compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention?

Outcome	Evidence statement
Safety	
Change in bone density: lumbar spine Certainty of evidence: very low	<p>This is an important outcome because childhood and adolescence is a key time for bone development and gender-affirming hormones may affect bone development, as shown by changes in lumbar spine bone density.</p> <p>Three uncontrolled, observational studies (2 retrospective and 1 prospective) provided evidence related to bone density: lumbar spine in children and adolescents with gender dysphoria. This was reported as either bone mineral density (BMD), bone mineral apparent density (BMAD), or both. One study reported change in bone density from start of treatment with gender-affirming hormones to age 22 years (Klink et al. 2015). Two studies reported change in bone density from start of gender-affirming hormones up to 24-month follow-up (Stoffers et al. 2019 and Vlot et al. 2017). All participants had previously been treated with a GnRH analogue. All outcomes were reported separately for transfemales and transmales; also see subgroups table below.</p> <p>Bone mineral apparent density (BMAD) Two uncontrolled, observational studies reported change in lumbar BMAD (Klink et al. 2015; Vlot et al. 2017). BMAD is a size adjusted value of BMD, incorporating bone size measurements using a UK reference population of growing cis-gender adolescents (up to age 17 years). BMAD is used to correct for height and height gain and may provide a more accurate estimate of bone density in growing adolescents. BMAD was reported as g/cm³ and as z-scores. Z-scores report how many standard deviations from the mean a measurement sits. A z-score of 0 is equal to the mean, a z-score of -1 is equal to 1 standard deviation below the mean, and a z-score of +1 is equal to 1 standard deviation above the mean. A cis-gender population was used to calculate the bone density z-score, meaning transfemales were compared with cis-males and transmales were compared with cis-females.</p> <p>In Klink et al. 2015 (n=34):</p> <ul style="list-style-type: none"> • There was no statistically significant difference in lumbar spine BMAD z-score from starting gender-affirming hormones to age 22 years in transfemales. • The z-score for lumbar spine BMAD was statistically significantly higher at age 22 years compared with the start of gender-affirming hormones in transmales (z-score [±SD]: start of hormones -0.50 [±0.81], age 22 years -0.033 [±0.95], p=0.002).

- Actual lumbar spine BMAD values in g/cm³ were statistically significantly higher at age 22 years compared with the start of gender-affirming hormones in transfemales and transmales (**VERY LOW**).

In [Vlot et al. 2017](#) (n=70):

- The z-score for lumbar spine BMAD in transfemales with a bone age of <15 years was statistically significantly higher at 24-month follow-up compared with start of gender-affirming hormones (z-score [range]: start of hormones -1.52 [-2.36 to 0.42], 24-month follow-up -1.10 [-2.44 to 0.69], p≤ 0.05). Statistically significant improvements in z-score for lumbar spine BMAD in transfemales with a bone age of ≥15 years were also seen (z-score [range]: start of hormones -1.15 [-2.21 to 0.08], 24-month follow-up -0.66 [-1.66 to 0.54], p≤ 0.05).
- The z-score for lumbar spine BMAD in transmales with a bone age of <14 years was statistically significantly higher at 24-month follow-up compared with start of gender-affirming hormones (z-score [range]: start of hormones -0.84 [-2.2 to 0.87], 24-month follow-up -0.15 [-1.38 to 0.94], p≤ 0.01). Statistically significant improvements in z-score for lumbar spine BMAD in transmales with a bone age of ≥14 years were also seen (z-score [range]: start of hormones -0.29 [-2.28 to 0.90], 24-month follow-up -0.06 [-1.75 to 1.61], p≤ 0.01).
- Actual lumbar spine BMAD values in g/cm³ were statistically significantly higher at 24-month follow-up compared with start of gender-affirming hormones in transfemales and transmales of all bone ages (**VERY LOW**).

Bone mineral density (BMD)

Two uncontrolled, observational studies reported change in lumbar BMD ([Klink et al. 2015](#); [Stoffers et al. 2019](#)). BMD was determined using dual energy x-ray absorptiometry (DXA-scan; HologicQDR4500, Hologic). BMD was reported as g/cm² and as z-scores – see BMAD above for more details).

In [Klink et al. 2015](#) (n=34):

- There was no statistically significant difference in lumbar spine BMD z-score from starting gender-affirming hormones to age 22 years in transfemales or transmales.
- Actual lumbar spine BMD values in g/cm² were statistically significantly higher at age 22 years compared with the start of gender-affirming hormones in transfemales and transmales (**VERY LOW**).

In [Stoffers et al. 2019](#) (n=62 at 6-month follow-up; n=15 at 24-month follow-up):

- There was no statistically significant difference in lumbar spine BMD z-score in transmales from starting gender-affirming hormones to any timepoint (6, 12 and 24 months).
- There was also no statistically significant difference in actual lumbar spine BMD values in g/cm² from starting gender-affirming hormones to any timepoint (6, 12 and 24 months) (**VERY LOW**).

	<p>These studies provide very low certainty evidence that lumbar spine bone density (measured by BMAD) increases during treatment with gender-affirming hormones (from baseline to follow-up of 2 to 5 years). Z-scores at the end of follow-up suggest the average lumbar spine bone density was generally lower than the equivalent cisgender population (transfemales compared with cis-males and transmales compared with cis-females). The results for bone density (measured by BMD) were inconsistent.</p>
<p>Change in bone density: femoral neck</p> <p>Certainty of evidence: very low</p>	<p>This is an important outcome because childhood and adolescence is a key time for bone development and gender-affirming hormones may affect bone development, as shown by changes in femoral neck bone density.</p> <p>Three uncontrolled, observational studies (2 retrospective and 1 prospective) provided evidence related to bone density: femoral neck in children and adolescents with gender dysphoria. This was reported as either bone mineral density (BMD), bone mineral apparent density (BMAD), or both. One study reported change in bone density from start of gender-affirming hormones to age 22 years (Klink et al. 2015). Two studies reported change in bone density from start of gender-affirming hormones up to 24-month follow-up (Stoffers et al. 2019 and Vlot et al. 2017). All participants had previously been treated with a GnRH analogue. All outcomes were reported separately for transfemales and transmales; also see subgroups table below.</p> <p>Bone mineral apparent density (BMAD)</p> <p>Two uncontrolled, observational studies reported change in femoral neck BMAD (Klink et al. 2015; Vlot et al. 2017). See above for more details on BMAD.</p> <p>In Klink et al. 2015 (n=34):</p> <ul style="list-style-type: none"> • The z-score for femoral neck BMAD was reported for the start of gender-affirming hormones but not at age 22 years in transfemales or transmales. No statistical analysis reported. • In transfemales there was no statistically significant difference in actual femoral neck BMAD values in g/cm³ at age 22 years compared with start of gender-affirming hormones. In transmales actual lumbar spine BMAD values in g/cm³ were statistically significantly higher at age 22 years compared with start of gender-affirming hormones (mean [±SD]: start of hormones 0.31 [±0.04], age 22 years 0.33 [±0.05], p=0.010) (VERY LOW). <p>In Vlot et al. 2017 (n=70):</p> <ul style="list-style-type: none"> • In transfemales (all bone ages), there was no statistically significant difference in femoral neck BMAD z-score from start of gender-affirming hormones to 24-month follow-up. • The z-score for femoral neck BMAD in transmales with a bone age of <14 years was statistically significantly higher at 24-month follow-up compared with start of gender-affirming hormones (z-score [range]: start of hormones -0.37 [-2.28 to 0.47], 24-month follow-up -0.37 [-2.03 to 0.85], p≤0.01). Statistically significant improvements in z-score for lumbar spine BMAD in transmales with a bone age of ≥14 years were also

	<p>seen (z-score [range]: start of hormones -0.27 [-1.91 to 1.29], 24-month follow-up 0.02 [-2.1 to 1.35], $p \leq 0.05$).</p> <ul style="list-style-type: none"> In transfemales of all bone ages, there was no statistically significant change in actual femoral neck BMAD values in g/cm^3 from start of gender-affirming hormones to 24-month follow-up. In transmales of all bone ages, actual femoral neck BMAD values in g/cm^3 were statistically significantly higher at 24-month follow-up compared with start of gender-affirming hormones (VERY LOW). <p>Bone mineral density (BMD)</p> <p>Two uncontrolled, observational studies reported change in femoral neck BMD (Klink et al. 2015; Stoffers et al. 2019). See above for more details on BMD.</p> <p>In Klink et al. 2015 (n=34):</p> <ul style="list-style-type: none"> In transfemales, there was no statistically significant difference in femoral neck BMD z-score from start of gender-affirming hormones to age 22 years. In transmales, femoral neck BMD z-score was statistically significantly higher at age 22 years compared with start of gender-affirming hormones (z-score [SD]: start of hormones -0.35 [0.79], age 22 years -0.35 [0.74], $p=0.006$). Actual femoral neck BMD values in g/cm^2 were statistically significantly higher at age 22 years compared with start of gender-affirming hormones in transfemales and transmales (VERY LOW). <p>In Stoffers et al. 2019 (n=62 at 6-month follow-up; n=15 at 24-month follow-up):</p> <ul style="list-style-type: none"> there was no statistically significant difference in right or left femoral neck BMD z-score in transmales, from the start of gender-affirming hormones to any timepoint (6, 12 and 24 months). There was also no statistically significant difference in transmales in right or left actual femoral neck BMD values in g/cm^2 from start of gender-affirming hormones to any timepoint (6, 12 and 24 months) (VERY LOW). <p>These studies provide very low certainty evidence that during treatment with gender-affirming hormones from baseline to follow-up of 2 to 5 years, femoral neck bone density (measured by BMAD) was unchanged in transfemales but was statistically significantly increased in transmales (although the absolute change was small). Z-scores at the end of follow-up suggest that average femoral neck bone density was lower in both transfemales and transmales than in the equivalent cisgender population (transfemales compared with cis-males and transmales compared with cis-females). The results for bone density (measured by BMD) were inconsistent.</p>
<p>Change in clinical parameters: glucose, insulin and HbA1c</p>	<p>This is an important outcome because the effect of gender-affirming hormones on insulin sensitivity and cardiovascular risk in children and adolescents with gender dysphoria is unknown.</p>

<p>Certainty of evidence: very low</p>	<p>Two uncontrolled, retrospective chart reviews (Klaver et al. 2020; Stoffers et al. 2019) provided evidence on glucose, insulin and HbA1c. All outcomes were reported separately for transfemales and transmales; also see subgroups table below.</p> <p>Glucose levels, insulin levels and insulin resistance</p> <p>One retrospective chart review (Klaver et al. 2020) reported non-comparative evidence on the change in glucose levels, insulin levels and insulin resistance (measured using Homeostatic Model Assessment of Insulin Resistance [HOMA-IR]) between starting gender-affirming hormones and age 22 years.</p> <p>In Klaver et al. 2020 (n=192):</p> <ul style="list-style-type: none"> • There was no statistically significant change in glucose levels, insulin levels and insulin resistance in transfemales. • There was no statistically significant change in glucose levels in transmales. • There was a statistically significant decrease in insulin levels in transmales (mean change [95% CI] -2.1 mU/L [-3.9 to -0.3], $p<0.05$; mean insulin level at 22 years [95% CI] 8.6 mU/L [6.9 to 10.2]). • There was a statistically significant decrease in insulin resistance in transmales (HOMA-IR; mean change [95% CI] -0.5 [-1.0 to -0.1], $p<0.05$; mean HOMA-IR at 22 years [95% CI] 1.8 [1.4 to 2.2]) (VERY LOW). <p>HbA1c</p> <p>One retrospective chart review (Stoffers et al. 2019; n=62) reported non-comparative evidence on the change in HbA1c in transmales between starting gender-affirming hormones and 24-month follow-up. There was no statistically significant change in HbA1c (VERY LOW).</p> <p>These studies provide very low certainty evidence that gender-affirming hormones do not affect HbA1c, glucose levels, insulin levels and insulin resistance.</p>
<p>Change in clinical parameters: lipids</p> <p>Certainty of evidence: very low</p>	<p>This is an important outcome because the effect of gender-affirming hormones on lipid profiles and cardiovascular risk in children and adolescents with gender dysphoria is unknown.</p> <p>One retrospective chart review (Klaver et al. 2020) provided non-comparative evidence on the change in lipids (total cholesterol, HDL cholesterol, LDL cholesterol and triglycerides) between starting gender-affirming hormones and age 22 years. All outcomes were reported separately for transfemales and transmales; also see subgroups table below.</p> <p>In Klaver et al. 2020 (n=192):</p> <ul style="list-style-type: none"> • There was no statistically significant change in total cholesterol, HDL cholesterol and LDL cholesterol in transfemales. • There was a statistically significant decrease (improvement) in triglycerides in transfemales (mean change [95% CI] +0.2 mmol/L [0.0 to 0.5], $p<0.05$; mean triglyceride level at 22 years [95% CI] 1.1 mmol/L [0.9 to 1.4]). • There was a statistically significant increase in total cholesterol in transmales (mean change [95% CI] +0.4 mmol/L [0.2 to 0.6],

	<p>p<0.001; mean total cholesterol at 22 years [95% CI] 4.6 mmol/L [4.3 to 4.8]).</p> <ul style="list-style-type: none"> • There was a statistically significant decrease (worsening) in HDL cholesterol (mean change in transmales [95% CI] -0.3 mmol/L [-0.4 to -0.1], p<0.001; mean HDL cholesterol at 22 years [95% CI] 1.3 mmol/L [1.2 to 1.3]). • There was a statistically significant increase (worsening) in LDL cholesterol in transmales (mean change [95% CI] +0.4 mmol/L [0.2 to 0.6], p<0.001; mean LDL cholesterol at 22 years [95% CI] 2.6 mmol/L [2.4 to 2.8]). • There was a statistically significant increase (worsening) in triglycerides in transmales (mean change [95% CI] +0.5 mmol/L [0.3 to 0.7], p<0.001; mean triglyceride level at 22 years [95% CI] 1.3 mmol/L [1.1 to 1.5]) (VERY LOW). <p>This study provides very low certainty evidence that gender-affirming hormones do not affect lipid profiles in transfemales. In transmales, there was a small but statistically significant worsening in cholesterol levels from start of gender-affirming hormone treatment to age 22 years, but mean cholesterol and triglyceride levels were within the UK reference range at the end of treatment.</p>
<p>Change in clinical parameters: blood pressure</p> <p>Certainty of evidence: very low</p>	<p>This is an important outcome because the effect of gender-affirming hormones on blood pressure and cardiovascular risk in children and adolescents with gender dysphoria is unknown.</p> <p>One retrospective chart review (Klaver et al. 2020) provided non-comparative evidence on the change in blood pressure between starting gender-affirming hormones and at age 22 years. All outcomes were reported separately for transfemales and transmales; also see subgroups table below.</p> <p>In Klaver et al. 2020 (n=192):</p> <ul style="list-style-type: none"> • There was no statistically significant change in systolic blood pressure (SBP) in transfemales. However, there was a statistically significant increase in diastolic blood pressure (DBP) in transfemales (mean change [95% CI] +6 mmHg [3 to 10], p<0.001; mean DBP at 22 years [95% CI] 75 [72 to 78]). • In transmales, there was a statistically significant increase in SBP (mean change [95% CI] +5 mmHg [1 to 9], p<0.05; mean SBP at 22 years [95% CI] 126 [122 to 130]), and DBP (mean change [95% CI] +6 mmHg [4 to 9], p<0.001; mean DBP at 22 years [95% CI] 74 [72 to 77]) (VERY LOW). <p>This study provides very low certainty evidence that gender-affirming hormones statistically significantly increase blood pressure from start of treatment to age 22 years, although the absolute increase was small.</p>
<p>Change in clinical parameters: body mass index (BMI)</p>	<p>This is an important outcome because the effect of gender-affirming hormones on weight gain and cardiovascular risk in children and adolescents with gender dysphoria is unknown.</p> <p>One retrospective chart review (Klaver et al. 2020) provided non-comparative evidence on the change in body mass index (BMI) between starting gender-affirming hormones and age 22 years. All</p>

<p>Certainty of evidence: very low</p>	<p>outcomes were reported separately for transfemales and transmales; also see subgroups table below.</p> <p>In Klaver et al. 2020 (n=192):</p> <ul style="list-style-type: none"> • There was a statistically significant increase in BMI in transfemales from the start of gender-affirming hormones to age 22 years (mean change [95% CI] +1.9 [0.6 to 3.2], $p<0.005$; mean BMI at 22 years [95% CI] 23.2 [21.6 to 24.8]. At age 22 years, 9.9% of transfemales were obese, compared with 3.0% in a reference population of cisgender men. • There was a statistically significant increase in BMI in transmales from the start of gender-affirming hormones to age 22 years (mean change [95% CI] +1.4 [0.8 to 2.0], $p<0.005$; mean BMI at 22 years [95% CI] 23.9 [23.0 to 24.7]). At age 22 years, 6.6% of transmales were obese, compared with 2.2% in a reference population of cisgender women (VERY LOW). <p>This study provides very low certainty evidence that gender-affirming hormones statistically significantly increase BMI from start of treatment to age 22 years, although most participants were within the healthy weight range.</p>
<p>Change in clinical parameters: liver function</p> <p>Certainty of evidence: very low</p>	<p>This is an important outcome because if treatment-induced liver injury (raised liver enzymes are a marker of this) is suspected, gender-affirming hormones may need to be stopped.</p> <p>One retrospective chart review (Stoffers et al. 2019) provided non-comparative evidence on the change in liver enzymes in transmales between starting gender-affirming hormones and up to 24-months follow-up.</p> <p>In Stoffers et al. 2019 (n=62):</p> <ul style="list-style-type: none"> • There was no statistically significant change in aspartate aminotransferase (AST), alanine aminotransferase (ALT) and gamma-glutamyltransferase (GCT) in transmales. • There was a statistically significant increase in alkaline phosphatase (ALP) levels from starting gender-affirming hormones to 6- and 12-months follow-up, although by 24-months the difference was not statistically significant (median [IQR]: start of hormones 102 [78 to 136], 6-month follow-up 115 [102 to 147] $p<0.001$, 12-month follow-up 112 [88 to 143] $p<0.001$) (VERY LOW). <p>This study provides very low certainty evidence that gender-affirming hormones do not affect liver function in transmales from baseline to 24 months follow-up.</p>
<p>Change in clinical parameters: kidney function</p> <p>Certainty of evidence: very low</p>	<p>This is an important outcome because if renal damage (raised serum creatinine and urea are markers of this) is suspected, treatment with gender-affirming hormones may need to be stopped.</p> <p>One retrospective chart review (Stoffers et al. 2019) provided non-comparative evidence on the change in serum creatinine and serum urea levels in transmales between starting gender-affirming hormones and up to 24-months follow-up.</p> <p>In Stoffers et al. 2019 (n=62):</p>

	<ul style="list-style-type: none"> • There was a statistically significant increase in creatinine levels in transmales at all timepoints up to 24 months (mean [SD]: start of hormones 62 umol/L [7], 6 months 70 umol/L [9], 12 months 74 umol/L [10], 24 months 81 umol/L [10], $p < 0.001$). • There was no statistically significant change in urea in transmales (follow-up duration not reported) (VERY LOW). <p>This study provides very low certainty evidence on the effects of gender-affirming hormones on kidney function in transmales from baseline to 24 months follow-up. A statistically significant increase in creatinine levels was seen, but these were within the UK reference range. Urea levels were unchanged.</p>
Treatment discontinuation Certainty of evidence: very low	<p>This is an important outcome because there is uncertainty about the short- and long-term impact of stopping treatment with gender-affirming hormones in children and adolescents with gender dysphoria.</p> <p>One uncontrolled, retrospective chart review (Khatchadourian et al. 2014) provided evidence relating to permanent or temporary treatment discontinuation in children and adolescents with gender dysphoria.</p> <p>Khatchadourian et al. 2014 narratively reported treatment discontinuation in a cohort of 63 adolescents (24 transfemales and 39 transmales) who received gender-affirming hormones:</p> <ul style="list-style-type: none"> • No participants permanently discontinued gender-affirming hormones. • No transfemales temporarily discontinued gender-affirming hormones. • Three transmales temporarily discontinued gender-affirming hormones due to: <ul style="list-style-type: none"> ◦ mental health comorbidities (n=2) ◦ androgenic alopecia (n=1). <p>All 3 participants eventually resumed treatment, although timescales were not reported (VERY LOW).</p> <p>This study provides very low certainty evidence that the rates of discontinuation during treatment with gender-affirming hormones are low (duration of treatment not reported).</p>
Adverse effects Certainty of evidence: very low	<p>This is an important outcome because if there are adverse effects, gender-affirming hormones may need to be stopped.</p> <p>One uncontrolled, retrospective chart review (Khatchadourian et al. 2014) provided evidence relating to adverse effects from gender-affirming hormones in children and adolescents with gender dysphoria.</p> <p>Khatchadourian et al. 2014 narratively reported adverse effects in a cohort of 63 adolescents (24 transfemales and 39 transmales) receiving treatment with gender-affirming hormones:</p> <ul style="list-style-type: none"> • No severe complications were reported. • No transfemales reported minor complications. • Twelve transmales developed minor complications, which were: <ul style="list-style-type: none"> ◦ severe acne, requiring isotretinoin treatment (n=7) ◦ androgenic alopecia (n=1) ◦ mild dyslipidaemia (further details not provided; n=3) ◦ significant mood swings (n=1) (VERY LOW).

	This study provides very low certainty evidence about the potential adverse effects of gender-affirming hormones (duration of treatment not reported). No conclusions could be drawn.
--	--

Abbreviations: ALP: alkaline phosphatase; ALT: alanine aminotransferase; AST: aspartate aminotransferase; BMAD: bone mineral apparent density; BMD: bone mineral density; BMI: body mass index; DBP: diastolic blood pressure; GGT: gamma-glutamyl transferase; HbA1c: glycated haemoglobin; HDL: high-density lipoproteins; HOMA-IR: Homeostatic Model Assessment of Insulin Resistance; IQR: interquartile range; LDL: low-density lipoproteins; p: p-value; SBP: systolic blood pressure; SD: standard deviation.

In children and adolescents with gender dysphoria, what is the cost-effectiveness of gender-affirming hormones compared to one or a combination of psychological support, social transitioning to the desired gender or no intervention?

Outcome	Evidence statement
Cost-effectiveness	No studies were identified to assess the cost-effectiveness of gender-affirming hormones for children and adolescents with gender dysphoria.

From the evidence selected, are there any subgroups of children and adolescents with gender dysphoria that may benefit from gender-affirming hormones more than the wider population of interest?

Subgroup	Evidence statement
Sex assigned at birth males (transfemales) Certainty of evidence: Very low	<p>Some studies reported data separately for sex assigned at birth males (transfemales). This included some direct comparisons with sex assigned at birth females (transmales).</p> <p>Impact on mental health: depression and anxiety One uncontrolled, prospective, longitudinal study (Kuper et al. 2020) reported the change in depression (measured using QIDS clinician-reported and self-reported), anxiety and anxiety-related symptoms (measured using SCARED) in transfemales. See the clinical effectiveness results above for full details.</p> <p>In Kuper et al. 2020 (n=33 to 45, varies by outcome), changes were seen in depression, anxiety and anxiety-related symptoms from baseline to follow-up but the authors did not report any statistical analyses, so it is unclear if any changes were statistically significant (VERY LOW).</p> <p>This study provides very low certainty evidence on the effects of gender-affirming hormones on depression, anxiety and anxiety-related symptoms over time in sex assigned at birth males (transfemales; mean duration of treatment 10.9 months). No conclusions could be drawn.</p> <p>Impact on mental health: suicidality</p>

	<p>One uncontrolled, retrospective, longitudinal study (Allen et al. 2019) reported the change in Ask Suicide-Screening Questions (ASQ) in transfemales compared with transmales. See the clinical effectiveness results above for full details.</p> <p>Between baseline and the final assessment, there was no statistically significant difference in change in ASQ score for transfemales compared with transmales ($p=0.79$; $n=47$) (VERY LOW).</p> <p>One uncontrolled, prospective, longitudinal study (Achille et al. 2020) reported the change in suicidal ideation in transfemales measured using additional questions from the PHQ 9_Modified for Teens. See the clinical effectiveness results above for full details.</p> <p>At baseline, 11.8% (2/17) of transfemales had suicidal ideation, compared with 5.9% (1/17) at about 12-months follow-up (no statistical analysis reported) (VERY LOW).</p> <p>These studies provide very low certainty evidence that any change in suicidal ideation is not different between sex assigned at birth males (transfemales) and sex assigned at birth females (transmales) from baseline to follow-up of about 12 months.</p> <p>Impact on quality of life</p> <p>One uncontrolled, retrospective, longitudinal study (Allen et al. 2019) reported the change in the GWBS of the Paediatric Quality of Life Inventory in transfemales compared with transmales. See the clinical effectiveness results above for full details.</p> <p>Between baseline and final assessment, there was no statistically significant difference in change in GWBS of the Paediatric Quality of Life Inventory for transfemales compared with transmales ($p=0.32$; $n=47$) (VERY LOW).</p> <p>This study provides very low certainty evidence that any change in general wellbeing is not different between sex assigned at birth males (transfemales) and sex assigned at birth females (transmales) from baseline to follow-up of about 12 months.</p> <p>Impact on body image</p> <p>One uncontrolled, prospective, longitudinal study (Kuper et al. 2020) reported change in Body Image Scale (BIS) in transfemales. See the clinical effectiveness results above for full details.</p> <p>In Kuper et al. 2020 ($n=30$), the mean (\pmSD) BIS score was 67.5 points (± 19.5) at baseline and 49.0 points (± 21.6) at follow-up (no statistical analysis reported) (VERY LOW).</p> <p>This study provides very low certainty evidence on the effects of gender-affirming hormones on body image over time in transfemales (mean duration of treatment 10.9 months). No conclusions could be drawn.</p> <p>Change in bone density: lumbar spine</p>
--	--

	<p>Two uncontrolled, observational, retrospective studies provided evidence relating to the effect of gender-affirming hormones on lumbar spine bone density in transfemales (Klink et al. 2015 and Vlot et al. 2017). See the safety results table above for a full description of the results.</p> <p>These studies provide very low certainty evidence that lumbar spine bone density (measured by BMAD) increases during treatment with gender-affirming hormones in sex assigned at birth males (transfemales). Z-scores at the end of follow-up suggest average lumbar spine bone density was generally lower than in the equivalent cisgender population. The results for lumbar spine bone density (measured by BMD) were inconsistent.</p> <p>Change in bone density: femoral neck Two uncontrolled, observational, retrospective studies provided evidence relating to the effect of gender-affirming hormones on femoral neck bone density in transfemales (Klink et al. 2015 and Vlot et al. 2017). See the safety results table above for a full description of the results.</p> <p>These studies provide very low certainty evidence that femoral neck bone density (measured by BMAD) was unchanged in sex assigned at birth males (transfemales) during treatment with gender-affirming hormones (follow-up between 2 and 5 years). Z-scores at the end of follow-up suggest and the average femoral neck bone density was lower than in the equivalent cisgender population. The results for femoral neck bone density (measured by BMD) were inconsistent.</p> <p>Change in clinical parameters: glucose, insulin and HbA1c One uncontrolled, retrospective chart review (Klaver et al. 2020) provided evidence on glucose, insulin and HbA1c in transfemales. See the safety results table above for a full description of the results.</p> <p>This study provided very low certainty evidence that gender-affirming hormones do not affect HbA1c, glucose levels, insulin levels and insulin resistance in sex assigned at birth males (transfemales) from the start of treatment to age 22 years.</p> <p>Change in clinical parameters: lipids One retrospective chart review (Klaver et al. 2020) provided evidence on the change in lipids (total cholesterol, HDL cholesterol, LDL cholesterol and triglycerides) in transfemales. See the safety results table above for a full description of the results.</p> <p>This study provides very low certainty evidence that gender-affirming hormones do not affect lipid profiles in sex assigned at birth males (transfemales) from the start of treatment to age 22 years.</p> <p>Change in clinical parameters: blood pressure</p>
--	---

	<p>One retrospective chart review (Klaver et al. 2020) provided evidence on the change in blood pressure in transfemales. See the safety results table above for a full description of the results.</p> <p>This study provides very low certainty evidence that gender-affirming hormones statistically significantly increase blood pressure in sex assigned at birth males (transfemales), although the absolute increase was small from the start of treatment to age 22 years.</p> <p>Change in clinical parameters: body mass index (BMI) One retrospective chart review (Klaver et al. 2020) provided evidence on the change in BMI in transfemales. See the safety results table above for a full description of the results.</p> <p>This study provides very low certainty evidence that gender-affirming hormones statistically significantly increase BMI in sex assigned at birth males (transfemales), although most participants were within the healthy weight range from the start of treatment to age 22 years.</p> <p>Treatment discontinuation One uncontrolled, retrospective chart review provided evidence relating to permanent or temporary discontinuation of gender-affirming hormones in transfemales (Khatchadourian et al. 2014).</p> <p>This study provides very low certainty evidence that the rates of discontinuation during treatment with gender-affirming hormones in sex assigned at birth males (transfemales) are low. Duration of treatment with gender-affirming hormones was not reported.</p> <p>Adverse effects One uncontrolled, retrospective chart review provided evidence relating to adverse effects from gender-affirming hormones in transfemales (Khatchadourian et al. 2014).</p> <p>This study provides very low certainty evidence about the potential adverse effects of gender-affirming hormones in sex assigned at birth males (transfemales). No conclusions could be drawn. Duration of treatment with gender-affirming hormones was not reported.</p>
<p>Sex assigned at birth females (transmales)</p> <p>Certainty of evidence: Very low</p>	<p>Some studies reported data separately for sex assigned at birth females (transmales). This included some direct comparisons with sex assigned at birth males (transfemales).</p> <p>Impact on mental health: depression and anxiety One uncontrolled, prospective, longitudinal study (Kuper et al. 2020) reported the change in depression (measured using QIDS clinician-reported and self-reported), anxiety and anxiety-related symptoms (measured using SCARED) in transmales. See the clinical effectiveness results above for full details.</p> <p>In Kuper et al. 2020 (n=65 to 78, varies by outcome), changes were seen in depression, anxiety and anxiety-related symptoms from</p>

	<p>baseline to follow-up but the authors did not report any statistical analysis, so it is unclear if any changes are statistically significant (VERY LOW).</p> <p>This study provides very low certainty evidence on the effects of gender-affirming hormones on depression, anxiety and anxiety-related symptoms over 10.9 months in transmales. No conclusions could be drawn.</p> <p>Impact on mental health: suicidality One uncontrolled, retrospective, longitudinal study (Allen et al. 2019) reported the change in Ask Suicide-Screening Questions (ASQ) in transmales compared with transfemales. See the sex assigned at birth males (transfemales) row above for full details of the results.</p> <p>One uncontrolled, prospective, longitudinal study (Achille et al. 2020) reported the change in suicidal ideation in transmales measured using additional questions from the PHQ 9 Modified for Teens. See the clinical effectiveness results above for full details.</p> <p>At baseline, 9.1% (3/33) of transmales had suicidal ideation, compared with 6.1% (2/33) at about 12-months follow-up (no statistical analysis reported) (VERY LOW).</p> <p>These studies provide very low certainty evidence that any change in suicidal ideation is not different between sex assigned at birth females (transmales) and sex assigned at birth males (transfemales). Mean duration of treatment about 12 months.</p> <p>Impact on quality of life One uncontrolled, retrospective, longitudinal study (Allen et al. 2019) reported the change in the GWBS of the Paediatric Quality of Life Inventory in transmales compared with transfemales. See the sex assigned at birth males (transfemales) row above for full details of the results.</p> <p>This study provides very low certainty evidence that any change in general wellbeing is not different between sex assigned at birth females (transmales) and sex assigned at birth males (transfemales). Mean duration of treatment about 12 months.</p> <p>Impact on body image One uncontrolled, prospective, longitudinal study (Kuper et al. 2020) reported change in Body Image Scale (BIS) in transmales. See the clinical effectiveness results above for full details.</p> <p>In Kuper et al. 2020 (n=66), the mean (\pmSD) BIS score was 71.1 points (\pm13.4) at baseline and 52.9 points (\pm16.8) at follow-up (no statistical analysis reported) (VERY LOW).</p> <p>This study provides very low certainty evidence on the effects of gender-affirming hormones on body image over 10.9 months in transmales. No conclusions could be drawn.</p> <p>Change in bone density: lumbar spine</p>
--	---

	<p>Three uncontrolled, observational, retrospective studies provided evidence relating to the effect of gender-affirming hormones on lumbar spine bone density in transmales (Klink et al. 2015, Stoffers et al. 2019 and Vlot et al. 2017). See the safety results table above for a full details of the results.</p> <p>These studies provide very low certainty evidence that lumbar spine bone density (measured by BMAD) increases during 2 to 5 years treatment with gender-affirming hormones in sex assigned at birth females (transmales). Z-scores at the end of follow-up suggest the average lumbar spine bone density was generally lower than in the equivalent cisgender population. The results for lumbar spine bone density (measured by BMD) were inconsistent.</p> <p>Change in bone density: femoral neck</p> <p>Three uncontrolled, observational, retrospective studies provided evidence relating to the effect of gender-affirming hormones on femoral neck bone density in transmales (Klink et al. 2015, Stoffers et al. 2019 and Vlot et al. 2017). See the safety results table above for a full details of the results.</p> <p>These studies provide very low certainty evidence that femoral neck bone density (measured by BMAD) statistically significantly increased in sex assigned at birth females (transmales) during 2 to 5 years treatment with gender-affirming hormones. Z-scores at the end of follow-up suggest the average femoral neck bone density was generally lower than in the equivalent cisgender population. The results for femoral neck bone density (measured by BMD) were inconsistent.</p> <p>Change in clinical parameters: glucose, insulin and HbA1c</p> <p>Two uncontrolled, retrospective chart reviews (Klaver et al. 2020; Stoffers et al. 2019) provided evidence on glucose, insulin and HbA1c in transmales. See the safety results table above for full details of the results.</p> <p>This study provided very low certainty evidence that gender-affirming hormones do not affect HbA1c, glucose levels, insulin levels and insulin resistance in sex assigned at birth females (transmales). Reported from start of treatment to age 22 years.</p> <p>Change in clinical parameters: lipids</p> <p>One retrospective chart review (Klaver et al. 2020) provided evidence on the change in lipids (total cholesterol, HDL cholesterol, LDL cholesterol and triglycerides) in transmales. See the safety results table above for full details of the results.</p> <p>This study provides very low certainty evidence that treatment with gender-affirming hormones is associated with a small but statistically significant worsening of cholesterol levels in sex assigned at birth females (transmales), but mean cholesterol and triglyceride levels were within the UK reference range at end of treatment, from start of treatment to age 22 years.</p>
--	--

	<p>Change in clinical parameters: blood pressure One retrospective chart review (Klaver et al. 2020) provided evidence on the change in blood pressure in transmales. See the safety results table above for full details of the results.</p> <p>This study provides very low certainty evidence that gender-affirming hormones statistically significantly increase blood pressure in sex assigned at birth females (transmales), although the absolute increase was small, from start of treatment to age 22 years.</p> <p>Change in clinical parameters: body mass index (BMI) One retrospective chart review (Klaver et al. 2020) provided evidence on the change in body mass index (BMI) in transmales. See the safety results table above for full details of the results.</p> <p>This study provides very low certainty evidence that gender-affirming hormones statistically significantly increase BMI in sex assigned at birth females (transmales), although most participants were within the healthy weight range, from start of treatment to age 22 years.</p> <p>Change in clinical parameters: liver function One retrospective chart review (Stoffers et al. 2019) provided non-comparative evidence on the change in liver enzymes in transmales between starting gender-affirming hormones and up to 24-months follow-up. See the safety results table above for full details of the results.</p> <p>This study provides very low certainty evidence that gender-affirming hormones for about 12 months do not affect liver function in sex assigned at birth females (transmales).</p> <p>Change in clinical parameters: kidney function One retrospective chart review (Stoffers et al. 2019) provided non-comparative evidence on the change in serum creatinine and serum urea levels in transmales between starting gender-affirming hormones and up to 24-months follow-up. See the safety results table above for full details of the results.</p> <p>This study provides very low certainty evidence on the effects of gender-affirming hormones on kidney function in sex assigned at birth females (transmales). A statistically significant increase in creatinine levels was seen at about 12 months follow-up, but these were within the UK reference range. 6. Discussion

A key limitation to identifying the effectiveness and safety of gender-affirming hormones for children and adolescents with gender dysphoria is the lack of reliable comparative studies. All the studies included in this evidence review are uncontrolled observational studies, which are subject to bias and confounding and were of very low certainty using modified GRADE. The size of the population with gender dysphoria means conducting a prospective trial may be unrealistic, at least on a single centre basis. There may also be ethical issues with a 'no treatment arm' in comparative trials of gender-affirming hormones, where there may be poor mental health outcomes if treatment is withheld. However, the use of an active comparator such as close psychological support may reduce ethical concerns in future trials. A fundamental limitation of all the uncontrolled studies included in this review is that any changes in scores from baseline to follow-up could be attributed to a regression-to-the-mean.

The included studies have relatively short follow-up, with an average duration of treatment with gender-affirming hormones between around 1 year and 5.8 years. Further studies with a longer follow-up are needed to determine the long-term effect of gender-affirming hormones for children and adolescents with gender dysphoria.

Most studies included in this review did not report comorbidities (physical or mental health) and no study reported concomitant treatments in detail. Because of this it is not clear whether any changes observed were due to gender-affirming hormones or other treatments the participants may have received. For example, we do not know if any improvement in depression symptom score over time was the result of gender-affirming hormones or the mental health support the person may be receiving (including medicines or counselling). This may be of particular importance for the mental health outcomes discussed in this review, since depression, anxiety and other related symptoms are common in children and adolescents with gender dysphoria. In [Achille et al. 2020](#), at baseline around one-third of participants were taking medicines for mental health problems and around two-thirds reported being depressed in the past year. In [Kaltiala et al. 2020](#), half the participants needed mental health treatment during and before gender identity assessment, with the most common reasons for treatment being depression, anxiety and suicidality. Only 1 study reported outcomes adjusted for engagement in counselling and medicines for mental health problems (Achille et al. 2020). This study found that gender-affirming hormones had no significant impact on depression and quality of life when adjusted for mental health care, despite significant improvements reported for the unadjusted results. However, it is not possible to draw conclusions on the impact of concurrent mental health treatment on the effect of gender-affirming hormones based on this study alone. Details of the mental health care provided are not reported in the study and results are presented for transfemales and transmales separately, resulting in small patient numbers and possible underpowering.

In most of the included studies, details of the gender-affirming hormone treatment regimens are poorly reported, with limited information provided about the medicines, doses and routes of administration used. It is not clear whether the interventions used in the studies are reflective of current UK practice for children and adolescents with gender dysphoria. There is also the suggestion that the hormone dose used in 1 study may have been too low; the authors of [Klink et al. 2015](#) suggest that the relatively low initial dose of oestrogen for transfemales may be the reason for the observed lack of effect on lumbar spine bone density. Duration of treatment with a GnRH analogue is also poorly reported and is only stated in 3/10 studies.

There is a degree of indirectness in some studies, with some participants included that fall outside of the population of this evidence review. For example, in [Kuper et al. 2020](#) 17% of participants received puberty suppression alone, and in Achille et al. 2020, 30% of participants received no treatment or puberty suppression alone. Some results and statistical analyses are only reported for the whole cohort in these studies and not the subgroup of participants who received gender-affirming hormones.

Participant numbers are poorly reported in some of the included studies. In [Achille et al. 2020](#), 47% (45/95) of the people who entered the study did not have follow-up data and were excluded from the analyses, with no explanation or description of those people lost to follow-up. In Kuper et al. 2020, the number of participants varied by outcome, with less than

two-thirds of participants providing data for some outcomes. The authors provide no explanation for this incomplete reporting.

It is not clear whether some outcome measures, specifically those related to psychosocial functioning, are relevant to the UK population. In Kaltiala et al. 2020, an observational study conducted in Finland, the proportion of participants living with parents or guardians is reported as marker of appropriate functioning. The authors state that in Finnish culture young people tend to leave the parental home early, with only around one-quarter of 20 to 24 year olds still living at home. This is lower than in the UK, where around half of 20 to 24 year olds live with their parents or guardians ([ONS: Why are more young people living with their parents?](#)).

It is difficult to draw firm conclusions for many of the effectiveness and safety outcomes reported in the included studies because many different scoring tools and methods were used to assess the same outcome, often with conflicting results. For example, bone density is reported as bone mineral density (BMD) and bone mineral apparent density (BMAD) in the same study, the latter being a size-adjusted measure often useful for people whose bones are still growing. For some populations (transfemale versus transmale) and bone regions (lumber spine versus femoral neck), statistically significant differences in BMD are reported but not for BMAD, and vice versa.

In addition to this, most outcomes reported across the included studies do not have an accepted minimal clinically important difference (MCID), making it difficult to determine whether any observed statistically significant changes are clinically meaningful. However, the authors of some studies report thresholds to interpret the results of the scoring tools, so some conclusions can be made. For example, the mean Utrecht Gender Dysphoria Scale (UGDS) score (a measure of gender dysphoria symptoms) reduced to about 15 points after treatment with gender-affirming hormones ([Lopez de Lara et al. 2020](#)). The authors state that scores of 40 points or above signify gender dysphoria, suggesting that after about 12 months of treatment with gender-affirming hormones, the majority of participants did not have symptoms of gender dysphoria.

The impact of gender-affirming hormones on bone density was reported in 3 studies (Klink et al. 2015, [Stoffers et al. 2019](#) and [Vlot et al. 2017](#)). Although these studies did not include a control group, comparisons to a reference population are reported using z-scores. Comparisons were made to a cisgender population, meaning for example that bone density in transfemales was compared with bone density in cisgender males. The authors of Klink et al. 2015 note that this may not be the ideal comparison, because androgens and oestrogens affect bone differently, and that bone properties in a trans population differ from their age- and sex assigned at birth-matched controls. Beyond this, a major limitation when trying to determine the impact of gender-affirming hormones on the short- and long-term bone health of children and adolescents is the lack of data on fracture rates and other patient-orientated outcomes, including rates of osteoporosis. Studies of GnRH analogues in children and adolescents with gender dysphoria suggest that GnRH analogue treatment may reduce the expected increase in bone density (which is expected during puberty). Although improvements in bone density were reported following treatment with gender-affirming hormones, Z-scores suggest that bone density remained lower in transfemales and transmales compared with an equivalent cisgender population.

One study reported on cardiovascular risk factors at age 22 years in people who started gender-affirming hormones for gender dysphoria as adolescents. While glucose levels, insulin levels and insulin resistance were broadly unchanged at 22 years, statistically significant increases in blood pressure and body mass index were seen. A small but statistically significant worsening of the lipid profile in transmales who received testosterone was also seen at age 22 years. However, further studies with a considerably longer follow-up and a focus on patient-oriented outcomes, including cardiovascular events and mortality are needed to determine the long-term impact on cardiovascular health of starting gender-affirming hormones during childhood and adolescence.

Only 1 study reported adverse events and discontinuation rates with gender-affirming hormones in children and adolescents. Conclusions on these outcomes cannot be made based on this study alone.

This review did not identify sub-groups of people who may benefit more from gender-affirming hormones. Limited evidence from 2 studies suggests there was no difference in response to treatment between transfemales and transmales for mental health and quality of life (Achille et al. 2020 and [Allen et al. 2019](#)).

7. Conclusion

This evidence review found limited evidence for the effectiveness and safety of gender-affirming hormones in children and adolescents with gender dysphoria, with all studies being uncontrolled, observational studies, and all outcomes of very low certainty. Any potential benefits of treatment must be weighed against the largely unknown long-term safety profile of these treatments.

The results from 5 uncontrolled, observational studies ([Achille et al. 2020](#), [Allen et al. 2019](#), [Kaltiala et al. 2020](#), [Kuper et al. 2020](#), [Lopez de Lara et al. 2020](#)) suggest that, in children and adolescents with gender dysphoria, gender-affirming hormones are likely to improve symptoms of gender dysphoria, and may also improve depression, anxiety, quality of life, suicidality, and psychosocial functioning. The impact of treatment on body image is unclear. All results were of very low certainty. The clinical relevance of any improvements to the person is difficult to determine because most outcomes do not have a recognised minimal clinically important difference, and the authors do not present statistical analysis for some outcomes.

A further 5 uncontrolled, observational studies ([Khatchadourian et al. 2014](#), [Klaver et al. 2020](#), [Klink et al. 2015](#), [Stoffers et al. 2019](#) and [Vlot et al. 2017](#)) reported on safety outcomes, all of which provided very low certainty evidence. Statistically significant increases in some measures of bone density were seen following treatment with gender-affirming hormones, although results varied by bone region (lumber spine versus femoral neck) and by population (transfemales versus transmales). However, z-scores suggest that bone density remained lower in transfemales and transmales compared with an equivalent cisgender population. Results from 1 study of gender-affirming hormones started during adolescence reported statistically significant increases in blood pressure and body mass index, and worsening of the lipid profile (in transmales) at age 22 years, although longer term studies that report on cardiovascular event rates are needed. Adverse events and discontinuation rates associated with gender-affirming hormones were only reported in 1 study, and no conclusions can be made on these outcomes.

This review did not identify sub-groups of people who may benefit more from gender-affirming hormones. Limited evidence from 2 studies suggests there was no difference in response to treatment between transfemales and transmales for mental health and quality of life (Achille et al. 2020 and Allen et al. 2019).

No cost-effectiveness evidence was found to determine whether gender-affirming hormones are a cost-effective treatment for children and adolescents with gender dysphoria.

Appendix A PICO

The review questions for this evidence review are:

1. For children and adolescents with gender dysphoria, what is the clinical effectiveness of treatment with gender-affirming hormones compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention?
2. For children and adolescents with gender dysphoria, what is the short-term and long-term safety of gender-affirming hormones compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention?
3. For children and adolescents with gender dysphoria, what is the cost-effectiveness of gender-affirming hormones compared to one or a combination of psychological support, social transitioning to the desired gender or no intervention?
4. From the evidence selected, are there particular sub-groups of children and adolescents with gender dysphoria that derive comparatively more (or less) benefit from treatment with gender-affirming hormones than the wider population of children and adolescents with gender dysphoria?
5. From the evidence selected,
 - (a) what are the criteria used by the research studies to define gender dysphoria, gender identity disorder and gender incongruence of childhood?
 - (b) what were the ages at which participants commenced treatment with gender-affirming hormones?
 - (c) what was the duration of GnRH analogues treatment?

PICO table

P –Population and Indication	<p>Children and adolescents aged 18 years or less who have gender dysphoria, gender identity disorder or gender incongruence of childhood as defined by the study.</p> <p>The following subgroups of children and adolescents with gender dysphoria, gender identity disorder or gender incongruence of childhood need to be considered:</p>
-------------------------------------	--

	<ul style="list-style-type: none"> • Sex assigned at birth males • Sex assigned at birth females • The duration of gender dysphoria: less than 6 months, 6-24 months, and more than 24 months) • The age at which treatment was initiated with GnRH analogues and with gender-affirming hormones. • The age of onset of gender dysphoria • The age of onset of puberty • Adolescents with gender dysphoria who have a pre-existing diagnosis of autistic spectrum disorder. • Adolescents with gender dysphoria who had a significant mental health symptom load at diagnosis including anxiety, depression (with or without a history of self-harm and suicidality), psychosis, personality disorder, Attention Deficit Hyperactivity Disorder and eating disorders.
I – Intervention	<p>Gender-affirming hormone treatments:</p> <ul style="list-style-type: none"> • A testosterone preparation for sex assigned at birth female patients which may include testosterone in the form of Sustanon injections*; testosterone enantate injections; Tostran gel*; Testogel; Testim gel; oral testosterone capsules in the form of testosterone undecanoate (Restandol); Andriol testocaps; Nebido • An oestradiol preparation** for sex assigned at birth male patients which may include: oral estradiol valerate*; oestrogen patches (7β-oestradiol patches e.g. Evorel or Estradem); Estradot patches; ethinyloestradiol *** <p>*These are the used by Leeds Hospital, England. ** Be aware that the American spelling is oestrogen without the 'o'. ***Ethinyloestradiol is rarely used.</p>
C – Comparator(s)	<p>One or a combination of:</p> <ul style="list-style-type: none"> • Psychological support • Social transitioning to the gender with which the individual identifies. <p>No intervention</p>
O – Outcomes	<p>There are no known minimal clinically important differences and there are no preferred timepoints for the outcome measures selected.</p> <p>All outcomes should be stratified by:</p> <ul style="list-style-type: none"> • The age at which treatment with gender-affirming hormones was initiated • The length of treatment with GnRH analogues where possible. <p><u>A: Clinical Effectiveness</u></p> <p><i>Critical to decision making</i></p> <ul style="list-style-type: none"> • Impact on gender dysphoria <p>This outcome is critical because gender dysphoria in adolescents and children is associated with significant distress and problems functioning. Impact on gender</p>

	<p>dysphoria may be measured by the Utrecht Gender Dysphoria Scale. Other measures as reported in studies may be used as an alternative to the stated measure.</p> <ul style="list-style-type: none"> Impact on mental health Examples of mental health problems include self-harm, thoughts of suicide, suicide attempts, suicide, eating disorders, depression/low mood and anxiety. These outcomes are critical because self-harm and thoughts of suicide have the potential to result in significant physical harm and for completed suicides the death of the young person. Disordered eating habits may cause significant morbidity in young people. Depression and anxiety are also critical outcomes because they may impact on social, occupational, or other areas of functioning of children and adolescents. The Child and Adolescent Psychiatric Assessment (CAPA) may be used to measure depression and anxiety. The impact on self-harm and suicidality (ideation and behaviour) may be measured using the Suicide Ideation Questionnaire Junior. Other measures may be used as an alternative to the stated measure. Impact on Quality of Life This outcome is critical because gender dysphoria in children and adolescents may be associated with a significant reduction in health-related quality of life. Quality of Life may be measured by the KINDL questionnaire, Kidscreen 52. Other measures as reported in studies may be used as an alternative to the stated measures. <i>Important to decision making</i> Impact on body image This outcome is important because some young people with gender dysphoria may desire to take steps to suppress features of their physical appearance associated with their sex assigned at birth or accentuate physical features of their experienced gender. The Body Image Scale could be used as a measure. Other measures as reported in studies may also be used as an alternative to the stated measure. Psychosocial Impact Examples of psychosocial impact are: coping mechanisms which may impact on substance misuse; family relationships; peer relationships. This outcome is important because gender dysphoria in adolescents and children is associated with internalising and externalising behaviours and emotional and behavioural problems which may impact on social and occupational functioning. The child behavioural check list (CBCL) may be used to measure the impact on psychosocial functioning. Other measures as reported in studies may be used as an alternative to the stated measure. Engagement with health care services This outcome is important because patient engagement with healthcare services will impact on their clinical outcomes. Engagement with health care services may be measured using the Youth Health Care measure-satisfaction, utilization, and needs (YHC-SUN) questionnaire. Loss to follow up and
--	---

	<p>should also be ascertained as part of this outcome. Alternative measures to the YHC-SUN questionnaire may be used as reported in studies.</p> <ul style="list-style-type: none"> • Transitioning surgery - Impact on extent of and satisfaction with surgery This outcome is important because some children and adolescents with gender dysphoria may in adulthood proceed to transitioning surgery. Stated measures of the extent of surgery and satisfaction with surgery in studies may be reported. • De-transition The proportion of patients who de-transition following the commencement of gender-affirming hormone treatment and the reasons why. This outcome is important to patients because there is uncertainty about the short and long term safety and adverse effects of gender-affirming hormones in children and adolescents with gender dysphoria. <p><u>B: Safety</u></p> <ul style="list-style-type: none"> • Short and long -term safety and adverse effects of taking gender-affirming hormones is important to assess whether treatment causes acute side effects that may lead to withdrawing the treatment or long term effects that may impact on decisions for transitioning or de-transitioning. <p>Aspects to be reported on should include Impact of the drug use such as clinically relevant derangement in renal and liver function tests, lipids, glucose, insulin and glycosylated haemoglobin, cognitive development and functioning.</p> <p>The clinical and physical impact of temporary and permanent withdrawal the drug such as when patients decide to de-transition – e.g. delay in the attainment of peak bone mass, attenuation of peak bone mass, permanent physical effects.</p> <p><u>C: Cost effectiveness</u></p> <p>Cost effectiveness studies should be reported.</p>
Inclusion criteria	
Study design	Systematic reviews, randomised controlled trials, controlled clinical trials, cohort studies. If no higher level quality evidence is found, case series can be considered.
Language	English only
Patients	Human studies only
Age	18 years or less
Date limits	2000-2020

Exclusion criteria	
Publication type	Conference abstracts, non-systematic reviews, narrative reviews, commentaries, letters, editorials, guidelines and pre-publication prints
Study design	Case reports, resource utilisation studies

Appendix B Search strategy

Medline, Embase, the Cochrane Library, HTA and APA PsycInfo were searched on 21 July 2020, limiting the search to papers published in English language in the last 20 years. Conference abstracts, non-systematic reviews, narrative reviews, commentaries, letters, editorials, guidelines, pre-publication prints, case reports and resource utilisation studies were excluded.

Appendix C Evidence selection

The literature searches identified 1,997 references. These were screened using their titles and abstracts and 54 references were obtained and assessed for relevance. Of these, 10 references are included in the evidence review. The remaining 44 references were excluded and are listed in [appendix D](#).

Figure 1 – Study selection flow diagram

References submitted with Preliminary Policy Proposal

There is no preliminary policy proposal for this policy.

Appendix D Excluded studies table

Study reference	Reason for exclusion
Aranda G, Mora M, Hanzu FA et al. (2019) Effects of sex steroids on cardiovascular risk profile in transgender men under gender affirming hormone therapy. <i>Endocrinologia, diabetes y nutricion</i> 66(6): 385–392	Excluded on population – adult study, participants not 18 years or less (mean age 27.1 years).
Arnold, Justin D, Sarkodie, Eleanor P, Coleman, Megan E et al. (2016) Incidence of Venous Thromboembolism in Transgender Women	Excluded on population – adult study, participants not 18 years or less (mean age 33.2 years).

Receiving Oral Estradiol. The journal of sexual medicine 13(11): 1773–1777	
Asscheman, Henk, Giltay, Erik J, Megens, Jos A J et al. (2011) A long-term follow-up study of mortality in transsexuals receiving treatment with cross-sex hormones. European journal of endocrinology 164(4): 635–42	Excluded on population – although some participants started gender-affirming hormones when young, the study does not report the proportion who started treatment when 18 years or less. Mean ages at start of treatment were 31.4 years (transfemales) and 26.1 years (transmales), suggesting the majority of participants were older than 18 years at the start of treatment. Outcomes not reported separately for people aged 18 years or less.
Author not, found (2014) Hormone therapy for the treatment of gender dysphoria. Lansdale, PA: HAYES, Inc	Full text paper not available.
Baba, T., Endo, T., Honnma, H. et al. (2007) Association between polycystic ovary syndrome and female-to-male transsexuality. Human Reproduction 22(4): 1011–1016	Excluded on population – although study included some younger people (age range 17 to 47), most participants were adults (mean age around 25 years) and the proportion who started treatment when 18 years or less is not reported. Outcomes not reported separately for people aged 18 years or less.
Becerra-Fernandez A, Perez-Lopez G, Roman MM et al. (2014) Prevalence of hyperandrogenism and polycystic ovary syndrome in female to male transsexuals. Endocrinologia y Nutricion: Organo de la Sociedad Espanola de Endocrinologia y Nutricion 61(7): 351–8	Excluded on population – although study included some younger people (age range 18 to 45), most participants were adults (mean age around 25 years) and the proportion who started treatment when 18 years or less is not reported. Outcomes not reported separately for people aged 18 years or less.
Becker I, Auer M, Barkmann C et al. (2018) A Cross-Sectional Multicenter Study of Multidimensional Body Image in Adolescents and Adults with Gender Dysphoria Before and After Transition-Related Medical Interventions. Archives of Sexual Behavior 47(8): 2335–2347	Excluded on population – study included people aged 14 to 21 years. Outcomes not reported separately for people aged 18 years or less. Better evidence available – only 11 participants received gender-affirming hormones. The majority of the study cohort were either pre-treatment, received puberty suppression alone, or received hormones and underwent surgery.
Chew D, Anderson J, Williams K et al. (2018) Hormonal Treatment in Young People With Gender Dysphoria: A Systematic Review. Pediatrics 141(4): e20173742	Excluded on better available evidence - systematic review did not meta-analyse results from. Individual studies from this systematic review are either

Study reference	Reason for exclusion
	included, or excluded because they did not meet the PICO criteria.
Connolly MD, Zervos MJ, Barone CJ 2nd et al. (2016) The Mental Health of Transgender Youth: Advances in Understanding. The Journal of Adolescent Health: Official Publication of the Society for Adolescent Medicine 59(5): 489–495	Excluded on intervention - review did not investigate gender-affirming hormones
de Vries ALC, McGuire JK, Steensma TD et al. (2014) Young adult psychological outcome after puberty suppression and gender reassignment. Pediatrics 134(4): 696–704	Exclude on intervention – all participants had surgery after gender-affirming hormones. Unable to determine whether changes were due to hormones or surgery. Complete data only available for 40 patients. Details of gender-affirming hormones are poorly reported. Outcomes reported in other study (with a population that more closely matches PICO)
Elamin MB, Garcia MZ, Murad MH et al. (2010) Effect of sex steroid use on cardiovascular risk in transsexual individuals: a systematic review and meta-analyses. Clinical Endocrinology 72(1): 1–10	Exclude on population – all included studies conducted in adult population. Unclear whether hormones were started when participants were aged 18 years or less. Outcomes not reported by age at treatment initiation.
Fernandez JD and Tannock LR (2016) Metabolic effects of hormone therapy in transgender patients. Endocrine Practice: Official Journal of the American College of Endocrinology and the American Association of Clinical Endocrinologists 22(4): 383–8	Excluded on population – adult study, participants not 18 years or less (mean ages 31 and 27 years).
Figuera TM, Ziegelmann PK, Da Silva TR et al. (2019) Bone mass effects of cross-sex hormone therapy in transgender people: Updated systematic review and meta-analysis. Journal of the Endocrine Society 3(5): 943–964	Excluded on population – all included studies conducted in adult population. Unclear whether hormones were started when participants were aged 18 years or less. Outcomes not reported by age at treatment initiation.
Getahun D, Nash R, Flanders WD et al. (2018) Cross-sex Hormones and Acute Cardiovascular Events in Transgender Persons: A Cohort Study. Annals of Internal Medicine 169(4): 205–213	Excluded on population – adult study, participants not 18 years or less.
Gomez-Gil E, Zubiaurre-Elorza L, de Antonio IE et al. (2014) Determinants of quality of life in Spanish transsexuals attending a gender unit before genital sex reassignment surgery. Quality of Life Research: an International Journal of Quality of Life Aspects of Treatment, Care and Rehabilitation 23(2): 669–76	Excluded on population – although study included some younger people (age range 16 to 67), most participants were adults (mean age 31.2 years) and the proportion who started treatment when 18 years or less is not reported. Outcomes not reported separately for people aged 18 years or less.
Gomez-Gil E, Zubiaurre-Elorza L, Esteva I et al. (2012) Hormone-treated transsexuals report less	Excluded on population – adult study, participants not 18 years or less (mean age 24.6 years).

social distress, anxiety and depression. Psychoneuroendocrinology 37(5): 662–70	
Gooren LJ, van Trotsenburg MAA, Giltay EJ et al. (2013) Breast cancer development in transsexual subjects receiving cross-sex hormone treatment. The Journal of Sexual Medicine 10(12): 3129–34	Excluded on population – study reports on cancer rates in people aged 18–80 years. The 3 cases of cancer all started gender-affirming hormone treatment >18 years.
Grimstad FW, Boskey E, Grey M (2020) New-Onset Abdominopelvic Pain After Initiation of Testosterone Therapy Among TransMasculine Persons: A Community-Based Exploratory Survey. LGBT health 7(5): Published Online:13 Jul 2020 https://doi.org/10.1089/lgbt.2019.0258	Excluded on population – adult study, participants not 18 years or less.
Hannema SE, Schagen SEE, Cohen-Kettenis PT et al. (2017) Efficacy and Safety of Pubertal Induction Using 17beta-Estradiol in Transgirls. The Journal of Clinical Endocrinology and Metabolism 102(7): 2356–2363	Excluded on better evidence available – small study (n=28) with high drop-out rate (n=16 at final follow-up). Same outcomes reported in larger studies.
Jarin J, Pine-Twaddell E, Trotman G et al. (2017) Cross-Sex Hormones and Metabolic Parameters in Adolescents With Gender Dysphoria. Pediatrics 139(5)	Excluded on population and better evidence available. Although the study included some younger people (age range 13 to 25; mean age 16 and 18), the proportion who started treatment when 18 years or less is not reported. Outcomes not reported separately for people aged 18 years or less. Outcomes were limited to physiological results (including haemoglobin, lipids and BMI). Follow-up only 6 months, other included studies report same outcomes with longer follow-up (12 to 31 months).
Keo-Meier CL, Herman LI, Reisner SL et al. (2015) Testosterone treatment and MMPI-2 improvement in transgender men: a prospective controlled study. Journal of consulting and clinical psychology 83(1): 143–56	Excluded on population – although study included some younger people (age range 18 to 54), most participants were adults (mean age 26.6 years) and the proportion who started treatment when 18 years or less is not reported. Outcomes not reported separately for people aged 18 years or less.
Klaver M, de Mutsert R, Wiepjes CM et al. (2018) Early Hormonal Treatment Affects Body Composition and Body Shape in Young Transgender Adolescents. The Journal of Sexual Medicine 15(2): 251–260	Excluded on outcomes – reported outcomes not included in PICO document. The risk of obesity with gender-affirmed hormones was reported in an included study.
McFarlane T, Zajac JD, Cheung AS (2018) Gender-affirming hormone therapy and the risk of sex hormone-dependent tumours in transgender individuals-A systematic review. Clinical Endocrinology 89(6): 700–711	Exclude on population – all included studies conducted in adult population.

Study reference	Reason for exclusion
Meriggiola MC, Armillotta F, Costantino A et al. (2008) Effects of testosterone undecanoate administered alone or in combination with letrozole or dutasteride in female to male transsexuals. The Journal of Sexual Medicine 5(10): 2442–53	Excluded on population – adult study, participants not 18 years or less.
Nota NM, Wiepjes CM, de Blok, CJM et al. (2018) The occurrence of benign brain tumours in transgender individuals during cross-sex hormone treatment. Brain: A Journal of Neurology 141(7): 2047–2054	Excluded on population – adult study, participants not 18 years or less.
Oda H and Kinoshita T (2017) Efficacy of hormonal and mental treatments with MMPI in FtM individuals: Cross-sectional and longitudinal studies. BMC Psychiatry 17(1): 256	Excluded on population – although study included some younger people (age range 15 to 43), most participants were adults (mean age around 25.6 years) and the proportion who started treatment when 18 years or less is not reported. Outcomes not reported separately for people aged 18 years or less.
Olson-Kennedy J, Okonta V, Clark LF et al. (2018) Physiologic Response to Gender-Affirming Hormones Among Transgender Youth. The Journal of Adolescent Health: Official Publication of the Society for Adolescent Medicine 62(4): 397–401	Excluded on population – although study included some younger people (age range 12 to 23; mean age 18 years). Outcomes not reported separately for people aged 18 years or less. Outcomes limited to physiological results (including haemoglobin, lipids, liver enzymes and BMI). Same outcomes reported in included studies that had a less indirect population and a longer follow-up.
Ott J, Kaufmann U, Bentz K et al. (2010) Incidence of thrombophilia and venous thrombosis in transsexuals under cross-sex hormone therapy. Fertility and sterility 93(4): 1267–72	Excluded on population – adult study, participants not 18 years or less.
Pakpoor J, Wotton CJ, Schmierer K et al. (2016) Gender identity disorders and multiple sclerosis risk: A national record-linkage study. Multiple sclerosis. Multiple Sclerosis Journal. 22(13): 1759–1762	Excluded on population – although study included some younger people, outcomes not reported separately for people aged 18 years or less. Also exclude for intervention – unclear if people received gender-affirming hormones.
Pyra M, Casimiro I, Rusie L et al. (2020) An Observational Study of Hypertension and Thromboembolism among Transgender Patients Using Gender-Affirming Hormone Therapy. Transgender Health 5(1): 1–9	Excluded on population – adult study (age range 20–70). Age at which gender-affirming hormones started not reported.
Quiros C, Patrascioiu I, Mora M et al. (2015) Effect of cross-sex hormone treatment on cardiovascular risk factors in transsexual individuals. Experience in a specialized unit in Catalonia. Endocrinología y nutrición : organo de la Sociedad Espanola de Endocrinología y Nutricion 62(5): 210–6	Excluded on population – adult study, participants not 18 years or less.

Appendix F Quality appraisal checklists

Newcastle-Ottawa Quality Assessment Form for Cohort Studies

Note: A study can be given a maximum of one star for each numbered item within the Selection and Outcome categories. A maximum of two stars can be given for Comparability.

Selection

- 1) Representativeness of the exposed cohort
 - a) Truly representative (one star)
 - b) Somewhat representative (one star)
 - c) Selected group
 - d) No description of the derivation of the cohort
- 2) Selection of the non-exposed cohort
 - a) Drawn from the same community as the exposed cohort (one star)
 - b) Drawn from a different source
 - c) No description of the derivation of the non exposed cohort
- 3) Ascertainment of exposure
 - a) Secure record (e.g., surgical record) (one star)
 - b) Structured interview (one star)
 - c) Written self report
 - d) No description
 - e) Other
- 4) Demonstration that outcome of interest was not present at start of study
 - a) Yes (one star)
 - b) No

Comparability

- 1) Comparability of cohorts on the basis of the design or analysis controlled for confounders
 - a) The study controls for age, sex and marital status (one star)
 - b) Study controls for other factors (list) _____
(one star)
 - c) Cohorts are not comparable on the basis of the design or analysis controlled for confounders

Outcome

- 1) Assessment of outcome
 - a) Independent blind assessment (one star)
 - b) Record linkage (one star)
 - c) Self report
 - d) No description
 - e) Other
- 2) Was follow-up long enough for outcomes to occur
 - a) Yes (one star)
 - b) No
Indicate the median duration of follow-up and a brief rationale for the assessment above: _____
- 3) Adequacy of follow-up of cohorts
 - a) Complete follow up- all subject accounted for (one star)

- b) Subjects lost to follow up unlikely to introduce bias- number lost less than or equal to 20% or description of those lost suggested no different from those followed. (one star)
- c) Follow up rate less than 80% and no description of those lost
- d) No statement

Thresholds for converting the Newcastle-Ottawa scales to AHRQ standards (good, fair, and poor):

Good quality: 3 or 4 stars in selection domain AND 1 or 2 stars in comparability domain AND 2 or 3 stars in outcome/exposure domain

Fair quality: 2 stars in selection domain AND 1 or 2 stars in comparability domain AND 2 or 3 stars in outcome/exposure domain

Poor quality: 0 or 1 star in selection domain OR 0 stars in comparability domain OR 0 or 1 stars in outcome/exposure domain

Appendix G Grade profiles

Table 2: Question 1: For children and adolescents with gender dysphoria, what is the clinical effectiveness of treatment with gender-affirming hormones compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention? - Gender dysphoria

QUALITY					Summary of findings			IMPORTANCE	CERTAINTY
					No of patients		Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result		
Impact on gender dysphoria (1 uncontrolled, prospective observational study)									
Change from baseline in mean gender dysphoria score, measured using the UGDS (duration of treatment 12 months). Higher scores indicate greater gender dysphoria.									
1 cohort study Lopez de Lara et al. 2020	Serious limitations ¹	No serious indirectness	No serious inconsistency	Not calculable	N=23	None	T0 (baseline) = 57.1 (SD 4.1) T1 (12 months) = 14.7 (SD 3.2) Statistically significant improvement, p<0.001	Critical	VERY LOW

Abbreviations: p: p-value; SD: standard deviation; UGDS: Utrecht Gender Dysphoria Scale

¹ Downgraded 1 level - the cohort study by Lopez de Lara et al. 2020 was assessed at high risk of bias (poor quality overall; lack of blinding and no control group)

Table 3: Question 1: For children and adolescents with gender dysphoria, what is the clinical effectiveness of treatment with gender-affirming hormones compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention? – Mental health

QUALITY					Summary of findings			IMPORTANCE	CERTAINTY
					No of events		Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result		
Impact on mental health (3 uncontrolled, prospective observational studies and 2 uncontrolled, retrospective observational studies)									
Change from baseline in mean depression score, measured using the BDI-II (duration of treatment 12 months). Higher scores indicate more severe depression.									

QUALITY					Summary of findings			IMPORTANCE	CERTAINTY
					No of events		Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result		
1 cohort study Lopez de Lara et al. 2020	Serious limitations ¹	No serious indirectness	No serious inconsistency	Not calculable	N=23	None	T0 (baseline) = 19.3 (SD 5.5) T1 (12 months) = 9.7 (SD 3.9) Statistically significant improvement, p<0.001	Critical	VERY LOW
Change from baseline in mean depression score, measured using the CESD-R (approximately 12-month follow-up). Higher scores indicate more severe depression.									
1 cohort study Achille et al. 2020	Serious limitations ²	Serious indirectness ³	No serious inconsistency	Not calculable	N=50	None	Wave 1 (baseline) = 21.4 Wave 3 (approx. 12 months) = 13.9 Statistically significant improvement (p<0.001)	Critical	VERY LOW
Change from baseline in depression score, measured using the Patient Health Questionnaire Modified for Teens (PHQ 9_Modified for Teens) (approximately 12-month follow-up). Higher scores indicate more severe depression.									
1 cohort study Achille et al. 2020	Serious limitations ²	Serious indirectness ³	No serious inconsistency	Not calculable	N=50	None	Statistically significant reductions in mean score, p<0.001 Results presented diagrammatically, numerical results for mean score not reported	Critical	VERY LOW
Change from baseline in depression symptoms, measured using the Quick Inventory of Depressive Symptoms (QIDS), self-reported (mean duration of gender-affirming hormone treatment 10.9 months). Higher scores indicate more severe depression.									
1 cohort study Kuper et al. 2020	Serious limitations ⁴	No serious indirectness	No serious inconsistency	Not calculable	N=105	None	Baseline = 9.6 (SD 5.0) Follow-up = 7.4 (SD 4.5) No statistical analysis reported for the sub-group of participants receiving gender-affirming hormones	Critical	VERY LOW
Change from baseline in depression symptoms, measured using the Quick Inventory of Depressive Symptoms (QIDS), clinician-reported (mean duration of gender-affirming hormone treatment 10.9 months). Higher scores indicate more severe depression.									
1 cohort study	Serious limitations ⁴	No serious indirectness	No serious inconsistency	Not calculable	N=106	None	Baseline = 5.9 (SD 4.1) Follow-up = 6.0 (SD 3.8)	Critical	VERY LOW

QUALITY					Summary of findings		IMPORTANCE	CERTAINTY
					No of events	Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result	
Kuper et al. 2020							No statistical analysis reported for the sub-group of participants who received gender-affirming hormones	
Need for treatment due to depression, during and before gender identity assessment, and during real life phase (approximately 12 months follow-up)								
1 cohort study Kaltiala et al. 2020	Serious limitations ⁷	No serious indirectness	No serious inconsistency	Not calculable	N=52	None	During and before gender identity assessment 54% (28/52) During real life phase 15% (8/52) Statistically significant reduction (p<0.001)	Critical VERY LOW
Change from baseline in anxiety score, measured using the STAI-State subscale (duration of treatment 12 months). Higher scores indicate more severe anxiety.								
1 cohort study Lopez de Lara et al. 2020	Serious limitations ¹	No serious indirectness	No serious inconsistency	Not calculable	N=23	None	T0 (baseline) = 33.3 (SD 9.1) T1 (12 months) = 16.8 (SD 8.1) Statistically significant improvement, p<0.001	Critical VERY LOW
Change from baseline in anxiety score, measured using the STAI-Trait subscale (duration of treatment 12 months). Higher scores indicate more severe anxiety.								
1 cohort study Lopez de Lara et al. 2020	Serious limitations ¹	No serious indirectness	No serious inconsistency	Not calculable	N=23	None	T0 (baseline) = 33.0 (SD 7.2) T1 (12 months) = 18.5 (SD 8.4) Statistically significant improvement, p<0.001	Critical VERY LOW
Change from baseline in anxiety symptoms, measured using the SCARED questionnaire (mean duration of gender-affirming hormone treatment 10.9 months). Higher scores indicate more severe anxiety.								
1 cohort study Kuper et al. 2020	Serious limitations ⁴	No serious indirectness	No serious inconsistency	Not calculable	N=80	None	Baseline = 32.6 (SD 16.3) Follow-up = 28.4 (SD 15.9) No statistical analysis reported for the sub-group of participants	Critical VERY LOW

QUALITY					Summary of findings			IMPORTANCE	CERTAINTY
					No of events		Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result		
							who received gender-affirming hormones		
Change from baseline in panic symptoms, measured using specific questions from the SCARED questionnaire (mean duration of gender-affirming hormone treatment 10.9 months). Higher scores indicate more severe symptoms.									
1 cohort study Kuper et al. 2020	Serious limitations ⁴	No serious indirectness	No serious inconsistency	Not calculable	N=82	None	Baseline = 8.1 (SD 6.3) Follow-up = 7.1 (SD 6.5) No statistical analysis reported for the sub-group of participants who received gender-affirming hormones	Critical	VERY LOW
Change from baseline in generalised anxiety symptoms, measured using specific questions from the SCARED questionnaire (mean duration of gender-affirming hormone treatment was 10.9 months). Higher scores indicate more severe symptoms.									
1 cohort study Kuper et al. 2020	Serious limitations ⁴	No serious indirectness	No serious inconsistency	Not calculable	N=82	None	Baseline = 10.0 (SD 5.1) Follow-up = 8.8 (SD 5.0) No statistical analysis reported for the sub-group of participants who received gender-affirming hormones	Critical	VERY LOW
Change from baseline in social anxiety symptoms, measured using specific questions from the SCARED questionnaire (mean duration of gender-affirming hormone treatment was 10.9 months). Higher scores indicate more severe symptoms.									
1 cohort study Kuper et al. 2020	Serious limitations ⁴	No serious indirectness	No serious inconsistency	Not calculable	N=82	None	Baseline = 8.5 (SD 4.1) Follow-up = 7.7 (SD 4.2) No statistical analysis reported for the sub-group of participants who received gender-affirming hormones	Critical	VERY LOW
Change from baseline in separation anxiety symptoms, measured using specific questions from the SCARED questionnaire (mean duration of gender-affirming hormone treatment was 10.9 months). Higher scores indicate more severe symptoms.									
1 cohort study Kuper et al. 2020	Serious limitations ⁴	No serious indirectness	No serious inconsistency	Not calculable	N=81	None	Baseline = 3.5 (SD 3.0) Follow-up = 3.1 (SD 2.5) No statistical analysis reported for the sub-group of participants	Critical	VERY LOW

QUALITY					Summary of findings			IMPORTANCE	CERTAINTY
					No of events		Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result		
							who received gender-affirming hormones		
Change from baseline in school avoidance, measured using specific questions from the SCARED questionnaire (mean duration of gender-affirming hormone treatment was 10.9 months). Higher scores indicate more severe symptoms.									
1 cohort study Kuper et al. 2020	Serious limitations ⁴	No serious indirectness	No serious inconsistency	Not calculable	N=80	None	Baseline = 2.6 (SD 2.1) Follow-up = 2.0 (SD 2.0) No statistical analysis reported for the sub-group of participants who received gender-affirming hormones	Critical	VERY LOW
Need for treatment due to anxiety, during and before gender identity assessment, and during real life phase (approximately 12 months follow-up)									
1 cohort study Kaltiala et al. 2020	Serious limitations ⁷	No serious indirectness	No serious inconsistency	Not calculable	N=52	None	During and before gender identity assessment 48% (25/52) During real life phase 15% (8/52) Statistically significant reduction (p<0.001)	Critical	VERY LOW
Change from baseline in adjusted mean suicidality score, measured using the ASQ instrument (mean treatment duration 349 days). Higher scores indicate a greater degree of suicidality.									
1 cohort study Allen et al. 2019	Serious limitations ⁵	No serious indirectness	No serious inconsistency	Not calculable	N=39	None	T0 (baseline) = 1.11 (SE 0.22) T1 (final assessment) = 0.27 (SE 0.12) Statistically significant improvement in score from T0 to T1, p<0.001	Critical	VERY LOW
Change from baseline in percentage of participants with suicidal ideation, measured using the additional questions from the PHQ 9 Modified for Teens (approximately 12-month follow-up)									
1 cohort study Achille et al. 2020	Serious limitations ²	Serious indirectness ³	No serious inconsistency	Not calculable	N=50	None	Wave 1 (baseline) = 10% (5/50) Wave 3 (approx. 12 months) = 6% (3/50)	Critical	VERY LOW

QUALITY					Summary of findings		IMPORTANCE	CERTAINTY
					No of events	Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result	
							No statistical analysis reported	
<i>Change from baseline in suicidal ideation (passive), information on which was collected by clinician, exact methods / tools not reported (mean duration of gender-affirming hormone treatment was 10.9 months)</i>								
1 cohort study Kuper et al. 2020	Serious limitations ⁴	Serious indirectness ⁶	No serious inconsistency	Not calculable	N=130	None	Lifetime = 81% (105 people) 1 month before initial assessment = 25% (33 people) Follow-up period = 38% (51 people) No statistical analysis reported	Critical VERY LOW
<i>Change from baseline in suicide attempts, information on which was collected by clinician, exact methods / tools not reported (mean duration of gender-affirming hormone treatment was 10.9 months)</i>								
1 cohort study Kuper et al. 2020	Serious limitations ⁴	Serious indirectness ⁶	No serious inconsistency	Not calculable	N=130	None	Lifetime = 15% (20 people) 3 months before initial assessment = 2% (3 people) Follow-up period = 5% (6 people) No statistical analysis reported	Critical VERY LOW
<i>Change from baseline in non-suicidal self-injury, information on which was collected by clinician, exact methods / tools not reported (mean duration of gender-affirming hormone treatment was 10.9 months)</i>								
1 cohort study Kuper et al. 2020	Serious limitations ⁴	Serious indirectness ⁶	No serious inconsistency	Not calculable	N=130	None	Lifetime = 52% (68 people) 3 months before initial assessment = 10% (13 people) Follow-up period = 17% (23 people) No statistical analysis reported	Critical VERY LOW
<i>Need for treatment due to suicidality / self-harm, during and before gender identity assessment, and during real life phase (approximately 12 months follow-up)</i>								
1 cohort study Kaltiala et al. 2020	Serious limitations ⁷	No serious indirectness	No serious inconsistency	Not calculable	N=52	None	During and before gender identity assessment 35% (18/52) During real life phase	Critical VERY LOW

QUALITY					Summary of findings		IMPORTANCE	CERTAINTY
					No of events	Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result	
							4% (2/52) Statistically significant reduction ($p < 0.001$)	
Need for mental health treatment, during and before gender identity assessment, and during real life phase (approximately 12 months follow-up)								
1 cohort study Kaltiala et al. 2020	Serious limitations ⁷	No serious indirectness	No serious inconsistency	Not calculable	N=52	None	During and before gender identity assessment 50% (26/52) During real life phase 46% (24/51) No statistically significant difference ($p = 0.77$)	Critical VERY LOW
Need for treatment due to conduct problems / antisocial, during and before gender identity assessment, and during real life phase (approximately 12 months follow-up)								
1 cohort study Kaltiala et al. 2020	Serious limitations ⁷	No serious indirectness	No serious inconsistency	Not calculable	N=52	None	During and before gender identity assessment 14% (7/52) During real life phase 6% (3/52) No statistically significant difference ($p = 0.18$)	Critical VERY LOW
Need for treatment due to psychotic symptoms or psychosis, during and before gender identity assessment, and during real life phase (approximately 12 months follow-up)								
1 cohort study Kaltiala et al. 2020	Serious limitations ⁷	No serious indirectness	No serious inconsistency	Not calculable	N=52	None	During and before gender identity assessment 2% (1/52) During real life phase 4% (2/52) No statistically significant difference ($p = 0.56$)	Critical VERY LOW
Need for treatment due to substance abuse, during and before gender identity assessment, and during real life phase (approximately 12 months follow-up)								

QUALITY					Summary of findings			IMPORTANCE	CERTAINTY
					No of events		Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result		
1 cohort study Kaltiala et al. 2020	Serious limitations ⁷	No serious indirectness	No serious inconsistency	Not calculable	N=52	None	During and before gender identity assessment 4% (2/52) During real life phase 2% (1/52) No statistically significant difference (p= 0.56)	Critical	VERY LOW
<i>Need for treatment due to autism, during and before gender identity assessment, and during real life phase (approximately 12 months follow-up)</i>									
1 cohort study Kaltiala et al. 2020	Serious limitations ⁷	No serious indirectness	No serious inconsistency	Not calculable	N=52	None	During and before gender identity assessment 12% (6/52) During real life phase 6% (3/52) No statistically significant difference (p= 0.30)	Critical	VERY LOW
<i>Need for treatment due to ADHD, during and before gender identity assessment, and during real life phase (approximately 12 months follow-up)</i>									
1 cohort study Kaltiala et al. 2020	Serious limitations ⁷	No serious indirectness	No serious inconsistency	Not calculable	N=52	None	During and before gender identity assessment 10% (5/52) During real life phase 2% (1/52) No statistically significant difference (p= 0.09)	Critical	VERY LOW
<i>Need for treatment due to eating disorder, during and before gender identity assessment, and during real life phase (approximately 12 months follow-up)</i>									
1 cohort study Kaltiala et al. 2020	Serious limitations ⁷	No serious indirectness	No serious inconsistency	Not calculable	N=52	None	During and before gender identity assessment 2% (1/52)	Critical	VERY LOW

QUALITY					Summary of findings			IMPORTANCE	CERTAINTY
					No of events		Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result		
							During real life phase 2% (1/52) No statistically significant difference (p=1.0)		

Abbreviations: ADHD: attention deficit hyperactivity disorder; ASQ: Ask Suicide-Screening Questions; CESD-R: Center for Epidemiologic Studies Depression Scale; BDI-II: Beck Depression Inventory II (BDI-II); p: p-value; PHQ 9_Modified for Teens: Patient Health Questionnaire Modified for Teens; SCARED: Screen for Child Anxiety Related Emotional Disorders; SD: standard deviation; STAI: State-Trait Anxiety Inventory

1 Downgraded 1 level - the cohort study by Lopez de Lara et al. (2020) was assessed at high risk of bias (poor quality; lack of blinding and no control group).

2 Downgraded 1 level - the cohort study by Achille et al (2020) was assessed at high risk of bias (poor quality; lack of blinding, no control group and high number of participants lost to follow-up).

3 Serious indirectness in Achille 2020- Outcome reported for full study cohort, of whom 30% were taking no treatment or puberty suppression alone at follow-up. Results for people taking gender-affirming hormones not reported separately.⁴ Downgraded 1 level - the cohort study by Kuper et al. (2020) was assessed at high risk of bias (poor quality).

5 Downgraded 1 level - the cohort study by Allen et al. (2019) was assessed at high risk of bias (poor quality; lack of blinding and no control group).

6 Serious indirectness in Kuper et al. 2020- Outcome reported for full study cohort, of whom approximately 17% received puberty suppression alone and did not receive gender-affirming hormones

7 Downgraded 1 level - the cohort study by Kaltiala et al. (2020) was assessed at high risk of bias (poor quality; lack of blinding and no control group).

Table 4: Question 1: For children and adolescents with gender dysphoria, what is the clinical effectiveness of treatment with gender-affirming hormones compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention? – Quality of life

QUALITY					Summary of findings			IMPORTANCE	CERTAINTY
					No of patients		Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result		
Impact on quality of life (1 uncontrolled, prospective observational study and 1 uncontrolled, retrospective observational study)									

QUALITY					Summary of findings			IMPORTANCE	CERTAINTY
					No of patients		Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result		
Change from baseline in mean quality of life score, measured using the QLES-Q-SF (approximately 12-month follow-up). Higher scores indicated better quality of life.									
1 cohort study Achille et al. 2020	Serious limitations ¹	Serious indirectness ²	No serious inconsistency	Not calculable	N=50	None	Numerical improvements in mean score reported from wave 1 (baseline) to wave 3 (approx. 12 months), but difference not statistically significant (p = 0.085) Results presented diagrammatically, numerical results for mean score not reported	Critical	VERY LOW
Change from baseline in adjusted mean well-being score, measured using the GWBS of the Pediatric Quality of Life Inventory (mean treatment duration 349 days). Higher scores indicated better well-being.									
1 cohort study Allen et al. 2019	Serious limitations ³	No serious indirectness	No serious inconsistency	Not calculable	N=39	None	T0 (baseline) = 61.70 (SE 2.43) T1 (final assessment) = 70.23 (SE 2.15) Statistically significant improvement in well-being score, p<0.002	Critical	VERY LOW

Abbreviations: GWBS: General Well-Being Scale; p: p-value; QLES-Q-SF: Quality of Life Enjoyment and Satisfaction Questionnaire; SE: standard error

¹ Downgraded 1 level - the cohort study by Achille et al (2020) was assessed at high risk of bias (poor quality; lack of blinding, no control group and high number of participants lost to follow-up).

² Serious indirectness in Achille et al. 2020 - Outcome reported for full study cohort, of whom 30% were taking no treatment or puberty suppression alone at follow-up. Results for people taking gender-affirming hormones not reported separately.

³ Downgraded 1 level - the cohort study by Allen et al. (2019) was assessed at high risk of bias (poor quality; lack of blinding and no control group).

Table 5: Question 1: For children and adolescents with gender dysphoria, what is the clinical effectiveness of treatment with gender-affirming hormones compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention? – Body image

QUALITY	Summary of findings	IMPORTANCE	CERTAINTY
---------	---------------------	------------	-----------

					No of patients		Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result		
Impact on body image (1 uncontrolled, prospective observational study)									
Change from baseline in mean body image, measured using the BIS (mean duration of gender-affirming hormone treatment was 10.9 months). Higher scores represent a higher degree of body dissatisfaction.									
1 cohort study Kuper et al. 2020	Serious limitations ¹	No serious indirectness	No serious inconsistency	Not calculable	N=86	None	Baseline = 70.7 (SD 15.2) Follow-up = 51.4 (SD 18.3) No statistical analysis reported for the sub-group of participants who received gender-affirming hormones	Important	VERY LOW

Abbreviations: BIS: Body Image Scale; p: p-value; SD: standard deviation

¹ Downgraded 1 level - the cohort study by Kuper et al. (2020) was assessed at high risk of bias (poor quality; lack of blinding, no control group and high number of participants lost to follow-up).

Table 6: Question 1: For children and adolescents with gender dysphoria, what is the clinical effectiveness of treatment with gender-affirming hormones compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention? – Psychological impact

QUALITY					Summary of findings			IMPORTANCE	CERTAINTY
					No of patients		Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result (95% CI)		
Psychosocial Impact (1 uncontrolled, prospective observational study and 1 uncontrolled, retrospective observational study)									
Change from baseline in family functioning, measured using the Family APGAR test. Higher scores suggest more family dysfunction.									
1 cohort study Lopez de Lara et al. 2020	Serious limitations ¹	No serious indirectness	No serious inconsistency	Not calculable	N=23	None	T0 (baseline) = 17.9 T1 (12 months) = 18.0 No statistical analysis reported	Important	VERY LOW
Change from baseline in mean patient strengths and difficulties score, measured using the SDQ, Spanish Version (total difficulties score) (duration of treatment 12 months). Higher scores suggest the presence of a behavioural disorder.									
1 cohort study	Serious limitations ¹	No serious indirectness	No serious inconsistency	Not calculable	N=23	None	T0 (baseline) = 14.7 (SD 3.3) T1 (12 months) = 10.3 (SD 2.9)	Important	VERY LOW

QUALITY					Summary of findings			IMPORTANCE	CERTAINTY
					No of patients		Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result (95% CI)		
Lopez de Lara et al. 2020							Statistically significant improvement $p < 0.001$		
Functioning in adolescent development: Living with parent(s)/ guardians² (outcome reported for the approximately 12-month period after starting gender-affirming hormones; referred to as the 'real-life phase' in Finland). Not living with parent(s) or guardian in your early 20s is a marker of age-appropriate functioning in Finnish culture.									
1 cohort study Kaltiala et al. 2020	Serious limitations ³	No serious indirectness	No serious inconsistency	Not calculable	N=52	None	During gender identity assessment = 73% (38/52) During real life phase = 40% (21/50) Statistically significant reduction ($p = 0.001$)	Important	VERY LOW
Functioning in adolescent development: Normative peer contacts⁴ (outcome reported for the approximately 12-month period after starting gender-affirming hormones; referred to as the 'real-life phase' in Finland)									
1 cohort study Kaltiala et al. 2020	Serious limitations ³	No serious indirectness	No serious inconsistency	Not calculable	N=52	None	During gender identity assessment = 89% (46/52) During real life phase = 81% (42/52) Statistically significant reduction ($p < 0.001$)	Important	VERY LOW
Functioning in adolescent development: Progresses normatively in school/ work⁵ (outcome reported for the approximately 12-month period after starting gender-affirming hormones; referred to as the 'real-life phase' in Finland)									
1 cohort study Kaltiala et al. 2020	Serious limitations ³	No serious indirectness	No serious inconsistency	Not calculable	N=52	None	During gender identity assessment = 64% (33/52) During real life phase = 60% (31/52) No statistically significant difference ($p = 0.69$)	Important	VERY LOW
Functioning in adolescent development: Has been dating or had steady relationships⁶ (outcome reported for the approximately 12-month period after starting gender-affirming hormones; referred to as the 'real-life phase' in Finland)									
1 cohort study	Serious limitations ³	No serious indirectness	No serious inconsistency	Not calculable	N=52	None	During gender identity assessment = 62% (32/50)	Important	VERY LOW

QUALITY					Summary of findings		IMPORTANCE	CERTAINTY
					No of patients	Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result (95% CI)	
Kaltiala et al. 2020							During real life phase = 58% (30/52) No statistically significant difference (p=0.51)	
Functioning in adolescent development: Is age-appropriately able to deal with matters outside of the home⁷ (outcome reported for the approximately 12-month period after starting gender-affirming hormones; referred to as the 'real-life phase' in Finland)								
1 cohort study Kaltiala et al. 2020	Serious limitations ²	No serious indirectness	No serious inconsistency	Not calculable	N=52	None	During gender identity assessment = 81% (42/52) During real life phase = 81% (42/52) No statistically significant difference (p=1.00)	Important VERY LOW

Abbreviations: APGAR: Adaptability, Partnership, Growth, Affection and Resolve; p: p-value; SD: standard deviation; SDQ: Strengths and Difficulties Questionnaire

1 Downgraded 1 level - the cohort study by Lopez de Lara et al. (2020) was assessed at high risk of bias (poor quality; lack of blinding and no control group).

2 Living arrangements were classified as (1) living with at least one parent/guardian, (2) living in a boarding school, with an adult relative, in some form of supported accommodation or the like, where supervision and guidance by a responsible adult is provided, (3) independently alone or in a shared household with a peer, (4) with a romantic partner. In the analyses dichotomised living arrangements as (a) parent(s)/guardian(s) vs. in other arrangements.

3 Downgraded 1 level - the cohort study by Kaltiala et al. (2020) was assessed at high risk of bias (poor quality; lack of blinding and no control group).

4 Peer relationships were classified as: (1) socialises with friends in leisure time, outside of activities supervised by adults, (2) socialises with peers only at school or in the context of rehabilitative activity, (3) spends time close to peers, for example in school or rehabilitative activity, but does not connect with them, (4) does not meet peers at all. In the analyses, peer relationships during (a) gender identity assessment and (b) the real-life phase were dichotomized to age-appropriate (normative) (1) vs. restricted or lacking (2–4).

5 School/work participation was classified as (1) age appropriate participation in mainstream curriculum, progresses without difficulties, (2) participates in mainstream curriculum with difficulty, (3) participates in rehabilitative educational or work activity, (4) not involved in education and working life. Age-appropriate participation during (1) was recorded if the adolescent attended mainstream secondary education or upper secondary education at a regular rate (a class per year in comprehensive school; has not changed more than once between tracks in upper secondary education) or had proceeded to work life after completing vocational education. Participation with difficulty (2) was recorded if the adolescent was enrolled in mainstream education but had to repeat a class, studied with special arrangements (for example, in a special small group), or followed some form of adjusted curriculum. In the analyses, school/work life during (a) gender identity assessment and (b) real-life phase was dichotomised to normative (1) vs. any other (2, 3 or 4).

6 Romantic involvement was recorded (1) has or has had a dating or steady relationship, not only online, (2) has had a romantic relationship only online, (3) has not had dating or steady relationships. In the analyses we compared has or has had (1) vs. has not had (2,3) a dating or steady relationship during (a) gender identity assessment and (b) real-life phase. Sexual history was recorded in more detail in case histories during gender identity assessment, and for this period we also collected the experiences of (French) kissing (yes/no), intercourse (yes/no) and experience of any genitally intimate contact with a partner (petting under clothes or naked, intercourse, oral sex) (yes/no).

7 In recording age-appropriate competence in managing everyday matters it was expected that early adolescents (up to 14 years) would be able, for example, to do shopping and travel alone on local public transport, and to help with household duties assigned by their parents. Middle adolescents (15–17 years) were further assumed, for example, to be able make telephone calls in matters important to them (for example, when seeking a summer job), to deal with school-related issues with school personnel without parental participation, to select and start new hobbies independently and to fulfil their role in summer jobs and in similar responsibilities of young people. Late adolescents (18 years and over), legally adults, were expected to have, in addition to the above, competence to talk to authorities such as professionals in health and social services, employment or educational institutions, to deal with banks or health insurance, to manage their financial issues and to manage their housekeeping if they chose to move to live independently of parents/guardians. Competence in managing everyday matters was recorded as follows: (1) the adolescent is able to cope age appropriately outside home, (2) the adolescent needs support in age-appropriate matters outside home but functions age-appropriately in the home (manages her/his own hygiene, clothing and nutrition, participates in (younger subjects) or takes responsibility for (older subjects) housekeeping) and (3) the adolescent's functioning is inadequate both at home and outside home. For the analyses, participants were determined to be able to age-appropriately cope with matters outside of the home (1) vs. not (2,3).

Table 7: Question 2: For children and adolescents with gender dysphoria, what is the short-term and long-term safety of gender-affirming hormones compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention? – Bone density

1 cohort study Kaltiala et al. 2020	Serious limitations ³	No serious indirectness	No serious inconsistency	Not calculable	N=49	None	Needed mental health treatment: 72% (23/32) managing well Did not need mental health treatment: 94% (16/17) managing well No statistically significant difference p=0.06	Important	VERY LOW
Functioning in adolescent development: Progresses normatively in school/ work during the real-life phase – impact on need for mental health treatment during the real-life phase									
1 cohort study Kaltiala et al. 2020	Serious limitations ³	No serious indirectness	No serious inconsistency	Not calculable	N=51	None	Needed mental health treatment: 42% (10/24) functioning well Did not need mental health treatment: 74% (20/27) functioning well Statistically significant difference p=0.02	Important	VERY LOW
Functioning in adolescent development: Is age-appropriately able to deal with matters outside of the home during the real-life phase – impact on need for mental health treatment during the real-life phase									
1 cohort study Kaltiala et al. 2020	Serious limitations ³	No serious indirectness	No serious inconsistency	Not calculable	N=51	None	Needed mental health treatment: 67% (16/24) managing well Did not need mental health treatment: 93% (25/27) managing well Statistically significant difference p=0.02	Important	VERY LOW

Abbreviations: CESD-R: Center for Epidemiologic Studies Depression; p: p-value; PHQ 9: Patient Health Questionnaire 9; QLES-Q-SF: Quality of Life Enjoyment and Satisfaction Questionnaire

1 Downgraded 1 level - the cohort study by Achille et al 2020 was assessed at high risk of bias (poor quality; lack of blinding, no control group and high number of participants lost to follow-up).

2 Serious indirectness in Achille 2020- Approximately 30% of the full sample received puberty suppression alone or were receiving no treatment at final follow-up.

3 Downgraded 1 level - the cohort study by Kaltiala et al. 2020 was assessed at high risk of bias (poor quality; lack of blinding and no control).

Table 15: From the evidence selected, are there particular sub-groups of children and adolescents with gender dysphoria that derive comparatively more (or less) benefit from treatment with gender-affirming hormones than the wider population of children and adolescents with gender dysphoria? – Tanner age

QUALITY					Summary of findings			IMPORTANCE	CERTAINTY
					No of patients		Effect		
Study	Risk of bias	Indirectness	Inconsistency	Imprecision	Intervention	Comparator	Result (95% CI)		
Impact on mental health (1 uncontrolled, retrospective observational study)									
Change from baseline in mental health problems – depression, anxiety and anxiety-related symptoms (mean duration of gender-affirming hormone treatment was 10.9 months)									
1 cohort study Kuper et al. 2020	Serious limitations ¹	No serious indirectness	No serious inconsistency	Not calculable	N=105	None	No difference in outcomes found by Tanner age. Numerical results, statistical analysis and information on specific outcomes not reported. It is unclear from the paper whether Tanner age is at initial assessment, start of GnRH analogues, start of gender-affirming hormones, or another timepoint	Critical	VERY LOW
Impact on body image (1 uncontrolled, prospective observational study)									
Change from baseline in mean body image, measured using the BIS (mean duration of gender-affirming hormone treatment was 10.9 months). Higher scores represent a higher degree of body dissatisfaction.									
1 cohort study Kuper et al. 2020	Serious limitations ¹	No serious indirectness	No serious inconsistency	Not calculable	N=105	None	No difference in body image score found by Tanner age. Numerical results, statistical analysis and information on specific outcomes not reported.	Important	VERY LOW

Glossary

Ask Suicide-Screening Questions (ASQ)	ASQ is a four-item dichotomous (yes, no) response measure with high sensitivity, designed to identify risk of suicide. A patient is considered to have screened positive if they answered yes to any item. The authors of Allen et al. 2019 altered the fourth item of the ASQ ("Have you ever tried to kill yourself?") and prefaced it with "In the past few weeks . . ." as they were not investigating lifetime suicidality. A response of 'no' was scored as 0 and a response of 'yes' was scored as 1; each item was summed, generating an overall score for suicidality on a scale ranging from 0 to 4, with higher scores indicating greater levels of suicidal ideation.
Beck Depression Inventory-II (BDI-II)	The BDI-II is a tool for assessing depressive symptoms. There are no specific scores to categorise depression severity, but it is suggested that 0 to 13 is minimal symptoms, 14 to 19 is mild depression, 20 to 28 is moderate depression, and severe depression is 29 to 63.
Body Image Scale (BIS)	The BIS is used to measure body satisfaction. The scale consists of 30 body features, which the person rates on a 5-point scale. Each of the 30 items falls into one of 3 basic groups based on its relative importance as a gender-defining body feature: primary sex characteristics, secondary sex characteristics, and neutral body characteristics. A higher score indicates more dissatisfaction.
Bone mineral apparent density (BMAD)	BMAD is a size adjusted value of bone mineral density (BMD) incorporating bone size measurements using UK norms in growing adolescents.
Center for Epidemiologic Studies Depression scale (CESD-R)	The CESD-R is a valid, widely used tool to assess depressive symptoms. The CESD-R asks about how frequently a person has felt or behaved in a certain way; with 20 questions scored from 0 score is calculated as a sum of 20 questions, ranging from 0 ("not at all or less than one day") to 3 ("5–7 days" and/or "nearly every day for 2 weeks"). Total score ranges from 0 to 60, with higher scores indicating more depressive symptoms.
Cisgender	Cisgender is a term for someone whose gender identity matches their birth-registered sex.
Family APGAR (Adaptability, Partnership, Growth, Affection and Resolve) test	The Family APGAR test is a 5-item questionnaire, with higher scores indicating better family functioning. The authors reported the following interpretation of the score: functional, 17-20 points; mildly dysfunctional, 16-13 points; moderately dysfunctional, 12-10 point; severely dysfunctional, <9 points.
Gender	The roles, behaviours, activities, attributes and opportunities that any society considers appropriate for girls and boys, and women and men.
Gender dysphoria	Discomfort or distress that is caused by a discrepancy between a person's gender identity (how they see themselves regarding their gender) and that person's sex assigned at birth (and the associated gender role, and/or primary and secondary sex characteristics).

General Well-Being Scale (GWBS) of the Pediatric Quality of Life Inventory score	The GWBS of the Pediatric Quality of Life Inventory uses a 5-point response scale, contains seven items, and measures two dimensions: general wellbeing (6 items) and general health (1 item). Each item is scored from 0 to 4, and the total score is linearly transformed to a 0 to 100 scale. High scores reflect fewer perceived problems and greater well-being.
GnRH analogue	GnRH analogues competitively block GnRH receptors to prevent the spontaneous release of two gonadotropin hormones, Follicular Stimulating Hormone (FSH) and Luteinising Hormone (LH) from the pituitary gland. The reduction in LH and FSH secretion reduces oestradiol secretion from the ovaries in those whose sex assigned at birth was female and testosterone secretion from the testes in those whose sex assigned at birth was male.
Patient Health Questionnaire Modified for Teens score (PHQ 9_Modified for Teens)	The PHQ 9_Modified for Teens is a validated tool to assess depression, dysthymia and suicide risk. The tool consists of 9 questions scored from 0 to 3 (total score 0 to 27), plus an additional 4 questions that are not scored. A score of 0 to 4 suggests no or minimal depressive symptoms, 5 to 9 mild, 10-14 moderate, 15-19 moderate and 20-27 severe symptoms.
Quick Inventory of Depressive Symptoms (QIDS)	Both the clinician- and self-reported QIDS are validated tools to assess depressive symptoms. The tool consists of 16 items, with the highest score for 9 items (sleep, weight, psychomotor changes, depressed mood, decreased interest, fatigue, guilt, concentration, and suicidal ideation) are added to give a total score ranging from 0 to 27. A score of 0 to 5 is suggestive of no depressive symptoms, 6 to 10 mild symptoms, 11 to 15 moderate symptoms, 16-20 severe symptoms and 21 to 27 very severe symptoms.
Quality of Life Enjoyment and Satisfaction Questionnaire (QLES-Q-SF)	QLES-Q-SF is a validated questionnaire, consisting of 15 questions that rate quality of life on a scale of 1 (poor) to 5 (very good).
Screen for Child Anxiety Related Emotional Disorders (SCARED) questionnaire	SCARED is a validated, 41-point questionnaire, with each item scored 0 to 2. A total score of 25 or more is suggestive of anxiety disorder, with scores above 30 being more specific. Certain scores for specific questions may indicate the presence of other anxiety-related disorders: A score of 7 or more in questions related to panic disorder or significant somatic symptoms may indicate the presence of these. A score of 9 or more in questions related to generalised anxiety disorder may indicate the presence of this. A score of 5 or more in questions related to separation anxiety may indicate the presence of this. A score of 8 or more in questions related to social anxiety disorder may indicate the presence of this. A score of 3 or more in questions related to significant school avoidance may indicate the presence of this.
State-Trait Anxiety Inventory (STAI) score	STAI is a validated and commonly used measure of state anxiety (current state of anxiety) and trait anxiety (general state of calmness, confidence and security). It has 40 items, the first 20 covering state anxiety, the second 20 covering trait anxiety. STAI

	can be used in clinical settings to diagnose anxiety and to distinguish it from depressive illness. Each subtest (state and trait) is scored between 20 and 80, with higher scores indicating greater anxiety. There is no published minimal clinically meaningful difference (MCID) for STAI or thresholds for anxiety severity.
Strengths and Difficulties Questionnaire (SDQ, Spanish version)	The SDQ, Spanish version includes 25-items covering emotional symptoms, conduct problems, hyperactivity/ inattention, peer relationship problems and prosocial behaviour. The authors state that a score of more than 20 is considered indicative of risk of having a disorder (normal: 0-15; borderline: 16-19, abnormal: 20-40).
Tanner stage	Tanner staging is a scale of physical development.
Transgender (including transmale and transfemale)	Transgender is a term for someone whose gender identity is not congruent with their birth-registered sex. A transfemale is a person who identifies as female and a transmale is a person who identifies as male.
Utrecht Gender Dysphoria Scale (UGDS)	The UGDS is a validated screening tool for both adolescents and adults to assess gender dysphoria. It consists of 12 items, to be answered on a 1- to 5-point scale, resulting in a sum score between 12 and 60. Higher scores indicate higher levels of gender dysphoria.

Evidence review: Gonadotrophin releasing hormone analogues for children and adolescents with gender dysphoria

This document will help inform Dr Hilary Cass' independent review into gender identity services for children and young people. It was commissioned by NHS England and Improvement who commissioned the Cass review. It aims to assess the evidence for the clinical effectiveness, safety and cost-effectiveness of gonadotrophin releasing hormone (GnRH) analogues for children and adolescents aged 18 years or under with gender dysphoria.

The document was prepared by NICE in October 2020.

The content of this evidence review was up to date on 14 October 2020. See [summaries of product characteristics](#) (SPCs), [British National Formulary](#) (BNF) or the [Medicines and Healthcare products Regulatory Agency](#) (MHRA) or [NICE](#) websites for up-to-date information.

1. Introduction

This review aims to assess the evidence for the clinical effectiveness, safety and cost-effectiveness of gonadotrophin releasing hormone (GnRH) analogues for children and adolescents aged 18 years or under with gender dysphoria. The review follows the NHS England Specialised Commissioning process and template and is based on the criteria outlined in the PICO framework (see [appendix A](#)). This document will help inform Dr Hilary Cass' independent review into gender identity services for children and young people.

Gender dysphoria in children, also known as gender identity disorder or gender incongruence of childhood ([World Health Organisation 2020](#)), refers to discomfort or distress that is caused by a discrepancy between a person's gender identity (how they see themselves¹ regarding their gender) and that person's sex assigned at birth and the associated gender role, and/or primary and secondary sex characteristics ([Diagnostic and Statistical Manual of Mental Disorders 2013](#)).

GnRH analogues suppress puberty by delaying the development of secondary sexual characteristics. The intention is to alleviate the distress associated with the development of secondary sex characteristics, thereby providing a time for on-going discussion and exploration of gender identity before deciding whether to take less reversible steps. In England, the GnRH analogue triptorelin (a synthetic decapeptide analogue of natural GnRH, which has marketing authorisations for the treatment of prostate cancer, endometriosis and precocious puberty [onset before 8 years in girls and 10 years in boys]) is used for this purpose. The use of triptorelin for children and adolescents with gender dysphoria is [off-label](#).

For children and adolescents with gender dysphoria it is recommended that management plans are tailored to the needs of the individual, and aim to ameliorate the potentially negative impact of gender dysphoria on general developmental processes, support young people and their families in managing the uncertainties inherent in gender identity development and provide on-going opportunities for exploration of gender identity. The plans may also include psychological support and exploration and, for some individuals, the use of GnRH analogues in adolescence to suppress puberty; this may be followed later with gender-affirming hormones of the desired sex ([NHS England 2013](#)).

2. Executive summary of the review

Nine observational studies were included in the evidence review. Five studies were retrospective observational studies ([Brik et al. 2020](#), [Joseph et al. 2019](#), [Khatchadourian et al. 2014](#), [Klink et al. 2015](#), [Vlot et al. 2017](#)), 3 studies were prospective longitudinal observational studies ([Costa et al. 2015](#), [de Vries et al. 2011](#), [Schagen et al. 2016](#)) and 1 study was a cross-sectional study ([Staphorsius et al. 2015](#)). Two studies (Costa et al. 2015

¹ Gender refers to the roles, behaviours, activities, attributes and opportunities that any society considers appropriate for girls and boys, and women and men ([World Health Organisation, Health Topics: Gender](#)).

and Staphorsius et al. 2015) provided comparative evidence and the remaining 7 studies used within-person, before and after comparisons.

The terminology used in this topic area is continually evolving and is different depending on stakeholder perspectives. In this evidence review we have used the phrase 'people's assigned sex at birth' rather than natal or biological sex, gonadotrophin releasing hormone (GnRH) analogues rather than 'puberty blockers' and gender-affirming hormones rather than 'cross sex hormones'. The research studies included in this evidence review may use historical terms which are no longer considered appropriate.

In children and adolescents with gender dysphoria, what is the clinical effectiveness of treatment with GnRH analogues compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention?

Critical outcomes

The critical outcomes for decision making are the impact on gender dysphoria, mental health and quality of life. The quality of evidence for these outcomes was assessed as very low certainty using modified GRADE.

Impact on gender dysphoria

The study by [de Vries et al. 2011](#) in 70 adolescents with gender dysphoria found that treatment with GnRH analogues before starting gender-affirming hormones does not affect gender dysphoria (measured using the Utrecht Gender Dysphoria Scale [UGDS]). The mean (\pm SD) gender dysphoria (UGDS) score was not statistically significantly different at baseline compared with follow-up ($n=41$, 53.20 [± 7.91] versus 53.9 [± 17.42], $p=0.333$).

Impact on mental health

The study by [de Vries et al. 2011](#) in 70 adolescents with gender dysphoria found that treatment with GnRH analogues before starting gender-affirming hormones may reduce depression (measured using the Beck Depression Inventory-II [BDI-II]). The mean (\pm SD) BDI score was statistically significantly lower (improved) from baseline compared with follow-up ($n=41$, 8.31 [± 7.12] versus 4.95 [± 6.72], $p=0.004$).

The study by [de Vries et al. 2011](#) in 70 adolescents with gender dysphoria found that treatment with GnRH analogues before starting gender-affirming hormones does not affect anger (measured using the Trait Anger Scale [TPI]). The mean (\pm SD) anger (TPI) score was not statistically significantly different at baseline compared with follow-up ($n=41$, 18.29 [± 5.54] versus 17.88 [± 5.24], $p=0.503$).

The study by [de Vries et al. 2011](#) in 70 adolescents with gender dysphoria found that treatment with GnRH analogues before starting gender-affirming hormones does not affect anxiety (measured using the Trait Anxiety Scale [STAI]). The mean (\pm SD) anxiety (STAI) score was not statistically significantly different at baseline compared with follow-up ($n=41$, 39.43 [± 10.07] versus 37.95 [± 9.38], $p=0.276$).

Impact on quality of life

No evidence was identified.

Important outcomes

The important outcomes for decision making are impact on body image, psychosocial impact, engagement with health care services, impact on extent of and satisfaction with surgery and stopping treatment. The quality of evidence for all these outcomes was assessed as very low certainty using modified GRADE.

Impact on body image

The study by [de Vries et al. 2011](#) in 70 adolescents with gender dysphoria found that treatment with GnRH analogues before starting gender-affirming hormones does not affect body image (measured using the Body Image Scale [BIS]). The mean [\pm SD] body image (BIS) scores were not statistically significantly different from baseline compared with follow-up for primary sexual characteristics (n=57, 4.10 [\pm 0.56] versus 3.98 [\pm 0.71], p=0.145), secondary sexual characteristics (n=57, 2.74 [\pm 0.65] versus 2.82 [\pm 0.68], p=0.569) or neutral body characteristics (n=57, 2.41 [\pm 0.63] versus 2.47 [\pm 0.56], p=0.620).

Psychosocial impact

The study by [de Vries et al. 2011](#) in 70 adolescents with gender dysphoria found that treatment with GnRH analogues before starting gender-affirming hormones may improve psychosocial impact over time (measured using the Children's Global Assessment Scale [CGAS]). The mean [\pm SD] CGAS score was statistically significantly higher (improved) from baseline compared with follow-up (n=41, 70.24 [\pm 10.12] versus 73.90 [\pm 9.63], p=0.005).

This study also found that psychosocial functioning may improve over time (measured using the Child Behaviour Checklist [CBCL] and the self-administered Youth Self-Report [YSR]). The mean [\pm SD] CBCL scores were statistically significantly lower (improved) from baseline compared with follow-up for Total T score (n=54, 60.70 [\pm 12.76] versus 54.46 [\pm 11.23], p<0.001), internalising T score (n=54, 61.00 [\pm 12.21] versus 52.17 [\pm 9.81], p<0.001) and externalising T score (n=54, 58.04 [\pm 12.99] versus 53.81 [\pm 11.86], p=0.001). The mean [\pm SD] YSR scores were statistically significantly lower (improved) from baseline compared with follow-up for Total T score (n=54, 55.46 [\pm 11.56] versus 50.00 [\pm 10.56], p<0.001), internalising T score (n=54, 56.04 [\pm 12.49] versus 49.78 [\pm 11.63], p<0.001) and externalising T score (n=54, 53.30 [\pm 11.87] versus 49.98 [\pm 9.35], p=0.009). The proportion of adolescents scoring in the clinical range decreased from baseline to follow up on the CBCL total problem scale (44.4% versus 22.2%, p=0.001) and the internalising scale of the YSR (29.6% versus 11.1%, p=0.017).

The study by [Costa et al. 2015](#) in 201 adolescents with gender dysphoria who had 6 months of psychological support followed by either GnRH analogues and continued psychological support or continued psychological support only, found that during treatment with GnRH analogues psychosocial impact in terms of global functioning may improve over time (measured using the CGAS). In the group receiving GnRH analogues, the mean [\pm SD] CGAS score was statistically significantly higher (improved) after 6 months (n=60, 64.70 [\pm 13.34]) and 12 months (n=35, 67.40 [\pm 13.39]) compared with baseline (n=101, 58.72 [\pm 11.38], p=0.003 and p<0.001, respectively). However, there was no statistically significant difference in global functioning (CGAS scores) between the group receiving GnRH analogues plus psychological support and the group receiving psychological support only at any time point.

The study by [Staphorsius et al. 2015](#) in 40 adolescents with gender dysphoria (20 of whom were receiving GnRH analogues) gave mean [\pm SD] CBCL scores for each group, but statistical analysis is unclear (transfemales receiving GnRH analogues 57.4 [\pm 9.8], transfemales not receiving GnRH analogues 58.2 [\pm 9.3], transmales receiving GnRH analogues 57.5 [\pm 9.4], transmales not receiving GnRH analogues 63.9 [\pm 10.5]).

Engagement with health care services

The study by [Brik et al. 2018](#) in 143 children and adolescents with gender dysphoria receiving GnRH analogues found that 9 adolescents in the original sampling frame (9/214, 4.2%) were excluded from the study because they stopped attending appointments.

The study by [Costa et al. 2015](#) in 201 adolescents with gender dysphoria who had 6 months of psychological support followed by either GnRH analogues and continued psychological support or continued psychological support only had a large loss to follow-up over time. The sample size at baseline and 6 months was 201, which dropped by 39.8% to 121 after 12 months and by 64.7% to 71 at 18 months follow-up. No explanation of the reasons for loss to follow-up are reported.

Impact on extent of and satisfaction with surgery

No evidence was identified.

Stopping treatment

The study by [Brik et al. 2018](#) in 143 children and adolescents with gender dysphoria receiving GnRH analogues reported the reasons for stopping GnRH analogues. During the follow-up period 6.2% (9/143) of adolescents had stopped GnRH analogues after a median duration of 0.8 years (range 0.1 to 3.0). Five adolescents stopped treatment because they no longer wished to receive gender-affirming treatment for various reasons. In 4 adolescents (all transmales), GnRH analogues were stopped mainly because of adverse effects (such as mood and emotional lability), although they wanted to continue treatments for gender dysphoria.

The study by [Khatchadourian et al. 2014](#) in 27 adolescents with gender dysphoria who started GnRH analogues reported the reasons for stopping them. Eleven out of 26 where data was available (42%) stopped GnRH analogues during follow up.

In children and adolescents with gender dysphoria, what is the short-term and long-term safety of GnRH analogues compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention?

Evidence was available for bone density, cognitive development or functioning, and other safety outcomes. The quality of evidence for all these outcomes was assessed as very low certainty using modified GRADE.

Bone density

The study by [Joseph et al. 2019](#) in 70 adolescents with gender dysphoria found that GnRH analogues may reduce the expected increase in lumbar or femoral bone density (measured with the z-score). However, the z-scores were largely within 1 standard deviation of normal,

and actual lumbar or femoral bone density values were not statistically significantly different between baseline and follow-up:

- The mean z-score [\pm SD] for lumbar bone mineral apparent density (BMAD) was statistically significantly lower at 1 year compared with baseline in transfemales (baseline 0.859 [\pm 0.154], 1 year -0.228 [\pm 1.027], $p=0.000$) and transmales (baseline -0.186 [\pm 1.230], 1 year -0.541 [\pm 1.396], $p=0.006$).
- The mean z-score [\pm SD] for lumbar BMAD was statistically significantly lower after receiving GnRH analogues for 2 years compared with baseline in transfemales (baseline 0.486 [\pm 0.809], 2 years -0.279 [\pm 0.930], $p=0.000$) and transmales (baseline -0.361 [\pm 1.439], 2 years -0.913 [\pm 1.318], $p=0.001$).
- The mean z-score [\pm SD] for femoral neck bone mineral density (BMD) was statistically significantly lower after receiving GnRH analogues for 2 years compared with baseline in transfemales (baseline 0.0450 [\pm 0.781], 2 years -0.600 [\pm 1.059], $p=0.002$) and transmales (baseline -1.075 [\pm 1.145], 2 years -1.779 [\pm 0.816], $p=0.001$).

The study by [Klink et al. 2015](#) in 34 adolescents with gender dysphoria found that GnRH analogues may reduce the expected increase in lumbar (transmales only), but not femoral bone density. However, the z-scores are largely within 1 standard deviation of normal. Actual lumbar or femoral bone density values were not statistically significantly different between baseline and follow-up (apart from BMD measurements in transmales):

- The mean z-score [\pm SD] for lumbar BMAD was not statistically significantly different between starting GnRH analogues and starting gender-affirming hormones in transfemales, but was statistically significantly lower when starting gender-affirming hormones in transmales (GnRH analogues 0.28 [\pm 0.90], gender-affirming hormones -0.50 [\pm 0.81], $p=0.004$).

The study by [Vlot et al. 2017](#) in 70 adolescents with gender dysphoria found that GnRH analogues may reduce the expected increase in lumbar or femoral bone density. However, the z-scores were largely within 1 standard deviation of normal. Actual lumbar or femoral bone density values were not statistically significantly different between baseline and follow-up (apart from in transmales with a bone age ≥ 14 years). This study reported change in bone density from starting GnRH analogues to starting gender-affirming hormones by bone age:

- The median z-score [range] for lumbar BMAD in transfemales with a bone age of <15 years was statistically significantly lower at starting gender-affirming hormones than at starting GnRH analogues (GnRH analogues -0.20 [-1.82 to 1.18], gender-affirming hormones -1.52 [-2.36 to 0.42], $p=0.001$) but was not statistically significantly different in transfemales with a bone age ≥ 15 years.
- The median z-score [range] for lumbar BMAD in transmales with a bone age of <14 years was statistically significantly lower at starting gender-affirming hormones than at starting GnRH analogues (GnRH analogues -0.05 [-0.78 to 2.94], gender-affirming hormones -0.84 [-2.20 to 0.87], $p=0.003$) and in transmales with a bone age ≥ 14 years (GnRH analogues 0.27 [-1.60 to 1.80], gender-affirming hormones -0.29 [-2.28 to 0.90], $p\leq 0.0001$).

- The median z-score [range] for femoral neck BMAD in transfemales with a bone age of <15 years was not statistically significantly lower at starting gender-affirming hormones than at starting GnRH analogues (GnRH analogues -0.71 [-3.35 to 0.37], gender-affirming hormones -1.32 [-3.39 to 0.21], $p \leq 0.1$) or in transfemales with a bone age ≥ 15 years (GnRH analogues -0.44 [-1.37 to 0.93], gender-affirming hormones -0.36 [-1.50 to 0.46]).
- The z-score for femoral neck BMAD in transmales with a bone age of <14 years was not statistically significantly lower at starting gender-affirming hormones than at starting GnRH analogues (GnRH analogues -0.01 [-1.30 to 0.91], gender-affirming hormone -0.37 [-2.28 to 0.47]) but was statistically significantly lower in transmales with a bone age ≥ 14 years (GnRH analogues 0.27 [-1.39 to 1.32], gender-affirming hormones -0.27 [-1.91 to 1.29], $p=0.002$).

Cognitive development or functioning

The study by [Staphorsius et al. 2015](#) in 40 adolescents with gender dysphoria (20 of whom were receiving GnRH analogues) measured cognitive development or functioning (using an IQ test, and reaction time and accuracy measured using the Tower of London task):

- The mean (\pm SD) IQ in transfemales receiving GnRH analogues was 94.0 (± 10.3) and 109.4 (± 21.2) in the control group. In transmales receiving GnRH analogues the mean (\pm SD) IQ was 95.8 (± 15.6) and 98.5 (± 15.9) in the control group.
- The mean (\pm SD) reaction time in transfemales receiving GnRH analogues was 10.9 (± 4.1) and 9.9 (± 3.1) in the control group. In transmales receiving GnRH analogue it was 9.9 (± 3.1) and 10.0 (± 2.0) in the control group.
- The mean (\pm SD) accuracy score in transfemales receiving GnRH analogues was 73.9 (± 9.1) and 83.4 (± 9.5) in the control group. In transmales receiving GnRH analogues it was 85.7 (± 10.5) and 88.8 (± 9.7) in the control group.

No statistical analyses or interpretation of the results was reported.

Other safety outcomes

The study by [Schagen et al. 2016](#) in 116 adolescents with gender dysphoria found that GnRH analogues do not affect renal or liver function:

- There was no statistically significant difference between baseline and 1 year results for serum creatinine in transfemales, but there was a statistically significant decrease between baseline and 1 year in transmales ($p=0.01$).
- Glutaryl transferase, alanine aminotransferase (ALT), and aspartate aminotransferase (AST) levels did not significantly change from baseline to 12 months of treatment.

The study by [Khatchadourian et al. 2014](#) in 27 adolescents with gender dysphoria who started GnRH analogues narratively reported adverse effects from GnRH analogues in 26 adolescents:

- 1 transmale developed sterile abscesses; they were switched from leuprolide acetate to triptorelin, and this was well tolerated
- 1 transmale developed leg pains and headaches, which eventually resolved
- 1 participant gained 19 kg within 9 months of starting GnRH analogues.

In children and adolescents with gender dysphoria, what is the cost-effectiveness of GnRH analogues compared to one or a combination of psychological support, social transitioning to the desired gender or no intervention?

No cost-effectiveness evidence was found for GnRH analogues in children and adolescents with gender dysphoria.

From the evidence selected, are there any subgroups of children and adolescents with gender dysphoria that may benefit from GnRH analogues more than the wider population of interest?

Some studies reported data separately for the following subgroups of children and adolescents with gender dysphoria: sex assigned at birth males (transfemales) and sex assigned at birth females (transmales). This included some direct comparisons of these subgroups, and differences were largely seen at baseline as well as follow up. No evidence was found for other specified subgroups.

Sex assigned at birth males (transfemales)

Impact on gender dysphoria

The study by [Costa et al. 2015](#) in 201 adolescents with gender dysphoria who had 6 months of psychological support followed by either GnRH analogues and continued psychological support or continued psychological support only, found that gender dysphoria (measured using the UGDS) in sex assigned at birth males is lower than in sex assigned at birth females. Sex assigned at birth males had a statistically significantly lower (improved) mean [\pm SD] UGDS score of 51.6 [\pm 9.7] compared with sex assigned at birth females (56.1 [\pm 4.3], $p < 0.001$), but it was not reported if this was at baseline or follow-up.

The study by [de Vries et al. 2011](#) in 70 adolescents with gender dysphoria found that gender dysphoria (measured using the UGDS) in sex assigned at birth males is lower than in sex assigned at birth females at baseline and follow up. The mean [\pm SD] UGDS score was statistically significantly lower (improved) in sex assigned at birth males compared with sex assigned at birth females at baseline (n =not reported, mean UGDS score: 47.95 [\pm 9.70] versus 56.57 [\pm 3.89]) and follow up (n =not reported, 49.67 [\pm 9.47] versus 56.62 [\pm 4.00]); between sex difference $p < 0.001$).

Impact on mental health

The study by [de Vries et al. 2011](#) in 70 adolescents with gender dysphoria found that the impact on mental health (depression, anger and anxiety) may be different in sex assigned at birth males compared with sex assigned at birth females. Over time there was no statistically significant difference between sex assigned at birth males and sex assigned at birth females for depression, but sex assigned at birth males had statistically significantly lower levels of anger and anxiety than sex assigned at birth females at baseline and follow up.

- The mean [\pm SD] depression (BDI-II) score was not statistically significantly different in sex assigned at birth males compared with sex assigned at birth females at baseline (n =not reported, mean BDI score [\pm SD]: 5.71 [\pm 4.31] versus 10.34 [\pm 8.24]) and follow-up (n =not reported, 3.50 [\pm 4.58] versus 6.09 [\pm 7.93]), between sex difference $p = 0.057$

- The mean [\pm SD] anger (TPI) score was statistically significantly lower (improved) in sex assigned at birth males compared with sex assigned at birth females at baseline (n=not reported, mean TPI score [\pm SD]: 5.22 [\pm 2.76] versus 6.43 [\pm 2.78]) and follow-up (n=not reported, 5.00 [\pm 3.07] versus 6.39 [\pm 2.59]), between sex difference $p=0.022$
- The mean [\pm SD] anxiety (STAI) score was statistically significantly lower (improved) in sex assigned at birth males compared with sex assigned at birth females at baseline (n=not reported, mean STAI score [\pm SD]: 4.33 [\pm 2.68] versus 7.00 [\pm 2.36]) and follow-up (n=not reported, 4.39 [\pm 2.64] versus 6.17 [\pm 2.69]), between sex difference $p<0.001$.

Impact on body image

The study by [de Vries et al. 2011](#) in 70 adolescents with gender dysphoria found that the impact on body image may be different in sex assigned at birth males compared with sex assigned at birth females. Sex assigned at birth males are less dissatisfied with their primary and secondary sex characteristics than sex assigned at birth females at both baseline and follow up, but the satisfaction with neutral body characteristics is not different.

- The mean [\pm SD] BIS score for primary sex characteristics was statistically significantly lower (improved) in sex assigned at birth males compared with sex assigned at birth females at baseline (n=not reported, mean BIS score [\pm SD]: 4.02 [\pm 0.61] versus 4.16 [\pm 0.52]) and follow up (n=not reported, 3.74 [\pm 0.78] versus 4.17 [\pm 0.58]) between sex difference $p=0.047$.
- The mean [\pm SD] BIS score for secondary sex was statistically significantly lower (improved) in sex assigned at birth males compared with sex assigned at birth females at baseline (n=not reported, mean BIS score [\pm SD]: 2.66 [\pm 0.50] versus 2.81 [\pm 0.76]) and follow up (n=not reported, 2.39 [\pm 0.69] versus 3.18 [\pm 0.42]), between sex difference $p=0.001$.
- The mean [\pm SD] BIS score for neutral body characteristics was not statistically significantly different in sex assigned at birth males compared with sex assigned at birth females at baseline (n=not reported, 2.60 [\pm 0.58] versus 2.24 [\pm 0.62]), between sex difference $p=0.777$.

Psychosocial impact

The study by [Costa et al. 2015](#) in 201 adolescents with gender dysphoria who had 6 months of psychological support followed by either GnRH analogues and continued psychological support or continued psychological support only, found that sex assigned at birth males had statistically significant lower mean [\pm SD] CGAS scores at baseline compared with sex assigned at birth females (n=201, 55.4 [\pm 12.7] versus 59.2 [\pm 11.8], $p=0.03$), but no conclusions could be drawn.

The study by [de Vries et al. 2011](#) in 70 adolescents with gender dysphoria found that psychosocial impact in terms of global functioning (CGAS) and psychosocial functioning (CBCL and YSR) may be different in sex assigned at birth males compared with sex assigned at birth females, but no conclusions could be drawn.

- There was no statistically significant difference between sex assigned at birth males and sex assigned at birth females (at baseline or follow up) for the CBCL Total T

score, the CBCL internalising T score, the YSR Total T score or the YSR internalising T score.

- Sex assigned at birth males had statistically higher mean [\pm SD] CGAS scores compared with sex assigned at birth females at baseline (n=54, 73.10 [\pm 8.44] versus 67.25 [\pm 11.06]) and follow up (n=54, 77.33 [\pm 8.69] versus 70.30 [\pm 9.44]), between sex difference p=0.021.
- Sex assigned at birth males had statistically lower mean [\pm SD] CBCL externalising T scores compared with sex assigned at birth females at baseline (n=54, 54.71 [\pm 12.91] versus 60.70 [\pm 12.64]) and follow up (n=54, 48.75 [\pm 10.22] versus 57.87 [\pm 11.66]), between sex difference p=0.015.
- Sex assigned at birth males had statistically lower mean [\pm SD] YSR externalising T scores compared with sex assigned at birth females at both baseline (n=54, 48.72 [\pm 11.38] versus 57.24 [\pm 10.59]) and follow up (n=54, 46.52 [\pm 9.23] versus 52.97 [\pm 8.51]), between sex difference p=0.004.

Bone density

The studies by [Joseph et al. 2019](#), [Klink et al. 2015](#) and [Vlot et al. 2017](#) provided evidence on bone density in sex assigned at birth males (see above for details).

Cognitive development or functioning

The study by [Staphorsius et al. 2015](#) provided evidence on cognitive development or functioning in sex assigned at birth males (see above for details).

Other safety outcomes

The study by [Schagen et al. 2016](#) provided evidence on renal function in sex assigned at birth males (see above).

Sex assigned at birth females (transmales)

Impact on gender dysphoria

The studies by [de Vries et al. 2011](#) and [Costa et al. 2015](#) found that gender dysphoria (measured using the UGDS) in sex assigned at birth females is higher than in sex assigned at birth males at baseline and follow up (see above for details).

Impact on mental health

The study by [de Vries et al. 2011](#) found that the impact on mental health (depression, anger and anxiety) may be different in sex assigned at birth females compared with sex assigned at birth males. Over time there was no statistically significant difference between sex assigned at birth females and sex assigned at birth males for depression, but sex assigned at birth females had statistically significantly greater levels of anger and anxiety than sex assigned at birth males at both baseline and follow up (see above for details).

Impact on body image

The study by [de Vries et al. 2011](#) found that the impact on body image may be different in sex assigned at birth females compared with sex assigned at birth males. Sex assigned at birth females are more dissatisfied with their primary and secondary sex characteristics than sex assigned at birth males at both baseline and follow up, but the satisfaction with neutral body characteristics is not different (see above for details).

Psychosocial impact

The studies by [de Vries et al. 2011](#) and [Costa et al. 2015](#) found that psychosocial impact in terms of global functioning (CGAS) and psychosocial functioning (CBCL and YSR) may be different in sex assigned at birth females compared with sex assigned at birth males, but no conclusions could be drawn (see above for details).

Bone density

The studies by [Joseph et al. 2019](#), [Klink et al. 2015](#) and [Vlot et al. 2017](#) provided evidence on bone density in sex assigned at birth females (see above for details).

Cognitive development or functioning

The study by [Staphorsius et al. 2015](#) provided evidence on cognitive development or functioning in sex assigned at birth females (see above for details).

Other safety outcomes

The study by [Schagen et al. 2016](#) provided evidence on renal function in sex assigned at birth females (see above for details).

From the evidence selected:

- (a) **what are the criteria used by the research studies to define gender dysphoria, gender identity disorder and gender incongruence of childhood?**
- (b) **what were the ages at which participants commenced treatment with GnRH analogues?**
- (c) **what was the duration of treatment with GnRH analogues?**

All studies that reported diagnostic criteria for gender dysphoria (6/9 studies) used the version of the Diagnostic and Statistical Manual of Mental Disorders (DSM) criteria that was in use at the time. In 5 studies ([Costa et al. 2015](#), [Klink et al. 2015](#), [Schagen et al. 2016](#), [Staphorsius et al. 2015](#) and [Vlot et al. 2017](#)) the DSM-fourth edition, text revision (IV-TR) criteria were used. The study by [Brik et al. 2020](#) used DSM-V criteria. It was not reported how gender dysphoria was defined in the remaining 3 studies.

The studies show variation in the age (11 to 18 years old) at which children and adolescents with gender dysphoria started GnRH analogues.

Most studies did not report the duration of treatment with GnRH analogues ([Joseph et al. 2019](#), [Khatchadourian et al. 2014](#), [Vlot et al. 2017](#), [Costa et al. 2015](#), [de Vries et al. 2011](#), [Schagen et al. 2016](#)), but where this was reported ([Brik et al. 2020](#), [Klink et al. 2015](#), [Staphorsius et al. 2015](#)) there was a wide variation ranging from a few months to about 5 years.

Discussion

A key limitation to identifying the effectiveness and safety of GnRH analogues for children and adolescents with gender dysphoria is the lack of reliable comparative studies. The lack of clear, expected outcomes from treatment with a GnRH analogue (the purpose of which is to suppress secondary sexual characteristics which may cause distress from unwanted pubertal changes) also makes interpreting the evidence difficult.

The studies included in this evidence review are all small, uncontrolled observational studies, which are subject to bias and confounding, and all the results are of very low certainty using modified GRADE. They all reported physical and mental health comorbidities and concomitant treatments very poorly. All the studies are from a limited number of, mainly European, care facilities. They are described as either tertiary referral or expert services but the low number of services providing such care and publishing evidence may bias the results towards the outcomes in these services only and limit extrapolation.

Many of the studies did not report statistical significance or confidence intervals. Changes in outcome scores for clinical effectiveness and bone density were assessed with regards to statistical significance. However, there is relatively little interpretation of whether the changes in outcomes are clinically meaningful.

In the observational, retrospective studies providing evidence on bone density, participants acted as their own controls and change in bone density was determined between starting GnRH analogues and follow up. Observational studies such as these can only show an association with GnRH analogues and bone density; they cannot show that GnRH analogues caused any differences in bone density seen. Because there was no comparator group and participants acted as their own controls, it is not known whether the findings are associated with GnRH analogues or due to changes over time.

Conclusion

The results of the studies that reported impact on the critical outcomes of gender dysphoria and mental health (depression, anger and anxiety), and the important outcomes of body image and psychosocial impact (global and psychosocial functioning), in children and adolescents with gender dysphoria are of very low certainty using modified GRADE. They suggest little change with GnRH analogues from baseline to follow-up.

Studies that found differences in outcomes could represent changes that are either of questionable clinical value, or the studies themselves are not reliable and changes could be due to confounding, bias or chance. It is plausible, however, that a lack of difference in scores from baseline to follow-up is the effect of GnRH analogues in children and adolescents with gender dysphoria, in whom the development of secondary sexual characteristics might be expected to be associated with an increased impact on gender dysphoria, depression, anxiety, anger and distress over time without treatment. The study by [de Vries et al. 2011](#) reported statistically significant reductions in the Child Behaviour Checklist (CBCL) and Youth Self-Report (YSR) scores from baseline to follow up, which include measures of distress. As the aim of GnRH analogues is to reduce distress caused by the development of secondary sexual characteristics, this may be an important finding. However, as the studies all lack appropriate controls who were not receiving GnRH analogues, any positive changes could be a regression to mean.

The results of the studies that reported bone density outcomes suggest that GnRH analogues may reduce the expected increase in bone density (which is expected during puberty). However, as the studies themselves are not reliable, the results could be due to confounding, bias or chance. While controlled trials may not be possible, comparative studies are needed to understand this association and whether the effects of GnRH analogues on bone density are seen after they are stopped. All the studies that reported safety outcomes provided very low certainty evidence.

No cost-effectiveness evidence was found to determine whether or not GnRH analogues are cost-effective for children and adolescents with gender dysphoria.

The results of the studies that reported outcomes for subgroups of children and adolescents with gender dysphoria, suggest there may be differences between sex assigned at birth males (transfemales) and sex assigned at birth females (transmales).

3. Methodology

Review questions

The review question(s) for this evidence review are:

1. For children and adolescents with gender dysphoria, what is the clinical effectiveness of treatment with GnRH analogues compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention?
2. For children and adolescents with gender dysphoria, what is the short-term and long-term safety of GnRH analogues compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention?
3. For children and adolescents with gender dysphoria, what is the cost-effectiveness of GnRH analogues compared to one or a combination of psychological support, social transitioning to the desired gender or no intervention?
4. From the evidence selected, are there any subgroups of children and adolescents with gender dysphoria that may derive more (or less) advantage from treatment with GnRH analogues than the wider population of children and adolescents with gender dysphoria?
5. From the evidence selected,
 - a) what are the criteria used by the research studies to define gender dysphoria, gender identity disorder and gender incongruence of childhood?
 - b) what were the ages at which participants commenced treatment with GnRH analogues?
 - c) what was the duration of treatment with GnRH analogues?

See [appendix A](#) for the full review protocol.

Review process

The methodology to undertake this review is specified by NHS England in their 'Guidance on conducting evidence reviews for Specialised Services Commissioning Products' (2020).

The searches for evidence were informed by the PICO document and were conducted on 23 July 2020

See [appendix B](#) for details of the search strategy.

Results from the literature searches were screened using their titles and abstracts for relevance against the criteria in the PICO framework. Full text references of potentially

relevant evidence were obtained and reviewed to determine whether they met the inclusion criteria for this evidence review.

See [appendix C](#) for evidence selection details and [appendix D](#) for the list of studies excluded from the review and the reasons for their exclusion.

Relevant details and outcomes were extracted from the included studies and were critically appraised using a checklist appropriate to the study design. See appendices [E](#) and [F](#) for individual study and checklist details.

The available evidence was assessed by outcome for certainty using modified GRADE. See [appendix G](#) for GRADE Profiles.

4. Summary of included studies

Nine observational studies were identified for inclusion. Five studies were retrospective observational studies ([Brik et al. 2020](#), [Joseph et al. 2019](#), [Khatchadourian et al. 2014](#), [Klink et al. 2015](#), [Vlot et al. 2017](#)), 3 studies were prospective longitudinal observational studies ([Costa et al. 2015](#), [de Vries et al. 2011](#), [Schagen et al. 2016](#)) and 1 study was a cross-sectional study ([Staphorsius et al. 2015](#)).

The terminology used in this topic area is continually evolving and is different depending on stakeholder perspectives. In this evidence review we have used the phrase 'people's assigned sex at birth' rather than natal or biological sex, gonadotrophin releasing hormone (GnRH) analogues rather than 'puberty blockers' and gender-affirming hormones rather than 'cross sex hormones'. The research studies included in this evidence review may use historical terms which are no longer considered appropriate.

Table 1 provides a summary of these included studies and full details are given in [appendix E](#).

Table 1 Summary of included studies

Study	Population	Intervention and comparison	Outcomes reported
Brik et al. 2020 Retrospective observational single-centre study Netherlands	The study was conducted at the Curium-Leiden University Medical Centre gender clinic in Leiden, the Netherlands and involved adolescents with gender dysphoria. The sample size was 143 adolescents (median age at start of treatment was 15.0 years, range 11.1 to 18.6 years in transfemales; 16.1 years, range 10.1 to 17.9 years in transmales) from a sampling frame of 269 children and adolescents registered at the clinic between November 2010 and January 2018.	Intervention 143 children and adolescents receiving GnRH analogues (no specific treatment, dose, route or frequency of administration reported). The median duration was 2.1 years (range 1.6–2.8 years). Comparison No comparator.	Critical Outcomes <ul style="list-style-type: none"> No critical outcomes reported Important outcomes <ul style="list-style-type: none"> Stopping treatment

Study	Population	Intervention and comparison	Outcomes reported
	Participants were included in the study if they were diagnosed with gender dysphoria according to the DSM-5 criteria, registered at the clinic, were prepubertal and within the appropriate age range, and had started GnRH analogues. No concomitant treatments were reported.		
Costa et al. 2015 Prospective longitudinal observational single centre cohort study United Kingdom	The study was conducted at the Gender Identity Development Service in London and involved adolescents with gender dysphoria. The sample size was 201 adolescents (mean [±SD] age 15.52±1.41 years, range 12 to 17 years) from a sampling frame of 436 consecutive adolescents referred to the service between 2010 and 2014. The mean [±SD] age at the start of GnRH analogues was 16.48 [±1.26] years, range 13 to 17 years. Participants were invited to participate following a 6-month diagnostic process using DSM-IV-TR criteria. No concomitant treatments were reported.	Intervention 101 adolescents assessed as being immediately eligible for GnRH analogues (no specific treatment, dose or route of administration reported) plus psychological support. The average duration of treatment was approximately 12 months (no exact figure given). Comparison 100 adolescents assessed as not immediately eligible for GnRH analogues (more time needed to make the decision to start GnRH analogues) who had psychological support only. None received GnRH analogues throughout the study.	Critical Outcomes <ul style="list-style-type: none"> No critical outcomes reported Important outcomes <ul style="list-style-type: none"> Psychosocial impact
de Vries et al. 2011 Prospective longitudinal observational single centre before and after study Netherlands	The study was conducted at the Amsterdam gender identity clinic of the VU University Medical Centre and involved adolescents who were defined as "transsexual". The sample size was 70 adolescents receiving GnRH analogues (mean age [±SD] at assessment 13.6±1.8 years) from a sampling frame of 196 consecutive adolescents referred to the service between 2000 and 2008. Participants were invited to participate if they subsequently started gender-affirming hormones between 2003 and 2009. No diagnostic criteria or concomitant treatments were reported.	Intervention 70 individuals assessed at baseline (T0) before the start of GnRH analogues (no specific treatment, dose or route of administration reported). Comparison No comparator.	Critical Outcomes <ul style="list-style-type: none"> Gender dysphoria Mental health (depression, anger and anxiety) Important outcomes <ul style="list-style-type: none"> Body image Psychosocial impact

Study	Population	Intervention and comparison	Outcomes reported
Joseph et al. 2019 Retrospective longitudinal observational single centre study United Kingdom	This study was conducted at the Early intervention clinic at University College London Hospital (all participants had been seen at the Gender Identity Development Service in London) and involved adolescents with gender dysphoria. The sample size was 70 adolescents with gender dysphoria (no diagnostic criteria described) all offered GnRH analogues. The mean age at the start of treatment was 13.2 years (SD ± 1.4) for transfemales and 12.6 years (SD ± 1.0) for transmales. Details of the sampling frame were not reported. Further details of how the sample was drawn are not reported. No concomitant treatments were reported.	Intervention GnRH analogues. No specific treatment, duration, dose or route of administration reported. Comparison No comparator.	Critical Outcomes <ul style="list-style-type: none"> No critical outcomes reported Important outcomes <ul style="list-style-type: none"> Safety: bone density
Khatchadourian et al. 2014 Retrospective observational chart review single centre study Canada	This study was conducted at the Endocrinology and Diabetes Unit at British Columbia Children's Hospital, Canada and involved youths with gender dysphoria. The sample size was 27 young people with gender dysphoria who started GnRH analogues (at mean age 14.7 [SD ± 1.9] years) out of 84 young people seen at the unit between 1998 and 2011. Diagnostic criteria and concomitant treatments were not reported.	Intervention 84 young people with gender dysphoria. For GnRH analogues no specific treatment, duration, dose or route of administration reported. Comparison No comparator.	Critical Outcomes <ul style="list-style-type: none"> No critical outcomes reported Important outcomes <ul style="list-style-type: none"> Stopping treatment Safety: adverse effects
Klink et al. 2015 Retrospective longitudinal observational single centre study Netherlands	This study was conducted in the Netherlands at a tertiary referral centre. It is unclear which centre this was. The sample size was 34 adolescents (mean age 14.9 [SD ± 1.9] years for transfemales and 15.0 [SD ± 2.0] years for transmales at start of GnRH analogues). Details of the sampling frame are not reported. Participants were included if they met DSM-IV-TR criteria for gender identity disorder of adolescence and had been treated with GnRH analogues and gender-affirming hormones during their pubertal years. No concomitant treatments were reported.	Intervention The intervention was GnRH analogue monotherapy (triptorelin 3.75 mg subcutaneously every 4 weeks) followed by gender-affirming hormones with discontinuation of GnRH analogues after gonadectomy. Duration of GnRH analogues was 1.3 years (range 0.5 to 3.8 years) in transfemales and 1.5 years (0.25 to 5.2 years) in transmales. Comparison No comparator.	Critical Outcomes <ul style="list-style-type: none"> No critical outcomes reported Important outcomes <ul style="list-style-type: none"> Safety: bone density

Study	Population	Intervention and comparison	Outcomes reported
Schagen et al. 2016 Prospective longitudinal study Netherlands	<p>This study was conducted at the Centre of Expertise on Gender Dysphoria at the VU University Medical Centre (Amsterdam, Netherlands) and involved adolescents with gender dysphoria. The sample size was 116 adolescents (median age [range] 13.6 years [11.6 to 17.9] in transfemales and 14.2 years [11.1 to 18.6] in transmales during first year of GnRH analogues) out of 128 adolescents who started GnRH analogues.</p> <p>Participants were included if they met DSM-IV-TR criteria for gender dysphoria, had lifelong extreme gender dysphoria, were psychologically stable and were living in a supportive environment. No concomitant treatments were reported.</p>	<p>Intervention The intervention was GnRH analogue monotherapy (triptorelin 3.75 mg at 0, 2 and 4 weeks followed by intramuscular injections every 4 weeks, for at least 3 months).</p> <p>Comparison No comparator.</p>	<p>Critical Outcomes</p> <ul style="list-style-type: none"> No critical outcomes reported <p>Important outcomes</p> <ul style="list-style-type: none"> Safety: liver and renal function.
Staphorsius et al. 2015 Cross-sectional (single time point) assessment single centre study Netherlands	<p>This study was conducted at the VU University Medical Centre (Amsterdam, Netherlands) and involved adolescents with gender dysphoria. The sample size was 85, of whom 40 were adolescents with gender dysphoria (20 of whom were being treated with GnRH analogues) and 45 were controls without gender dysphoria (not further reported here). Mean (\pmSD) age 15.1 (\pm2.4) years in transfemales and 15.8 (\pm1.9) years in transmales. Details of the sampling frame are not reported.</p> <p>Participants were included if they were diagnosed with Gender Identity Disorder according to the DSM-IV-TR and at least 12 years old and Tanner stage of at least B2 or G2 to G3 with measurable oestradiol and testosterone levels in girls and boys, respectively. No concomitant treatments were reported.</p>	<p>Intervention The intervention was a GnRH analogue (triptorelin 3.75 mg every 4 weeks subcutaneously or intramuscularly). The mean duration of treatment was 1.6 years (SD \pm1.0).</p> <p>Comparison Adolescents with gender dysphoria not treated with GnRH analogues.</p>	<p>Critical Outcomes</p> <ul style="list-style-type: none"> No critical outcomes reported <p>Important outcomes</p> <ul style="list-style-type: none"> Psychosocial impact Safety: cognitive functioning
Vlot et al. 2017 Retrospective observational data analysis study	<p>This study was conducted at the VU University Medical Centre (Amsterdam, Netherlands) and involved adolescents with gender dysphoria. The sample size was 70 adolescents (median age [range] 15.1 years [11.7 to 18.6] for</p>	<p>Intervention The intervention was a GnRH analogue (triptorelin 3.75 mg every 4 weeks subcutaneously).</p> <p>Comparison No comparator.</p>	<p>Critical Outcomes</p> <ul style="list-style-type: none"> No critical outcomes reported <p>Important outcomes</p>

5. Results

In children and adolescents with gender dysphoria, what is the clinical effectiveness of treatment with GnRH analogues compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention?

Outcome	Evidence statement
Clinical Effectiveness	
Critical outcomes	
Impact on gender dysphoria Certainty of evidence: very low	<p>This is a critical outcome because gender dysphoria in children and adolescents is associated with significant distress and problems with functioning.</p> <p>One uncontrolled, prospective observational longitudinal study (de Vries et al. 2011) provided evidence relating to the impact on gender dysphoria in adolescents, measured using the Utrecht Gender Dysphoria Scale (UGDS). The UGDS is a validated screening tool for both adolescents and adults to assess gender dysphoria. It consists of 12 items, to be answered on a 1- to 5-point scale, resulting in a sum score between 12 and 60. The higher the UGDS score the greater the gender dysphoria.</p> <p>The study measured the impact on gender dysphoria at 2 time points:</p> <ul style="list-style-type: none"> before starting a GnRH analogue (mean [\pmSD] age: 14.75 [\pm1.92] years), and shortly before starting gender-affirming hormones (mean [\pmSD] age: 16.64 [\pm1.90] years). <p>The mean (\pmSD) UGDS score was not statistically significantly different at baseline compared with follow-up (n=41, 53.20 [\pm7.91] versus 53.9 [\pm17.42], p=0.333) (VERY LOW).</p>

	<p>This study provides very low certainty evidence that treatment with GnRH analogues, before starting gender-affirming hormones, does not affect gender dysphoria.</p>
<p>Impact on mental health: depression</p> <p>Certainty of evidence: very low</p>	<p>This is a critical outcome because self-harm and thoughts of suicide have the potential to result in significant physical harm and, for completed suicides, the death of the young person.</p> <p>One uncontrolled, prospective observational longitudinal study (de Vries et al. 2011) provided evidence relating to the impact on depression in children and adolescents with gender dysphoria. Depression was measured using the Beck Depression Inventory-II (BDI-II). The BDI-II is a valid, reliable, and widely used tool for assessing depressive symptoms. There are no specific scores to categorise depression severity, but it is suggested that 0 to 13 is minimal symptoms, 14 to 19 is mild depression, 20 to 28 is moderate depression, and severe depression is 29 to 63.</p> <p>The study provided evidence for depression measured at 2 time points:</p> <ul style="list-style-type: none"> • before starting a GnRH analogue (mean [\pmSD] age: 14.75 [\pm1.92] years), and • shortly before starting gender-affirming hormones (mean [\pmSD] age: 16.64 [\pm1.90] years). <p>The mean (\pmSD) depression (BDI) score was statistically significantly lower (improved) from baseline compared with follow-up (n=41, 8.31 [\pm7.12] versus 4.95 [\pm6.72], p=0.004) (VERY LOW).</p> <p>This study provides very low certainty evidence that treatment with GnRH analogues, before starting gender-affirming hormones, may reduce depression.</p>
<p>Impact on mental health: anger</p> <p>Certainty of evidence: very low</p>	<p>This is a critical outcome because self-harm and thoughts of suicide have the potential to result in significant physical harm and, for completed suicides, the death of the young person.</p> <p>One uncontrolled, prospective observational longitudinal study (de Vries et al. 2011) provided evidence relating to the impact on anger in children and adolescents with gender dysphoria. Anger was measured using the Trait Anger Scale of the State-Trait Personality Inventory (TPI). This is a validated 20-item inventory tool which measures the intensity of anger as the disposition to experience angry feelings as a personality trait. Higher scores indicate greater anger.</p> <p>The study provided evidence for anger measured at 2 time points:</p> <ul style="list-style-type: none"> • before starting a GnRH analogue (mean [\pmSD] age: 14.75 [\pm1.92] years), and • shortly before starting gender-affirming hormones (mean [\pmSD] age: 16.64 [\pm1.90] years). <p>The mean (\pmSD) anger (TPI) score was not statistically significantly different at baseline compared with follow-up (n=41, 18.29 [\pm5.54] versus 17.88 [\pm5.24], p=0.503) (VERY LOW).</p> <p>This study provides very low certainty evidence that treatment with GnRH analogues, before starting gender-affirming hormones, does not affect anger.</p>

<p>Impact on mental health: anxiety</p> <p>Certainty of evidence: very low</p>	<p>This is a critical outcome because self-harm and thoughts of suicide have the potential to result in significant physical harm and, for completed suicides, the death of the young person.</p> <p>One uncontrolled, prospective observational longitudinal study (de Vries et al. 2011) provided evidence relating to the impact on anxiety in children and adolescents with gender dysphoria. Anxiety was measured using the Trait Anxiety Scale of the State-Trait Personality Inventory (STAI). This is a validated and commonly used measure of trait and state anxiety. It has 20 items and can be used in clinical settings to diagnose anxiety and to distinguish it from depressive illness. Higher scores indicate greater anxiety.</p> <p>The study provided evidence for anxiety at 2 time points:</p> <ul style="list-style-type: none"> • before starting a GnRH analogue (mean [\pmSD] age: 14.75 [\pm1.92] years), and • shortly before starting gender-affirming hormones (mean [\pmSD] age: 16.64 [\pm1.90] years). <p>The mean (\pmSD) anxiety (STAI) score was not statistically significantly different at baseline compared with follow-up (n=41, 39.43 [\pm10.07] versus 37.95 [\pm9.38], p=0.276) (VERY LOW).</p> <p>This study provides very low certainty evidence that treatment with GnRH analogues, before starting gender-affirming hormones, does not affect levels of anxiety.</p>
<p>Quality of life</p>	<p>This is a critical outcome because gender dysphoria in children and adolescents may be associated with a significant reduction in health-related quality of life.</p> <p>No evidence was identified.</p>
<p>Important outcomes</p>	
<p>Impact on body image</p> <p>Certainty of evidence: very low</p>	<p>This is an important outcome because some children and adolescents with gender dysphoria may want to take steps to suppress features of their physical appearance associated with their sex assigned at birth or accentuate physical features of their desired gender.</p> <p>One uncontrolled, prospective observational longitudinal study provided evidence relating to the impact on body image (de Vries et al. 2011). Body image was measured using the Body Image Scale (BIS) which is a validated 30-item scale covering 3 aspects: primary, secondary and neutral body characteristics. Higher scores represent a higher degree of body dissatisfaction.</p> <p>The study (de Vries et al. 2011) provided evidence for body image measured at 2 time points:</p> <ul style="list-style-type: none"> • before starting a GnRH analogue (mean [\pmSD] age: 14.75 [\pm1.92] years), and • shortly before starting gender-affirming hormones (mean [\pmSD] age: 16.64 [\pm1.90] years). <p>The mean (\pmSD) body image (BIS) scores for were not statistically significantly different from baseline compared with follow-up for:</p>

	<ul style="list-style-type: none"> • primary sexual characteristics (n=57, 4.10 [\pm0.56] versus 3.98 [\pm0.71], p=0.145) • secondary sexual characteristics (n=57, 2.74 [\pm0.65] versus 2.82 [\pm0.68], p=0.569) • neutral body characteristics (n=57, 2.41 [\pm0.63] versus 2.47 [\pm0.56], p=0.620) (VERY LOW). <p>This study provides very low certainty evidence that treatment with GnRH analogues, before starting gender affirming hormones, does not affect body image.</p>
<p>Psychosocial impact: global functioning</p> <p>Certainty of evidence: very low</p>	<p>This is an important outcome because gender dysphoria in children and adolescents is associated with internalising and externalising behaviours, and emotional and behavioural problems which may impact on social and occupational functioning.</p> <p>One uncontrolled, observational, prospective cohort study (de Vries et al 2011) and one prospective cross-sectional cohort study (Costa et al. 2015) provided evidence relating to psychosocial impact in terms of global functioning. Global functioning was measured using the Children's Global Assessment Scale (CGAS). The CGAS tool is a validated measure of global functioning on a single rating scale from 1 to 100. Lower scores indicate poorer functioning.</p> <p>One study (de Vries et al. 2011) provided evidence for global functioning (CGAS) at 2 time points:</p> <ul style="list-style-type: none"> • before starting a GnRH analogue (mean [\pmSD] age: 14.75 [\pm1.92] years), and • shortly before starting gender-affirming hormones (mean [\pmSD] age: 16.64 [\pm1.90] years). <p>The mean (\pmSD) CGAS score was statistically significantly higher (improved) from baseline compared with follow-up (n=41, 70.24 [\pm10.12] versus 73.90 [\pm9.63], p=0.005) (VERY LOW).</p> <p>One study (Costa et al. 2015) in adolescents with gender dysphoria who had 6 months of psychological support followed by either GnRH analogues and continued psychological support (the immediately eligible group) or continued psychological support only (the delayed eligible group who did not receive GnRH analogues) provided evidence for global functioning (CGAS) measured at 4 time points:</p> <ul style="list-style-type: none"> • at baseline (T0) in both groups, • after 6 months of psychological support in both groups (T1), • after 6 months of GnRH analogues and 12 months of psychological support in the immediately eligible group and 12 months of psychological support only in the delayed eligible group (T2), and • after 18 months of psychological support and 12 months of GnRH analogues in the immediately eligible group and after 18 months of psychological support only in the delayed eligible group (T3). <p>The mean [\pmSD] CGAS score was statistically significantly higher (improved) for all adolescents (including those not receiving GnRH analogues) at T1, T2 or T3 compared with baseline (T0).</p>

	<p>For the immediately eligible group (who received GnRH analogues) versus the delayed eligible group (who did not receive GnRH analogues) there were no statistically significant differences in CGAS scores between the 2 groups at baseline T0 (n=201, p=0.23), T1 (n=201, p=0.73), T2 (n=121, p=0.49) or T3 (n=71, p=0.14) time points.</p> <p>For the immediately eligible group (who received GnRH analogues), the mean (\pmSD) CGAS score was not statistically significantly different at:</p> <ul style="list-style-type: none"> • T1 compared with T0 • T2 compared with T1 • T3 compared with T2. <p>The mean (\pmSD) CGAS score was statistically significantly higher (improved) at:</p> <ul style="list-style-type: none"> • T2 compared with T0 (n=60, 64.70 [\pm13.34] versus n=101, 58.72 [\pm11.38], p=0.003) • T3 compared with T0 (n=35, 67.40 [\pm13.39] versus n=101, 58.72 [\pm11.38], p<0.001) • T3 compared with T1 (n=35, 67.40 [\pm13.93] versus n=101, 60.89 [\pm12.17], p<0.001) (VERY LOW). <p>These studies provide very low certainty evidence that during treatment with GnRH analogues, global functioning may improve over time. However, there was no statistically significant difference in global functioning between GnRH analogues plus psychological support compared with psychological support only at any time point.</p>
<p>Psychosocial impact: psychosocial functioning</p> <p>Certainty of evidence: very low</p>	<p>This is an important outcome because gender dysphoria in children and adolescents is associated with internalising and externalising behaviours, and emotional and behavioural problems which may impact on social and occupational functioning.</p> <p>Two studies provided evidence for this outcome. One uncontrolled, observational, prospective cohort study (de Vries et al. 2011) and 1 cross-sectional observational study (Staphorsius et al. 2015) assessed psychosocial functioning using the Child Behaviour Checklist (CBCL) and the self-administered Youth Self-Report (YSR). The CBCL is a checklist parents complete to detect emotional and behavioural problems in children and adolescents. YSR is similar but is self-completed by the child or adolescent. The scales consist of a Total problems score, which is the sum of the scores of all the problem items. An internalising problem scale sums the anxious/depressed, withdrawn-depressed, and somatic complaints scores while the externalising problem scale combines rule-breaking and aggressive behaviour. The standard scores are scaled so that 50 is average for the child or adolescent's age and gender, with a SD of 10 points. Higher scores indicate greater problems, with a T-score above 63 considered to be in the clinical range.</p> <p>One study (de Vries et al. 2011) provided evidence for psychosocial functioning (CBCL and YSR scores) at 2 time points:</p> <ul style="list-style-type: none"> • before starting a GnRH analogue (mean [\pmSD] age: 14.75 [\pm1.92] years), and

	<ul style="list-style-type: none"> • shortly before starting gender-affirming hormones (mean [±SD] age: 16.64 [±1.90] years). <p>At follow up, the mean (±SD) CBCL scores were statistically significantly lower (improved) compared with baseline for:</p> <ul style="list-style-type: none"> • Total T score (n=54, 60.70 [±12.76] versus 54.46 [±11.23], p<0.001 • Internalising T score (n=54, 61.00 [±12.21] versus 52.17 [±9.81], p<0.001) • Externalising T score (n=54, 58.04 [±12.99] versus 53.81 [±11.86], p=0.001). <p>At follow up, the mean (±SD) YSR scores were statistically significantly lower (improved) compared with baseline for:</p> <ul style="list-style-type: none"> • Total T score (n=54, 55.46 [±11.56] versus 50.00 [±10.56], p<0.001) • Internalising T score (n=54, 56.04 [±12.49] versus 49.78 [±11.63], p<0.001) • Externalising T score (n=54, 53.30 [±11.87] versus 49.98 [±9.35], p=0.009). <p>The proportion of adolescents scoring in the clinical range decreased from baseline to follow up on the CBCL total problem scale (44.4% versus 22.2%, p=0.001) and the internalising scale of the YSR (29.6% versus 11.1%, p=0.017) (VERY LOW).</p> <p>One study (Staphorsius et al. 2015) assessed CBCL in a cohort of adolescents with gender dysphoria (transfemale: n=18, mean [±SD] age 15.1 [±2.4] years and transmale: n=22, mean [±SD] age 15.8 [±1.9] years) either receiving GnRH analogues (transfemale, n=8 and transmale, n=12), or not receiving GnRH analogues (transfemale, n=10 and transmale, n=10).</p> <p>The mean (±SD) CBCL scores for each group were (statistical analysis unclear):</p> <ul style="list-style-type: none"> • transfemales (total) 57.8 [±9.2] • transfemales receiving GnRH analogues 57.4 [±9.8] • transfemales not receiving GnRH analogues 58.2 [±9.3] • transmales (total) 60.4 [±10.2] • transmales receiving GnRH analogues 57.5 [±9.4] • transmales not receiving GnRH analogues 63.9 [±10.5] (VERY LOW). <p>These studies provide very low certainty evidence that during treatment with GnRH analogues psychosocial functioning may improve, with the proportion of adolescents in the clinical range for some CBCL and YSR scores decreasing over time.</p>
<p>Engagement with health care services</p> <p>Certainty of evidence: very low</p>	<p>This is an important outcome because patient engagement with health care services will impact on their clinical outcomes.</p> <p>Two uncontrolled observational cohort studies provided evidence relating to loss to follow up, which could be a marker of engagement with health care services (Brik et al. 2018 and Costa et al. 2015).</p>

	<p>In one retrospective study (Brik et al. 2018), 9 adolescents (9/214, 4.2%) who had stopped attending appointments were excluded from the study between November 2010 and July 2019 (VERY LOW).</p> <p>One prospective study (Costa et al. 2015) had evidence for a large loss to follow-up over time. The sample size at baseline (T0) and 6 months (T1) was 201, which dropped by 39.8% to 121 after 12 months (T2) and by 64.7% to 71 at 18 months follow-up (T3). No explanation of the reasons for loss to follow-up are reported (VERY LOW).</p> <p>Due to their design there was no reported loss to follow-up in the other 3 effectiveness studies (de Vries et al 2011; Khatchadourian et al. 2014; Staphorsius et al. 2015).</p> <p>These studies provide very low certainty evidence about loss to follow up, which could be a marker of engagement with health care services, during treatment with GnRH analogues. Due to the large variation in rates between studies no conclusions could be drawn.</p>
Impact on extent of and satisfaction with surgery	<p>This is an important outcome because some children and adolescents with gender dysphoria may proceed to transitioning surgery.</p> <p>No evidence was identified.</p>
Stopping treatment Certainty of evidence: very low	<p>This is an important outcome because there is uncertainty about the short- and long-term safety and adverse effects of GnRH analogues in children and adolescents with gender dysphoria.</p> <p>Two uncontrolled, retrospective, observational cohort studies provided evidence relating to stopping GnRH analogues. One study had complete reporting of the cohort (Brik et al. 2018), the other (Khatchadourian et al. 2014) had incomplete reporting of its cohort, particularly for transfemales where outcomes for only 4/11 were reported.</p> <p>Brik et al. 2018 narratively reported the reasons for stopping GnRH analogues in a cohort of 143 adolescents (38 transfemales and 105 transmales). Median age at the start of GnRH analogues was 15.0 years (range, 11.1–18.6 years) in transfemales and 16.1 years (range, 10.1–17.9 years) in transmales. Of these adolescents, 125 (87%, 36 transfemales, 89 transmales) subsequently started gender-affirming hormones after 1.0 (0.5–3.8) and 0.8 (0.3–3.7) years of GnRH analogues. At the time of data collection, the median duration of GnRH analogue use was 2.1 years (1.6–2.8).</p> <p>During the follow-up period 6.3% (9/143) of adolescents had discontinued GnRH analogues after a median duration of 0.8 years (range 0.1 to 3.0). The percentages and reasons for stopping were:</p> <ul style="list-style-type: none"> • 2.8% (4/143) stopped GnRH analogues although they wanted to continue endocrine treatments for gender dysphoria: <ul style="list-style-type: none"> ○ 1 transmale stopped due to increase in mood problems, suicidal thoughts and confusion attributed to GnRH analogues ○ 1 transmale had hot flushes, increased migraines, fear of injections, stress at school and unrelated medical issues, and temporarily stopped treatment (after 4 months) and restarted 5 months later.

	<ul style="list-style-type: none"> ○ 1 transmale had mood swings 4 months after starting GnRH analogues. After 2.2 years had unexplained severe nausea and rapid weight loss and discontinued GnRH analogues after 2.4 years ○ 1 transmale stopped GnRH analogues because of inability to regularly collect medication and attend appointments for injections. ● 3.5% (5/143) stopped treatment because they no longer wished to receive gender-affirming treatment for various reasons (VERY LOW). <p>Khatchadourian et al. 2014 narratively reported the reasons for stopping GnRH analogues in a cohort of 26 adolescents (15 transmales and 11 transfemales), 42% (11/26) discontinued GnRH analogues during follow-up between 1998 and 2011.</p> <p>Of 15 transmales receiving GnRH analogues, 14 received testosterone during the observation period, of which:</p> <ul style="list-style-type: none"> ● 7 continued GnRH analogues after starting testosterone ● 7 stopped GnRH analogues after a median of 3.0 years (range 0.2 to 9.2 years), of which: <ul style="list-style-type: none"> ○ 5 stopped after hysterectomy and salpingo-oophorectomy ○ 1 stopped after 2.2 years (transitioned to gender-affirming hormones) ○ 1 stopped after <2 months due to mood and emotional lability (VERY LOW). <p>Of 11 transfemales receiving GnRH analogues, 5 received oestrogen during the observation period, of which:</p> <ul style="list-style-type: none"> ● 4 continued GnRH analogues after starting oestrogen ● 1 stopped GnRH analogues when taking oestrogen (no reason reported) (VERY LOW). <p>Of the remaining 6 transfemales taking GnRH analogues:</p> <ul style="list-style-type: none"> ● 1 stopped GnRH analogues after a few months due to emotional lability ● 1 stopped GnRH analogues before taking oestrogen (the following year delayed due to heavy smoking) ● 1 stopped GnRH analogues after 13 months due not to pursuing transition (VERY LOW). <p>These studies provide very low certainty evidence for the number of adolescents who stop GnRH analogues and the reasons for this.</p>

In children and adolescents with gender dysphoria, what is the short-term and long-term safety of GnRH analogues compared with one or a combination of psychological support, social transitioning to the desired gender or no intervention?

Outcome	Evidence statement
---------	--------------------

Safety	
<p>Change in bone density: lumbar</p> <p>Certainty of evidence: very low</p>	<p>This is an important outcome because puberty is an important time for bone development and puberty suppression may affect bone development, as shown by changes in lumbar bone density.</p> <p>Three uncontrolled, observational, retrospective studies provided evidence relating to the effect of GnRH analogues on bone density (based on lumbar BMAD) between starting with a GnRH analogue and at 1 and 2 year intervals (Joseph et al. 2019), and between starting GnRH analogues and starting gender-affirming hormones (Klink et al. 2015 and Vlot et al. 2017). All outcomes were reported separately for transfemales and transmales; also see subgroups table below.</p> <p>BMAD is a size adjusted value of BMD incorporating body size measurements using UK norms in growing adolescents. It was reported as g/cm³ and as z-scores. Z-scores report how many standard deviations from the mean a measurement sits. A z-score of 0 is equal to the mean, a z-score of -1 is equal to 1 standard deviation below the mean, and a z-score of +1 is equal to 1 standard deviation above the mean.</p> <p>One retrospective observational study (Joseph et al. 2019, n=70) provided non-comparative evidence on change in lumbar BMAD increase using z-scores.</p> <ul style="list-style-type: none"> • The z-score for lumbar BMAD was statistically significantly lower at 2 years compared with baseline in transfemales (z-score [±SD]: baseline 0.486 [0.809], 2 years -0.279 [0.930], p=0.000) and transmales (baseline -0.361 [1.439], 2 years -0.913 [1.318], p=0.001) (VERY LOW). • The z-score for lumbar BMAD was statistically significantly lower at 1 year compared with baseline in transfemales (baseline 0.859 [0.154], 1 year -0.228 [1.027], p=0.000) and transmales (baseline -0.186 [1.230], 1 year -0.541 [1.396], p=0.006) (VERY LOW). • Actual lumbar BMAD values in g/cm³ were not statistically significantly different between baseline and 1 or 2 years in transfemales or transmales (VERY LOW). <p>Two retrospective observational studies (Klink et al. 2015 and Vlot et al. 2017, n=104 in total) provided non-comparative evidence on change in lumbar BMAD between starting GnRH analogues and starting gender-affirming hormones. All outcomes were reported separately for transfemales and transmales; also see subgroups table below.</p> <p>In Klink et al. 2015 the z-score for lumbar BMAD was not statistically significantly different between starting GnRH analogues and starting gender-affirming hormones in transfemales but was statistically significantly lower when starting gender-affirming hormones in transmales (z-score mean [±SD]: GnRH analogue 0.28 [±0.90], gender-affirming hormone -0.50 [±0.81], p=0.004). Actual lumbar BMAD values in g/cm³ were not statistically significantly different between starting GnRH analogues and starting gender-affirming hormones in transfemales or transmales (VERY LOW).</p>

Vlot et al. 2017 reported change from starting GnRH analogues to starting gender-affirming hormones in lumbar BMAD by bone age.

- The z-score for lumbar BMAD in transfemales with a bone age of <15 years was statistically significantly lower at starting gender-affirming hormone treatment than at starting GnRH analogues (z-score median [range]: GnRH analogue -0.20 [-1.82 to 1.18], gender-affirming hormone -1.52 [-2.36 to 0.42], $p=0.001$) but was not statistically significantly different in transfemales with a bone age ≥ 15 years (**VERY LOW**).
- The z-score for lumbar BMAD in transmales with a bone age of <14 years was statistically significantly lower at starting gender-affirming hormone treatment than at starting GnRH analogues (z-score median [range]: GnRH analogue -0.05 [-0.78 to 2.94], gender-affirming hormone -0.84 [-2.20 to 0.87], $p=0.003$) and in transmales with a bone age ≥ 14 years (GnRH analogue 0.27 [-1.60 to 1.80], gender-affirming hormone -0.29 [-2.28 to 0.90], $p\leq 0.0001$) (**VERY LOW**).
- Actual lumbar BMAD values in g/cm^3 were not statistically significantly different between starting GnRH analogues and starting gender-affirming hormones in transfemales or transmales with young or old bone age (**VERY LOW**).

Two uncontrolled, observational, retrospective studies provided evidence for the effect of GnRH analogues on bone density (based on lumbar BMD) between starting GnRH analogues and either at 1 or 2 year intervals ([Joseph et al. 2019](#)), or starting gender-affirming hormones ([Klink et al. 2015](#)). All outcomes were reported separately for transfemales and transmales; also see subgroups table below.

One retrospective observational study ([Joseph et al. 2019](#), $n=70$) provided non-comparative evidence on change in lumbar BMD increase using z-scores.

- The z-score for lumbar BMD was statistically significantly lower at 2 years compared with baseline in transfemales (z-score mean [\pm SD]: baseline 0.130 [0.972], 2 years -0.890 [± 1.075], $p=0.000$) and transmales (baseline -0.715 [± 1.406], 2 years -2.000 [1.384], $p=0.000$) (**VERY LOW**).
- The z-score for lumbar BMD was statistically significantly lower at 1 year compared with baseline in transfemales (z-score mean [\pm SD]: baseline -0.016 [± 1.106], 1 year -0.461 [± 1.121], $p=0.003$) and transmales (baseline -0.395 [± 1.428], 1 year -1.276 [± 1.410], $p=0.000$) (**VERY LOW**).
- With the exception of transmales, where lumbar BMD in kg/m^2 increased between baseline and 1 year (mean [\pm SD]: baseline 0.694 [± 0.149], 1 year 0.718 [± 0.124], $p=0.006$), actual lumbar BMD values were not statistically significantly different between baseline and 1 or 2 years in transfemales or between 0 and 2 years in transmales (**VERY LOW**).

One retrospective observational study ([Klink et al. 2015](#), $n=34$) provided non-comparative evidence on change in lumbar BMD between starting GnRH analogues and starting gender-affirming hormones.

- The z-score for lumbar BMD was not statistically significantly different between starting GnRH analogue and starting gender-affirming hormone treatment in transfemales, but was

	<p>statistically significantly lower when starting gender-affirming hormones in transmales (z-score mean [±SD]: GnRH analogue 0.17 [±1.18], gender-affirming hormone -0.72 [±0.99], $p < 0.001$) (VERY LOW).</p> <ul style="list-style-type: none"> Actual lumbar BMD in g/cm² was not statistically significantly different between starting GnRH analogues and starting gender-affirming hormones in transfemales but was statistically significantly lower when starting gender-affirming hormones in transmales (mean [±SD]: GnRH analogues 0.95 [±0.12], gender-affirming hormones 0.91 [±0.10], $p = 0.006$) (VERY LOW). <p>These studies provide very low certainty evidence that GnRH analogues reduce the expected increase in lumbar bone density (BMAD or BMD) compared with baseline (although some findings were not statistically significant). These studies also show that GnRH analogues do not statistically significantly decrease actual lumbar bone density (BMAD or BMD).</p>
<p>Change in bone density: femoral</p> <p>Certainty of evidence: very low</p>	<p>This is an important outcome because puberty is an important time for bone development and puberty suppression may affect bone development, as shown by changes in femoral bone density.</p> <p>Two uncontrolled, observational, retrospective studies provided evidence relating to the effect of GnRH analogues on bone density (based on femoral BMAD) between starting treatment with a GnRH analogue and starting gender-affirming hormones (Klink et al. 2015 and Vlot et al. 2017). All outcomes were reported separately for transfemales and transmales; also see subgroups table below.</p> <p>One retrospective observational study (Klink et al. 2015, $n = 34$) provided non-comparative evidence on change in femoral area BMAD between starting GnRH analogues and starting gender-affirming hormones. All outcomes were reported separately for transfemales and transmales.</p> <ul style="list-style-type: none"> The z-score for femoral area BMAD was not statistically significantly different between starting GnRH analogues and starting gender-affirming hormones in transfemales or transmales (VERY LOW). Actual femoral area BMAD values were not statistically significantly different between starting GnRH analogues and starting gender-affirming hormones in transmales or transfemales (VERY LOW). <p>One retrospective observational study (Vlot et al. 2017, $n = 70$) provided non-comparative evidence on change in femoral neck (hip) BMAD between starting GnRH analogues and starting gender-affirming hormones. All outcomes were reported separately for transfemales and transmales; also see subgroups table below.</p> <ul style="list-style-type: none"> The z-score for femoral neck BMAD in transfemales with a bone age of <15 years was not statistically significantly lower at starting gender-affirming hormones than at starting GnRH analogues (z-score median [range]: GnRH analogue -0.71 [-3.35 to 0.37], gender-affirming hormone -1.32 [-3.39 to 0.21], $p \leq 0.1$) or in transfemales with a bone age ≥ 15 years (GnRH analogue -0.44 [-1.37 to 0.93], gender-affirming hormone -0.36 [-1.50 to 0.46]) (VERY LOW).

- The z-score for femoral neck BMAD in transmales with a bone age of <14 years was not statistically significantly lower at starting gender-affirming hormones than at starting GnRH analogues (z-score median [range]: GnRH analogue -0.01 [-1.30 to 0.91], gender-affirming hormone -0.37 [-2.28 to 0.47]) but was statistically significantly lower in transmales with a bone age ≥14 years (GnRH analogue 0.27 [-1.39 to 1.32], gender-affirming hormone -0.27 [-1.91 to 1.29], p=0.002) (**VERY LOW**).
- Actual femoral neck BMAD values were not statistically significantly different between starting GnRH analogues and starting gender-affirming hormones in transfemales or in transmales with a young bone age, but were statistically significantly lower in transmales with a bone age ≥14 years (GnRH analogue 0.33 [0.25 to 0.39], gender-affirming hormone 0.30 [0.23 to 0.41], p≤0.01) (**VERY LOW**).

Two uncontrolled, observational, retrospective studies provided evidence for the effect of GnRH analogues on bone density (based on femoral BMD) between starting GnRH analogues and either at 1 or 2 year intervals (Joseph et al. 2019), or starting gender-affirming hormones (Klink et al. 2015). All outcomes were reported separately for transfemales and transmales; also see subgroups table below.

One retrospective observational study (Joseph et al. 2019, n=70) provided non-comparative evidence on change in femoral neck BMD increase using z-scores. All outcomes were reported separately for transfemales and transmales.

- The z-score for femoral neck BMD was statistically significantly lower at 2 years compared with baseline in transfemales (z-score mean [±SD]: baseline 0.0450 [±0.781], 2 years -0.600 [±1.059], p=0.002) and transmales (baseline -1.075 [±1.145], 2 years -1.779 [±0.816], p=0.001) (**VERY LOW**).
- The z-score for femoral neck BMD was statistically significantly lower at 1 year compared with baseline in transfemales (z-score mean [±SD]: baseline 0.157 [±0.905], 1 year -0.340 [±0.816], p=0.002) and transmales (baseline -0.863 [±1.215], 1 year -1.440 [±1.075], p=0.000) (**VERY LOW**).
- Actual femoral neck BMD values in kg/m² were not statistically significantly different between baseline and 1 or 2 years in transmales or transfemales (**VERY LOW**).

One retrospective observational study (Klink et al. 2015, n=34) provided non-comparative evidence on change in femoral area BMD between starting GnRH analogues and starting gender-affirming hormones. All outcomes were reported separately for transfemales and transmales.

- The z-score for femoral area BMD was not statistically significantly different between starting GnRH analogues and starting gender-affirming hormones in transfemales, but was statistically significantly lower in transmales (z-score mean [±SD]: GnRH analogue 0.36 [±0.88], gender-affirming hormone -0.35 [±0.79], p=0.001) (**VERY LOW**).
- Actual femoral area BMD values were not statistically significantly different between starting GnRH analogues and starting gender-affirming hormones in transfemales, but were

	<p>statistically significantly lower in transmales (mean [±SD] GnRH analogue 0.92 [±0.10], gender-affirming hormone 0.88 [±0.09], $p=0.005$) (VERY LOW).</p> <p>These studies provide very low certainty evidence that GnRH analogues may reduce the expected increase in femoral bone density (femoral neck or area BMAD or BMD) compared with baseline (although some findings were not statistically significant). These studies also show that GnRH analogues do not statistically significantly decrease actual femoral bone density (femoral area BMAD or femoral neck BMD), apart from actual femoral area BMD in transmales.</p>
<p>Cognitive development or functioning</p> <p>Certainty of evidence: very low</p>	<p>This is an important outcome because puberty is an important time for cognitive development and puberty suppression may affect cognitive development or functioning.</p> <p>One cross-sectional observational study (Staphorsius et al. 2015, $n=70$) provided comparative evidence on cognitive development or functioning in adolescents with gender dysphoria on GnRH analogues compared with adolescents with gender dysphoria not on GnRH analogues. Cognitive functioning was measured using an IQ test. Reaction time (in seconds) and accuracy (percentage of correct trials) were measured using the Tower of London (ToL) task. All outcomes were reported separately for transfemales and transmales; also see subgroups table below. No statistical analyses or interpretation of the results in these groups were reported:</p> <ul style="list-style-type: none"> • IQ in transfemales (mean [±SD] GnRH analogue 94.0 [±10.3], control 109.4 [±21.2]). IQ transmales (GnRH analogue 95.8 [±15.6], control 98.5 [±15.9]). • Reaction time in transfemales (mean [±SD] GnRH analogue 10.9 [±4.1], control: 9.9 [±3.1]). Reaction time transmales (GnRH analogue 9.9 [±3.1], control 10.0 [±2.0]). • Accuracy score in transfemales (GnRH analogue 73.9 [±9.1], control 83.4 [±9.5]). Accuracy score in transmales (GnRH analogue 85.7 [±10.5], control 88.8 [±9.7]). <p>This study provides very low certainty evidence (with no statistical analysis) on the effects of GnRH analogues on cognitive development or functioning. No conclusions could be drawn.</p>
<p>Other safety outcomes: kidney function</p> <p>Certainty of evidence: very low</p>	<p>This is an important outcome because if renal damage (raised serum creatinine is a marker of this) is suspected, GnRH analogues may need to be stopped.</p> <p>One prospective observational study (Schagen et al. 2016, $n=116$) provided non-comparative evidence on change in serum creatinine between starting GnRH analogues and at 1 year. All outcomes were reported separately for transfemales and transmales; also see subgroups table below.</p> <ul style="list-style-type: none"> • There was no statistically significant difference between baseline and 1 year for serum creatinine in transfemales (mean [±SD] baseline 70 [±12], 1 year 66 [±13], $p=0.20$). • There was a statistically significant decrease between baseline and 1 year for serum creatinine in transmales (baseline 73 [±8], 1 year 68 [±13], $p=0.01$).

	<p>This study provides very low certainty evidence that GnRH analogues do not affect renal function.</p>
<p>Other safety outcomes: liver function</p> <p>Certainty of evidence: very low</p>	<p>This is an important outcome because if treatment-induced liver injury (raised liver enzymes are a marker of this) is suspected, GnRH analogues may need to be stopped.</p> <p>One prospective observational study (Schagen et al. 2016, n=116) provided non-comparative evidence on elevated liver enzymes between starting GnRH analogues and during use. No comparative values or statistical analyses were reported.</p> <ul style="list-style-type: none"> • Glutaryl transferase was not elevated at baseline or during use in any person. • Mild elevations of AST and ALT above the reference range were present at baseline but were not more prevalent during use than at baseline. • Glutaryl transferase, AST, and ALT levels did not significantly change from baseline to 12 months of use. <p>This study provides very low certainty evidence (with no statistical analysis) that GnRH analogues do not affect liver function.</p>
<p>Other safety outcomes: adverse effects</p> <p>Certainty of evidence: very low</p>	<p>This is an important outcome because if there are adverse effects, GnRH analogues may need to be stopped.</p> <p>One uncontrolled, retrospective, observational cohort study (Khatchadourian et al. 2014) provided evidence relating to adverse effects from GnRH analogues. It had incomplete reporting of its cohort, particularly for transfemales where outcomes for only 4/11 were reported.</p> <p>Khatchadourian et al. 2014 reported adverse effects in a cohort of 26 adolescents (15 transmales and 11 transfemales) receiving GnRH analogues. Of these:</p> <ul style="list-style-type: none"> • 1 transmale developed sterile abscesses; they were switched from leuprolide acetate to triptorelin, and this was well tolerated. • 1 transmale developed leg pains and headaches, which eventually resolved • 1 participant gained 19 kg within 9 months of starting GnRH analogues. <p>This study provides very low certainty evidence about potential adverse effects of GnRH analogues. No conclusions could be drawn.</p>

Abbreviations: ALT, alanine aminotransferase; AST, aspartate aminotransferase; BMAD, bone mineral apparent density; BMD, bone mineral density; GnRH, gonadotrophin releasing hormone; IQ, intelligence quotient; NS, not significant; SD, standard deviation.

In children and adolescents with gender dysphoria, what is the cost-effectiveness of GnRH analogues compared to one or a combination of psychological support, social transitioning to the desired gender or no intervention?

Outcome	Evidence statement
---------	--------------------

Cost-effectiveness	No studies were identified to assess the cost-effectiveness of GnRH analogues for children and adolescents with gender dysphoria.
---------------------------	---

From the evidence selected, are there any subgroups of children and adolescents with gender dysphoria that may benefit from GnRH analogues more than the wider population of interest?

Subgroup	Evidence statement
Sex assigned at birth males (transfemales) Certainty of evidence: Very low	<p>Some studies reported data separately for sex assigned at birth males (transfemales). This included some direct comparisons with sex assigned at birth females (transmales).</p> <p>Impact on gender dysphoria One uncontrolled prospective observational longitudinal study (de Vries et al. 2011) provided evidence for gender dysphoria in sex assigned at birth males. See the clinical effectiveness results table above for a full description of the study. The mean (\pmSD) UGDS score was statistically significantly lower (improved) in sex assigned at birth males compared with sex assigned at birth females at both baseline (T0) (n=not reported, mean UGDS score [\pmSD]: 47.95 [\pm9.70] versus 56.57 [\pm3.89]) and T1 (n=not reported, 49.67 [\pm9.47] versus 56.62 [\pm4.00]); between sex difference $p < 0.001$ (VERY LOW).</p> <p>One further prospective observational longitudinal study (Costa et al. 2015) provided evidence for the impact on gender dysphoria in sex assigned at birth males. See the clinical effectiveness results table above for a full description of the study. Sex assigned at birth males had a statistically significantly lower (improved) mean (\pmSD) UGDS score of 51.6 [\pm9.7] compared with sex assigned at birth females (56.1 [\pm4.3], $p < 0.001$). However, it was not reported if this was baseline or follow-up (VERY LOW).</p> <p>These studies provide very low certainty evidence that in sex assigned at birth males (transfemales), gender dysphoria is lower than in sex assigned at birth females (transmales).</p> <p>Impact on mental health One uncontrolled prospective observational longitudinal study (de Vries et al. 2011) provided evidence for the impact on mental health (depression, anger and anxiety) in sex assigned at birth males. See the clinical effectiveness results table above for a full description of the study.</p> <ul style="list-style-type: none"> • The mean (\pmSD) depression (BDI-II) score was not statistically significantly different in sex assigned at birth males compared with sex assigned at birth females at both baseline (T0) (n=not reported, mean BDI score [\pmSD]: 5.71 [\pm4.31] versus 10.34 [\pm8.24]) and T1 (n=not reported, 3.50 [\pm4.58] versus 6.09 [\pm7.93]), between sex difference $p = 0.057$ • The mean (\pmSD) anger (TPI) score was statistically significantly lower (improved) in sex assigned at birth males compared with sex assigned at birth females at both baseline (T0) (n=not reported, mean TPI score [\pmSD]: 5.22 [\pm2.76]

	<p>versus 6.43 [± 2.78]) and T1 (n=not reported, 5.00 [± 3.07] versus 6.39 [± 2.59]), between sex difference $p=0.022$</p> <ul style="list-style-type: none"> • The mean (\pmSD) anxiety (STAI) score was statistically significantly lower (improved) in sex assigned at birth males compared with sex assigned at birth females at both baseline (T0) (n=not reported, mean STAI score [\pmSD]: 4.33 [± 2.68] versus 7.00 [± 2.36]) and T1 (n=not reported, 4.39 [± 2.64] versus 6.17 [± 2.69]), between sex difference $p<0.001$ (VERY LOW). <p>This study provides very low certainty evidence that the impact on mental health (depression, anger and anxiety) may be different in sex assigned at birth males (transfemales) compared with sex assigned at birth females (transmales). Over time there was no statistically significant difference between sex assigned at birth males and sex assigned at birth females for depression. However, sex assigned at birth males had statistically significantly lower levels of anger and anxiety than sex assigned at birth females at both baseline and follow up.</p> <p>Impact on body image</p> <p>One uncontrolled prospective observational longitudinal study (de Vries et al. 2011) provided evidence relating to the impact on body image in sex assigned at birth males.</p> <ul style="list-style-type: none"> • The mean (\pmSD) BIS score for primary sex characteristics was statistically significantly lower (improved) in sex assigned at birth males compared with sex assigned at birth females at both baseline (T0) (n=not reported, mean BIS score [\pmSD]: 4.02 [± 0.61] versus 4.16 [± 0.52]) and T1 (n=not reported, 3.74 [± 0.78] versus 4.17 [± 0.58]), between sex difference $p=0.047$ • The mean (\pmSD) BIS score for secondary sex was statistically significantly lower (improved) in sex assigned at birth males compared with sex assigned at birth females at both baseline (T0) (n=not reported, mean BIS score [\pmSD]: 2.66 [± 0.50] versus 2.81 [± 0.76]) and T1 (n=not reported, 2.39 [± 0.69] versus 3.18 [± 0.42]), between sex difference $p=0.001$ • The mean (\pmSD) BIS score for neutral body characteristics was not statistically significantly different in sex assigned at birth males compared with sex assigned at birth females at both baseline (T0) (n=not reported, mean BIS score [\pmSD]: 2.60 [± 0.58] versus 2.24 [± 0.62]) and T1 (n=not reported, 2.32 [± 0.59] versus 2.61 [± 0.50]), between sex difference $p=0.777$ (VERY LOW). <p>This study provides very low certainty evidence that the impact on body image may be different in sex assigned at birth males (transfemales) compared with sex assigned at birth females (transmales). Sex assigned at birth males are less dissatisfied with their primary and secondary sex characteristics than sex assigned at birth females at both baseline and follow up, but the satisfaction with neutral body characteristics is not different.</p> <p>Psychosocial impact</p> <p>One uncontrolled prospective observational longitudinal study (de Vries et al. 2011) provided evidence for psychosocial impact in terms</p>
--	--

of global functioning (CGAS) and psychosocial functioning (CBCL and YSR) in sex assigned at birth males.

- Sex assigned at birth males had statistically higher mean (\pm SD) CGAS scores compared with sex assigned at birth females at both baseline (T0) (n=54, 73.10 [\pm 8.44] versus 67.25 [\pm 11.06]) and T1 (n=54, 77.33 [\pm 8.69] versus 70.30 [\pm 9.44]), between sex difference p=0.021
- There was no statistically significant difference between sex assigned at birth males and sex assigned at birth females for the CBCL Total T score at T0 or T1 (n=54, p=0.110)
- There was no statistically significant difference between sex assigned at birth males and sex assigned at birth females for the CBCL internalising T score at T0 or T1 (n=54, p=0.286)
- Sex assigned at birth males had statistically lower mean (\pm SD) CBCL externalising T scores compared with sex assigned at birth females at both T0 (n=54, 54.71 [\pm 12.91] versus 60.70 [\pm 12.64]) and T1 (n=54, 48.75 [\pm 10.22] versus 57.87 [\pm 11.66]), between sex difference p=0.015
- There was no statistically significant difference between sex assigned at birth males and sex assigned at birth females for the YSR Total T score at T0 or T1 (n=54, p=0.164)
- There was no statistically significant difference between sex assigned at birth males and sex assigned at birth females for the YSR internalising T score at T0 or T1 (n=54, p=0.825)
- Sex assigned at birth males had statistically lower mean (\pm SD) YSR externalising T scores compared with sex assigned at birth females at both T0 (n=54, 48.72 [\pm 11.38] versus 57.24 [\pm 10.59]) and T1 (n=54, 46.52 [\pm 9.23] versus 52.97 [\pm 8.51]), between sex difference p=0.004 (**VERY LOW**).

One uncontrolled, observational, prospective cohort study ([Costa et al. 2015](#)) provided evidence for psychosocial impact in terms of global functioning (CGAS) in sex assigned at birth males.

- Sex assigned at birth males had statistically significant lower mean (\pm SD CGAS scores at baseline) compared with sex assigned at birth females (n=201, 55.4 [\pm 12.7] versus 59.2 [\pm 11.8], p=0.03) (**VERY LOW**).

These studies provide very low certainty evidence that psychosocial impact may be different in sex assigned at birth males (transfemales) compared with sex assigned at birth females (transmales). However, no conclusions could be drawn.

Change in bone density: lumbar

Three uncontrolled, observational, retrospective studies provided evidence relating to the effect of GnRH analogues on lumbar bone density in sex assigned at birth males ([Joseph et al. 2019](#), [Klink et al. 2015](#) and [Vlot et al. 2017](#)). See the safety results table above for a full description of the results.

These studies provide very low certainty evidence that GnRH analogues reduce the expected increase in lumbar bone density (BMAD or BMD) in sex assigned at birth males (transfemales; although some findings were not statistically significant). These studies also show that GnRH analogues do not statistically

	<p>significantly decrease actual lumbar bone density (BMAD or BMD) in sex assigned at birth males (transfemales).</p> <p>Change in bone density: femoral Three uncontrolled, observational, retrospective studies provided evidence for the effect of GnRH analogues on femoral bone density in sex assigned at birth males (Joseph et al. 2019, Klink et al. 2015 and Vlot et al. 2017). See the safety results table above for a full description of the results.</p> <p>These studies provide very low certainty evidence that GnRH analogues may reduce the expected increase in femoral bone density (femoral neck or area BMAD or BMD) in sex assigned at birth males (transfemales; although some findings were not statistically significant). These studies also show that GnRH analogues do not statistically significantly decrease actual femoral bone density (femoral area BMAD or femoral neck BMD) in sex assigned at birth males (transfemales).</p> <p>Cognitive development or functioning One cross-sectional observational study (Staphorsius et al. 2015) provided comparative evidence on cognitive development or functioning in sex assigned at birth males. See the safety results table above for a full description of the results.</p> <p>This study provides very low certainty evidence (with no statistical analysis) on the effects of GnRH analogues on cognitive development or functioning in sex assigned at birth males (transfemales). No conclusions could be drawn.</p> <p>Other safety outcomes: kidney function One prospective observational study (Schagen et al. 2016) provided non-comparative evidence on change in serum creatinine in sex assigned at birth males. See the safety results table above for a full description of the results.</p> <p>This study provides very low certainty evidence that GnRH analogues do not affect renal function in sex assigned at birth males (transfemales).</p>
<p>Sex assigned at birth females (transmales)</p> <p>Certainty of evidence: Very low</p>	<p>Some studies reported data separately for sex assigned at birth females (transmales). This included some direct comparisons with sex assigned at birth males (transfemales).</p> <p>Impact on gender dysphoria One uncontrolled prospective observational longitudinal study (de Vries et al. 2011) and one prospective observational longitudinal study (Costa et al. 2015) provided evidence for gender dysphoria in sex assigned at birth females. See the sex assigned at birth males (transfemales) row above for a full description of the results.</p> <p>These studies provide very low certainty evidence that in sex assigned at birth females (transmales), gender dysphoria is higher than in sex assigned at birth males (transfemales) at both baseline and follow up.</p>

	<p>Impact on mental health</p> <p>One uncontrolled prospective observational longitudinal study (de Vries et al. 2011) provided evidence relating to the impact on mental health (depression, anger and anxiety) in sex assigned at birth females. See the sex assigned at birth males (transfemales) row above for a full description of the results.</p> <p>This study provides very low certainty evidence that the impact on mental health (depression, anger and anxiety) may be different in sex assigned at birth females (transmales) compared with sex assigned at birth males (transfemales). Duration of gender dysphoria	No evidence was identified.
Age at onset of gender dysphoria	No evidence was identified.
Age at which GnRH analogue started	No evidence was identified.
Age at onset of puberty	No evidence was identified.

Tanner stage at which GnRH analogue started	No evidence was identified.
Diagnosis of autistic spectrum disorder	No evidence was identified.
Diagnosis of mental health condition	No evidence was identified.

Abbreviations: BDI-II, Beck Depression Inventory-II; BIS, Body Image Scale; CBCL, Child Behaviour Checklist; CGAS, Children's Global Assessment Scale; SD, standard deviation; STAI, Trait Anxiety Scale of the State-Trait Personality Inventory; TPI, Trait Anger Scale of the State-Trait Personality Inventory; UGDS, Utrecht Gender Dysphoria Scale; YSR, Youth Self-Report

From the evidence selected,

- (a) what are the criteria used by the research studies to define gender dysphoria, gender identity disorder and gender incongruence of childhood?
- (b) what were the ages at which participants commenced treatment with GnRH analogues?
- (c) what was the duration of treatment with GnRH analogues?

Outcome	Evidence statement										
Diagnostic criteria	<p>In 5 studies (Costa et al. 2015, Klink et al. 2015, Schagen et al. 2016, Staphorsius et al. 2015 and Vlot et al. 2017) the DSM-IV-TR criteria of gender identity disorder was used.</p> <p>The study by Brik et al. 2020 used DSM-V criteria. The DSM-V has one overarching definition of gender dysphoria with separate specific criteria for children and for adolescents and adults. The general definition describes a conflict associated with significant distress and/or problems functioning associated with this conflict between the way they feel and the way they think of themselves which must have lasted at least 6 months.</p> <p>It was not reported how gender dysphoria was defined in the remaining 3 studies (VERY LOW).</p> <p>From the evidence selected, all studies that reported diagnostic criteria for gender dysphoria (6/9 studies) used the DSM criteria in use at the time the study was conducted.</p>										
Age when GnRH analogues started	<p>8/9 studies reported the age at which participants started GnRH analogues, either as the mean age (with SD) or median age (with the range):</p> <table border="1"> <thead> <tr> <th>Study</th><th>Mean age (±SD)</th></tr> </thead> <tbody> <tr> <td>Costa et al. 2015</td><td>16.5 years (±1.3)</td></tr> <tr> <td>de Vries et al. 2011</td><td>13.6 years (±1.8)</td></tr> <tr> <td>Joseph et al. 2019</td><td>13.2 years (±1.4) in transfemales 12.6 years (±1.0) in transmales</td></tr> <tr> <td>Khatchadourian et al. 2014</td><td>14.7 years (±1.9)</td></tr> </tbody> </table>	Study	Mean age (±SD)	Costa et al. 2015	16.5 years (±1.3)	de Vries et al. 2011	13.6 years (±1.8)	Joseph et al. 2019	13.2 years (±1.4) in transfemales 12.6 years (±1.0) in transmales	Khatchadourian et al. 2014	14.7 years (±1.9)
Study	Mean age (±SD)										
Costa et al. 2015	16.5 years (±1.3)										
de Vries et al. 2011	13.6 years (±1.8)

6. Discussion

A key limitation to identifying the effectiveness and safety of GnRH analogues for children and adolescents with gender dysphoria is the lack of reliable comparative studies. The lack of clear, expected outcomes from treatment with a GnRH analogue (the purpose of which is to suppress secondary sexual characteristics which may cause distress from unwanted pubertal changes) also makes interpreting the evidence difficult. The size of the population with gender dysphoria means conducting a prospective trial may be unrealistic, at least on a single centre basis. There may also be ethical issues with a 'no treatment arm' in comparative trials of GnRH analogues, where there may be poor mental health outcomes if treatment is withheld. However, the use of an active comparator such as close psychological support may reduce ethical concerns in future trials.

The studies included in this evidence review are all small, uncontrolled observational studies, which are subject to bias and confounding, and are of very low certainty as

assessed using modified GRADE. All the included studies reported physical and mental health comorbidities and concomitant treatments very poorly. For example, very little data are reported on how many children and adolescents needed additional mental health support, and for what reasons, or whether additional interventions, and what form and duration (for example drug treatment or counselling) that took. This is a possible confounder for the treatment outcomes in the studies because changes in critical and important outcomes may be attributable to external care rather than the psychological support or GnRH analogues used in the studies.

The studies that reported diagnostic criteria for gender dysphoria (6/9 studies) used the Diagnostic and Statistical Manual of Mental Disorders (DSM) criteria in use at the time the study was conducted (either DSM-IV-TR or DSM-V). The definition was unclear in the remaining studies. There was wide variation in the ages at which participants started a GnRH analogue, typically ranging from about 11 to 18 years. Similarly, there was a wide variation in the duration of use, but few studies reported this.

Changes in outcome scores for clinical effectiveness were assessed for statistical significance in the 3 studies reporting these outcomes ([Costa et al. 2015](#); [de Vries et al. 2011](#); [Staphorsius et al. 2015](#)). However, there is relatively little interpretation of whether the changes in outcome scores seen in these studies are clinically meaningful.

For some outcomes there was no statistically significant difference from before starting GnRH analogues until just before starting gender-affirming hormones. These were the Utrecht Gender Dysphoria Scale (UGDS) (which was assessed in 1 study [de Vries et al. 2011](#)), the Trait Anger (TPI) and Trait Anxiety (STAI) Scales (which were assessed in 1 study [de Vries et al. 2011](#)), and Body Image Scale (BIS) which was assessed in 1 study ([de Vries et al. 2011](#)).

The Beck Depression Inventory (BDI-II) was used in 1 study ([de Vries et al. 2011](#)) to assess change in depression from before starting GnRH analogues to just before starting gender-affirming hormones. The result is statistically significant, with the mean (\pm SD) BDI-II score decreasing from 8.31 (\pm 7.12) at baseline to 4.95 (\pm 6.27) at follow up ($p=0.004$). However, both scores fall into the minimal range using the general guidelines for interpretation of BDI-II (0 to 13 minimal, 14 to 19 mild depression, 20 to 28 moderate depression and 29 to 63 severe depression), suggesting that while statistically significant, it is unclear if this is a clinically meaningful change.

Psychosocial outcomes were assessed in 3 studies ([Costa et al. 2015](#); [de Vries et al. 2011](#); [Staphorsius et al. 2015](#)) using the Children's Global Assessment Scale (CGAS) and Child Behavior Checklist/Youth Self-Report (CBCL/YSR). The CGAS score was assessed in 2 studies ([Costa et al. 2015](#); [de Vries et al. 2011](#)). In [de Vries et al. 2011](#) the mean (\pm SD) CGAS score statistically significantly increased over time from 70.24 [\pm 10.12] at baseline to 73.90 [\pm 9.63] at follow up. CGAS scores are clinically categorised into 10 categories (10 to 1, 20 to 11 and so on until 100 to 91) and both scores reported were in a single category (71 to 80, no more than slight impairment) suggesting that while statistically significant, it is unclear if this is a clinically meaningful change. The [Costa et al. 2015](#) study does highlight a larger change in CGAS scores from baseline to follow-up (mean [\pm SD] 58.72 [\pm 11.38] compared with 67.40 [\pm 13.39]), but whether this is clinically meaningful is unclear. The average score moved from the clinical category of 60 to 51 (variable functioning with sporadic difficulties) at baseline to 70 to 61 (some difficulty in a single area, but generally

functioning pretty well) at follow up, but the large standard deviations suggest clinically significant overlaps between the scores from baseline to follow-up.

Psychosocial functioning using the CBCL/YSR was assessed in 2 studies ([de Vries et al. 2011](#); [Staphorsius et al. 2015](#)). In de Vries et al. 2011 there was a statistically significant reduction in both CBCL and YSR scores from before starting GnRH analogues to just before starting gender-affirming hormones. The study interpreted the CBCL/YSR with a proportion of adolescents who scored in the clinical range (a T-score above 63), which allows changes in clinically meaningful scores to be assessed, and proportions of adolescents in the clinical range for some CBCL and YSR scores decreased over time. One cross-sectional study ([Staphorsius et al. 2015](#)) assessed CBCL scores only, but it was unclear if this was the Total T score, or whether subscales of internalising or externalising scores were also assessed, and whether the results were statistically significant.

The 2 prospective observational studies ([Costa et al. 2015](#); [de Vries et al. 2011](#)) are confounded by a number of common factors. Firstly, the single assessment of scores at baseline means it is unclear if scores were stable, already improving or declining before starting treatment. Secondly, in an uncontrolled study any changes in scores from baseline to follow-up could be attributed to a regression-to-mean, for example getting older has been positively associated with maturity and wellbeing. The studies use mean and standard deviations in the descriptive statistics and analyses; however, they do not report testing the normality of data which would support the use of parametric measures. The study by de Vries et al. 2011 used general linear models (regression) to examine between and within group variances (changes in outcomes). In using such models, the data is assumed to be balanced (measured at regular intervals and without missing data), but the large ranges in ages at which participants were assessed and started on various interventions suggests that ascertainment of outcome was unlikely to be regular and missing data was likely. Missing data was handled through listwise deletion (omits those cases with the missing data and analyses the remaining data) which is acceptable if data loss is completely random but for some outcomes where there was incomplete data for individual items this was not random (items were introduced by the authors after the first eligible adolescents had started GnRH analogues). The study provided no detail on whether these assumptions for the modeling were met, they also provided no adequate assessment of whether any regression diagnostics (analysis that seek to assess the validity of a model) or model fit (how much of the variance in outcome is explained by the between and within group variance) were undertaken.

The 2 retrospective observational studies ([Brik et al. 2020](#); [Khatchadourian et al. 2014](#)) both only report absolute numbers for each trajectory along with reasons for stopping GnRH analogues. It is difficult to assess outcomes from such single centre studies because there is little comparative data for outcomes from other such services. A lack of any critical or other important outcomes also means the success of the treatment across all the participants is difficult to judge.

Three uncontrolled, observational, retrospective studies provided evidence relating to the effect of GnRH analogues on bone density ([Joseph et al. 2019](#); [Klink et al. 2015](#); [Vlot et al. 2017](#)). In all 3 studies, the participants acted as their own controls and change in bone density was determined between starting GnRH analogues and either after 1 and 2 year follow-up timepoints ([Joseph et al. 2019](#)) or when gender-affirming hormones were started

(Klink et al. 2015 and Vlot et al. 2017). Observational studies such as these can only show an association with GnRH analogues and bone density; they cannot show that GnRH analogues caused any differences in bone density seen. Because there was no comparator group and participants acted as their own controls, it is unclear whether the findings are associated with GnRH analogues or due to changes over time. The authors reported z-scores which allows for comparison with the expected increase in bone density in the general population. However, because no concomitant treatments or comorbidities were reported it is possible that the findings may not be because of GnRH analogues and there is another way in which the study population differs from the general population.
