- **Closing Remarks and Administrative Matters**
- **Meeting Adjourns**

Notice of Meeting/Workshop Hearing

DEPARTMENT OF HEALTH BOARD OF MEDICINE

RULE NO.: RULE TITLE:
64B8-9.019 Practice Standards for the Treatment of Gender Dysphoria

The **Florida Boards of Medicine and Osteopathic Medicine Joint Rules/Legislative Committee** announce a workshop to which all persons are invited.

DATE AND TIME: Friday, October 28, 2022, 8:00 a.m. EDT and ending no later than 1:00 p.m. EDT

PLACE: Hyatt Regency Orlando International Airport, 9300 Jeff Fuqua Boulevard, Orlando, Florida 32827

GENERAL SUBJECT MATTER TO BE CONSIDERED: The Florida Boards of Medicine and Osteopathic Medicine Joint Rules/Legislative Committee will conduct a rule workshop and meeting to receive and consider presentations from subject matter experts and comments from the public, and to discuss and develop draft rule language related to practice standards for the treatment of gender dysphoria. A copy of the agenda may be obtained by contacting: Board of Medicine by email at BOM.MeetingMaterials@flhealth.gov or by calling the Board of Medicine at (850)245-4131. Written public comments should not be sent to this email address. Information regarding written public comment submissions is provided below.

Public comments presented at the workshop will be limited to no more than two hours in total. Any person who wants to make public comments must notify board staff in writing. Speaker cards will be available at the workshop for this purpose. Public comments will be limited to three minutes per person. This time will not include time spent by the public commenter responding to questions imposed by Committee members, staff, or board counsel. If a group or faction of persons consisting of five or more persons wishes to address the Committee, please identify one individual who will speak on behalf of the group. Public commenters may use pseudonyms if they do not wish to identify themselves on the record. All public comments received at the workshop will become part of the rulemaking record.

Written public comments may be submitted to the Committee between the publication of this notice until 24 hours following the conclusion of the workshop. The email address for such submissions is BOMPublicComment@flhealth.gov. All comments received at this email address, including the sender's email address, will become part of the rulemaking record and will be a public record.

Public participation is solicited without regard to race, color, national origin, age, sex, gender, religion, disability, or family status.

Pursuant to the provisions of the Americans with Disabilities Act, any person requiring special accommodations to participate in this workshop is asked to advise the Committee at least seven days before the workshop by contacting the Board of Medicine by email at BOM.MeetingMaterials@flhealth.gov or by calling the Board of Medicine at (850)245-4131.

If you are hearing or speech impaired, please contact the Committee using the Florida Relay Service at 1(800)955-8771 (TDD) or (800) 955-8770 (Voice).

If any person decides to appeal any decision made by the Boards with respect to any matter considered at this meeting or hearing, they will need to ensure that a verbatim record of the proceeding is made, including the testimony and evidence from which the appeal is to be issued.

For more information, you may contact: Florida Board of Medicine by email at BOM.MeetingMaterials@flhealth.gov or by calling the Board at (850)245-4131.

19 September 2022

Paul A. Vazquez, J.D.
Executive Director
Florida Board of Medicine

Dear Florida Board of Medicine,

This submission is made to assist your deliberation on the treatment of children and young people suffering from gender dysphoria, specifically on the use of ‘puberty blockers’.

I have published on the origin of this treatment in the Netherlands 1990s (Biggs 2022b) and on the initial British experiment in the 2010s (Biggs 2019b). I was the first to call on the British Tavistock and Portman NHS Foundation Trust’s Gender Identity Development Service (GIDS) to publish the results of its experiment (Tominey and Walsh 2019), and I was the first to publish preliminary results from the experiment (Biggs 2020a). Provoked by the poor quality of data and analysis in this field of medicine, I have published on the effects of puberty suppression on psychological functioning (Biggs 2019a), on suicidality (Biggs 2020b), and on bone density (Biggs 2021), as well as on the suicide rate of transgender adolescents (Biggs 2022a). This work has appeared in *Archives of Sexual Behavior*, *Journal of Sex and Marital Therapy*, *Journal of Sexual Medicine*, and *Journal of Pediatric Endocrinology and Metabolism*.

Puberty suppression as a treatment for gender dysphoria

1. Dutch clinicians started using Gonadotropin-Releasing Hormone agonist (GnRHa) to suppress puberty in children suffering from gender dysphoria—who they designated as ‘juvenile transsexuals’ (Gooren and Delemarre-van de Waal 1996)—in the 1990s. The Dutch protocol had three stages (Delemarre-van de Waal and Cohen-Kettenis 2006). GnRHa would be given from the age of 12, once the child had reached Tanner Stage 2: the first growth of pubic hair and for girls by budding breasts and for boys by growing testicles. Cross-sex hormones would be administered from 16, and surgeries would commence at 18. For this purpose, GnRHa is used off-label, for it has never been licensed to treat gender dysphoria, anywhere in the world. It is licensed to treat precocious puberty—when puberty commences before the age of 7 (approximately) in girls or 9 in boys. That treatment involves delaying a puberty that arrives abnormally early so that the child can undergo puberty at the normal age,

whereas puberty suppression for gender dysphoria entails stopping normal puberty in order to prepare the child for taking hormones of the opposite sex.

2. Puberty suppression as a treatment for gender dysphoria was never tested in any randomized clinical trial. Nor were there any preliminary experiments on non-human animals. Only two decades after this treatment was first used on children were any experiments conducted on sheep and mice (Hough, Bellingham, Haraldsen, McLaughlin, Rennie, et al. 2017; Hough, Bellingham, Haraldsen, McLaughlin, Robinson, et al. 2017; Anacker et al. 2021). The Dutch clinicians published outcomes from a longitudinal study of the first cohort of 70 children whose puberty was suppressed (de Vries et al. 2011; 2014). About half the psychological measures showed improvement. The reported improvement in gender dysphoria is flawed because the researchers switched the questionnaires used to construct the measure. A male who wanted to become a woman was given the male version at baseline and then the female version at follow-up, including irrelevant questions such as about menstruation (Levine, Abbruzzese, and Mason 2022). Notably, one teenager died during vaginoplasty—and so the death rate exceeded 1%. This cohort have not been followed up since their early twenties, just after surgery. Only one patient—the very first to receive puberty suppression for gender dysphoria—has been followed up in the long term. At the age of 35, he was depressed. Due to ‘shame about his genital appearance and his feelings of inadequacy in sexual matters’, he could not sustain a romantic relationship with a girlfriend (Cohen-Kettenis et al. 2011, 845). The clinicians concluded optimistically that ‘the negative side effects are limited’ (Cohen-Kettenis et al. 2011, 843).
3. While gender clinics in many other countries adopted the Dutch protocol from the late 2000s, they did not collect data on outcomes or decided not to publish it. The GIDS started puberty suppression as an experiment in 2011, involving 44 children aged 12 to 15 (Viner et al. 2010). Before the last subject had been recruited, it was pronounced a success by the Director of GIDS and used to justify a new policy of lowering the age of puberty suppression: ‘Now we’ve done the study and the results thus far have been positive we’ve decided to continue with it’ (Manning and Adams 2014). The lack of publication of the results led to my protracted campaign involving news media (e.g., Tominey and Walsh 2019), complaints to the NHS ethics committee (Health Research Authority 2019), and questions in Parliament (Blackwood of North Oxford 2019). The GIDS delayed publication until the day after the verdict was delivered in the judicial review launched by Keira Bell (Carmichael et al. 2020; 2021). The researchers acknowledge that puberty suppression, after two years, produced no positive effects. These results were significantly inferior to the Dutch results following puberty suppression (Biggs 2020a). The subjects of this experiment have not been followed up after cross-sex hormones; the GIDS admits that it loses track of its patients after the age of 18 (Butler et al. 2018). One of the subjects in the experiment appeared on Twitter (as @mediocredruid): she is deeply distressed by her treatment—GnRHa at 15 led to testosterone, double mastectomy, hysterectomy, vaginectomy, and metoidioplasty—but does not know whether to detransition because the physical changes have been so extreme that she might not be able to pass as a woman.
4. In the United States, puberty suppression became widely adopted from 2008 onwards (Biggs 2020b). Dozens of children’s gender clinics were established to tap into this new lucrative market. The National Institutes of Health awarded \$5.7 million for a prospective longitudinal

study of the effects of GnRHa and cross-sex hormones on children (Children’s Hospital Los Angeles 2015). Subjects were recruited between 2016 and 2018 (Olson-Kennedy et al. 2019). Outcomes after two years on GnRHa were thus collected by 2020, but the researchers have only published on the characteristics of the cohort *before* treatment (Chen et al. 2021; Lee et al. 2020) and on the respective merits of two brands of GnRHa (Olson-Kennedy et al. 2021). As in Britain, practitioners of gender medicine are curiously reluctant to publish the outcomes of puberty suppression for psychological functioning and gender dysphoria—even though those outcomes were the primary justification for the treatment.

The association of gender dysphoria with same-sex attraction and autism spectrum conditions

5. Puberty suppression is founded on the assumption that a child suffering from gender dysphoria at age 12—or even younger, if Tanner stage 2 is reached earlier—is a ‘juvenile transsexual’ whose destiny is fixed. This assumption was known to be false by the clinicians who invented the Dutch protocol, who initially recognized that ‘most GID [gender identity disorder, the precursor to gender dysphoria] children under 12 will not grow up to become transsexuals’ (Cohen-Kettenis and van Goozen 1997, 246). ‘Prospective studies of GID boys show that this phenomenon is more closely related to later homosexuality than to later transsexualism’ (Cohen-Kettenis and Gooren 1999, 319). One of the four studies cited is a famous study of ‘sissy boys’ who were selected because they were thought to be ‘pretranssexuals’; after fifteen years, however, two thirds of the 44 had become bisexual or homosexual men and only one was contemplating transsexuality (Green 1987). A representative longitudinal study of 14,000 children born in 1991–92 shows that those who as infants gravitated towards toys and activities typical of the opposite sex were far more likely by the age of 15 to grow up to be gay or lesbian (Li, Kung, and Hines 2017). All this evidence predates the promotion of transgenderism in healthcare and schools and on social media. The manifesto for the Dutch protocol fails to mention homosexuality and does not cite any of the studies of feminine boys (Delemarre-van de Waal and Cohen-Kettenis 2006). Unpublished data on 27 of the Dutch adolescents were given GnRHa reveals that 26 were homosexual and 1 was bisexual (de Vries 2010, 103). The suspicion must be that at least some of these children could have grown up to be typical gays and lesbians, without requiring lifetime medical treatment and without loss of fertility and sexual function.
6. The overlap between gender dysphoria and autistic spectrum conditions (ASC) is well documented (Socialstyrelsen 2020; Warrier et al. 2020). ‘GD [gender dysphoria] and ASD [autism spectrum disorder, another term for ASC] were found to co-occur frequently—sometimes characterized by atypical presentation of GD, which makes a correct diagnosis and determination of treatment options for GD difficult’ (van der Miesen, Hurley, and de Vries 2016, 70). Children on the autistic spectrum are more likely to face difficulties fitting in with their same-sex peers, which makes a transgender identity obviously appealing as both an explanation and a solution. From a sample of over 700 referrals to the GIDS in 2012 and 2015, 14–15% were diagnosed with ASC (Morandini et al. 2021). This was more than ten times greater than the rate for students in England, 0.8%–1.1% (Department for Education 2012; 2015). The proportion among those subjected to GnRHa could be even higher. Out of the first 30 subjects enrolled in the GIDS experiment on puberty suppression, almost half had

ASC traits: mid to moderate in 9 children, and severe in 5 (Gender Identity Development Service 2015).

The risk of suicide for children suffering from gender dysphoria

7. Surveys demonstrate that adolescents who identify as transgender are vulnerable to suicidal thoughts and self-harming behaviors (dickey and Budge 2020; Hatchel, Polanin, and Espelage 2021; Mann et al. 2019). In New Zealand, 20% of transgender students reported attempting suicide in the past 12 months, compared to 4% of all students (Clark et al. 2014). In the United States, 15% of transgender students reported a suicide attempt requiring medical treatment in the last 12 months, compared to 3% of all students (Centers for Disease Control and Prevention 2018; Jackman et al. 2021; Johns et al. 2019). In another American survey, 41% of transgender students reported having attempted suicide during their lifetime, compared to 14% of all students (Toomey, Syvertsen, and Shramko 2018).
8. Respondents who report suicide attempts are not necessarily indicating an intent to die. One survey of the American population found that almost half the respondents who reported attempting suicide subsequently stated that their action was a cry for help and not intended to be fatal (Nock and Kessler 2006). In two small samples of non-heterosexual youth, half the respondents who initially reported attempting suicide subsequently clarified that they went no further than imagining or planning it; for the remainder who did actually commit suicide, their actions were usually not life-threatening. To an extent, then, 'the reports were attempts to communicate the hardships of lives or to identify with a gay community' (Savin-Williams 2001). Such elaborate survey methods have not been used to study transgender populations, but there is anecdotal evidence for a disjuncture between self-harm and suicidal ideation on one hand and fatal suicide on the other. The pediatric endocrinologist who established the first clinic for transgender children in the United States stated that 'the majority of self-harmful actions that I see in my clinic are not real suicide attempts and are not usually life threatening' (Spack 2009, 312).
9. Two published studies have reported suicide fatalities among transgender adolescents. Belgium's pediatric gender clinic provided counselling to 172 youth aged from 12 and 18 years, who had been referred between 2007 and 2016: 5 of them (2.9%) committed suicide (Van Cauwenberg, Dhondt, and Motmans 2021). The mean age of referral was 15, implying a mean duration of 3 years before transition to an adult clinic, which translates to an annual suicide rate of 969 per 100,000.
10. At the Tavistock GIDS, which serves young people under 18 from England, Wales, and Northern Ireland, 4 patients were known or suspected to have died by suicide between 2010 and 2020. The clinic had referrals for approximately 15,000 patients in this period. To calculate the annual suicide rate, the total number of years spent by patients under the clinic's care is estimated at about 30,000. This yields an annual suicide rate of 13 per 100,000 (95% confidence interval: 4–34). Compared to the United Kingdom population of the same age and sexual composition, the suicide rate for patients at the GIDS was 5.5 times higher (Biggs 2022a). It is not clear what explains the enormous disparity in suicide rates at these two clinics; the Belgian rate is 70 times higher. The suicide rate at the Tavistock is much closer to the rate calculated from 8,000 adults who visited the Amsterdam clinic between 1972 and 2017, which was quadruple that of the Dutch population (Wiepjes et al. 2020).

11. The elevated suicide rate of children who identify as transgender could be explained by some combination of gender dysphoria, accompanying psychological conditions, and ensuing social disadvantages such as bullying. The association between ASC and gender dysphoria was pointed out above. Autism is known to increase the risk of suicide mortality, especially in females (Socialstyrelsen 2020; Hirvikoski et al. 2016; Kirby et al. 2019). To some extent, therefore, the elevated suicide rate for transgender youth compared to their peers reflects the higher incidence of ASC. The same holds for other psychiatric disorders associated with gender dysphoria (Dhejne et al. 2016).
12. The claim that puberty suppression reduces suicidality in children suffering from gender dysphoria is not implausible. Because the risk of suicide increases greatly from prepubescence to late adolescence, halting normal cognitive and emotional development with GnRHa could reduce the risk of suicide by preventing the child from maturing. As yet there is no evidence, however, that endocrinological interventions reduce the risk of suicide. At the GIDS from 2010 to 2020, there is no detectable difference between the suicide rate for patients on the waiting list and for patients who were being seen (Biggs 2022a). In the Belgian clinic which experienced the exceptionally high suicide rate, subsequent correspondence reveals that ‘suicide was related to many more (psychological) problems than their GD [gender dysphoria], and occurred mostly a few years after the start on hormonal treatment’ (email from Gaia Van Cauwenberg to Avi Ring, 27 May 2022).
13. One study claims that puberty suppression reduced subsequent suicidality in adults (Turban et al. 2020). This finding derives from a nonrepresentative survey of transgender adults in the United States, which included 89 respondents who reported taking puberty blockers. Six measures of suicidality and three other measures of mental health and substance abuse were examined, but only one yielded a statistically significant association after controlling for other factors: the respondents who reported taking puberty blockers were less likely to have thought about killing themselves than were the respondents who reported wanting blockers but not obtaining them. This study has numerous serious flaws (Biggs 2020b). Most fundamentally, without information on the respondents’ mental health during adolescence, the causal direction cannot be ascertained. The association could well be explained by clinicians refusing to prescribe GnRHa to adolescents with significant psychological problems, as indeed was then recommended by the Endocrine Society (Hembree et al. 2009). The study did not disclose the fact that one of its authors had been paid by Endo Pharmaceuticals, which manufactures a GnRHa drug (histrelin acetate under the brand Supprelin). At my insistence, the journal issued a correction to admit this conflict of interest (Pediatrics 2021).
14. There are anecdotal reports of children experiencing increased suicidal feelings after GnRHa. At the Leiden clinic, one teenager ‘stopped treatment because of an increase in mood problems and suicidal thoughts and confusion attributed to GnRHa treatment’ (Brik et al. 2020, 2614). One English teenager recalled that GnRHa led to suicidal feelings (Klotz 2022). The triptorelin formulations used in Britain—Gonapeptyl® Depot and Decapeptyl® SR—carry warnings that depression is a common side effect, affecting between 1% and 10% of patients (Ferring Pharmaceuticals Ltd 2016), and ‘may be severe’ (Ipsen Ltd 2017).

The effect of puberty suppression on mental health

15. The first Dutch cohort of 70 children given GnRHa reported generally positive outcomes, by age 16, when they graduated to cross-sex hormones (de Vries et al. 2011). (The actual number of observations ranged from 41 to 57, depending on measure.) Psychological functioning improved, depressive symptoms declined, and behavioural and emotional problems decreased. Gender dysphoria, however, worsened for females. Using the same measures as the Dutch, the first GIDS cohort of 44 children reported no improvement in psychological functioning or gender dysphoria after two years (Carmichael et al. 2021). There was a misleading earlier article from the GIDS which claimed that puberty suppression improved psychological functioning (Costa et al. 2015). It had an extraordinarily high attrition rate—almost half the subjects vanished over 12 months, without explanation—and the claimed effect was actually not statistically significant (Biggs 2019a). It nevertheless continues to be cited as credible evidence for the beneficial effects of puberty suppression.
16. According to a recent study from the Seattle Children’s Gender Clinic, 69 youth aged 13 to 16 experienced dramatically reduced rates of depression and of self-harm or suicidal thoughts after 12 months on GnRHa or cross-sex hormones (Tordoff et al. 2022). (The authors unfortunately do not differentiate these two interventions.) In fact the data for these youth showed no change over time (Singal 2022). The false claim was derived from statistical comparison with youth from the clinic who had not received these endocrinological interventions, whose mental health worsened over time. But this comparison group numbered only 6 patients after 12 months. One obvious explanation is that the clinicians were following the World Professional Association of Transgender Health’s recommendations against commencing medical intervention when an adolescent is experiencing an acute mental health crisis. (This is the same fallacy of causal inference that vitiated Turban et al.’s (2020) study of suicidality.)
17. A proper randomized control trial of the effect of suppressing puberty in mice using GnRHa demonstrated that it caused significantly higher levels of stress in males, and increased anxiety and despair-like behaviour in females (Anacker et al. 2021).

The effect of puberty suppression on bone density

18. The Dutch pioneers warned at the outset that patients could ‘end with a decreased bone density, which is associated with a high risk of osteoporosis’ (Delemarre-van de Waal and Cohen-Kettenis 2006, S134). The fact that GnRHa prevents the accrual of normal bone mass is well documented from Dutch and British studies (Klink et al. 2015; Schagen et al. 2020; Stoffers, de Vries, and Hannema 2019; Vlot et al. 2017; Joseph, Ting, and Butler 2019). In addition, children given GnRHa already have unusually low bone density, perhaps due to the high prevalence of eating disorders. The combined effect can be appreciated by looking at the proportion of adolescents who end up after treatment with severely low bone density, two standard deviations below the average—putting them at risk for osteoporosis. Reanalysis of 31 of the GIDS patients demonstrates that after two years on GnRHa, up to a third had reached this very low range, depending on the measure (hip or spine); only 2.3% of the population would be this low. Moreover, four patients (13%) had spine bone density over

three standard deviations from the mean; only 0.13% of the population would be so extremely low (Biggs 2021).

19. Whether such abnormally low bone density has increased the risk of fractures is unknown because clinics apparently do not collect data on fractures. Anecdotally, a British female patient who started GnRHa at age 12 then experienced four broken bones by the age of 16 (Bannerman 2019). A Swedish documentary highlighted the case of a female who was given GnRHa from age 11 to 15, and now suffers from severe osteoporosis, including continual skeletal pain (SVT 2021).

The effect of puberty suppression on sexual function

20. When GnRHa is used to treat prostate cancer, one side effect is that ‘sexual desire, sexual interest and sexual intercourse were totally annulled’ (Marumo, Baba, and Murai 1999, 19). This is why GnRHa is licensed to chemically castrate men who are sex offenders (Ho et al. 2012; Turner and Briken 2018). Clinicians who use GnRHa off-label to treat gender dysphoria have ignored its effects on sexuality. The Dutch studies, for example, included no measures for libido or capacity for orgasm (de Vries et al. 2011; 2014). The lead author recently described orgasm as ‘a very interesting and so far not studied question’ (Klotz 2022). A Californian surgeon who has performed over 2,000 vaginoplasties (and who is also transgender) recently acknowledged that ‘every single child who was, or adolescent, who was truly blocked at Tanner Stage 2, has never experienced orgasm. I mean, it’s really about zero’ (Bowers 2022). This remark refers to males. The effects of puberty suppression at such an early stage on females is unknown.

The effect of puberty suppression on subsequent medical transition

21. Dutch clinicians initially promoted puberty suppression as providing space for therapeutic exploration of gender identity, without the pressure of the physical changes accompanying puberty (Delemarre-van de Waal and Cohen-Kettenis 2006). This was plausible, perhaps, though it was also plausible that stopping normal sexual and cognitive development would impede such exploration. As the Dutch clinicians admitted at the time, ‘none of the [54] patients who were selected for pubertal suppression has decided to stop taking GnRHa’ (Delemarre-van de Waal and Cohen-Kettenis 2006, S136). It could have been argued that this was due to careful selection of a small number of adolescents for this experimental treatment.
22. Although the number of children subjected to puberty suppression has increased dramatically, they almost invariably continue to cross-sex hormones. Out of 333 children given GnRHa in the Amsterdam clinic to the end of 2015, 326 (98%) continued to cross-sex hormones (Wiepjes et al. 2018). Out of 133 children given GnRHa at the Leiden clinic in the Netherlands who attained the age of eligibility for cross-sex hormones, 128 (96%) continued (Brik et al. 2020). Out of 44 children enrolled in the GIDS experiment with GnRHa, 43 (98%) continued to cross-sex hormones (Carmichael et al. 2021). Out of 54 children given GnRHa by the Royal Children’s Hospital Gender Service in Australia, 53 (98%) continued to cross-sex hormones (Tollit et al. 2021). The suspicion is that puberty suppression reinforces gender dysphoria.
23. Given the fact that there are almost no cases of children ceasing GnRHa, the claim for reversibility is moot. The article that first proposed puberty suppression deemed it to be ‘fully

reversible; in other words, no lasting undesired effects are to be expected’ (Gooren and Delemarre-van de Waal 1996, 72). The phrasing acknowledged the lack of actual evidence. Suppressing puberty for just one month would have a negligible effect on a child’s development, of course, but the Dutch protocol entails suppression for up to four years (from age 12 to 16). It is simply incredible to claim that suppressing puberty for many years would have no lasting effect if the child were to stop GnRHa and restart their natal sex hormones. The manifesto for the Dutch protocol admitted as much: ‘It is not clear yet how pubertal suppression will influence brain development’ (Delemarre-van de Waal and Cohen-Kettenis 2006, S137). Randomized experiments with sheep now provide compelling evidence on this point: GnRHa impairs spatial memory, and this impairment remains after the treatment is stopped and puberty is restarted (Hough et al. 2017a; Hough et al. 2017b).

Recent evaluations of puberty suppression by the English and Swedish health systems

24. NHS England commissioned a systematic evaluation of every study on puberty suppression published up to July 2020. From detailed analysis spanning 131 pages, it concluded: ‘The studies included in this evidence review are all small, uncontrolled observational studies, which are subject to bias and confounding, and all the results are of very low certainty using modified GRADE [Grading of Recommendations, Assessment, Development and Evaluations, a framework for summarizing medical evidence]. They all reported physical and mental health comorbidities and concomitant treatments very poorly’ (National Institute for Clinical Excellence 2020, 23).
25. The Swedish National Board of Health and Welfare updated its recommendations in February 2022, based on a systematic review of the scientific evidence by the Agency for Health Technology Assessment and Assessment of Social Services (Statens beredning för medicinsk och social utvärdering 2022). It states that ‘the risks of puberty suppressing treatment with GnRH-analogues and gender-affirming [cross-sex] hormonal treatment currently outweigh the possible benefits, and that the treatments should be offered only in exceptional cases’, in part due to the ‘continued lack of reliable scientific evidence concerning the efficacy and the safety of both treatments’ (Socialstyrelsen 2022, 3).

Yours sincerely,

A handwritten signature in black ink, appearing to read 'Michael Biggs', with a stylized, cursive script.

19 September 2022

Paul A. Vazquez, J.D.
Executive Director
Florida Board of Medicine

Dear Florida Board of Medicine,

This submission is made to assist your deliberation on the treatment of children and young people suffering from gender dysphoria, specifically on the use of ‘puberty blockers’.

I have published on the origin of this treatment in the Netherlands 1990s (Biggs 2022b) and on the initial British experiment in the 2010s (Biggs 2019b). I was the first to call on the British Tavistock and Portman NHS Foundation Trust’s Gender Identity Development Service (GIDS) to publish the results of its experiment (Tominey and Walsh 2019), and I was the first to publish preliminary results from the experiment (Biggs 2020a). Provoked by the poor quality of data and analysis in this field of medicine, I have published on the effects of puberty suppression on psychological functioning (Biggs 2019a), on suicidality (Biggs 2020b), and on bone density (Biggs 2021), as well as on the suicide rate of transgender adolescents (Biggs 2022a). This work has appeared in *Archives of Sexual Behavior*, *Journal of Sex and Marital Therapy*, *Journal of Sexual Medicine*, and *Journal of Pediatric Endocrinology and Metabolism*.

Puberty suppression as a treatment for gender dysphoria

1. Dutch clinicians started using Gonadotropin-Releasing Hormone agonist (GnRHa) to suppress puberty in children suffering from gender dysphoria—who they designated as ‘juvenile transsexuals’ (Gooren and Delemarre-van de Waal 1996)—in the 1990s. The Dutch protocol had three stages (Delemarre-van de Waal and Cohen-Kettenis 2006). GnRHa would be given from the age of 12, once the child had reached Tanner Stage 2: the first growth of pubic hair and for girls by budding breasts and for boys by growing testicles. Cross-sex hormones would be administered from 16, and surgeries would commence at 18. For this purpose, GnRHa is used off-label, for it has never been licensed to treat gender dysphoria, anywhere in the world. It is licensed to treat precocious puberty—when puberty commences before the age of 7 (approximately) in girls or 9 in boys. That treatment involves delaying a puberty that arrives abnormally early so that the child can undergo puberty at the normal age,

whereas puberty suppression for gender dysphoria entails stopping normal puberty in order to prepare the child for taking hormones of the opposite sex.

2. Puberty suppression as a treatment for gender dysphoria was never tested in any randomized clinical trial. Nor were there any preliminary experiments on non-human animals. Only two decades after this treatment was first used on children were any experiments conducted on sheep and mice (Hough, Bellingham, Haraldsen, McLaughlin, Rennie, et al. 2017; Hough, Bellingham, Haraldsen, McLaughlin, Robinson, et al. 2017; Anacker et al. 2021). The Dutch clinicians published outcomes from a longitudinal study of the first cohort of 70 children whose puberty was suppressed (de Vries et al. 2011; 2014). About half the psychological measures showed improvement. The reported improvement in gender dysphoria is flawed because the researchers switched the questionnaires used to construct the measure. A male who wanted to become a woman was given the male version at baseline and then the female version at follow-up, including irrelevant questions such as about menstruation (Levine, Abbruzzese, and Mason 2022). Notably, one teenager died during vaginoplasty—and so the death rate exceeded 1%. This cohort have not been followed up since their early twenties, just after surgery. Only one patient—the very first to receive puberty suppression for gender dysphoria—has been followed up in the long term. At the age of 35, he was depressed. Due to ‘shame about his genital appearance and his feelings of inadequacy in sexual matters’, he could not sustain a romantic relationship with a girlfriend (Cohen-Kettenis et al. 2011, 845). The clinicians concluded optimistically that ‘the negative side effects are limited’ (Cohen-Kettenis et al. 2011, 843).
3. While gender clinics in many other countries adopted the Dutch protocol from the late 2000s, they did not collect data on outcomes or decided not to publish it. The GIDS started puberty suppression as an experiment in 2011, involving 44 children aged 12 to 15 (Viner et al. 2010). Before the last subject had been recruited, it was pronounced a success by the Director of GIDS and used to justify a new policy of lowering the age of puberty suppression: ‘Now we’ve done the study and the results thus far have been positive we’ve decided to continue with it’ (Manning and Adams 2014). The lack of publication of the results led to my protracted campaign involving news media (e.g., Tominey and Walsh 2019), complaints to the NHS ethics committee (Health Research Authority 2019), and questions in Parliament (Blackwood of North Oxford 2019). The GIDS delayed publication until the day after the verdict was delivered in the judicial review launched by Keira Bell (Carmichael et al. 2020; 2021). The researchers acknowledge that puberty suppression, after two years, produced no positive effects. These results were significantly inferior to the Dutch results following puberty suppression (Biggs 2020a). The subjects of this experiment have not been followed up after cross-sex hormones; the GIDS admits that it loses track of its patients after the age of 18 (Butler et al. 2018). One of the subjects in the experiment appeared on Twitter (as @mediocredruid): she is deeply distressed by her treatment—GnRHa at 15 led to testosterone, double mastectomy, hysterectomy, vaginectomy, and metoidioplasty—but does not know whether to detransition because the physical changes have been so extreme that she might not be able to pass as a woman.
4. In the United States, puberty suppression became widely adopted from 2008 onwards (Biggs 2020b). Dozens of children’s gender clinics were established to tap into this new lucrative market. The National Institutes of Health awarded \$5.7 million for a prospective longitudinal

study of the effects of GnRHa and cross-sex hormones on children (Children’s Hospital Los Angeles 2015). Subjects were recruited between 2016 and 2018 (Olson-Kennedy et al. 2019). Outcomes after two years on GnRHa were thus collected by 2020, but the researchers have only published on the characteristics of the cohort *before* treatment (Chen et al. 2021; Lee et al. 2020) and on the respective merits of two brands of GnRHa (Olson-Kennedy et al. 2021). As in Britain, practitioners of gender medicine are curiously reluctant to publish the outcomes of puberty suppression for psychological functioning and gender dysphoria—even though those outcomes were the primary justification for the treatment.

The association of gender dysphoria with same-sex attraction and autism spectrum conditions

5. Puberty suppression is founded on the assumption that a child suffering from gender dysphoria at age 12—or even younger, if Tanner stage 2 is reached earlier—is a ‘juvenile transsexual’ whose destiny is fixed. This assumption was known to be false by the clinicians who invented the Dutch protocol, who initially recognized that ‘most GID [gender identity disorder, the precursor to gender dysphoria] children under 12 will not grow up to become transsexuals’ (Cohen-Kettenis and van Goozen 1997, 246). ‘Prospective studies of GID boys show that this phenomenon is more closely related to later homosexuality than to later transsexualism’ (Cohen-Kettenis and Gooren 1999, 319). One of the four studies cited is a famous study of ‘sissy boys’ who were selected because they were thought to be ‘pretranssexuals’; after fifteen years, however, two thirds of the 44 had become bisexual or homosexual men and only one was contemplating transsexuality (Green 1987). A representative longitudinal study of 14,000 children born in 1991–92 shows that those who as infants gravitated towards toys and activities typical of the opposite sex were far more likely by the age of 15 to grow up to be gay or lesbian (Li, Kung, and Hines 2017). All this evidence predates the promotion of transgenderism in healthcare and schools and on social media. The manifesto for the Dutch protocol fails to mention homosexuality and does not cite any of the studies of feminine boys (Delemarre-van de Waal and Cohen-Kettenis 2006). Unpublished data on 27 of the Dutch adolescents were given GnRHa reveals that 26 were homosexual and 1 was bisexual (de Vries 2010, 103). The suspicion must be that at least some of these children could have grown up to be typical gays and lesbians, without requiring lifetime medical treatment and without loss of fertility and sexual function.
6. The overlap between gender dysphoria and autistic spectrum conditions (ASC) is well documented (Socialstyrelsen 2020; Warrier et al. 2020). ‘GD [gender dysphoria] and ASD [autism spectrum disorder, another term for ASC] were found to co-occur frequently—sometimes characterized by atypical presentation of GD, which makes a correct diagnosis and determination of treatment options for GD difficult’ (van der Miesen, Hurley, and de Vries 2016, 70). Children on the autistic spectrum are more likely to face difficulties fitting in with their same-sex peers, which makes a transgender identity obviously appealing as both an explanation and a solution. From a sample of over 700 referrals to the GIDS in 2012 and 2015, 14–15% were diagnosed with ASC (Morandini et al. 2021). This was more than ten times greater than the rate for students in England, 0.8%–1.1% (Department for Education 2012; 2015). The proportion among those subjected to GnRHa could be even higher. Out of the first 30 subjects enrolled in the GIDS experiment on puberty suppression, almost half had

ASC traits: mid to moderate in 9 children, and severe in 5 (Gender Identity Development Service 2015).

The risk of suicide for children suffering from gender dysphoria

7. Surveys demonstrate that adolescents who identify as transgender are vulnerable to suicidal thoughts and self-harming behaviors (dickey and Budge 2020; Hatchel, Polanin, and Espelage 2021; Mann et al. 2019). In New Zealand, 20% of transgender students reported attempting suicide in the past 12 months, compared to 4% of all students (Clark et al. 2014). In the United States, 15% of transgender students reported a suicide attempt requiring medical treatment in the last 12 months, compared to 3% of all students (Centers for Disease Control and Prevention 2018; Jackman et al. 2021; Johns et al. 2019). In another American survey, 41% of transgender students reported having attempted suicide during their lifetime, compared to 14% of all students (Toomey, Syvertsen, and Shramko 2018).
8. Respondents who report suicide attempts are not necessarily indicating an intent to die. One survey of the American population found that almost half the respondents who reported attempting suicide subsequently stated that their action was a cry for help and not intended to be fatal (Nock and Kessler 2006). In two small samples of non-heterosexual youth, half the respondents who initially reported attempting suicide subsequently clarified that they went no further than imagining or planning it; for the remainder who did actually commit suicide, their actions were usually not life-threatening. To an extent, then, ‘the reports were attempts to communicate the hardships of lives or to identify with a gay community’ (Savin-Williams 2001). Such elaborate survey methods have not been used to study transgender populations, but there is anecdotal evidence for a disjuncture between self-harm and suicidal ideation on one hand and fatal suicide on the other. The pediatric endocrinologist who established the first clinic for transgender children in the United States stated that ‘the majority of self-harmful actions that I see in my clinic are not real suicide attempts and are not usually life threatening’ (Spack 2009, 312).
9. Two published studies have reported suicide fatalities among transgender adolescents. Belgium’s pediatric gender clinic provided counselling to 172 youth aged from 12 and 18 years, who had been referred between 2007 and 2016: 5 of them (2.9%) committed suicide (Van Cauwenberg, Dhondt, and Motmans 2021). The mean age of referral was 15, implying a mean duration of 3 years before transition to an adult clinic, which translates to an annual suicide rate of 969 per 100,000.
10. At the Tavistock GIDS, which serves young people under 18 from England, Wales, and Northern Ireland, 4 patients were known or suspected to have died by suicide between 2010 and 2020. The clinic had referrals for approximately 15,000 patients in this period. To calculate the annual suicide rate, the total number of years spent by patients under the clinic’s care is estimated at about 30,000. This yields an annual suicide rate of 13 per 100,000 (95% confidence interval: 4–34). Compared to the United Kingdom population of the same age and sexual composition, the suicide rate for patients at the GIDS was 5.5 times higher (Biggs 2022a). It is not clear what explains the enormous disparity in suicide rates at these two clinics; the Belgian rate is 70 times higher. The suicide rate at the Tavistock is much closer to the rate calculated from 8,000 adults who visited the Amsterdam clinic between 1972 and 2017, which was quadruple that of the Dutch population (Wiepjes et al. 2020).

11. The elevated suicide rate of children who identify as transgender could be explained by some combination of gender dysphoria, accompanying psychological conditions, and ensuing social disadvantages such as bullying. The association between ASC and gender dysphoria was pointed out above. Autism is known to increase the risk of suicide mortality, especially in females (Socialstyrelsen 2020; Hirvikoski et al. 2016; Kirby et al. 2019). To some extent, therefore, the elevated suicide rate for transgender youth compared to their peers reflects the higher incidence of ASC. The same holds for other psychiatric disorders associated with gender dysphoria (Dhejne et al. 2016).
12. The claim that puberty suppression reduces suicidality in children suffering from gender dysphoria is not implausible. Because the risk of suicide increases greatly from prepubescence to late adolescence, halting normal cognitive and emotional development with GnRHa could reduce the risk of suicide by preventing the child from maturing. As yet there is no evidence, however, that endocrinological interventions reduce the risk of suicide. At the GIDS from 2010 to 2020, there is no detectable difference between the suicide rate for patients on the waiting list and for patients who were being seen (Biggs 2022a). In the Belgian clinic which experienced the exceptionally high suicide rate, subsequent correspondence reveals that ‘suicide was related to many more (psychological) problems than their GD [gender dysphoria], and occurred mostly a few years after the start on hormonal treatment’ (email from Gaia Van Cauwenberg to Avi Ring, 27 May 2022).
13. One study claims that puberty suppression reduced subsequent suicidality in adults (Turban et al. 2020). This finding derives from a nonrepresentative survey of transgender adults in the United States, which included 89 respondents who reported taking puberty blockers. Six measures of suicidality and three other measures of mental health and substance abuse were examined, but only one yielded a statistically significant association after controlling for other factors: the respondents who reported taking puberty blockers were less likely to have thought about killing themselves than were the respondents who reported wanting blockers but not obtaining them. This study has numerous serious flaws (Biggs 2020b). Most fundamentally, without information on the respondents’ mental health during adolescence, the causal direction cannot be ascertained. The association could well be explained by clinicians refusing to prescribe GnRHa to adolescents with significant psychological problems, as indeed was then recommended by the Endocrine Society (Hembree et al. 2009). The study did not disclose the fact that one of its authors had been paid by Endo Pharmaceuticals, which manufactures a GnRHa drug (histrelin acetate under the brand Supprelin). At my insistence, the journal issued a correction to admit this conflict of interest (Pediatrics 2021).
14. There are anecdotal reports of children experiencing increased suicidal feelings after GnRHa. At the Leiden clinic, one teenager ‘stopped treatment because of an increase in mood problems and suicidal thoughts and confusion attributed to GnRHa treatment’ (Brik et al. 2020, 2614). One English teenager recalled that GnRHa led to suicidal feelings (Klotz 2022). The triptorelin formulations used in Britain—Gonapeptyl® Depot and Decapeptyl® SR—carry warnings that depression is a common side effect, affecting between 1% and 10% of patients (Ferring Pharmaceuticals Ltd 2016), and ‘may be severe’ (Ipsen Ltd 2017).

The effect of puberty suppression on mental health

15. The first Dutch cohort of 70 children given GnRHa reported generally positive outcomes, by age 16, when they graduated to cross-sex hormones (de Vries et al. 2011). (The actual number of observations ranged from 41 to 57, depending on measure.) Psychological functioning improved, depressive symptoms declined, and behavioural and emotional problems decreased. Gender dysphoria, however, worsened for females. Using the same measures as the Dutch, the first GIDS cohort of 44 children reported no improvement in psychological functioning or gender dysphoria after two years (Carmichael et al. 2021). There was a misleading earlier article from the GIDS which claimed that puberty suppression improved psychological functioning (Costa et al. 2015). It had an extraordinarily high attrition rate—almost half the subjects vanished over 12 months, without explanation—and the claimed effect was actually not statistically significant (Biggs 2019a). It nevertheless continues to be cited as credible evidence for the beneficial effects of puberty suppression.
16. According to a recent study from the Seattle Children’s Gender Clinic, 69 youth aged 13 to 16 experienced dramatically reduced rates of depression and of self-harm or suicidal thoughts after 12 months on GnRHa or cross-sex hormones (Tordoff et al. 2022). (The authors unfortunately do not differentiate these two interventions.) In fact the data for these youth showed no change over time (Singal 2022). The false claim was derived from statistical comparison with youth from the clinic who had not received these endocrinological interventions, whose mental health worsened over time. But this comparison group numbered only 6 patients after 12 months. One obvious explanation is that the clinicians were following the World Professional Association of Transgender Health’s recommendations against commencing medical intervention when an adolescent is experiencing an acute mental health crisis. (This is the same fallacy of causal inference that vitiated Turban et al.’s (2020) study of suicidality.)
17. A proper randomized control trial of the effect of suppressing puberty in mice using GnRHa demonstrated that it caused significantly higher levels of stress in males, and increased anxiety and despair-like behaviour in females (Anacker et al. 2021).

The effect of puberty suppression on bone density

18. The Dutch pioneers warned at the outset that patients could ‘end with a decreased bone density, which is associated with a high risk of osteoporosis’ (Delemarre-van de Waal and Cohen-Kettenis 2006, S134). The fact that GnRHa prevents the accrual of normal bone mass is well documented from Dutch and British studies (Klink et al. 2015; Schagen et al. 2020; Stoffers, de Vries, and Hannema 2019; Vlot et al. 2017; Joseph, Ting, and Butler 2019). In addition, children given GnRHa already have unusually low bone density, perhaps due to the high prevalence of eating disorders. The combined effect can be appreciated by looking at the proportion of adolescents who end up after treatment with severely low bone density, two standard deviations below the average—putting them at risk for osteoporosis. Reanalysis of 31 of the GIDS patients demonstrates that after two years on GnRHa, up to a third had reached this very low range, depending on the measure (hip or spine); only 2.3% of the population would be this low. Moreover, four patients (13%) had spine bone density over

three standard deviations from the mean; only 0.13% of the population would be so extremely low (Biggs 2021).

19. Whether such abnormally low bone density has increased the risk of fractures is unknown because clinics apparently do not collect data on fractures. Anecdotally, a British female patient who started GnRHa at age 12 then experienced four broken bones by the age of 16 (Bannerman 2019). A Swedish documentary highlighted the case of a female who was given GnRHa from age 11 to 15, and now suffers from severe osteoporosis, including continual skeletal pain (SVT 2021).

The effect of puberty suppression on sexual function

20. When GnRHa is used to treat prostate cancer, one side effect is that ‘sexual desire, sexual interest and sexual intercourse were totally annulled’ (Marumo, Baba, and Murai 1999, 19). This is why GnRHa is licensed to chemically castrate men who are sex offenders (Ho et al. 2012; Turner and Briken 2018). Clinicians who use GnRHa off-label to treat gender dysphoria have ignored its effects on sexuality. The Dutch studies, for example, included no measures for libido or capacity for orgasm (de Vries et al. 2011; 2014). The lead author recently described orgasm as ‘a very interesting and so far not studied question’ (Klotz 2022). A Californian surgeon who has performed over 2,000 vaginoplasties (and who is also transgender) recently acknowledged that ‘every single child who was, or adolescent, who was truly blocked at Tanner Stage 2, has never experienced orgasm. I mean, it’s really about zero’ (Bowers 2022). This remark refers to males. The effects of puberty suppression at such an early stage on females is unknown.

The effect of puberty suppression on subsequent medical transition

21. Dutch clinicians initially promoted puberty suppression as providing space for therapeutic exploration of gender identity, without the pressure of the physical changes accompanying puberty (Delemarre-van de Waal and Cohen-Kettenis 2006). This was plausible, perhaps, though it was also plausible that stopping normal sexual and cognitive development would impede such exploration. As the Dutch clinicians admitted at the time, ‘none of the [54] patients who were selected for pubertal suppression has decided to stop taking GnRHa’ (Delemarre-van de Waal and Cohen-Kettenis 2006, S136). It could have been argued that this was due to careful selection of a small number of adolescents for this experimental treatment.
22. Although the number of children subjected to puberty suppression has increased dramatically, they almost invariably continue to cross-sex hormones. Out of 333 children given GnRHa in the Amsterdam clinic to the end of 2015, 326 (98%) continued to cross-sex hormones (Wiepjes et al. 2018). Out of 133 children given GnRHa at the Leiden clinic in the Netherlands who attained the age of eligibility for cross-sex hormones, 128 (96%) continued (Brik et al. 2020). Out of 44 children enrolled in the GIDS experiment with GnRHa, 43 (98%) continued to cross-sex hormones (Carmichael et al. 2021). Out of 54 children given GnRHa by the Royal Children’s Hospital Gender Service in Australia, 53 (98%) continued to cross-sex hormones (Tollit et al. 2021). The suspicion is that puberty suppression reinforces gender dysphoria.
23. Given the fact that there are almost no cases of children ceasing GnRHa, the claim for reversibility is moot. The article that first proposed puberty suppression deemed it to be ‘fully

reversible; in other words, no lasting undesired effects are to be expected' (Gooren and Delemarre-van de Waal 1996, 72). The phrasing acknowledged the lack of actual evidence. Suppressing puberty for just one month would have a negligible effect on a child's development, of course, but the Dutch protocol entails suppression for up to four years (from age 12 to 16). It is simply incredible to claim that suppressing puberty for many years would have no lasting effect if the child were to stop GnRHa and restart their natal sex hormones. The manifesto for the Dutch protocol admitted as much: 'It is not clear yet how pubertal suppression will influence brain development' (Delemarre-van de Waal and Cohen-Kettenis 2006, S137). Randomized experiments with sheep now provide compelling evidence on this point: GnRHa impairs spatial memory, and this impairment remains after the treatment is stopped and puberty is restarted (Hough et al. 2017a; Hough et al. 2017b).

Recent evaluations of puberty suppression by the English and Swedish health systems

24. NHS England commissioned a systematic evaluation of every study on puberty suppression published up to July 2020. From detailed analysis spanning 131 pages, it concluded: 'The studies included in this evidence review are all small, uncontrolled observational studies, which are subject to bias and confounding, and all the results are of very low certainty using modified GRADE [Grading of Recommendations, Assessment, Development and Evaluations, a framework for summarizing medical evidence]. They all reported physical and mental health comorbidities and concomitant treatments very poorly' (National Institute for Clinical Excellence 2020, 23).
25. The Swedish National Board of Health and Welfare updated its recommendations in February 2022, based on a systematic review of the scientific evidence by the Agency for Health Technology Assessment and Assessment of Social Services (Statens beredning för medicinsk och social utvärdering 2022). It states that 'the risks of puberty suppressing treatment with GnRH-analogues and gender-affirming [cross-sex] hormonal treatment currently outweigh the possible benefits, and that the treatments should be offered only in exceptional cases', in part due to the 'continued lack of reliable scientific evidence concerning the efficacy and the safety of both treatments' (Socialstyrelsen 2022, 3).

Yours sincerely,

A handwritten signature in black ink, appearing to read 'Michael Biggs', with a stylized, cursive script.

Dr Michael Biggs (BA Hons Victoria University of Wellington; PhD Harvard)

Letter to the Editor

Michael Biggs*

Revisiting the effect of GnRH analogue treatment on bone mineral density in young adolescents with gender dysphoria

<https://doi.org/10.1515/jpem-2021-0180>

Received March 14, 2021; accepted March 24, 2021;

published online April 26, 2021

Keywords: bone mineral density; gender dysphoria; GnRHa treatment; transgender.

To the Editors,

I write to respond to Joseph, Ting, and Butler's recent article, describing the effect of administering gonadotropin-releasing hormone analogue (GnRHa) to suppress puberty in adolescents diagnosed with gender dysphoria [1]. The mean of the patients' bone mineral density (BMD)—relative to the norm for their sex and age—declined significantly over 2 years. What really matters is the lower tail of the distribution, but this information was omitted by Joseph et al. This letter analyses individual data on 24 patients from Joseph et al.'s sample of 31 [2]. It finds that after 2 years of GnRHa, up to a third of patients had abnormally low bone density, in the lowest 2.3% of the distribution for their sex and age. A few patients recorded extremely low values, in the lowest 0.13% of the distribution. This finding undermines Joseph et al.'s conclusions.

The Dutch pioneers of this experimental treatment for gender dysphoria warned that patients could 'end with a decreased bone density, which is associated with a high risk of osteoporosis' [3]. The effects on bone density have been described by four Dutch studies [4–7], besides Joseph et al. BMD is measured by a dual energy X-ray absorptiometry (DXA) scan over the spine (lumbar) and the hip (femoral neck). The absolute value of BMD is standardized as a Z-score, expressing this individual's BMD relative to the population of the same sex and age. BMD can be adjusted for

height to derive the volumetric bone mineral apparent density (BMAD), which is likewise standardized as a Z-score.

A Z-score below -2 is considered low; it indicates bone density in the lowest 2.3% of the population of the same sex and age [8]. Joseph et al. argue that 'this is not the sole definition of low bone mass in children, nor is this criterion a recognized predictor of later fracture risk'. But this threshold was prominent in the experiment which introduced puberty suppression for gender dysphoria to Britain. The original experimental protocol (co-authored by Butler) in 2010 excluded any child with a spine or hip BMD Z-score below -2 . In 2012, however, this exclusion criterion was relaxed 'in exceptional circumstances'—if clinicians 'feel that on the balance of risks, pubertal suppression is an appropriate option despite risks of osteoporosis in later adult life' and patients 'understand the risks of GnRH analogue treatment for bone density (i.e., risks of later osteoporosis)' [9].

Information on the lower tail of the distribution of Z-scores—below -2 —is omitted by Joseph et al. and by three out of four Dutch studies. Describing distributions by mean (and standard deviation) is not sufficient when clinical concern focuses on very low values. This will be illustrated for patients experiencing 2 years of puberty suppression. Joseph et al.'s sample after 24 months on GnRHa comprised 31 patients. Data on 24 of these patients—or at least patients from the same clinic at University College London Hospital—have recently been released, though sex is unavailable [2]. These patients were enrolled in the British experiment which recruited patients from 2011 to 2015. The Stata do file to replicate the analysis is posted at <https://doi.org/10.7910/DVN/FSOMME>.

Table 1 shows mean Z-scores for Joseph et al.'s three measures of BMD, at baseline and at 24 months (the hip measure is missing for three patients). The 2011–15 sample is naturally similar to Joseph et al.'s. The decline in the mean of all three scores is statistically significant in both samples ($p \leq 0.004$ in every paired t-test).

Using data from the 2011–15 sample, Figure 1 depicts the distributions of Z-scores at 24 months, along with the

Table 1: Bone density in adolescents undergoing puberty suppression.

	Hip BMD		Spine BMD		Spine BMAD	
	Joseph et al.	2011–15	Joseph et al.	2011–15	Joseph et al.	2011–15
Mean Z-score at baseline	−0.58	−0.55	−0.44	−0.34	−0.09	−0.46
Mean Z-score at 24 months	−1.40	−1.45	−1.64	−1.46	−0.71	−1.28
Change in Z-score	−0.82	−0.90	−1.20	−1.12	−0.62	−0.81
p-value (two-tailed)	0.000	0.000	0.000	0.000	0.000	0.004
n	31	21	31	24	31	24

BMD, bone mineral density; BMAD, bone mineral apparent density.

n = 24 for spine, 21 for hip. BMAD, bone mineral apparent density; BMD, bone mineral density.

Figure 1: Bone density after 24 months of puberty suppression.

Normal distribution to compare with the population of the same sex and age. For hip BMD, a third of patients had a low Z-score, below −2. For spine BMD, more than a quarter of patients had low Z-scores. The lower tail extended far beyond. Indeed, four patients had Z-scores below −3, putting them in the bottom 0.13% of the population. Adjusting for height, by computing spine BMAD, does not shrink the lower tail.

Given that puberty suppression left up to a third of patients with abnormally low bone density, Joseph et al.'s recommendations are surprisingly complacent. One is to reduce DXA monitoring which 'can have significant financial implications for healthcare providers'. Another is to change the computation of Z-scores; 'reference ranges may need to be re-defined for this select patient cohort'. Rather than altering a measure that provides inconvenient findings, practitioners of puberty suppression must record fractures as adverse events. One British patient who started GnRHa at age 12 then experienced four broken bones by the age of 16 [10]. This history, if it were combined with BMD Z-scores below −2, would meet the diagnostic criteria for

paediatric osteoporosis [11]. Whether this case is exceptional is unknown because clinicians have failed to collect relevant data.

Suicide by Clinic-Referred Transgender Adolescents in the United Kingdom

Introduction

Surveys show that adolescents who identify as transgender are vulnerable to suicidal thoughts and self-harming behaviors (Dickey & Budge, 2020; Hatchel et al., 2021; Mann et al., 2019). Little is known about death by suicide. This Letter presents data from the Gender Identity Development Service (GIDS), the publicly funded clinic for children and adolescents aged under 18 from England, Wales, and Northern Ireland. From 2010 to 2020, four patients were known or suspected to have died by suicide, out of about 15,000 patients (including those on the waiting list). To calculate the annual suicide rate, the total number of years spent by patients under the clinic's care is estimated at about 30,000. This yields an annual suicide rate of 13 per 100,000 (95% confidence interval: 4–34). Compared to the United Kingdom population of similar age and sexual composition, the suicide rate for patients at the GIDS was 5.5 times higher. The proportion of patients dying by suicide was far lower than in the only pediatric gender clinic which has published data, in Belgium (Van Cauwenberg et al., 2021).

Suicidality in Transgender Adolescents

“About half of young trans people...attempt suicide,” declared the United Kingdom Parliament's Women and Equalities Committee (2015). Similar figures are cited by news media and campaigning organizations. The *Guardian* reported Stonewall's statistic that “almost half” of transgender young people “have attempted to kill themselves” (Weale, 2017). “Fifty percent of transgender youth attempt suicide before they are at age 21” stated the mother of the most famous transgender youth in the English-speaking world (Jennings & Jennings, 2016). As a transgender theologian has

observed, “the statistic about suicide attempts has, in essence, developed a life of its own” (Tanis, 2016).

Representative surveys of students in high schools provide one source of evidence for this statistic. In New Zealand, 20% of transgender students reported attempting suicide in the past 12 months, compared to 4% of all students (Clark et al., 2014). In the United States, 15% of transgender students reported a suicide attempt requiring medical treatment in the last 12 months, compared to 3% of all students (Centers for Disease Control & Prevention, 2018; Jackman et al., 2021; Johns et al., 2019). In another American survey, 41% of transgender students reported having attempted suicide during their lifetime, compared to 14% of all students (Toomey et al., 2018).

To what extent are self-reported suicide attempts reflected in fatalities? The connection is not straightforward. Respondents who report suicide attempts are not necessarily indicating an intent to die. One survey of the American population found that almost half the respondents who reported attempting suicide subsequently stated that their action was a cry for help and not intended to be fatal (Nock & Kessler, 2006). In two small samples of non-heterosexual youth, half the respondents who initially reported attempting suicide subsequently clarified that they went no further than imagining or planning it; for the remainder who did actually attempt suicide, their actions were usually not life-threatening. To an extent, then, “the reports were attempts to communicate the hardships of lives or to identify with a gay community” (Savin-Williams, 2001). Although such elaborate survey methods have not been used to study transgender populations, there is anecdotal evidence for a similar disjuncture. The pediatric endocrinologist who established the first clinic for transgender children in the United States stated that “the majority of self-harmful actions that I see in my clinic are not real suicide attempts and are not usually life threatening” (Spack, 2009).

Suicide mortality has been studied in the transgender population using registry data. The annual suicide rate is calculated by dividing the number of suicides by the total number of years each person was at risk. An individual who was observed for 20 years, for instance, contributes 20 person-years to the denominator. The

largest study covers over 8,000 patients who visited the gender clinic in Amsterdam from 1972 to 2017 (Wiepjes et al., 2020). The annual suicide rate was 29 per 100,000 for transmen, quadruple the rate for the female population, and 64 for transwomen, quadruple the rate for the male population. A Swedish study of 324 individuals who had undergone genital surgery between 1973 and 2003 found much higher annual suicide rates: 250 per 100,000 for transmen, 43 times the rate for matched female controls, and 285 for transwomen, 16 times the rate for matched male controls (M. Boman, personal communication, 12 April 2021; Dhejne et al., 2011). Only one published study has reported suicide fatalities among transgender adolescents. Belgium's pediatric gender clinic provided counseling to 177 youth aged from 12 to 18 years, who had been referred between 2007 and 2016: five of them (2.8%) committed suicide (Van Cauwenberg et al., 2021). The mean age of referral was 15, implying a mean duration of 3 years before transition to an adult clinic, which translates to an annual suicide rate of 942 per 100,000. This is the highest suicide mortality recorded for any transgender population.

Method

This Letter estimates the suicide rate at the world's largest pediatric gender clinic. Based in London, the GIDS is part of the Tavistock and Portman NHS Foundation Trust, and serves youth under 18 from England, Wales, and Northern Ireland who are "experiencing difficulties with their gender identity development" (Carmichael & Davidson, 2009). Like all such services throughout Western Europe and North America, it has experienced enormous growth; referrals increased from 100 in 2009 to a peak of 2700 in 2019. The waiting list in April 2021 exceeded 5300.

The GIDS patients manifest typically high rates of self-harming behavior. In a sample of 900 adolescents (aged from 13 to 17) admitted to the clinic from 2009 to 2017 and given the Youth Self-Report questionnaire, 44% answered that they sometimes or very often "deliberately try to hurt or kill myself" (de Graaf et al., 2020). Unfortunately, both behaviors are combined in this question. In a different sample of over 700 children and adolescents (aged from 4 to 17) assessed by the GIDS in 2012 and 2015, 10% were flagged by clinicians as having attempted suicide (Morandini et al., 2021).

Suicides

Since the early 2000s, the National Health Service has implemented mandatory reporting of "serious incidents" (Department of Health, 2001, 2010). The death of any patient—including those on the waiting list—suspected to be suicide is reported to the Tavistock's Board of Directors. The Tavistock cooperates with a comprehensive surveillance system for every death

classified as suicide or (after an open verdict by the coroner) probable suicide in the United Kingdom (National Confidential Inquiry into Suicide & Homicide by People with Mental Illness, 1999; National Confidential Inquiry into Suicide and Safety in Mental Health, 2019). Papers for the Tavistock's Board meetings are available from April 2007 onwards; those not on the Trust's website were acquired by a Freedom of Information request. The pdf files of the *Agenda and Papers* (through September 2021) were searched for the keyword "suicid"; all 442 instances were inspected. From 2007 to 2020, four patients of the GIDS died by suspected suicide: two on the waiting list, in 2016 and 2017; and two after having been seen, in 2017 and 2020. The last case was described as "likely" to be suicide, because the inquest has not yet been held. These figures were confirmed by Freedom of Information requests to the Tavistock.

Triangulation is possible from two sources. Comprehensive mortality data on all adolescents aged from 10 to 19 who committed suicide in the United Kingdom from 2014 to 2016 include five transgender individuals (Rodway et al., 2020). Due to confidentiality restrictions, it is not possible to disaggregate these further by age or by country. Presumably, one of these is the patient of GIDS who died in 2016. The remaining four might have been 18 or 19—the risk of suicide increases significantly in the late teens—or might have lived in Scotland. Alternatively, they might have been eligible for the GIDS but had not sought a clinical referral (made by the local Child and Adolescent Mental Health Service, the child's general practitioner, social worker, or teacher) or had not obtained it.

Another source is the Transgender Day of Remembrance website, which aims to record all deaths by suicide or violence (Metcalf, 2021). For the United Kingdom between 2007 and 2020, the website names 3 adolescents under the age of 18 who committed suicide. One was one of the GIDS patients (the match is certain because they were named in the *Agenda and Papers*). The other two had no involvement with the GIDS (or any other gender clinician), as was evident from their inquests, though one was under the psychiatric care of another NHS Trust (BBC News, 2021; Bunyan, 2008). In addition, the website lists suicides by two "young" transgender people, sourced from Twitter, without information on their name or age. In one case, it is not clear whether the person lived in the United Kingdom.

Patients

With suicides as numerator, two denominators are relevant. Because comprehensive data on patient numbers became available from 2010, the period will be the 11 years from 2010 to 2020. (These are financial years; thus, 2020 runs from April 2020 to March 2021.) The first denominator is the total number of individual patients, estimated by summing the annual number of referrals to the GIDS from 2010 to 2020—excluding those aged 18 or over, as they are not accepted. The total number is 15,032. This sum omits patients at the clinic who had been referred before

2010, and so is a slight underestimate. (The Online Supplement provides full details.)

The second denominator is the total number of patient-years: the sum of the number of years spent by each individual as a patient of the GIDS. The number of patients seen by the GIDS each year was available from 2014 to 2020. Before 2014 only the number of patients first seen was available. From 2014 to 2016, the number of patients seen was consistently double the number first seen, and so the former number for 2010 to 2013 was estimated by doubling the latter. All these numbers exclude patients on the waiting list. The number waiting at the beginning of each year from 2016 to 2020 was obtained by Freedom of Information request. Before then the number was not available, and so must be treated as zero. This leads to an underestimate, of course, but the waiting list became appreciable only from 2015. The total number of patient-years over this period is estimated as 30,080. In other words, patients spent on average 2 years at the GIDS (including time on the waiting list). Time on the waiting list contributed 41% of the total patient-years.

Results

From 2010 to 2020, the four suicide deaths equate to 0.03% of the 15,032 patients. Taking the denominator as 30,080 patient-years, the annual suicide rate is calculated as 13 per 100,000 (95% confidence interval: 4 to 34 per 100,000). For comparison, the annual suicide rate in England and Wales between 2010 and 2020 for adolescents aged from 15 to 19 years averaged 4.7 (Office for National Statistics, 2021). This does not quite correspond to the age range of the GIDS patients, however. At referral, the patients ranged in age from 3 to 17 years; only 7% were younger than 10. The mean was 14 years and the median 15. Most patients stay with the GIDS until transitioning to an adult service. Therefore, the average age of patients at any point in time will lie somewhere between 14 and 17. A better comparison is therefore the overall suicide rate for adolescents aged from 14 to 17 (available only for the entire United Kingdom for 2015–2017), which was 2.7 per 100,000 (Office for National Statistics, 2018; Rodway et al., 2020). Comparison should also account for the difference between the sexes, because males are more likely to commit suicide than females. Of the GIDS patients, 69% were female. Adjusting for sex, the GIDS patients were 5.5 times more likely to commit suicide than the overall population of adolescents aged 14 to 17.

Discussion

How reliable are these estimates? The chief uncertainty about the numerator is whether the fourth death will be ruled as suicide when the inquest is eventually held. It could be speculated that there were further suicides unknown to the Tavistock and

to the National Confidential Inquiry into Suicide and Safety in Mental Health. All that can be said is that the single suicide by a GIDS patient from 2014 to 2016 is not out of line with comprehensive mortality data on suicides by transgender adolescents in the United Kingdom which counted five suicides in a longer age range and wider geographical area. The denominator for the annual suicide rate, however, is pieced together from various series and so is inevitably approximate. Statistics from the early 2010s are less reliable, though they make only a small contribution to the grand total; the last three years contribute more than half of the total number of patient-years. The most significant limitation is the lack of information on the age and sex of all the patients who committed suicide.

Direct comparison can be made with the Belgian pediatric gender clinic (Van Cauwenberg et al., 2021). Its annual suicide rate was about 70 times greater than the rate at the GIDS. This is especially puzzling because patients at the Belgian clinic scored better, on average, than those at the GIDS on tests of psychological functioning (de Graaf et al., 2018). The explanation for the huge disparity in suicide is not clear. The Amsterdam's clinic annual suicide rate was four times greater than the rate at the GIDS. The higher rate is not surprising, however, because the Dutch clinical population was dominated by older adults: the median age at first visit was 25 (Wiepjes et al., 2020). Suicide rates peak in middle age, and so a population of older adults would be at higher risk than a population of adolescents.

The suicide rate of the GIDS patients is not necessarily indicative of the rate among all adolescents who identify as transgender. On the one hand, individuals with more serious problems (and their families) would be particularly motivated to seek referral and more likely to obtain it, and so the clinical subset would be more prone to suicide. One study suggests that a child who frequently attempted suicide was more readily referred to the GIDS (Carlile et al., 2021). On the other hand, young people facing hostility from their families would be less able to seek referral, and this hostility could make them especially vulnerable to suicide.

Taking into account these limitations, the estimated suicide rate at the GIDS provides the strongest evidence yet published that transgender adolescents are more likely to commit suicide than the overall adolescent population. The higher risk could have various causes: gender dysphoria, accompanying psychological conditions, and ensuing social disadvantages such as bullying. Studies of young people referred to the GIDS in 2012 and 2015 found a high prevalence of eating disorders, depression, and autism spectrum conditions (ASC) (Holt et al., 2016; Morandini et al., 2021)—all known to increase the probability of suicide (Simon & VonKorff, 1998; Smith et al., 2018). Eating disorders and depression could be consequences of transgender identity and its ensuing social repercussions, but this is implausible for ASC insofar as it originates in genes or the prenatal environment. From a sample of over 700 referrals to the GIDS in 2012 and 2015, 14–15% were diagnosed with ASC (Morandini

et al., 2021). This compared to 0.8–1.1% of students in England (Department for Education, 2012, 2015). The association between autism and gender dysphoria is found in many populations (Socialstyrelsen, 2020; Warrier et al., 2020). Autism is known to increase the risk of suicide mortality, especially in females (Hirvikoski et al., 2016; Kirby et al., 2019; Socialstyrelsen, 2020). To some extent, therefore, the elevated suicide rate for transgender youth compared to their peers reflects the higher incidence of ASC. The same holds for other psychiatric disorders associated with gender dysphoria (Dhejne et al., 2016). Ideally, the suicide rate for patients of the GIDS would be compared to the suicide rate for patients in contact with other NHS mental health services, but the latter rate is not available.

One final caveat is that these data shed no light on the question of whether counseling or endocrinological interventions—gonadotropin-releasing hormone agonist or cross-sex hormones—affect the risk of suicide (Biggs, 2020; Turban et al., 2020). Although two out of the four suicides were of patients on the waiting list, and thus would not have obtained treatment, this is not disproportionate: the waiting list contributed nearly half of the total patient-years.

Conclusion

Data from the world's largest clinic for transgender youth over 11 years yield an estimated annual suicide rate of 13 per 100,000. This rate was 5.5 times greater than the overall suicide rate of adolescents of similar age, adjusting for sex composition. The estimate demonstrates the elevated risk of suicide among adolescents who identify as transgender, albeit without adjusting for accompanying psychological conditions such as autism. The proportion of individual patients who died by suicide was 0.03%, which is orders of magnitude smaller than the proportion of transgender adolescents who report attempting suicide when surveyed. The fact that deaths were so rare should provide some reassurance to transgender youth and their families, though of course this does not detract from the distress caused by self-harming behaviors that are non-fatal. It is irresponsible to exaggerate the prevalence of suicide. Aside from anything else, this trope might exacerbate the vulnerability of transgender adolescents. As the former lead psychologist at the Tavistock has warned, “when inaccurate data and alarmist opinion are conveyed very authoritatively to families we have to wonder what the impact would be on children’s understanding of the kind of person they are...and their likely fate” (Wren, 2015).

The Dutch Protocol for Juvenile Transsexuals: Origins and Evidence

Michael Biggs

Department of Sociology, University of Oxford, Oxford, UK

ABSTRACT

It has been a quarter of a century since Dutch clinicians proposed puberty suppression as an intervention for “juvenile transsexuals,” which became the international standard for treating gender dysphoria. This paper reviews the history of this intervention and scrutinizes the evidence adduced to support it. The intervention was justified by claims that it was reversible and that it was a tool for diagnosis, but these claims are increasingly implausible. The main evidence for the Dutch protocol came from a longitudinal study of 70 adolescents who had been subjected to puberty suppression followed by cross-sex hormones and surgery. Their outcomes shortly after surgery appeared positive, except for the one patient who died, but these findings rested on a small number of observations and incommensurable measures of gender dysphoria. A replication study conducted in Britain found no improvement. While some effects of puberty suppression have been carefully studied, such as on bone density, others have been ignored, like on sexual functioning.

The use of Gonadotropin-Releasing Hormone agonist (GnRHa) drugs to suppress puberty in “juvenile transsexuals” was first proposed in print in the mid-1990s (Gooren & Delemarre-van de Waal, 1996). Developed by three clinicians at Utrecht and Amsterdam, this intervention became known as the Dutch protocol. It rapidly became standard practice in the treatment of adolescents diagnosed with gender dysphoria (HBIGDA, 2001). This intervention has been described in several manifestos by its proponents (e.g. de Vries & Cohen-Kettenis, 2012; Delemarre-van de Waal, 2014; Delemarre-van de Waal & Cohen-Kettenis, 2006) and subjected to brief critical commentaries (Byng et al., 2018; Laidlaw et al., 2019; Levine et al., 2022). The aim of this paper to provide an historical account of the invention of the Dutch protocol and a critical review of the evidence that has accumulated in the quarter of a century since it was proposed.

Before proceeding, some definitions are in order. Gender dysphoria will be used here to describe a persistent desire to become the opposite sex (Zucker, 2010). Medical terminology has changed over time, from “gender identity disorder” and “transsexualism” (both introduced in the *Diagnostic and Statistical Manual of Mental Disorders-III* in 1980) to “gender dysphoria” (as renamed in the 2013 *DSM-5*) and “gender incongruence” (as renamed in the 2019 *International Classification of Diseases-11*). There is no need to dwell on these diagnostic criteria because the condition in practice is defined by the patient’s wish for endocrinological and surgical interventions. In the nomenclature of transgender medicine, “puberty blockers” denote GnRHa drugs (alternatively known as Luteinizing Hormone-Releasing Hormone agonists) which stop the production of sex hormones.¹ Drugs in this class include triptorelin (branded Decapeptyl or

Gonapeptyl), which is used in the Netherlands and Britain, and leuporelin (branded Lupron) in North America. GnRHa drugs are licensed to treat several medical conditions including precocious puberty in children; endometriosis and uterine fibroids in women; and advanced prostate cancer and sexual deviance in men. The drugs have never been licensed as a treatment for gender dysphoria.

The paper begins by describing how puberty suppression was invented, primarily by the psychologist Peggy Cohen-Kettenis, in the 1990s. It reveals the gap between the protocol described in formal manifestos and actual clinical practice. The second section examines the rationale for this intervention, focusing on two claims—that GnRHa is reversible and that it serves as diagnosis—and two omissions—the association between gender dysphoria and homosexuality and the effect of GnRHa on sexual development. The third section traces the international adoption of the Dutch protocol. The fourth section scrutinizes evidence from an early cohort of 70 adolescents subjected to puberty suppression at the Amsterdam clinic (de Vries et al., 2011, 2014). This cohort provides the only significant evidence that GnRHa followed by cross-sex hormones and surgery results in improved psychological function and reduced gender dysphoria. The evidence is less persuasive than it appears: the number of observations was considerably fewer than 70, the reported reduction in gender dysphoria depended on incommensurable scales, and the outcomes omit one patient who died because puberty suppression dictated a riskier vaginoplasty. The fifth section pursues the British study designed to replicate the Dutch one; it was withheld from publication for some years, presumably because puberty suppression in this sample failed to improve gender dysphoria or psychological functioning. The poor quality of American studies is also noted. The final section evaluates evidence for the side effects of GnRHa. The negative effect on the accrual of bone mass is well studied, while there is increasing evidence for negative effects on cognitive and emotional development and on sexual functioning.

Origins of the Dutch protocol

Transsexualism as a concept emerged in the mid-twentieth century, following the discovery of cross-sex hormones and advances in plastic surgery (Hausman, 1995). Novel physical interventions were justified by the new theoretical construct of “gender identity” invented by American psychologists and psychiatrists, most notably John Money (1994). Gender identity was conceived as developing in infancy (e.g. Green, 1968), but physical interventions for transsexuals under the age of 18 were vanishingly rare. Money in 1973 advised a doctor to prescribe testosterone to a 15-year-old girl and even to consider mastectomy—but he was unusually reckless and there is no evidence that his advice was followed (Gill-Peterson, 2018, pp. 163–164). Specialist clinics for children and adolescents with gender identity problems were founded in Toronto in 1975, in Utrecht in 1987, and in London in 1989. They provided counseling. Cross-sex hormones had to wait until the patient was referred to an adult clinic, at an age ranging from 16 to 18 (Bradley & Zucker, 1990). Surgeries were not performed under the age of 18 (Petersen & Dickey, 1995). Referrals of children were rare. The London clinic—the only specialized clinic for children with gender dysphoria in the United Kingdom—over its first decade accepted an annual average of 14 patients (Di Ceglie, 2018). In its first seven years the Utrecht clinic averaged 9 per year (Cohen-Kettenis, 1994).

Lowering the age of intervention was driven by the founder of the Utrecht children’s clinic, Peggy Cohen-Kettenis. She had established herself in the field of gender medicine in the 1980s, presenting research to international conferences of the Harry Benjamin International Gender Dysphoria Association (HBIGDA), which had been formed by clinicians and academics. She eventually became professor of psychology in the Department of Child and Adolescent Psychiatry at University Medical Center Utrecht (Everaerd et al., 2014). She was closely connected to clinicians at VU Medical Center Amsterdam (affiliated with Vrije Universiteit Amsterdam), which housed the country’s clinic for adult transsexuals.

Cohen-Kettenis believed that transsexuals would experience better outcomes if they started treatment before adulthood. By the mid-1990s, she was referring some patients aged 16 and 17 to the Amsterdam clinic for endocrinological intervention prior to cross-sex hormones (Cohen-Kettenis, 1994). Males were given an antiandrogen, cyproterone acetate, which prevented erections and caused breast tissue to grow; females were given progesterin to stop menstruation (Gooren & Delemarre-van de Waal, 1996). Johanna, for example, “fulfilled all necessary requirements for early treatment”: she did not favor girly things (though neither did her sisters), she was fond of soccer, she never dated in school (perhaps not surprising given that she was homosexual), and her parents discovered her wearing a tight t-shirt to conceal her breasts (Cohen-Kettenis et al., 1998, p. 124). Brought to the clinic at 17, she was prescribed progesterin for four months and then testosterone. Within two years Jaap (as Johanna had become) underwent mastectomy, hysterectomy, and oophorectomy, and obtained a new birth certificate. Evidence to support such early treatment came from the first 22 patients from the Utrecht clinic, interviewed in their twenties, from one to five years after surgery (Cohen-Kettenis & van Goozen, 1997; Kuiper & Cohen-Kettenis, 1988). They were compared to a larger group of transsexuals who had transitioned later in adulthood in previous decades (Kuiper and Cohen-Kettenis 1988). Her former patients showed better psychological functioning and “more easily pass in the desired gender role” (Cohen-Kettenis & van Goozen, 1997, p. 270). One problem with the comparison is that they had transitioned in a more tolerant era. Another is the fact that they were still young; most had no sexual partner. Moreover they had not reached an age at which they might regret their inability to conceive children. (This group has not since been followed up.) Cohen-Kettenis’ initiative was praised by Money: he singled out her contribution to a conference in London as “the bravest” (1998, p. xviii).

Cohen-Kettenis had two collaborators at Amsterdam. One was Henriette Delemarre-van de Waal, a pediatric endocrinologist. She had expertise using the new GnRHa drugs—developed in the 1980s—to treat precocious puberty and other conditions (e.g. Schroor et al. 1995). The other was Louis Gooren, a psychiatrist and endocrinologist who was installed as the world’s first professor of transsexuality in 1989. His inaugural professorial lecture was addressed by Cohen-Kettenis and by Money, who flew over from Johns Hopkins University (Nederlands Tijdschrift voor Geneeskunde 1989). Like the pioneering generation who created transsexualism, Gooren saw gender dysphoria as an intersex condition: “there is a contradiction between the genetic, gonadal and genital sex on the one hand, and the brain sex on the other” and therefore “we must provide them with reassignment treatment which meets their needs” (Gooren, 1993, p. 238). This hypothesis was apparently vindicated when he coauthored an article in *Nature* showing that the volume of the central subdivision of the bed nucleus of the stria terminalis in six male-to-female transsexuals was closer to the volume found in females than in males (Zhou et al., 1995). “Unfortunately,” as he recently acknowledged, “the research has never been replicated” (Gooren, 2021, p. 50; see also Kreukels & Burke, 2020).

GnRHa was introduced as a treatment for gender dysphoria in two articles. Gooren and Delemarre-van de Waal (1996) proposed the “Feasibility of Endocrine Interventions in Juvenile Transsexuals.” More influential was a case study of the first “adolescent transsexual” treated with GnRHa (Cohen-Kettenis and van Goozen 1998). From the age of 5, FG “had made it very clear that I was supposed to be a boy” (FG, 2021, p. 131). It later transpired that FG was sexually attracted to women. FG’s father, an Italian with traditional views on gender, disapproved of his daughter’s masculinity, and serious conflict ensued. Extensive psychotherapy did not improve matters; FG wrote a suicide note at the age of 12. When FG was 13, Delemarre-van de Waal prescribed triptorelin.² Three years later, around 1990, FG came to the Utrecht gender clinic, and Cohen-Kettenis was impressed by FG’s “boyish appearance” (Cohen-Kettenis, 2021, p. 115). The clinic provided therapy and introduced FG to other adolescent girls who identified as transsexual. (Whether FG was introduced to any adolescents who identified as lesbian is not recorded.) FG’s puberty suppression continued until the age of 18, when testosterone commenced, followed by multiple surgeries: mastectomy, hysterectomy, oophorectomy, and

metoidioplasty. Awaiting the last surgery at the age of 20, FG was “happy with his life” and “never felt any regrets”; gender dysphoria was apparently cured (Cohen-Kettenis & van Goozen, 1998, p. 247).

Puberty suppression remained exceptional for some years. By 2000, GnRHa had been administered to only 7 children under the age of 16 (Cohen-Kettenis et al., 2000). The new treatment regime was codified at VU Medical Center in Amsterdam, where Cohen-Kettenis was appointed professor of medical psychology in 2002, moving with her clinic. The “Dutch protocol” was published in an influential article in 2006, supported financially by Ferring Pharmaceuticals, the manufacturer of triptorelin (Delemarre-van de Waal & Cohen-Kettenis, 2006, p. S137). GnRHa could be administered to transsexuals as young as Tanner stage 2—marked by the first growth of pubic hair and for girls by budding breasts and for boys by growing testicles—as long as they had reached the age of 12. The adolescent would usually then begin “to live permanently in the role of their desired sex” (Delemarre-van de Waal & Cohen-Kettenis, 2006, p. S132). After some years of puberty suppression, the youth would start cross-sex hormones at the age of 16 and then surgeries at the age of 18. Eligibility criteria for puberty suppression appeared strict. First, gender dysphoria should have begun early in childhood, and dysphoria should have worsened with the onset of puberty. Second, the patient should be psychologically stable, and not suffer from other mental health problems. Third, the patient should have support from their family. As the protocol was formalized, the number of children undergoing puberty suppression increased markedly. Between 2000 and 2008, GnRHa was prescribed to 111 children, about one per month (de Vries et al., 2011). One of them was Valentijn de Hingh, the subject of a television documentary (Nietsch, 2007). After a teacher was disconcerted by the boy’s passion for dolls, de Hingh at the age of 5 was diagnosed with gender dysphoria by Cohen-Kettenis (de Hingh, 2021). GnRHa was administered from the age of 12 in 2002.

The protocol as published was not always strictly followed by the clinicians. The minimum age of 12 for puberty suppression was not observed in every case (de Vries, 2010, p. 104). De Hingh had regular endocrinological checkups from the age of 10, presumably so that puberty suppression could commence as soon as Tanner stage 2 was reached. Likewise, cross-sex hormones sometimes started before the age of 16, as young as 13.9 years (de Vries et al., 2011, p. 2278). Family support was not essential, as the clinic administered GnRHa to a 14-year-old—who was institutionalized due to a physical handicap—against the parents’ objections (Cohen-Kettenis and Pfäfflin 2003). A British television documentary from the mid-1990s provides a glimpse of actual practice (Morse, 1996). *The Wrong Body* took three English young people to Amsterdam and Utrecht, to see transgender medicine at its most advanced. Fredd Foley, aged 13, met Gooren to learn about puberty suppression; this was around the time it was proposed in the medical literature (Gooren & Delemarre-van de Waal 1996). After returning to England and being refused GnRHa by the London clinic, Foley’s mother telephoned Gooren who agreed to write a three-month prescription of triptorelin. “If your child knows for sure he is transsexual,” he said, “I would not let puberty happen.” Gooren’s willingness to prescribe drugs for a child in another country, met briefly in front of the cameras, against the wishes of the child’s own psychiatrist, hints that the assessment process was not always as rigorous as portrayed in the published literature. As Cohen-Kettenis said in the documentary, “it’s very difficult to give exact criteria, in some cases you have the feeling that the adolescent has thought about it and knows pretty well what she or he is doing.”

The Dutch protocol scrutinized

The Dutch protocol comprised not just a drug (GnRHa) and a treatment regime (from age 12 or Tanner stage 2) but also two discursive claims. The first was reversibility. The initial article declared GnRHa to be “fully reversible; in other words, no lasting undesired effects are to be expected” (Gooren & Delemarre-van de Waal, 1996, p. 72). The phrasing hinted at the lack of actual evidence. Suppressing puberty for a short time, on the order of months, might be expected

to have a negligible effect on a child's development. Yet the Dutch protocol entailed suppression for up to four years (from age 12 to 16); for FG it lasted at least five years (from 13 to 18). It was implausible to claim that suppressing puberty for so many years would have no lasting effect if the child were to stop GnRHa and restart their natal sex hormones. On occasion this was acknowledged, as when Delemarre-van de Waal and Cohen-Kettenis' (2006, p. S137) manifesto stated that "It is not clear yet how pubertal suppression will influence brain development." Ten years later, however, Cohen-Kettenis still claimed that puberty suppression was "completely reversible" (Cohen-Kettenis, 2016; see also de Vries et al., 2016). The postulate of reversibility, however implausible, helped to avoid the question of whether a child aged 12 (or below) could give consent to this endocrinological experiment. HBGDA's Standards of Care warned that cross-sex hormones "are not, or are not readily, reversible" (HBGDA, 1985, p. 83). By pronouncing GnRHa to be reversible, the Dutch protocol demarcated a boundary between one endocrinological intervention and another.

The second claim was that puberty suppression was a diagnostic tool. The case study of FG described GnRHa as an "aid in diagnosis and treatment" (Cohen-Kettenis & van Goozen, 1998). This echoed the conception of cross-sex hormones as "both therapeutic and diagnostic in that the patient requesting such therapy either reports satisfaction or dissatisfaction regarding the results" (HBGDA, 1985, p. 85). GnRHa was posited to provide space for therapeutic exploration of gender identity, without the pressure of the physical changes accompanying puberty (Delemarre-van de Waal & Cohen-Kettenis, 2006). This claim was plausible, though it was also plausible that stopping normal cognitive, emotional, and sexual development would impede such exploration. In the event, the Dutch clinicians found that the diagnostic test invariably yielded the same result: "none of the [54] patients who were selected for pubertal suppression has decided to stop taking GnRHa" (Delemarre-van de Waal & Cohen-Kettenis, 2006, p. S136). This might be explained by a rigorous selection process. An alternative explanation is that puberty suppression becomes a self-fulfilling prophecy. Subsequent experience in the Netherlands and in other countries confirms the fact that 96%–98% of children who undergo puberty suppression continue to cross-sex hormones (Brik et al., 2020; Carmichael et al., 2021; Wiepjes et al., 2018).

The framing of GnRHa as diagnostic circumvented a problem recognized in the earliest articles. "Not all children with GID [Gender Identity Disorder] will turn out to be transsexuals after puberty," acknowledged Cohen-Kettenis and Gooren (1999, p. 319). "Prospective studies of GID boys show that this phenomenon is more closely related to later homosexuality than to later transsexualism." They cited three longitudinal studies of feminine boys (Green, 1987; Money & Russo, 1979; Zuger, 1984).³ The best known is Richard Green's attempt at "studying pretranssexuals" by selecting a group of "sissy boys" (Green, 1987, p. 12). After fifteen years, to his surprise, only one out of 44 was contemplating transsexuality, whereas two thirds had become bisexual or homosexual men. Given such studies, Cohen-Kettenis concluded that "most GID children under 12 will not grow up to become transsexuals" (Cohen-Kettenis & van Goozen, 1997, p. 246). These findings were downplayed in subsequent publications; the key manifestos for the Dutch protocol did not mention homosexuality and did not cite any study of feminine boys (Cohen-Kettenis et al., 2008; Delemarre-van de Waal & Cohen-Kettenis, 2006). The assertion that "GID persisting into early puberty appears to be highly persistent" rested on slender evidence (Cohen-Kettenis et al., 2008, p. 1895). The only relevant cited source described adolescents who had been first assessed at ages ranging from 13 to 18, a range extending well beyond early puberty (Smith et al., 2001). This source did not support the hypothesis that the probability of gender dysphoria persisting to adulthood jumped suddenly on the cusp of age 12, from under 50% to virtually 100%. What is known is that most adolescents subjected to puberty suppression were homosexual. Of the first 70 adolescents referred to the Amsterdam clinic from 2000 to 2008 and given GnRHa, 62 were homosexual while only 1 was heterosexual (de Vries et al., 2011).

The crucial advantage of puberty suppression was creating "individuals who more easily pass in to the opposite gender role" (Delemarre-van de Waal & Cohen-Kettenis, 2006, p. 155). The emphasis was on external appearance, especially height.⁴ That word appears 23 times in

Delemarre-van de Waal's review of puberty suppression (Delemarre-van de Waal, 2014). There is one cursory reference to "loss of fertility." The words orgasm, libido, and sexuality do not appear. This is curious because it was well known that men taking GnRHa for prostate cancer experience complete loss of erotic interest (Marumo et al., 1999). The drug is therefore licensed to chemically castrate men with sexual obsessions. Gooren was an early advocate for this usage. He warned that the side effects "may be very uncomfortable" for men with paraphilias (Gijs & Gooren, 1996, p. 279); no such warning accompanied his recommendation of the same drug for adolescents experiencing gender dysphoria. The Dutch clinicians did not ask whether blocking the normal development of erotic desire would affect their patients' understanding of their own body and their interest in future sexual and romantic relationships.

One significant disadvantage of puberty suppression for males was not mentioned in the 2006 manifesto for the Dutch protocol, though it had been raised at a conference in the previous year (GIRES, 2005). Stopping sexual development meant the penis did not grow, and so "the genital tissue available for vaginoplasty may be less than optimal" (Cohen-Kettenis et al., 2008, p. 1895). This made it more likely that the orifice would need to be lined with a portion of the patient's intestine rather than the inverted penis (van de Grift et al., 2020). Out of 49 patients at Amsterdam who started GnRHa at Tanner stage 2 or 3, 71% required intestinal vaginoplasty (van der Sluis et al., 2021). This procedure is more invasive, requiring a second surgical site, and it entails greater risk of complications such as rectal fistula. Surgical techniques have been refined so that the "possible occurrence of intestinal discharge could be kept under control" (Bouman, 2021, p. 141), but one quarter of the patients need further corrective surgeries (Bouman et al., 2016).

International adoption of the Dutch protocol

The Dutch protocol immediately attracted interest in other countries. Cohen-Kettenis and Gooren were already prominent in the field of transgender medicine, exemplified by their election to the Board of Directors of HBGDA (the former served two four-year terms from 1995 and 2003, while the latter served one term from 1999). Puberty suppression soon entered HBGDA's Standards of Care in the Sixth Version, approved in 2001. It closely followed the Dutch protocol, but did not specify any minimum age. It was "recommended that the adolescent experience the onset of puberty in his or her biologic sex, at least to Tanner stage Two," while also allowing earlier intervention on the recommendation of more than one psychiatrist (HBGDA, 2001, p. 10). Recall that the published evidence for the benefits of puberty suppression then comprised a single case study of one patient—FG—awaiting final surgery.

In the United States, adoption was led by Norman Spack, a pediatric endocrinologist. More than once he recalled "salivating" at the prospect of treating patients with GnRHa (Hartocollis 2015; Spack 2008, xi). In 2007 he cofounded the Gender Management Service at Boston Children's Hospital, which was the first dedicated clinic for transgender children in America. Its program was based on the Dutch model; the hospital sent a psychologist to Amsterdam to be trained by Cohen-Kettenis (Tishelman et al., 2015). From the outset the Boston clinic offered GnRHa at Tanner stage 2 or 3 with no minimum age (Spack et al. 2012). Spack joined Cohen-Kettenis, Gooren, and Delemarre-van de Waal on the Endocrine Society's committee tasked with writing their first clinical guidelines for "transsexual persons," which recommended GnRHa for children at Tanner stage 2 or 3 (Hembree et al., 2009). "There was an attitudinal shift to be able to say that the Endocrine Society supports this," he later recalled (Ruttimann, 2013, p. 19). The shift is visible in data from 43 children's hospitals on prescriptions of one GnRHa drug (histrelin acetate): it was never prescribed for gender dysphoria between 2004 and 2009 and was then prescribed to 92 patients from 2010 to 2016, most in the final years of the period (Lopez et al., 2018).

Oprah Winfrey Television broadcast the documentary *I Am Jazz: A Family in Transition* in 2011 (Stocks, 2011). Its dramatic structure was similar to *The Wrong Body*, focusing on the

looming threat of puberty as Jazz Jennings reached the age of 11. Jennings had been diagnosed with gender dysphoria at the age of 3 and had appeared on national television at the age of 7, when the family created the TransKids Purple Rainbow Foundation (Jennings & Jennings, 2016). The documentary showed the family consulting with a pediatric endocrinologist, who confirmed that Tanner stage 2 had been reached. The denouement was not shown, but Jennings's mother was clear: "you have to kinda nip puberty in the bud, you want to block it" (Stocks, 2011). Jennings did indeed commence puberty suppression some months later. The number of clinics for "gender-nonconforming children and adolescents" multiplied, and within a few years 32 of them advertised puberty blockers (Hsieh & Leininger, 2014).

England provides an example of adoption driven by patients rather than clinicians. *The Wrong Body* had promoted the Dutch approach to 3 million viewers (Nataf, 1999). Dissatisfaction at the cautious policy of the London clinic—still headed by its founder, Domenico Di Ceglie—became increasingly vocal. Sustained pressure came from the parents of children who identified as transgender, organized in the Gender Identity Research and Education Society (GIRES) and Mermaids. GIRES obtained funding from medical charities to organize an international symposium in London in 2005 to develop consensus guidelines for endocrinological intervention, which was attended by Cohen-Kettenis, Delemarre-van de Waal, and Spack. GIRES (2006) warned that "those who can in any way afford to do so have to consider taking their children to the USA." The first was Susie Green, later the chief executive of Mermaids. In 2007 she took her son Jackie, aged 12, to Boston to obtain GnRHa from Spack (Sloan, 2011). A presentation at Mermaids instructed parents in this medical tourism (Mermaids, 2007). Spack treated seven more British children over the next few years (Glass, 2012). The conflict between parents and clinicians climaxed in 2008, with two clashing conferences. The Royal Society of Medicine organized a meeting on adolescent gender dysphoria, which drew criticism for the lack of overseas speakers advocating for puberty blockers, even though it had invited Delemarre-van de Waal. The cofounder of GIRES, whose child had transitioned in their late teens two decades earlier, used the new epithet "transphobic" to describe the cautious clinicians (Groskop, 2008). Richard Green—the author of *Sissy Boys*, then in London as a visiting professor—quickly organized a rival conference to demand puberty suppression (Green, 2008). Speakers included the usual cast of clinicians, including Spack, and also patients and their parents, including two Dutch transgender adolescents. The demand for puberty suppression was becoming irresistible.

Di Ceglie was soon replaced as director of the London clinic (renamed the Gender Identity Development Service and located at the Tavistock and Portman NHS Foundation Trust) by Polly Carmichael, a clinical psychologist. The clinic in 2011 began to offer GnRHa from the age of 12, initially as part of an experimental study (Biggs, 2019b, 2019c). Before any outcomes were published, Carmichael declared success: "Now we've done the study and the results thus far have been positive we've decided to continue with it" (Manning and Adams, 2014). She even appeared on BBC Children's Television to promote puberty suppression, in a documentary about a 13-year-old girl who wanted to be a boy, Leo. Carmichael reassured Leo about GnRHa: "the good thing about it is, if you stop the injections, it's like pressing a start button and the body just carries on developing as it would if you hadn't taken the injection" (Niland, 2014). In 2015 the National Health Service adopted a policy of offering GnRHa for adolescents at Tanner stage 2, without age restriction (NHS England, 2015).

Evidence from the Amsterdam clinic

By the mid-2010s, then, the Dutch protocol was established as the standard for transgender medicine. It was apparently vindicated when longitudinal data was published on a cohort of 70 adolescents referred to the clinic between 2000 and 2008 and then subjected to puberty suppression. The lead author, Annelou de Vries, received her doctorate under the supervision of Cohen-Kettenis. Outcomes were initially measured as the patient was transitioning from GnRHa to cross-sex hormones, at ages ranging from 14 to 19. "Behavioral and emotional problems and

depressive symptoms decreased, while general functioning improved” (de Vries et al., 2011, p. 2276). Outcomes were subsequently measured soon after the patient’s final surgery (vaginoplasty or mastectomy and hysterectomy with oophorectomy), at ages ranging from 19 to 22. The authors concluded that “gender dysphoria had resolved, psychological functioning had steadily improved, and well-being was comparable to same-age peers” (de Vries et al., 2014, p. 696).

When scrutinized, however, the evidence is less persuasive. The sample was small: final outcome measures were available for subsets of patients numbering between 32 and 55. The finding that gender dysphoria had resolved depended on the Utrecht Gender Dysphoria Scale and the Body Image Scale, which have separate questionnaires for each sex. The researchers switched versions over the course of the study (Levine et al., 2022). A boy who wanted to become a girl, for example, answered the male questionnaires at baseline before puberty suppression, and then the female versions following surgery—so would be rating agreement with the statement “I hate menstruating because it makes me feel like a girl” (C. Schneider et al., 2016) and satisfaction with “ovaries-uterus” (Lindgren & Pauly, 1975). The inclusion of such meaningless questions compromises the measurement of change in gender dysphoria. The results after surgery exclude eight patients who refused to participate in the follow-up or were ineligible for surgery, and one patient killed by necrotizing fasciitis during vaginoplasty. The authors did not mention the fact that this death was a consequence of puberty suppression: the patient’s penis, prevented from developing normally, was too small for the regular vaginoplasty and so surgery was attempted with a portion of the intestine, which became infected (Negenborn et al., 2017). A fatality rate exceeding 1% would surely halt any other experimental treatment on healthy teenagers.

One inevitable limitation of the study was the measurement of results soon after surgery, which repeated the problem with the first study of adolescent transsexuals (Cohen-Kettenis & van Goozen, 1997). As Cohen-Kettenis notes, “a truly proper follow-up needs to span a minimum period of 20 years” (Cohen-Kettenis, 2021, pp. 117–118). A subsequent follow-up of this cohort is in preparation (Bazelon, 2022). The only long-term outcome published in the literature is that of the very first patient, FG, who was followed up again at the age of 35. FG did not regret transition, but scored high on the measure for depression. Owing to “shame about his genital appearance and his feelings of inadequacy in sexual matters,” he could not sustain a romantic relationship with a girlfriend (Cohen-Kettenis et al., 2011, p. 845). Ironically, a “strong dislike of one’s sexual anatomy” is one of the diagnostic criteria for gender dysphoria in children (according to *DSM-5*), and so in this respect it is not clear how the dysphoria had been resolved. The clinicians were more interested in FG’s height, which they compared punctiliously to the Italian as well as the Dutch height distribution. Cohen-Kettenis concluded that “the negative side effects are limited” (Cohen-Kettenis et al., 2011, p. 843). Delemarre-van de Waal’s (2014, p. 194) summary was even more optimistic: “He was functioning well psychologically, intellectually, and socially.” Now aged 48, FG has given two recent interviews. FG’s situation seems to have improved, and he now has a serious girlfriend. He describes puberty suppression as “life-saving” in his case (FG, 2021, p. 132) but also recommends that it should require a significant assessment process (Bazelon, 2022). In a recent interview, Valentijn de Hingh, who at the age of 31 now identifies as non-binary, emphasizes that “diagnosis and treatment at a young age were not wrong.” At the same time, de Hingh wonders “wasn’t that very young? To have been seeing a psychologist, having been examined and diagnosed from the age of five” (de Hingh, 2021, p. 182).

Replicating the Dutch results

An international study of puberty suppression—involving London and Boston as well as Amsterdam—was first mooted in 2005 (GIRES, 2005). The Boston clinic dropped out, but eventually an experiment along Dutch lines was begun in London in 2010. The entry criteria were “consistent with the protocol used at the Amsterdam Gender Clinic” (Viner et al., 2010, p. 6) and the outcome measures replicated those used by the Amsterdam longitudinal study (de

Vries et al., 2011, 2014). From 2011 to 2014, 44 adolescents aged from 12 to 15 years commenced puberty suppression. Outcomes for all subjects after two years on GnRHa were thus collected by 2016. Preliminary results were presented to the World Professional Association for Transgender Health (as HBGDA had been renamed) in Amsterdam. In her keynote address, Carmichael observed that “our results have been different to the Dutch” (Carmichael, 2016). According to one presentation, adolescents after one year of GnRHa “report an increase in internalising problems and body dissatisfaction, especially natal girls” (Carmichael et al., 2016). Another presentation was also negative: “Expectations of improvement in functioning and relief of the dysphoria are not as extensive as anticipated, and psychometric indices do not always improve nor does the prevalence of measures of disturbance such as deliberate self harm improve” (Butler, 2016). These conference papers were not published as articles, following the typical fate of medical experiments that fail to produce positive results (Johnson & Dickersin, 2007).

Instead, the London clinic published an article claiming that “adolescents receiving also puberty suppression had significantly better psychosocial functioning after 12 months of GnRHa ... compared with when they had received only psychological support” (Costa et al., 2015, p. 2206). The group subjected to puberty suppression were aged between 13 and 17, and must have included some of the 44 experimental subjects. This group comprised 101 adolescents at the outset, diminishing to 35 after twelve months. This high rate of attrition was not explained in the article. Anyway, the data showed no statistically significant difference between the group given GnRHa and counseling and the group given only counseling (Biggs, 2019a).

The full outcomes from the experiment were published following a protracted campaign involving publicity in newspapers and television (e.g. Tominey & Walsh, 2019), complaints to the ethics committee which approved the research (Health Research Authority, 2019), a Parliamentary question (Blackwood of North Oxford, 2019), and a judicial review (Keira Bell and Mrs A v Tavistock NHS Trust, 2020). Out of the 44 subjects in the experiment, all but one transitioned to cross-sex hormones. Outcomes were taken after 12 months of puberty suppression for all patients, and after 24 months for the subset waiting to reach the age of 16 when they could start cross-sex hormones. The headline finding was that “GnRHa treatment brought no measurable benefit nor harm to psychological function in these young people,” and gender dysphoria likewise did not improve (Carmichael et al., 2021, p. 20). This is all the more surprising because a placebo response would be expected in patients who had volunteered to pioneer this intervention in Britain (Kirsch, 2019). There was no disaggregation by sex, which is unfortunate because outcomes were evidently worse for natal girls than for boys (Biggs, 2020; Carmichael et al., 2016).

The researchers did not compare their findings to the outcomes from the Amsterdam clinic after puberty suppression (de Vries et al., 2011). Comparison is undertaken here, using available data on two question batteries.⁵ The Youth Self-Report (YSR) enables the adolescent to describe their problems, while the Child Behavior Checklist (CBCL) provides a parent’s assessment. YSR and CBCL each yield three *T*-scores: one for Internalizing Problems like anxiety; one for Externalizing Problems like anger; and a Total Problem score, combining these two along with other problems such as social isolation (Achenbach & Rescorla, 2001). *T*-scores are normalized relative to reference scores (for males and for females aged 12–18), with a mean of 50 and standard deviation of 10. The Amsterdam clinic reported these measures for 54 subjects, compared to 41 for the London clinic. The two samples were similar at the outset of puberty suppression: the mean age at Amsterdam was 14.8, the median at London was 13.6; females comprised 53% of the Amsterdam sample, 43% of the London one. Figure 1 depicts the mean scores at baseline before the commencement of puberty suppression, along with the 95% confidence interval. There was no discernible difference between the Amsterdam and London samples in any component of CBCL or YSR. At the Amsterdam clinic, the subjects completed the questionnaires again when they transitioned to cross-sex hormones, after a mean of 1.9 years. At the London clinic, the questionnaires were completed at 12-month intervals, and so I take the latest available before the end of puberty suppression; the mean duration is 1.4 years. Figure 2

Figure 1. Psychological functioning before puberty suppression with GnRHa. The circle shows the mean *T*-score at baseline. The line traces the 95% confidence interval. *N* = 54 at Amsterdam, 41 at London. Data from de Vries et al. (2011, Table 2) and Carmichael et al. (2021).

Figure 2. Change in psychological functioning after puberty suppression with GnRHa. The bar shows the change in *T*-score from baseline; negative values indicate reduced problems. The line traces the 95% confidence interval. *N* = 54 at Amsterdam, 41 at London. Data reported from de Vries et al. (2011, Table 2) and Carmichael et al. (2021).

shows how the scores changed since baseline. The Amsterdam sample improved—fewer problems were reported by the subjects and their parents—on all six measures ($p = .000004 \dots .003$). The London sample, by contrast, experienced no discernible change ($p = .16 \dots .82$). With one exception (YSR Externalizing Problems), the differences between the change in Amsterdam and the change in London are statistically significant ($p = .0006 \dots .03$, assuming equal variance).

The London clinic's failure to replicate the positive results found by the Amsterdam clinic after puberty suppression demonstrates that the Dutch results cannot be extrapolated to other countries. The reason for the failure to replicate could perhaps lie in the quality of care offered by the clinics or in the characteristics of their patients. Although the two samples had indistinguishable baseline scores on YSR and CBCL, on another measure of psychological functioning—the Children's Global Assessment Scale (CGAS), which is scored by the clinician—the adolescents attending the London clinic were significantly worse at the outset. This fits the general pattern in adolescents referred to European gender clinics: those at Amsterdam have fewer psychological problems and better peer relationships than those at London (de Graaf et al., 2018). The failure

to replicate could simply exemplify a general phenomenon in medicine (and science generally): a large effect found in a nonrandomized study with a small sample usually either declines in magnitude or disappears altogether in subsequent studies (e.g. Ioannidis, 2005). Given the London clinic's failure to find favorable results after puberty suppression, it has no incentive to follow up the 43 subjects who transitioned to cross-sex hormones and potential surgery. It loses track of all its patients after the age of 18, blaming "the frequent change in nominal and legal identity, including NHS number in those referred on to adult services" (Butler et al., 2018, p. 635).

One other clinic has published a comparable longitudinal study of puberty suppression. The Hamburg Gender Identity Service followed 11 adolescents who were administered GnRHa for an average of one year, but such a tiny sample provides insufficient statistical power for any conclusions (Becker-Hebly et al., 2021). Three American studies of puberty suppression have been published: from Stony Brook (Achille et al., 2020), Dallas (Kuper et al., 2020), and Seattle (Tordoff et al., 2022).⁶ None tried to replicate the Amsterdam and London longitudinal studies, choosing completely different measures, with one exception (BIS is used by Kuper et al., 2020). Each introduced a different set of measures: Quick Inventory of Depressive Symptoms, Screen for Child Anxiety Related Emotional Disorders, Center for Epidemiologic Studies Depression Scale, Quality of Life Enjoyment and Satisfaction Questionnaire, Generalized Anxiety Disorder 7-item scale, and the Patient Health Questionnaire 9-item scale. The last scale was common to two studies, but even they were not comparable: one used the version for teenagers, the other the adult version which the researchers chose to dichotomize. All the samples were tiny: 19, 23 (including an unspecified number of males given anti-androgens and females given medroxy-progesterone rather than GnRHa), and 25. Results were reported inconsistently: sometimes the outcomes for the sample subjected to puberty suppression were combined with a much larger sample on cross-sex hormones; sometimes the parameters of complex multivariate models were reported while the within-subject change during puberty suppression was concealed (Singal, 2022). Finally, some results were vitiated by high—and unexplained—rates of attrition: 47% of the subjects in one study were excluded because they failed to fill in the questionnaires at three points in time (Achille et al., 2020). What is frustrating is that if these researchers had simply followed the methods of de Vries et al. (2011), these three small samples would have contributed to cumulative knowledge. Finally, a large-scale American study recruited 90 subjects for puberty suppression—from Boston, Chicago, Los Angeles, and San Francisco—between 2016 and 2018 (Olson-Kennedy et al., 2019). Outcomes after 24 months have evidently been collected, but only baseline results have been published (Chen et al., 2021).

Evidence on side effects

On the side effects of puberty suppression, there is most evidence on bone density. That GnRHa would cause "an insufficient formation of bone mass" was initially dismissed "of no great concern" (Gooren & Delemarre-van de Waal, 1996, p. 72). Then it was recognized that patients could "end with a decreased bone density, which is associated with a high risk of osteoporosis" (Delemarre-van de Waal & Cohen-Kettenis, 2006, p. S134). The detrimental effect of GnRHa on the accrual of normal bone mass has been documented in several longitudinal studies from the Amsterdam clinic (Klink et al., 2015; Schagen et al., 2020; Stoffers et al., 2019; Vlot et al., 2017), the London clinic (Biggs, 2021; Joseph et al., 2019), and a clinic in Ottawa (Navabi et al., 2021). Less obviously, adolescents who seek GnRHa for gender dysphoria have a lower distribution of bone density compared to the population of the same sex and age (see also Lee et al., 2020). This reflects in part the high prevalence of eating disorders.

Bone mineral density (BMD) is measured by a dual energy X-ray absorptiometry scan over the spine and the hip. The absolute value of BMD is standardized as a Z-score, expressing this individual's BMD relative to the population of the same sex and age. BMD can be adjusted for height to derive the volumetric bone mineral apparent density (BMAD), which is likewise standardized as a Z-score. A Z-score below -2 is considered low; it indicates bone density in the

lowest 2.3% of the population. The salience of this threshold is revealed by the London clinic's protocol which required both spine and hip Z-scores to exceed -2 to be eligible for GnRHa (Viner et al., 2010). This was subsequently relaxed "in exceptional circumstances" if clinicians "feel that on the balance of risks, pubertal suppression is an appropriate option despite risks of osteoporosis in later adult life" and patients "understand the risks of GnRH analogue treatment for bone density (i.e. risks of later osteoporosis)" (Viner et al., 2012).

Most studies of bone density after puberty suppression summarize the distribution of Z-scores by mean and standard deviation; only two provide information on the lower tail of the distribution, which is what matters clinically. At the Amsterdam clinic, 56 transgender adolescents were treated with GnRHa, commencing at ages ranging from 11 to 18, for an average duration of 1.7 years. After puberty suppression, the minimum Z-score for spine BMAD was -2.4 , and the minimum hip BMAD was -3.4 (Vlot et al., 2017). Normally we would expect to find a Z-score below -3 in only 0.13% of the population—1 in 741. At the London clinic, 24 adolescents were treated with GnRHa, commencing at ages ranging from 12 to 14, for a duration of 24 months. After puberty suppression, the hip BMD Z-score was below -2 for 7 patients. The spine BMD Z-score was below -2 for 7 patients, including 4 patients with Z-score below -3 ; the spine BMAD Z-score was below -2 for 8 patients, including 3 with Z-score below -3 (Biggs, 2021). Clearly, then, a significant minority of patients have abnormally low bone density after puberty suppression. The subsequent administration of cross-sex hormones increases bone mass, but Z-scores remain below the baseline recorded at the outset of puberty suppression (Klink et al., 2015; Stoffers et al., 2019; Vlot et al., 2017), with the possible exception of females who take testosterone after starting GnRHa early in puberty (Schagen et al., 2020).

What is not clear is the consequence of abnormally low bone density. Information on fractures, for example, has been published only for adults taking cross-sex hormones who had not undergone puberty suppression (Wiepjes et al., 2020). Anecdotally, a female patient at the London clinic who started GnRHa at age 12 then experienced four broken bones by the age of 16 (Bannerman, 2019). A Swedish television documentary discovered one female who was given GnRHa from age 11 to 15 by the Karolinska University Hospital in Stockholm, and now suffers from severe osteoporosis, including continual skeletal pain (SVT, 2022). This case—along with two others whose puberty suppression was terminated following concerns about bone density—led Sweden to restrict the use of GnRHa for adolescents with gender dysphoria.

The effects of puberty suppression on emotional and cognitive development are more difficult to ascertain, but more consequential as they could potentially affect the capacity to consent to cross-sex hormones and surgery. One case report of puberty suppression commencing just before age of 12 measured a drop in IQ by 10 points after 28 months (M. A. Schneider et al., 2017). A single case is insubstantial, of course, but there are similar findings from children treated with GnRHa for precocious puberty. A study of 25 children measured a drop of 7 points after two years (Mul et al., 2007); another study found a gap of 8 points between 15 treated children and a matched control group (Hayes, 2017; Wojniusz et al., 2016). Unfortunately the Amsterdam clinic's longitudinal study of puberty suppression measured IQ only at baseline and did not measure it again (de Vries et al., 2011, 2014). A small study from the clinic found that 8 adolescent males undergoing puberty suppression performed worse in a test of executive functioning than three control groups; the differences are statistically significant, but the samples are small (Staphorsius et al., 2015). Randomized control trials of non-human animals provide evidence of the substantial effects of puberty suppression. In sheep, GnRHa impairs spatial memory, and this effect remains after the treatment is stopped—thus demonstrating the irreversibility of puberty suppression (Hough et al. 2017a; 2017b). Counterintuitively, GnRHa also leads to greater differences between males and females in foraging behavior (Wojniusz et al., 2011). In mice, the effects of GnRHa vary by sex: males develop stronger preference for other males and an increased stress response; females exhibit increased anxiety and despair-like behavior (Anacker et al., 2021).

Even less is known about the effects of puberty suppression on sexual functioning. Jennings, who started on GnRHa at the age of 11, has no libido and cannot orgasm. Jennings' surgeon,

Marci Bowers, who has performed over 2,000 vaginoplasties, acknowledges that “every single child ... who was truly blocked at Tanner stage 2, has never experienced orgasm. I mean, it’s really about zero” (Bowers, 2022). This remark refers to males. The effects of puberty suppression at such an early stage on females is unknown. FG is reportedly able to orgasm (de Vries et al., 2011). One patient at the London clinic who took GnRHa from the age of 12 to 16 but did not continue to cross-sex hormones has experienced no sexual desire in the two years since ceasing GnRHa (Bannerman, 2022). According to de Vries, orgasm is “a very interesting and so far not studied question” (Klotz, 2022).

Conclusion

The use of GnRHa to suppress puberty has proved more popular than could have been envisaged in the mid-1990s. It has become the international standard for treating gender dysphoria and has attracted increasing numbers of patients. Down to 2015, the Amsterdam clinic administered GnRHa to a total of 333 youth aged under the age of 18 (Wiepjes et al., 2018). From 2012 to 2020, the London clinic administered GnRHa to 344 children under the age of 15. Both clinics were overwhelmed by referrals from the mid-2010s, and the lengthening waiting lists provided scope for unscrupulous commercial operations. GenderGP, for example, is a company registered in Singapore and owned by a Welsh doctor which will diagnose a 9-year-old with gender dysphoria over video and prescribe GnRHa on the same day (Medical Practitioners Tribunal Service, 2022). The total number of patients subjected to puberty suppression, worldwide, must run to several thousand. The proponents of GnRHa never reassessed the rationale for the intervention as the numbers multiplied. It is one thing to assert that very rare cases of extreme gender dysphoria—one per year in the Netherlands in the late 1990s—should be treated as juvenile transsexuals. It is another to make this claim for numerous adolescents—currently over a hundred a year in the Netherlands. Given the fact that gender dysphoria lacks an objective diagnosis, the potential for puberty suppression is expansive. When a recent survey in one American school district found 7% of students identifying as “gender diverse,” the authors urged that all receive “access to gender affirming care,” which in effect means giving GnRHa on request (Kidd et al., 2021, p. 3).⁷

Whether the availability of puberty suppression has increased demand is a question that should be raised. Taking GnRHa early in puberty promises a more passable resemblance to the opposite sex, and this is why it proved so fascinating to television audiences. It is no coincidence that media coverage of transgender youth focuses on those who suppressed puberty at a young age, most famously Jennings. Positive media coverage is known to increase referrals to gender clinics, at least over the short term (Indremo et al., 2022; Pang, de Graaf, et al., 2020). Although Dutch clinicians advise against “a complete social transition ... before the very early stages of puberty” (de Vries & Cohen-Kettenis, 2012, pp. 308–309), the availability of GnRHa now makes it feasible for parents to treat a young child as the opposite sex, which guarantees that the child will experience the onset of puberty as catastrophic and thus demand endocrinological intervention. For boys, social transition prior to puberty is a powerful predictor of gender dysphoria persisting into adolescence, even controlling for the degree of dysphoria in childhood (Steensma et al., 2013). This pathway is illustrated by interviews with 30 British parents who had started raising their children as the opposite sex between the ages of 3 and 10. According to one parent, “If you don’t give a child puberty-blockers there is a consequence—it’s not that nothing happens. There’s a massive consequence” (Horton, 2022, p. 13). Another candidly described their child’s attitude to counseling at the gender clinic: “at the end of the day, he’s just gonna say whatever it is, that makes you shut up, so that he can get the blocker” (Horton, 2022, p. 14).

What has happened to the majority of children with gender dysphoria who used to grow up into gay or lesbian adults? The original articles promoting GnRHa (Cohen-Kettenis & van Goozen, 1998; Gooren & Delemarre-van de Waal, 1996) hypothesized that children whose dysphoria persisted to the age of 12 were destined to become transsexual. This arbitrary age threshold

was soon forgotten. Outside the Netherlands, GnRHa was adopted with no minimum age, and has been prescribed to children as young as 8 years old.⁸ Delemarre-van de Waal eventually advocated for GnRHa to be administered before Tanner stage 2, “right at the onset of puberty,” followed quickly by cross-sex hormones (Delemarre-van de Waal, 2014, p. 202). And of course the transsexual pathway now begins long before puberty, with social transition and psychological diagnosis. As de Hingh observes, “a diagnosis says you’ve got a problem that needs to be treated ... The medical process, with pills and protocols, takes over the normal process of identification formation” (de Hingh, 2021, pp. 182–183). Clinicians need to explain how they are sure that some of the adolescents being prescribed GnRHa would not have grown into gay or lesbian adults, with their sexuality and fertility intact.

The article that introduced puberty suppression to the medical literature was accurately titled: this endocrinological intervention is designed for juvenile transsexuals (Gooren & Delemarre-van de Waal, 1996). This fact should not be obscured by claiming that puberty suppression is reversible and diagnostic. It is not diagnostic because over 95% of adolescents given GnRHa will continue to cross-sex hormones, and this fraction has not declined even as the number of youths subjected to GnRHa has multiplied by two orders of magnitude. The claim for reversibility was contradicted from the outset by the unknown effect of puberty suppression on brain development. Irreversibility has now been demonstrated by randomized control trials in non-human animals. The central justification for puberty suppression was that it increases outward resemblance to the opposite sex and requires less surgical intervention. Paradoxically, however, early puberty suppression for males will most likely make subsequent genital surgery more risky—this is what killed one of the initial Dutch cohort—with worse results.

Evidence for the benefits of puberty suppression must be acknowledged as slender. Decisions made by clinicians have prevented the collection of robust evidence. The Dutch proponents of GnRHa chose not to conduct a randomized control trial, giving two reasons (de Vries et al., 2011). Firstly, adolescents would have refused to participate, which does not make sense unless they could have obtained GnRHa from another source. Secondly, it would have been unethical to withhold GnRHa from the control group, because the clinicians believed the treatment to be beneficial—this rationale is circular because discovering whether a treatment is truly beneficial requires a randomized control trial. A lesson can be drawn from the use of GnRHa to pause precocious puberty. This was supposed to mitigate short stature, as was apparently shown by small uncontrolled studies (Hayes, 2016), but this effect was called into question by a randomized control trial (Cassio et al., 1999). When the London clinic designed a study to replicate the findings from Amsterdam, the same reasons for avoiding a randomized control study were repeated, along with an argument that subjects would soon realize whether they were receiving treatment or placebo (Viner et al., 2010). Yet this had been no impediment to the trial for children with early puberty.

The decision to rely on uncontrolled studies was exacerbated by other decisions. The Dutch clinicians chose incommensurable scales to measure gender dysphoria, which calls into question their finding that dysphoria declined following cross-sex hormones and surgery. Worse still, American clinicians eschewed the measures of psychological functioning used by the Amsterdam and London clinics (YSR, CBCL, and CGAS), thus ensuring that their tiny samples could not contribute to cumulative knowledge. One final point to remember in evaluating published studies is that the field of transgender medicine is subject to the same publication bias as every other field: unsuccessful results will not be published. This bias is illustrated by the London clinic’s attempt to replicate the Amsterdam clinic’s findings: the lack of improvement on GnRHa appeared in print only after the clinic was taken to the High Court of Justice for England and Wales.

While the use of GnRHa to suppress puberty helped to create the juvenile transsexual, it could now be creating another “new way of being a person” (Wren, 2020): a sexless adult. This follows from the premise that natal puberty can be a kind of disease, and therefore failure to prevent an “irreversible development of secondary sex characteristics ... may be considered unethical” (de Vries et al., 2011, p. 2282). Although the Dutch protocol envisages GnRHa as a

preparatory phase before cross-sex hormones—imagined as undergoing puberty of the opposite sex—the logical conclusion is that hormones of either sex can be treated as vectors of disease. An Australian girl, Phoenix, was socially transitioned into a nonbinary identity at the age of 5 and took GnRHa from age 11. Reaching the age of 16, Phoenix refused to take testosterone because “remaining in an androgynous, peripubertal state is the only way their body can truly reflect their non-binary gender identity” (Notini et al., 2020, p. 743). The clinicians agreed to provide perpetual puberty suppression, despite the known deleterious physical effects—most obviously on bone density—and despite the unknown effects on emotional and cognitive development—which would affect Phoenix’s capacity to consent. Phoenix is not the only individual seeking indefinite puberty suppression (Pang, Notini, et al., 2020). Such cases are still exceptional. But cases like FG also used to be exceptional.

Notes

1. The literature sometimes refers to GnRH (or LHRH) analogues, which is a broader classification comprising antagonists as well as agonists.
2. The pediatric endocrinologist was not named in the original article, but her identity is clear from later sources (e.g. Delemarre-van de Waal, 2014). FG is known as “B” in the published literature.
3. Bailey and Zucker (1995) had by then reviewed four additional prospective studies in the same vein as well as numerous retrospective ones. Later prospective studies demonstrated that girls who manifested cross-gender behavior as infants were also more likely to grow up as lesbian, though the association was weaker than for boys (e.g. Li et al., 2017).
4. Pediatric endocrinology’s obsession with height has motivated the use of artificial estrogen to accelerate puberty in girls judged as too tall (Cohen & Cosgrove, 2009) and the use of GnRHa to delay puberty in girls judged as too short (Hayes, 2016).
5. A previous comparison (Biggs, 2020) included only 30 subjects from the London clinic and measured outcomes after 12 months. The Stata do-file is posted on Harvard dataverse at <https://doi.org/10.7910/DVN/QPRCRI>.
6. De Vries (2022) also cites a study from Kansas City (Allen et al., 2019) which includes an unknown number of children subjected to GnRHa before cross-sex hormones, but it took no baseline measure before puberty suppression.
7. The authors calculate the “gender diverse” proportion as 9% because they omit students who skipped the question (Kidd et al., 2021). It is more plausible to include the latter in the denominator, which yields 7%.
8. The London clinic referred a 7-year-old for endocrinological intervention, but it is not known whether GnRHa was actually prescribed before she turned 8 (Butler et al., 2022).

Curriculum Vitae

Aron Janssen, M.D.
312-227-7783
aronjans@gmail.com

Personal Data

Born Papillion, Nebraska
Citizenship USA

Academic Appointments

2011-2017 Clinical Assistant Professor of Child and Adolescent Psychiatry
2011-2019 Founder & Clinical Director, NYU Gender and Sexuality Service
Director, LGBT Mental Health Elective, NYULMC
2015-2019 Co-Director, NYU Pediatric Consultation Liaison Service
New York University Department of Child and Adolescent Psychiatry
2017-present Clinical Associate Professor of Child and Adolescent Psychiatry
2019-present Vice Chair, Pritzker Department of Psychiatry and Behavioral Health
Ann and Robert H. Lurie Children's Hospital of Chicago
2020-present Medical Director, Outpatient Psychiatric Services
Ann and Robert H. Lurie Children's Hospital of Chicago

Education

Year	Degree	Field	Institution
6/97	Diploma		Liberty High School
5/01	B.A.	Biochemistry	University of Colorado
5/06	M.D.	Medicine	University of Colorado

Postdoctoral Training

2006-2009 Psychiatry Residency Ze'ev Levin, M.D. NYU Department of Psychiatry
2009-2011 Child and Adolescent Psychiatry Fellowship – Fellow and Clinical Instructor
Jess Shatkin, M.D. NYU Dept of Child/Adolescent Psychiatry

Licensure and Certification

2007-2018 New York State Medical License
2017-present Illinois Medical License
2011-present Certification in Adult Psychiatry, American Board of Psychiatry and Neurology
2013-present Certification in Child and Adolescent Psychiatry, ABPN

Academic Appointments

2009-2011 Clinical Instructor, NYU Department of Child and Adolescent Psychiatry
2011-2017 Clinical Asst Professor, NYU Dept of Child and Adolescent Psychiatry
2017-2019 Clinical Assoc Professor, NYU Dept of Child and Adolescent Psychiatry
2011-2019 Clinical Director, NYU Gender and Sexuality Service
2015-2019 Co-Director, NYU Pediatric Consultation-Liaison Service
2019-present Associate Professor of Child and Adolescent Psychiatry, Northwestern University
2019-present Vice Chair of Clinical Affairs, Pritzker Department of Psychiatry and Behavioral

Major Committee Assignments

International, National and Regional

2021-present	Sexual Orientation and Gender Identity Committee, Chair, AACAP
2019-present	WPATH Standards of Care Revision Committee, Children
2019-present	WPATH Standards of Care Revision Committee, Adult Mental Health
2015-2019	Department of Child Psychiatry Diversity Ambassador
2013-2021	Sexual Orientation and Gender Identity Committee Member, AACAP
2012-2019	Founder and Director, Gender Variant Youth and Family Network
2012-present	Association of Gay and Lesbian Psychiatrists, Transgender Health Committee
2012-2019	NYULMC, Chair LGBTQ Advisory Council
2012-2019	NYULMC, Child Abuse and Protection Committee
2013-2015	NYULMC, Pediatric Palliative Care Team
2003-2004	American Association of Medical Colleges (AAMC), Medical Education Delegate
2004-2006	AAMC, Western Regional Chair

Psychiatry Residency

2006-2009	Resident Member, Education Committee
2007-2008	Resident Member, Veterans Affairs (VA) Committee

Medical School

2002-2006	Chair, Diversity Curriculum Development Committee
2002-2006	AAMC, Student Representative
2003-2004	American Medical Student Assoc. (AMSA) World AIDS Day Coordinator
2003-2004	AMSA, Primary Care Week Coordinator
2004-2006	Chair, Humanism in Medicine Committee

Memberships, Offices, and Committee Assignments in Professional Societies

2006-present	American Psychiatric Association (APA)
2009-present	American Academy of Child and Adolescent Psychiatry (AACAP)
2011-present	World Professional Association for Transgender Health (WPATH)
2011-2019	Director, Gender Variant Youth and Family Network, NYC
2013-2019	Chair, NYU Langone Medical Center LGBTQ Council

Editorial Positions

2016-2018	Clinical Assistant Editor, <i>Transgender Health</i>
2014-present	Ad Hoc Reviewer, <i>LGBT Health</i> .
2016-present	Ad Hoc Reviewer, <i>JAACAP</i>
2018-present	Associate Editor, <i>Transgender Health</i>
2020-present	Ad Hoc Reviewer, <i>Pediatrics</i>

Principal Clinical and Hospital Service Responsibilities

2011-2019	Staff Psychiatrist, Pediatric Consultation Liaison Service
2011-2019	Faculty Physician, NYU Child Study Center
2011-2019	Founder and Clinical Director, NYU Gender & Sexuality Service
2015-2019	Co-Director, Pediatric Consultation Liaison Service
2019-present	Vice Chair, Pritzker Dept of Psychiatry and Behavioral Health

2019-present	Chief Psychiatrist, Gender Development Program
2020-present	Medical Director, Outpatient Psychiatry Services

Relevant Program Development

Gender and Sexuality Service

- founded by Aron Janssen in 2011, who continues to direct the service
- first mental health service dedicated to transgender youth in NYC
- served over 200 families in consultation, with 2-3 referrals to the gender clinic per week
- trained over 500 mental health practitioners in transgender mental health – 1 or 2 full day trainings in partnership with the Ackerman Institute’s Gender and Family Project (GFP) and with WPATH Global Educational Initiative (GEI)
- New hires in Adolescent Medicine, Psychology, Plastic Surgery, Urology, Gynecology, Endocrinology, Social Work, Department of Population Health with focus on transgender care has led to expansion of available services for transgender youth at NYULMC in partnership with the Gender and Sexuality Service
- development of partnerships with Ackerman Institute, Callen-Lorde Health Center – both institutions have been granted access to our IRB and have agreed to develop shared research and clinical priorities with the Gender and Sexuality Service.
- multiple IRB research projects underway, including in partnership with national and international clinics
- model has been internationally recognized

Clinical Specialties/Interests

Gender and Sexual Identity Development
 Co-Occurring Mental Health Disorders in Transgender children, adolescents and adults
 Pediatric Consultation/Liaison Psychiatry
 Psychotherapy
 -Gender Affirmative Therapy, Supportive Psychotherapy, CBT, MI

Teaching Experience

2002-2006 Course Developer and Instructor, LGBT Health (University of Colorado School of Medicine)
 2011-2019 Instructor, Cultural Competency in Child Psychiatry (NYU Department of Child and Adolescent Psychiatry) – 4 hours per year
 2011-2019 Course Director, Instructor “Sex Matters: Identity, Behavior and Development” – 100 hours per year
 2011-2019 Course Director, LGBT Mental Health Elective (NYU Department of Psychiatry) - 50 hours of direct supervision/instruction per year
 2011-2019 Course Director, Transgender Mental Health (NYU Department of Child and Adolescent Psychiatry – course to begin in Spring 2018.
 2015-2019 Instructor, Gender & Health Selective (NYU School of Medicine) – 4 hours per year.

Academic Assignments/Course Development

New York University Department of Child and Adolescent Mental Health Studies
 -Teacher and Course Director: “Sex Matters: Identity, Behavior and Development.”
 A full semester 4 credit course, taught to approximately 50 student per year since

2011, with several students now in graduate school studying sexual and gender identity development as a result of my mentorship.

NYU Department of Child and Adolescent Psychiatry

-Instructor: Cultural Competency in Child and Adolescent Psychiatry

-Director: LGBTQ Mental Health Elective

World Professional Association of Transgender Health

-Official Trainer: Global Education Initiative – one of two child psychiatrists charged with training providers in care of transgender youth and adults.

EMPLOYMENT

2006-Present Michael K Laidlaw, MD Inc. Private Practice – Endocrinology, Diabetes, and Metabolism. Rocklin, CA

EDUCATION

2004-2006 Endocrinology and Metabolism Fellowship - Los Angeles County/University of Southern California Keck School of Medicine
2001-2004 Internal Medicine Residency - Los Angeles County/University of Southern California Keck School of Medicine
1997-2001 University of Southern California Keck School of Medicine
Doctor of Medicine Degree May 2001
1990-1997 San Jose State University
Bachelor of Science Degree in Biology with a concentration in Molecular Biology, Cum Laude

LICENSURE

California Medical License – Physician and Surgeon: # A81060: Nov 6, 2002. Exp 5/31/2024.

PROFESSIONAL AFFILIATIONS

Endocrine Society 2006-2022
American Board of Internal Medicine - Endocrinology, Diabetes, and Metabolism – 2006
American Board of Internal Medicine - Internal Medicine - 2005
National Board of Physicians and Surgeons - Endocrinology, Diabetes, & Metabolism 2018-2024
National Board of Physicians and Surgeons - Internal Medicine 2018-2024

HONORS AND RECOGNITION

2010 Endocrine Society Harold Vigersky Practicing Physician Travel Award
2004-2005 Vice President - Joint Council of Interns and Residents
2002-2004 Council Member – Joint Council of Interns and Residents
1996, 1997 Dean's Scholar, San Jose State University
1995 Golden Key National Honor Society

Medical Dangers of Gender Affirmative Therapy: What is known and unknown

Presented to the Florida Board of Medicine

**By Michael K. Laidlaw, MD
Endocrinologist. Rocklin, CA**

October 28, 2022

Letter to the Editor: “Endocrine Treatment of Gender-Dysphoric/Gender-Incongruent Persons: An Endocrine Society* Clinical Practice Guideline”

Michael K Laidlaw, Quentin Van Meter, Paul W Hruz, Andre Van Mol, William J Malone

The Journal of Clinical Endocrinology & Metabolism
Endocrine Society

Submitted: September 05, 2018

Accepted: November 20, 2018

First Online: November 23, 2018

Our criticism of gender affirmative therapy for minors was first published in 2018.

Definitions

- ❑ **Gender Identity - an internal feeling of being a boy, a girl, or some variation**
- ❑ **Gender Dysphoria - a discomfort with one's sex & perceived gender leading to significant distress and impairment of functioning lasting at least 6 months**
- ❑ **Desistance of Children by adulthood: 50-98%***

**Ristori J, Steensma TD. Gender dysphoria in childhood. Int Rev Psychiatry. 2016;28(1):13–20.*

Also From the DSM-5: “Rates of persistence of gender dysphoria from childhood into adolescence or adulthood vary...In natal males, persistence has ranged from 2.2% to 30%. In natal females, persistence has ranged from 12% to 50%” (American Psychiatric Association, 2013).

Where do I find the gender identity?

Q: CT, Ultrasound, Blood Test, MRI, Brain biopsy, genetic testing?

A: None of the above.

There are only two human sexes

*There are only two types of gametes each originating from either a male or a female. No other type of human gamete exists.

Michael K. Laidlaw, MD. 28 Oct 2022

Permanent Sexual Developmental Differentiation

Sexual organ differentiation occurs between gestational weeks 8-12. There is a bifurcation in the pathway for males and females. Unique structures are created for each. The unused ductal system is obliterated. A person cannot change from one path to the other.

Side Effects of High Dose Testosterone/ Anabolic Steroid Abuse

<i>Symptoms</i>
Irritability
Aggressiveness
Euphoria
Grandiose Beliefs
Hyperactivity
Reckless or Dangerous Behavior

- **Psychiatric symptoms become more common and severe as the dose increases**

Studies have shown:

- **23% of subjects using high doses of steroids met DSM criteria for a major mood syndrome (mania, hypomania, and major depression)**
- **3.4-12% developed psychotic symptoms**

Hall Ryan CW, Hall Richard CW, Chapman MJ. "Psychiatric Complications of Anabolic Steroid Abuse". Psychosomatics 46:4, July-August 2005. Michael K. Laidlaw, MD. 28 Oct 2022

Laboratory Reference Ranges

Q. If a woman has a normal hematocrit of 36, but then identifies as a male (male gender identity), does she at that point become anemic because she has switched over to the reference range for males?

A. No, she does not become anemic. The gender identity is a psychological concept that has no direct bearing on human physiology. Conversely, an increase of hematocrit to 46, if she goes on to take testosterone, is consistent with erythrocytosis. <http://www.gendersanity.org/>

Surgical Conversion Therapy - Mastectomy

Endocrine Society Gender Guidelines 2017

Disclaimer: The Endocrine Society's clinical practice guidelines are developed to be of assistance to endocrinologists by providing guidance and recommendations for particular areas of practice. The guidelines should not be considered inclusive of all proper approaches or methods, or exclusive of others. The guidelines cannot guarantee any specific outcome, nor do they establish a standard of care. The guidelines are not intended to dictate the treatment of a particular patient. Treatment decisions must be made based on the independent judgement of healthcare providers and each patient's individual circumstances.

p. 3895

Not Standard of Care!!

Endocrine Society Guidelines 2017

2.0 Treatment of adolescents

- 2.1. We suggest that adolescents who meet diagnostic criteria for GD/gender incongruence, fulfill criteria for treatment, and are requesting treatment should initially undergo treatment to suppress pubertal development. (2 ⊕⊕○○)
- 2.2. We suggest that clinicians begin pubertal hormone suppression after girls and boys first exhibit physical changes of puberty. (2 ⊕⊕○○)
- 2.3. We recommend that, where indicated, GnRH analogues are used to suppress pubertal hormones. (1 ⊕⊕○○)
- 2.4. In adolescents who request sex hormone treatment (given this is a partly irreversible treatment), we recommend initiating treatment using a gradually increasing dose schedule after a multidisciplinary team of medical and MHPs has

confirmed the persistence of GD/gender incongruence and sufficient mental capacity to give informed consent, which most adolescents have by age 16 years. (1 ⊕⊕○○).

- 2.5. We recognize that there may be compelling reasons to initiate sex hormone treatment prior to the age of 16 years in some adolescents with GD/gender incongruence, even though there are minimal published studies of gender-affirming hormone treatments administered before age 13.5 to 14 years. As with the care of adolescents ≥16 years of age, we recommend that an expert multidisciplinary team of medical and MHPs manage this treatment. (1 ⊕○○○)
- 2.6. We suggest monitoring clinical pubertal development every 3 to 6 months and laboratory parameters every 6 to 12 months during sex hormone treatment. (2 ⊕⊕○○)

recommendation and the quality of evidence. In terms of the strength of the recommendation, strong recommendations use the phrase “we recommend” and the number 1, and weak recommendations use the phrase “we suggest” and the number 2. Cross-filled circles indicate the quality of the evidence, such that ⊕○○○ denotes very low-quality evidence; ⊕⊕○○, low quality; ⊕⊕⊕○, moderate quality; and ⊕⊕⊕⊕, high quality. The task

Michael K.
Laidlaw,
MD. 28 Oct
2022

All of the guidelines for adolescents are low, very low quality or absent evidence.

WPATH SOC 8

- **In a correction to the SOC 8, all guidelines for minimum age of surgery were removed,** meaning a minor of any age could be referred for any of following GAT surgeries:
 - – Chest masculinization: had been 15 years old
 - – Breast augmentation, Facial Surgery: had been 16 years old
 - – Metoidioplasty, Orchiectomy, Vaginoplasty, Hysterectomy, Fronto-orbital remodeling: had been 17 years old
 - – Phalloplasty: had been 18 years old (WPATH SOC 8 Correction, p. S261).
- **All guidelines for minimum age of opposite sex hormones were also removed.**
- **The minimum age recommendations were retracted, it appears, *in contradiction to the recommendation of their own expert consensus*:** "On page S66, the following text was removed: 'Age recommendations for irreversible surgical procedures were determined by a review of existing literature and the expert consensus of mental health providers, medical providers, and surgeons highly experienced in providing care to TGD adolescents.'" (WPATH SOC 8 Correction, p. S260)

WPATH SOC 8 Correction, International Journal of Transgender Health, 23:sup1, S259- S261,
DOI: 10.1080/26895269.2022.2125695

WPATH SOC 8

- **The SOC8 used an aberrant form of the GRADE approach for systematic reviews that removed the grading of quality of evidence** (which should be categorized as very low, low, moderate, and high quality). Instead any recommendation of "recommend" is automatically assigned as high quality of evidence. (Coleman et. al, 2022, p. S250)
- **SOC 8 also failed to provide evidence profile tables which should include “an explicit judgment of each factor that determines the quality of evidence for each outcome”** (Guyatt et al., 2021).
- **A chapter regarding eunuchs was inserted into SOC 8 that gives recommendations for how to induce hypogonadism in men who have the eunuch "gender identity" by either orchiectomy [testicle removal] or chemical castration such as with GnRH analogues** (Coleman et al., 2022, p. S88).
- **WPATH SOC 8 is an extreme document and presents a grave danger to minors.**

Coleman E, et al. "Standards of Care for the Health of Transgender and Gender Diverse People, Version 8". International Journal of Transgender Health. 06 Sep 2022. International Journal of Transgender Health.

Gender Dysphoria

How can these kids be helped?

- Investigate autism, depression, anxiety, bipolar disorder, physical or sexual abuse, self harm. Family problems - marital dissolution, interfamily conflict
- Identify and Properly Treat psychological comorbidities
- Individual Counseling
- Family Counseling

Child/Adolescent Affirmative Therapy

- This is not standard of care.
- We do not have the technology to make a male become a female, or a female become a male
- We do not know the long term outcomes of these medical/surgical interventions. No long term studies to assess the degree of harm in this age group.
- Medications are being used off-label and at high doses without proper FDA risk assessment profiles.
- The quality of evidence in the Endocrine Society's own guidelines for children and adolescents is low to very low quality or absent.
- WPATH SOC 8 is an extreme document and presents a grave danger to minors.
- Desisters have been ignored.

Medical Dangers of Gender Affirmative Therapy: What is known and unknown

**Michael K. Laidlaw, MD
Endocrinologist. Rocklin, CA**

September 24, 2022

Introduction

- Because of the inherent risks and unknowns, several nations of the world are turning away from gender affirmative therapy for children and adolescents.
- These nations include the UK, Sweden, and Finland.
- On July 28, the UK's NHS announced that the Tavistock Gender Identity Development Service would be closed. Regional Clinics would handle cases.
- Why?
- The following should help provide answers.

[NHS to close Tavistock child gender identity clinic - BBC News](https://www.bbc.com/news/uk-62335665)

<https://www.bbc.com/news/uk-62335665>

Overview

- Objective reality vs. Subjective Feelings
- Definitions
- Identifying Sex
- Normal Sexual Development
- Gender Dysphoria
- Gender Affirmative Therapy
- Dangers of Hormones and Surgeries
- Nations question gender affirmative therapy (GAT)
- Assessment of the gender dysphoric child/adolescent

What does all of this hinge upon?

Objective Biology vs Subjective Feelings

“ 20. Gender identity—a person’s core internal sense of their own gender—is the *primary factor* in determining a person’s sex.”*

*Drew Adams vs. The School Board of St John’s Florida. First Amended Complaint. 9/7/2017

This is incorrect! What a person feels inside does not change the material reality of their sex.

Q. Can one defy the laws of physics* by their internal sense of self?

A. No.

*or biology?

Definitions

- ❑ **Gender Identity - an internal feeling of being a boy, a girl, or some variation**
- ❑ **Gender Dysphoria - a discomfort with one's sex & perceived gender leading to significant distress and impairment of functioning lasting at least 6 months**
- ❑ **Desistance of Children by adulthood: 50-98%***

**Ristori J, Steensma TD. Gender dysphoria in childhood. Int Rev Psychiatry. 2016;28(1):13–20.*

Also From the DSM-5: “Rates of persistence of gender dysphoria from childhood into adolescence or adulthood vary...In natal males, persistence has ranged from 2.2% to 30%. In natal females, persistence has ranged from 12% to 50%” (American Psychiatric Association, 2013).

Where do I find the gender identity?

Q: CT, Ultrasound, Blood Test, MRI, Brain biopsy, genetic testing?

A: None of the above.

RESEARCH ARTICLE

Rapid-onset gender dysphoria in adolescents and young adults: A study of parental reports

Lisa Littman*

Department of Behavioral and Social Sciences, Brown University School of Public Health, Providence, Rhode Island, United States of America

* Lisa_Littman@brown.edu

Abstract

Purpose

In on-line forums, parents have been reporting that their children are experiencing what is described here as “rapid-onset gender dysphoria,” appearing for the first time during puberty or even after its completion. The onset of gender dysphoria seemed to occur in the context of belonging to a peer group where one, multiple, or even all of the friends have become gender dysphoric and transgender-identified during the same timeframe. Parents also report that their children exhibited an increase in social media/internet use prior to disclosure of a transgender identity. The purpose of this study was to document and explore these observations and describe the resulting presentation of gender dysphoria, which is inconsis-

Puberty Blockers - Pathway to Sterilization

- In a Dutch study that included seventy adolescents who took puberty blockers, all seventy decided to go on to hormones of the opposite sex (de Vries, et al. 2011).
- In a follow-up study, the overwhelming majority went on to have sex reassignment surgery by either vaginoplasty for males or hysterectomy with ovariectomy for females (de Vries, et al. 2014).
- These surgeries resulted in sterilization. This is why puberty blockers, rather than being a “pause” to consider aspects of mental health, are instead a pathway towards future sterilizing surgeries.

Cross Sex Hormones - Testosterone

6-100X higher than endogenous female levels

Image by Michael K Laidlaw, MD. Approximate total testosterone in ng/dL based on laboratory, etc. FtM transition from 2017 Endo Society Guidelines on Gender Dysphoria. With PCOS testosterone levels may be as high as 150. With endocrine tumors testosterone may be in the 150-1000 range. The recommendations of the Endocrine Society/WPATH are to bring levels into the 300-1000 range which is 6-100 times higher than normal endogenous adult female levels.

Testosterone - Controlled substance. Abuse Risk.

- Testosterone is an anabolic steroid of high potency.
- It is classified as a Schedule 3 controlled substance by the DEA: "Substances in this schedule have a potential for abuse less than substances in Schedules I or II and abuse may lead to moderate or low physical dependence or high psychological dependence" (DEA, 2022).
- A licensed physician with a valid DEA registration is required to prescribe testosterone.
- "Testosterone has been subject to abuse, typically at doses higher than recommended for the approved indication" (Actavis Pharma, 2018)
- "Anabolic androgenic steroid abuse can lead to serious cardiovascular and psychiatric adverse reactions." *Id.*
- "Abuse and misuse of testosterone are seen in male and female adults and adolescents." *Id.*

Side Effects of High Dose Testosterone/ Anabolic Steroid Abuse

<i>Symptoms</i>
Irritability
Aggressiveness
Euphoria
Grandiose Beliefs
Hyperactivity
Reckless or Dangerous Behavior

- **Psychiatric symptoms become more common and severe as the dose increases**

Studies have shown:

- **23% of subjects using high doses of steroids met DSM criteria for a major mood syndrome (mania, hypomania, and major depression)**
- **3.4-12% developed psychotic symptoms**

Laboratory Reference Ranges

Q. If a woman has a normal hematocrit of 36, but then identifies as a male (male gender identity), does she at that point become anemic because she has switched over to the reference range for males?

A. No, she does not become anemic. The gender identity is a psychological concept that has no direct bearing on human physiology. Conversely, an increase of hematocrit to 46, if she goes on to take testosterone, is consistent with erythrocytosis. <http://www.gendersanity.org/>

Testosterone - Erythrocytosis and CV Risk

- High dose Testosterone given to females causes erythrocytosis
- Having high red blood cell counts (erythrocytosis) puts females at increased risk of cardiovascular disease, coronary heart disease and death due to both as shown in the landmark [Framingham Study](#).
- Studies of trans males have already shown up to a [nearly five fold increased risk of myocardial](#) infarction compared to females not taking testosterone.*
- In the Framingham study, the younger female group (ages 35-64) at the highest range of hematocrit (above 45) had increased risk of cardiovascular disease, myocardial infarction and death due to both *.

Comprehensive Interdisciplinary Medical Services for Transgender, Non-Binary, and Gender-Expansive Transgender Children and Adolescents

Ongoing Research

UCSF has formed a research network consortium with Boston Children's Hospital (Harvard), Lurie Children's Hospital of Chicago (Northwestern University), and Children's Hospital Los Angeles (University of Southern California) -- The Trans Youth Network. We are presently engaged in a research project funded by the National Institutes of Health studying metabolic and quality of life issues for transgender youth undergoing treatment with puberty blockers or cross-sex hormones.

Gathering this data will also be important to encourage insurers to cover medical treatment for gender dysphoria, as **the drugs used do not have FDA approval for treatment of this condition.** In addition to increasing our knowledge, it is hoped that the research findings will impact the future of trans care for children and adolescents. We have applied for a second grant through the National Institute of Health to study prepubertal children exploring their gender, assessing developmental pathways and psychological outcomes.

Surgery - Mastectomy

- The surgery results in a permanent loss of the ability to breastfeed and significant scarring of 7 to 10 inches.
- The scars are prone to widening and thickening due to the stresses of breathing and arm movement.
- Other potential complications include the loss of normal nipple sensation and difficulties with wound healing (American Cancer Society, 2022).
- It is important to note that this operation cannot be reversed. The female will never regain healthy breasts capable of producing milk to feed a child (Mayo Clinic, Top Surgery, 2022).

Michael K. Laidlaw, MD. 24 Sep 2022

GAT Surgeries of the Male

- Removal of the testicles alone to permanently lower testosterone levels. This is by nature a sterilizing procedure.
- Further surgeries may be done in an attempt to create a pseudo-vagina which is called vaginoplasty. In this procedure, the penis is surgically opened and the erectile tissue is removed. The skin is then closed and inverted into a newly created cavity in order to simulate a vagina. A dilator must be placed in the new cavity for some time so that it does not naturally close.
- Potential surgical complications may include urethral strictures, infection, prolapse, fistulas and injury to the sensory nerves with partial or complete loss of erotic sensation (Mayo Clinic, Feminizing Surgery, 2022)

Mayo Clinic. “Feminizing Surgery”.

<https://www.mayoclinic.org/tests-procedures/feminizing-surgery/about/pac-20385102>

Accessed 07/01/2022

Surgical Conversion Therapy

Because of very small penis size due to puberty blockers, a segment of large bowel is used to extend the pseudo-vaginal cavity.

Figure 2 A and B - (A) Colocolostomy has been completed and the distal end of the colonic segment has been anastomosed to the opened rudimentary vaginal pit, (B): The peritoneum was closed above the transposed bowel and the neovagina was loosely packed with Vaseline gauze.

A

INTESTINAL VAGINOPLASTY

B

GAT Surgeries of the Female

- Other types of surgery for females include those of the genitalia and reproductive tract. For example, the ovaries, uterus, fallopian tubes, cervix and the vagina may be surgically removed. Removal of the ovaries results in sterilization.
- Phalloplasty: a roll of skin and subcutaneous tissue is removed from one area of the body, say the thigh or the forearm, and transplanted to the pelvis. Erectile devices such as rods or inflatable devices may be placed within the tube of transplanted tissue in order to simulate erection (Hembree, Endo Guidelines 2017). The labia may also be expanded to create a simulated scrotum containing prosthetic objects to provide the appearance of testicles.
- Complications of phalloplasty may include urinary stricture, problems with blood supply to the transplanted roll of tissue, large scarring to the forearm or thigh, infections including peritonitis, and possible injury to the sensory nerve of the clitoris (Mayo Clinic, Masculinizing Surgery, 2022).

CMS - Evidence Inconclusive

- The Centers for Medicare and Medicaid Services (“CMS”) has found “inconclusive” clinical evidence regarding gender reassignment surgery.
- Specifically, the CMS Decision Memo for Gender Dysphoria and Gender Reassignment Surgery (CAG-00446N) (June 19, 2019) states: “The Centers for Medicare & Medicaid Services (CMS) is not issuing a National Coverage Determination (NCD) at this time on gender reassignment surgery for Medicare beneficiaries with gender dysphoria because the clinical evidence is inconclusive for the Medicare population.”

Endocrine Society Gender Guidelines 2017

Disclaimer: The Endocrine Society's clinical practice guidelines are developed to be of assistance to endocrinologists by providing guidance and recommendations for particular areas of practice. The guidelines should not be considered inclusive of all proper approaches or methods, or exclusive of others. The guidelines cannot guarantee any specific outcome, nor do they establish a standard of care. The guidelines are not intended to dictate the treatment of a particular patient. Treatment decisions must be made based on the independent judgement of healthcare providers and each patient's individual circumstances.

p. 3895

Not Standard of Care!!

Endocrine Society Guidelines 2017

2.0 Treatment of adolescents

- 2.1. We suggest that adolescents who meet diagnostic criteria for GD/gender incongruence, fulfill criteria for treatment, and are requesting treatment should initially undergo treatment to suppress pubertal development. (2 ⊕⊕○○)
- 2.2. We suggest that clinicians begin pubertal hormone suppression after girls and boys first exhibit physical changes of puberty. (2 ⊕⊕○○)
- 2.3. We recommend that, where indicated, GnRH analogues are used to suppress pubertal hormones. (1 ⊕⊕○○)
- 2.4. In adolescents who request sex hormone treatment (given this is a partly irreversible treatment), we recommend initiating treatment using a gradually increasing dose schedule after a multidisciplinary team of medical and MHPs has

confirmed the persistence of GD/gender incongruence and sufficient mental capacity to give informed consent, which most adolescents have by age 16 years. (1 ⊕⊕○○).

- 2.5. We recognize that there may be compelling reasons to initiate sex hormone treatment prior to the age of 16 years in some adolescents with GD/gender incongruence, even though there are minimal published studies of gender-affirming hormone treatments administered before age 13.5 to 14 years. As with the care of adolescents ≥16 years of age, we recommend that an expert multidisciplinary team of medical and MHPs manage this treatment. (1 ⊕○○○)
- 2.6. We suggest monitoring clinical pubertal development every 3 to 6 months and laboratory parameters every 6 to 12 months during sex hormone treatment. (2 ⊕⊕○○)

mendation and the quality of evidence. In terms of the strength of the recommendation, strong recommendations use the phrase “we recommend” and the number 1, and weak recommendations use the phrase “we suggest” and the number 2. Cross-filled circles indicate the quality of the evidence, such that ⊕○○○ denotes very low-quality evidence; ⊕⊕○○, low quality; ⊕⊕⊕○, moderate quality; and ⊕⊕⊕⊕, high quality. The task

Michael K.
Laidlaw, MD.
24 Sep 2022

All of the guidelines for adolescents are low, very low quality or absent evidence.

WPATH SOC 8

- **In a correction to the SOC 8, all guidelines for minimum age of surgery were removed,** meaning a minor of any age could be referred for any of following GAT surgeries:
 - – Chest masculinization: had been 15 years old
 - – Breast augmentation, Facial Surgery: had been 16 years old
 - – Metoidioplasty, Orchiectomy, Vaginoplasty, Hysterectomy, Fronto-orbital remodeling: had been 17 years old
 - – Phalloplasty: had been 18 years old (WPATH SOC 8 Correction, p. S261).
- **All guidelines for minimum age of opposite sex hormones were also removed.**
- **The minimum age recommendations were retracted,** it appears, ***in contradiction to the recommendation of their own expert consensus***: "On page S66, the following text was removed: 'Age recommendations for irreversible surgical procedures were determined by a review of existing literature and the expert consensus of mental health providers, medical providers, and surgeons highly experienced in providing care to TGD adolescents.'" (WPATH SOC 8 Correction, p. S260)

WPATH SOC 8 Correction, International Journal of Transgender Health, 23:sup1, S259- S261,
DOI: 10.1080/26895269.2022.2125695

WPATH SOC 8

- **The SOC8 used an aberrant form of the GRADE approach for systematic reviews that removed the grading of quality of evidence** (which should be categorized as very low, low, moderate, and high quality). Instead any recommendation of "recommend" is automatically assigned as high quality of evidence. (Coleman et. al, 2022, p. S250)
- **SOC 8 also failed to provide evidence profile tables which should include “an explicit judgment of each factor that determines the quality of evidence for each outcome”** (Guyatt et al., 2021).
- **A chapter regarding eunuchs was inserted into SOC 8 that gives recommendations for how to induce hypogonadism in men who have the eunuch "gender identity" by either orchiectomy [testicle removal] or chemical castration such as with GnRH analogues** (Coleman et al., 2022, p. S88).

Coleman E, et al. "Standards of Care for the Health of Transgender and Gender Diverse People, Version 8". International Journal of Transgender Health. 06 Sep 2022. International Journal of Transgender Health. <https://doi.org/10.1080/26895269.2022.2100644>.

WPATH SOC 8 is Dangerous

**For at least the reasons above, in my professional opinion,
WPATH SOC 8 represents a grave and immediate danger to
minors, young adults, and adults
and should not be followed by any physician, mental health care
provider, or other medical professional.**

Nations Question and Reverse Course on GAT

- Finland 2020 - recognized that “[r]esearch data on the treatment of dysphoria due to gender identity conflicts in minors is limited,” and recommended prioritizing psychotherapy for gender dysphoria and mental health comorbidities over medical gender affirmation (Council for Choices in Healthcare in Finland, 2020). Additionally, “[s]urgical treatments are not part of the treatment methods for dysphoria caused by gender-related conflicts in minors”.
- Sweden 2021 - the largest adolescent gender clinic announced that it would no longer prescribe puberty blockers or cross-sex hormones to youth under 18 years outside clinical trials (SEGM, 2021). "These treatments are potentially fraught with extensive and irreversible adverse consequences such as cardiovascular disease, osteoporosis, infertility, increased cancer risk, and thrombosis. This makes it challenging to assess the risk / benefit for the individual patient, and even more challenging for the minors or their guardians to be in a position of an informed stance regarding these treatments" (Gauffen and Norgren, 2021).

Society for Evidence Based Gender Medicine (SEGM). Sweden's Karolinska Ends All Use of Puberty Blockers and Cross-Sex Hormones for Minors Outside of Clinical Studies (May 5, 2021), https://bit.ly/SEGM_SwedenStopsHormones.

Gauffen D and Norgren S. "Policy Change Regarding Hormonal Treatment of Minors with Gender Dysphoria at Tema Barn - Astrid Lindgren Children's Hospital". 2021.

<https://segm.org/sites/default/files/Karolinska%20Guideline%20K2021-4144%20April%202021%20%28English%2C%20unofficial%20translation%29.pdf>

Nations Question and Reverse Course on GAT

- Dr Hilary Cass "was appointed by NHS England and NHS Improvement to chair the Independent Review of Gender Identity Services for children and young people in late 2020" (The Cass Review website, 2022). In her interim report dated February 2022, it states that "[e]vidence on the appropriate management of children and young people with gender incongruence and dysphoria is inconclusive both nationally and internationally" (Cass, 2022).

Cass, Hillary. The Cass Review Interim Report. Feb, 2022.
<https://cass.independent-review.uk/publications/interim-report/44>

Gender Dysphoria

How can these kids be helped?

- Investigate autism, depression, anxiety, bipolar disorder, physical or sexual abuse, self harm. Family problems - marital dissolution, interfamily conflict
- Identify and Properly Treat psychological comorbidities
- Individual Counseling
- Family Counseling

Child/Adolescent Affirmative Therapy

- This is not standard of care.
- We do not have the technology to make a male become a female, or a female become a male
- We do not know the long term outcomes of these medical/surgical interventions. No long term studies to assess the degree of harm in this age group.
- Medications are being used off-label and at high doses without proper FDA risk assessment profiles.
- The quality of evidence in the Endocrine Society's own guidelines for children and adolescents is low to very low quality or absent.
- WPATH SOC 8 is an extreme document and presents a grave danger to minors.
- Desisters have been ignored.

Assessment of the Patient with Gender dysphoria

In light of the very serious medical concerns and potential harms of gender affirmative therapy, there are several criteria that I believe would be important to fulfill before applying the Gender Affirmative Therapy model to a patient.

1. Patients should be evaluated to determine if they will follow the natural pattern of desistance which 50 to 98% of pediatric age children will follow.
2. Patients, parents and guardians should be made aware of other options for treatment of gender dysphoria including active psychosocial treatment or watching and waiting with support in order to help with natural desistance.
3. The patient should be provided an assessment by a qualified psychologist or psychiatrist who does not follow the WPATH GAT model. If underlying psychological conditions are diagnosed then these should be adequately evaluated and treated before proceeding to hormones and surgery.

Assessment of the Patient with Gender dysphoria

4. If a medicalized approach with hormones such as testosterone or medications to stop menstruation or puberty are being considered then a clear description of the risks and benefits needs to be conveyed to the minor and the parent or guardian. It needs to be verified that they fully understand these risks.

5. If surgical procedures such as mastectomy, hysterectomy, ovariectomy, orchiectomy, vaginoplasty, or phalloplasty are being considered then clear descriptions of the risks and benefits need to be conveyed to the minor and the parent or guardian.

However, even if a minor and their parents or guardian are made fully aware of the risks and benefits of hormones and surgeries, in my opinion, the minor does not have adequate maturity and judgment to make permanent changes to their body that may result in infertility/sterility and the permanent loss of organs such as breasts whose functions will not be fully utilized (such as breastfeeding) until adulthood.

Greetings,

My name is Vanessa Uphoff. I wish to provide public commentary in opposition to the proposed rules on "Setting the Standard of Care for Treatment of Gender Dysphoria". It is my understanding that the hearing on this matter is taking place on August 5th at 8AM at Marriott Fort Lauderdale Airport, 166 North Compass Way, Dania Beach, FL 33004.

Please let me know who I should send a written request to so that I may make a public comment on this issue. Please also let me know if my understanding of the time and place for this hearing is correct.

Sincerely,

Vanessa Uphoff

Dear FBOM,

Another note to, again, ask that you vote to reject establishing an alternative standard of care that conflicts with medical consensus for children seeking gender-affirming treatment.

I am a pediatrician and member of the AAP and Florida Chapter of the AAP and agree with their summary regarding gender-affirming care:

- Prohibiting gender-affirming care for children suffering from gender dysphoria runs counter to guidance from every major medical society, including the Florida Chapter of the American Academy of Pediatrics, the American Academy of Pediatrics, the American Medical Association, the American Psychiatric Association, and many more.
- Children who receive evidence-based gender-affirming care and support experience sharply reduced incidence of mental health comorbidities including anxiety, depression, and suicidal ideation.
- The current standard of care and clinical guidelines for gender-affirming care—developed by the World Professional Association for Transgender Health (WPATH) and the Endocrine Society—are evidence-based, well researched, and widely accepted as the gold standard for the care of children and adolescents with gender dysphoria.
- Overriding the established standard of care for transgender youth cuts off necessary treatment for transgender children and puts the physical and mental health of vulnerable children at risk.
- The Florida Department of Health study the state is using in its decision-making process fails to conform to established research methodologies and norms, as outlined in [this analysis](#) by the Yale School of Medicine.
- Physicians in all areas of practice should reject government's attempts to insert itself into the doctor-patient relationship and to enact one-size-fits-all rulemaking to the practice of medicine.

Please do no harm and do what is evidenced-based for transgender youth in Florida!

Thanks,
Kate Rooney-Otero, MD

Dear Dr. Diamond-

I am writing to express concern about plans to politicize medical treatment of transgender youth. As a pediatrician, I feel that we need to keep the health and well-being of children as our highest priority. Some well-meaning groups have strong opinions about this, but we need to separate the emotions from the science. The major medical societies are in agreement that gender-affirming care supports better outcomes and children who receive evidence-based gender-affirming care experience sharply reduced incidence of mental health co-morbidities including anxiety, depression, and suicidal ideation.

Overriding the established standard of care for transgender youth cuts off necessary treatment for transgender children and puts the physical and mental health of vulnerable children at risk. Do you feel that a group of politicians should take on that role? Unfortunately, the Florida Department of Health has fallen victim to the politicization of medical treatment and would like to expose transgender children to this risk.

As a physician, I recognize my boundaries and try to stay within them. Regardless of strong beliefs, this country was founded on the principles that keep governments from interfering with people's lives. Please do not undermine the foundations of our country by allowing government to dictate things that should be within the boundaries of physicians and their patients/families. This is a dangerous path and holds great risk.

Sincerely-
Elaine Donoghue, MD

Hello,

Please find attached a letter I wholeheartedly agree with regarding the preservation of the rights of children to access gender-affirming care in our state. Below are some of the highlights:

- Prohibiting gender-affirming care for children suffering from gender dysphoria runs counter to guidance from every major medical society, including the Florida Chapter of the American Academy of Pediatrics, the American Academy of Pediatrics, the American Medical Association, the American Psychiatric Association, and many more.
- Children who receive evidence-based gender-affirming care and support experience sharply reduced incidence of mental health comorbidities including anxiety, depression, and suicidal ideation.
- The current standard of care and clinical guidelines for gender-affirming care—developed by the World Professional Association for Transgender Health (WPATH) and the Endocrine Society—are evidence-based, well researched, and widely accepted as the gold standard for the care of children and adolescents with gender dysphoria.
- Overriding the established standard of care for transgender youth cuts off necessary treatment for transgender children and puts the physical and mental health of vulnerable children at risk.
- The Florida Department of Health study the state is using in its decision-making process fails to conform to established research methodologies and norms, as outlined in [this analysis](#) by the Yale School of Medicine.
- Physicians in all areas of practice should reject government's attempts to insert itself into the doctor-patient relationship and to enact one-size-fits-all rulemaking to the practice of medicine.

I ask that you continue to allow physicians to be able to provide gender-affirming care to the children of our state for their physical, mental, and emotional well-being.

Dear Dr Diamond,

The American Academy of Pediatrics (AAP), a nonprofit organization representing 67,000 pediatricians dedicated to the health, safety and well-being of all children and the Florida Chapter of American Academy of Pediatrics, Inc (FCAAP), a nonprofit organization representing more than 2,600 pediatricians committed to serving all children across the state, writes to express our concern regarding the request from the Florida Surgeon General for the Florida Board of Medicine to develop new standards of care for the treatment of gender dysphoria.

Gender-affirming care is the widely accepted standard of care for treating transgender adolescents with gender dysphoria. Gender-affirming care is endorsed and recommended by the American Academy of Pediatrics;ⁱ the Florida Chapter of the American Academy of Pediatrics, Inc;ⁱⁱ the American Medical Association;ⁱⁱⁱ the American College of Obstetricians and Gynecologists;^{iv} the American College of Physicians;^v the American Psychiatric Association;^{vi} the American Psychological Association;^{vii} the American Academy of Family Physicians;^{viii} the American Academy of Child and Adolescent Psychiatry;^{ix} the Endocrine Society;^x the Society for Adolescent Health and Medicine;^{xi} the Pediatric Endocrine Society;^{xii} the World Professional Association for Transgender Health (WPATH);^{xiii} and many more medical organizations committed to providing the best evidence-based care.^{xiv}

WPATH and the Endocrine Society have developed well-researched and evidence-based standards of care and clinical guidelines for the care of children and adolescents with gender dysphoria. WPATH's Standards of Care for the Health of Transsexual, Transgender, and Gender-Nonconforming People, Version 7^{xv} and the Endocrine Society's Endocrine Treatment of Gender-Dysphoric/Gender-Incongruent Persons: An Endocrine Society Clinical Practice Guideline^{xvi} (both are herein referenced as "standards of care") are well recognized and accepted among the medical community as the gold standard for treating gender dysphoria.

Included in the Board's meeting agenda to discuss the development of new standards of care for the treatment of gender dysphoria is the June 2, 2022 Florida Medicaid: Generally Accepted Professional Medical Standards Determination on the Treatment of Gender Dysphoria report (GAPMS)^{xvii}. The AAP and FCAAP provided in-depth comments in opposition of both the GAPMS report and the proposed Medicaid rule to ban coverage of gender-affirming care. Our joint comments are included in our communication to the Florida Board of Medicine and we encourage you to review them. The GAPMS report, which serves as the evidentiary basis for the attempt to develop new standards of care, fails to satisfy even the basic tenets of scientific

inquiry and research.^{xviii} Experts from Yale University recently released a critical review of the GAPMS report and found:

- Contrary to the June 2 Report's repeated claims, medical care for gender dysphoria is supported by a robust scientific consensus, meets generally accepted professional medical standards, and is neither experimental nor investigational.
- The June 2 Report appears to be a scientific report, but its veneer hides a flawed analysis that ignores the scientific evidence and relies instead on pseudo-science, particularly purported "expert" reports that are biased, inexperienced, and full of errors. The claimed "expert" reports are written by authors whose testimony has been disqualified in court and who have known ties to anti-LGBTQ advocacy groups.
- Nothing in the June 2 Report calls into question the scientific foundations of standard medical care for gender dysphoria. The June 2 Report makes unfounded criticisms of robust and well-regarded clinical research and instead cites sources with little or no scientific merit, including journalism, a blog entry, letters to the editor, and opinion pieces.
- The linchpin of the June 2 Report is an analysis by two epidemiologists that claims to undermine the scientific evidence supporting medical care for gender dysphoria. Their analysis is extremely narrow in scope, inexperienced, and so flawed that it merits no scientific weight at all.
- The June 2 Report repeatedly and erroneously dismisses solid studies as "low quality." If Florida's Medicaid program applied the June 2 Report's approach to all medical procedures equally, it would have to deny coverage for widely-used medications like statins (cardioprotective cholesterol-lowering drugs taken by millions of older Americans) and common medical procedures like mammograms and routine surgeries.^{xix}

Adolescents with gender dysphoria face increased challenges in life compared to their cisgender peers. Bullying, discrimination, harassment, and a lack of social acceptance are issues adolescents with gender dysphoria deal with on a daily basis and all these issues lead to increased risks of suicide and other mental health conditions.^{xx} In a study of more than 1,000 transgender adolescents, transgender adolescents had higher odds of all suicide outcomes compared to cisgender adolescents, and were at greater risk for suicidal ideations and attempts compared to their cisgender peers.^{xxi} Additionally, in the first large scale (N = 120,670) study examining the relationship between transgender adolescents and suicide, the authors found that between 30-51% of transgender adolescents reported engaging in suicidal behavior, compared to between 10-18% of their cisgender peers.^{xxii}

By proposing an alternative standard of care, Florida is ignoring the broad consensus among the medical community and the weight of peer reviewed medical literature. We call on the Florida Board of Medicine to reject the call for the development of new standards of care and ensure that the existing evidence-based standards of care are allowed to be used to care for children and adolescents with gender dysphoria. Only by doing so will the health and well-being of children and adolescents with gender dysphoria in Florida be preserved.

Thank you for your consideration of our comments.

Sincerely,

A handwritten signature in cursive script that reads "Moira Szilaygi".

Hello,

Please find attached a letter I wholeheartedly agree with regarding the preservation of the rights of children to access gender-affirming care in our state. Below are some of the highlights:

- Prohibiting gender-affirming care for children suffering from gender dysphoria runs counter to guidance from every major medical society, including the Florida Chapter of the American Academy of Pediatrics, the American Academy of Pediatrics, the American Medical Association, the American Psychiatric Association, and many more.
- Children who receive evidence-based gender-affirming care and support experience sharply reduced incidence of mental health comorbidities including anxiety, depression, and suicidal ideation.
- The current standard of care and clinical guidelines for gender-affirming care—developed by the World Professional Association for Transgender Health (WPATH) and the Endocrine Society—are evidence-based, well researched, and widely accepted as the gold standard for the care of children and adolescents with gender dysphoria.
- Overriding the established standard of care for transgender youth cuts off necessary treatment for transgender children and puts the physical and mental health of vulnerable children at risk.
- The Florida Department of Health study the state is using in its decision-making process fails to conform to established research methodologies and norms, as outlined in [this analysis](#) by the Yale School of Medicine.
- Physicians in all areas of practice should reject government's attempts to insert itself into the doctor-patient relationship and to enact one-size-fits-all rulemaking to the practice of medicine.

I ask that you continue to allow physicians to be able to provide gender-affirming care to the children of our state for their physical, mental, and emotional well-being.

Dear Dr Diamond,

The American Academy of Pediatrics (AAP), a nonprofit organization representing 67,000 pediatricians dedicated to the health, safety and well-being of all children and the Florida Chapter of American Academy of Pediatrics, Inc (FCAAP), a nonprofit organization representing more than 2,600 pediatricians committed to serving all children across the state, writes to express our concern regarding the request from the Florida Surgeon General for the Florida Board of Medicine to develop new standards of care for the treatment of gender dysphoria.

Gender-affirming care is the widely accepted standard of care for treating transgender adolescents with gender dysphoria. Gender-affirming care is endorsed and recommended by the American Academy of Pediatrics;ⁱ the Florida Chapter of the American Academy of Pediatrics, Inc;ⁱⁱ the American Medical Association;ⁱⁱⁱ the American College of Obstetricians and Gynecologists;^{iv} the American College of Physicians;^v the American Psychiatric Association;^{vi} the American Psychological Association;^{vii} the American Academy of Family Physicians;^{viii} the American Academy of Child and Adolescent Psychiatry;^{ix} the Endocrine Society;^x the Society for Adolescent Health and Medicine;^{xi} the Pediatric Endocrine Society;^{xii} the World Professional Association for Transgender Health (WPATH);^{xiii} and many more medical organizations committed to providing the best evidence-based care.^{xiv}

WPATH and the Endocrine Society have developed well-researched and evidence-based standards of care and clinical guidelines for the care of children and adolescents with gender dysphoria. WPATH's Standards of Care for the Health of Transsexual, Transgender, and Gender-Nonconforming People, Version 7^{xv} and the Endocrine Society's Endocrine Treatment of Gender-Dysphoric/Gender-Incongruent Persons: An Endocrine Society Clinical Practice Guideline^{xvi} (both are herein referenced as "standards of care") are well recognized and accepted among the medical community as the gold standard for treating gender dysphoria.

Included in the Board's meeting agenda to discuss the development of new standards of care for the treatment of gender dysphoria is the June 2, 2022 Florida Medicaid: Generally Accepted Professional Medical Standards Determination on the Treatment of Gender Dysphoria report (GAPMS)^{xvii}. The AAP and FCAAP provided in-depth comments in opposition of both the GAPMS report and the proposed Medicaid rule to ban coverage of gender-affirming care. Our joint comments are included in our communication to the Florida Board of Medicine and we encourage you to review them. The GAPMS report, which serves as the evidentiary basis for the attempt to develop new standards of care, fails to satisfy even the basic tenets of scientific

inquiry and research.^{xviii} Experts from Yale University recently released a critical review of the GAPMS report and found:

- Contrary to the June 2 Report's repeated claims, medical care for gender dysphoria is supported by a robust scientific consensus, meets generally accepted professional medical standards, and is neither experimental nor investigational.
- The June 2 Report appears to be a scientific report, but its veneer hides a flawed analysis that ignores the scientific evidence and relies instead on pseudo-science, particularly purported "expert" reports that are biased, inexperienced, and full of errors. The claimed "expert" reports are written by authors whose testimony has been disqualified in court and who have known ties to anti-LGBTQ advocacy groups.
- Nothing in the June 2 Report calls into question the scientific foundations of standard medical care for gender dysphoria. The June 2 Report makes unfounded criticisms of robust and well-regarded clinical research and instead cites sources with little or no scientific merit, including journalism, a blog entry, letters to the editor, and opinion pieces.
- The linchpin of the June 2 Report is an analysis by two epidemiologists that claims to undermine the scientific evidence supporting medical care for gender dysphoria. Their analysis is extremely narrow in scope, inexperienced, and so flawed that it merits no scientific weight at all.
- The June 2 Report repeatedly and erroneously dismisses solid studies as "low quality." If Florida's Medicaid program applied the June 2 Report's approach to all medical procedures equally, it would have to deny coverage for widely-used medications like statins (cardioprotective cholesterol-lowering drugs taken by millions of older Americans) and common medical procedures like mammograms and routine surgeries.^{xix}

Adolescents with gender dysphoria face increased challenges in life compared to their cisgender peers. Bullying, discrimination, harassment, and a lack of social acceptance are issues adolescents with gender dysphoria deal with on a daily basis and all these issues lead to increased risks of suicide and other mental health conditions.^{xx} In a study of more than 1,000 transgender adolescents, transgender adolescents had higher odds of all suicide outcomes compared to cisgender adolescents, and were at greater risk for suicidal ideations and attempts compared to their cisgender peers.^{xxi} Additionally, in the first large scale (N = 120,670) study examining the relationship between transgender adolescents and suicide, the authors found that between 30-51% of transgender adolescents reported engaging in suicidal behavior, compared to between 10-18% of their cisgender peers.^{xxii}

By proposing an alternative standard of care, Florida is ignoring the broad consensus among the medical community and the weight of peer reviewed medical literature. We call on the Florida Board of Medicine to reject the call for the development of new standards of care and ensure that the existing evidence-based standards of care are allowed to be used to care for children and adolescents with gender dysphoria. Only by doing so will the health and well-being of children and adolescents with gender dysphoria in Florida be preserved.

Thank you for your consideration of our comments.

Sincerely,

A handwritten signature in cursive script that reads "Moira Szilaygi".

I am writing to you in strong opposition to any proposed policy to limit or prohibit access to potentially lifesaving medical care for transgender youth. Here is why opposing such measures is so crucial:

- Prohibiting gender-affirming care for children suffering from gender dysphoria runs counter to guidance from every major medical society, including the Florida Chapter of the American Academy of Pediatrics, the American Academy of Pediatrics, the American Medical Association, the American Psychiatric Association, and many more.
- Children who receive evidence-based gender-affirming care and support experience sharply reduced incidence of mental health comorbidities including anxiety, depression, and suicidal ideation.
- The current standard of care and clinical guidelines for gender-affirming care—developed by the World Professional Association for Transgender Health (WPATH) and the Endocrine Society—are evidence-based, well researched, and widely accepted as the gold standard for the care of children and adolescents with gender dysphoria.
- Overriding the established standard of care for transgender youth cuts off necessary treatment for transgender children and puts the physical and mental health of vulnerable children at risk.
- The Florida Department of Health study the state is using in its decision-making process fails to conform to established research methodologies and norms, as outlined in [this analysis](#) by the Yale School of Medicine.
- Physicians in all areas of practice should reject government's attempts to insert itself into the doctor-patient relationship and to enact one-size-fits-all rulemaking to the practice of medicine.

Sincerely,

Richard Wilde, MD, FAAP

Dear Members of the FL Board of Medicine,

I'm writing to urge you to vote against the proposal to bar physicians from providing treatment to transgender youth this Friday. A "standard of care" that denies care that is sought by a patient is unethical and contrary to the medical oath of physicians to do no harm. The proposed rule discriminates against transgender youth, limits their access to care, and contradicts the Board of Medicine's purpose of ensuring minimum requirements for the safe practice of medicine.

A report from Yale and other universities (<https://medicine.yale.edu/lgbtqi/research/gender-affirming-care/>) debunk the scientific basis used by the FL Department of Health to deny gender-affirming care ("Flawed Medicaid Report in Florida" and "Biased Science in Texas & Alabama").

I urge you to not succumb to political pressure and to use valid and verifiable science as a basis for your decisions. The Board that licenses and regulates medical providers for the State of Florida must uphold the standards of the medical profession and not compromise its integrity by supporting policy based on disinformation.

Sincerely,
Kristin Hoffschmidt

August 3rd, 2022

Dr. David Diamond, Chair Florida Board of Medicine
4052 Bald Cypress Way Bin C-03 Tallahassee, FL 32399-3253

To the Board of Medicine

We would like you not to approve any legislation regarding the removal of gender-affirming care that will risk the lives and well beings of transgender youths.

They are Floridians and we must respect and uphold their rights to healthcare.

I invite you to examine the stance the Academy of Pediatrics Florida Chapter and the American Academy of Pediatrics take in support of gender-affirming care.

"Adolescentes with gender dysphoria face increased challenges in life compared to their cisgender peers. Bullying, discrimination, harassment, and a lack of social acceptance are issues adolescents with gender dysphoria deal with on a daily basis and all these issues lead to increased risks of suicide and other mental health conditions. In a study of more than 1,000 transgender adolescents, transgender adolescents had higher odds of all suicide outcomes compared to cisgender adolescents, and were at greater risk for suicidal ideations and attempts compared to their cisgender peers.

By proposing an alternative standard of care, Florida is ignoring the broad consensus among the medical community and the weight of peer reviewed medical literature. We call on the Florida Board of Medicine to reject the call for the development of new standards of care and ensure that the existing evidence-based standards of care are allowed to be used to care for children and adolescents with gender dysphoria. Only by doing so will the health and well-being of children and adolescents with gender dysphoria in Florida be preserved.

Thank you for your consideration.”

Sincerely,

Beny Rub MD

Re: Reject the Proposed Guidance by Surgeon General Ladapo's Department of Health on Gender Dysphoria in Children and Adolescents
Letter of Opposition from Latina Institute for Reproductive Justice Florida

Dear Chair Diamond, Vice-Chair Cairns, and members of the Florida Board of Medicine:

Latina Institute for Reproductive Justice Florida writes to express its strong opposition to the proposed rule to ban transgender medical care from the Florida Department of Health. A part of National Latina Institute for Reproductive Justice, we are a nonpartisan, non-profit organization that fights for equal access to reproductive health for Latina/x communities. The reproductive justice framework is rooted in the belief that all individuals and communities should have the resources and power they need to make their own decisions about their bodies, genders, sexualities, families, and lives.¹

This proposed rule would unnecessarily complicate healthcare, and cut off access to healthcare altogether, for Transgender and gender non-conforming/gender diverse Floridians. Transgender and gender non-conforming/gender diverse folks who are also “people of color, immigrants, sex workers, living with disabilities, or living with HIV face additional forms of marginalization, discrimination and violence.”² Study after study shows “that gender-affirming care—a medical and psychosocial health care designed to affirm individuals' gender identities—greatly improves the mental health and overall well-being of gender diverse, transgender, and nonbinary children and adolescents.”³ According to The Trevor Project's 2020 National Survey on LGBTQ Youth Mental Health, “54 percent of young people who identified as transgender or nonbinary reported having seriously considered suicide in the last year, and 29 percent have

¹ <https://healthlaw.org/medicaid-as-an-lgbtq-reproductive-justice-issue-a-primer/>

² <https://www.pwn-usa.org/issues/policy-agenda/trans-rights-safety-justice/trans-centered-rj/>

³ <https://www.columbiapsychiatry.org/news/gender-affirming-care-saves-lives#:~:text=Research%20demonstrates%20that%20gender%2Daffirming,and%20nonbinary%20children%20and%20adolescents.>

made an attempt to end their lives. In contrast, numerous research studies have found that gender-affirming care leads to improved mental health among TGNB youth.”⁴

In this current climate, Transgender and gender non-conforming/gender diverse folks already experience barriers in access accurate and compassionate healthcare.

- One in three Transgender and gender non-conforming/gender diverse people delayed or avoided preventive health care, like a pelvic exam or STI screening, out of fear of discrimination or disrespect. This number is even higher – almost one in two — for transgender men. (NRDS, 2015)⁵
- One in five Transgender and gender non-conforming/gender diverse people report having been turned away by a doctor because of their transgender or gender non-conforming status. (NRDS, 2015)⁶
- One half for Transgender and gender non-conforming/gender diverse people report having to teach their health care provider some aspect of transgender care. That number jumps to 62% for transgender men. (NRDS, 2015)⁷

The nation’s leading health organizations support gender-affirming care for Transgender and gender non-conforming/gender diverse people -- including the American Academy of Pediatrics; the American Medical Association; The American College of Obstetricians and Gynecologists; The American College of Physicians; The American Psychiatric Association; The American Psychological Association; The American Academy of Family Physicians; The Endocrine Society; The Pediatric Endocrine Society; American Nurses Association; American Public Health Association; American Heart Association; National Association of Social Workers; World Medical Association; and The World Professional Association for Transgender Health, among others. (Equality Florida)

These continued attacks on Transgender and gender non-conforming/gender diverse Floridians, which are not based on science, medicine, and evidence-based approach from the U.S. Department of Health and Human Services (HHS), are dangerous, life-threatening, and abusive. “Rather than protect trans youth, all it does is aim to push them back into the closet, an approach which is tantamount to state-endorsed conversion therapy. Rather than affirm parental rights, all it does is deny parents the autonomy to make the best decisions for their children to support their development.”⁸

⁴ <https://www.columbiapsychiatry.org/news/gender-affirming-care-saves-lives#:~:text=Research%20demonstrates%20that%20gender%2Daffirming,and%20nonbinary%20children%20and%20adolescents.>

⁸ https://hrc-prod-requests.s3-us-west-2.amazonaws.com/FL-Dept-of-Health-Rebuttal_042122_v3.pdf

We urge you and fellow members of the Board of Medicine to reject this dangerous proposed rule. The actual harm is caused by the barriers to care and in the criminalization of our communities. We must ensure that Transgender and gender non-conforming/gender diverse Floridians are not targeted and criminalized simply for accessing healthcare, owning their bodies, and reclaiming control of their autonomy. If you should have any questions regarding Latina Institute's Florida opposition to this proposed rule, please contact Aurelie Colon Larrauri, FL State Policy Advocate, at aurelie@latinainstitute.org.

Sincerely,

Aurelie Colon Larrauri (she/they)

Please support equal and full access to gender-affirming health care for transgender youths and adults. Medical care is a human right. The best people to determine what types of health care are needed and helpful are the patients, their parents (for minors), and their health care providers. Government should not bar physicians and other health care providers from providing services that can save lives and enhance the welfare of any group, particularly, groups that are more vulnerable to discrimination.

Thank you,
Allan Barsky, PhD

To the Florida Board of Medicine,

I am planning to speak at the meeting today, but in the case that I am not able to speak I wanted to send my thoughts to you via email.

My name is Brittany Bruggeman, and I am a pediatric endocrinologist at the University of Florida. In my practice I see patients with endocrine disorders, with diabetes, and patients in our Youth Gender Program. I'm also an NIH-funded physician scientist. I was born and raised in Florida, attended UF for all of my 10 years of medical training in pediatric endocrinology, and am a member of the Gold Humanism Honor Society. It is an immense privilege for me to care for each of my patients with all of the empathy and art and science of medicine that this requires of us as physicians. I teach and mentor medical students and residents on a daily basis and have the honor of helping them to internalize their responsibility to provide the best evidence-based, compassionate, and patient-centric care.

Even prior to the pandemic, but especially now, as physicians we have withstood attacks on our training and expertise. However, as the Board of Medicine, my fellow physicians on the Board will understand the difficult decisions that we have to make every day. Every decision is a balance of risks and benefits, and as a pediatrician these risks and benefits must be weighed together by the medical team, the patient, and the family before a treatment decision is made.

Our current guidelines for the treatment of adolescents with gender dysphoria are supported by every major medical association including the AMA, AAP, Endocrine Society, and Pediatric Endocrine Society. Additionally, the level of evidence supporting this care is higher than the evidence that I use to start statins, ACE inhibitors, and even fast-acting insulin in my patients with diabetes. As you know, insulin especially is a medication with potentially severe and even fatal adverse events, but I must do what all physicians do: use the guidelines and evidence that I have, weigh the risks and benefits of treatment alongside the patient and family in front of me to make the best treatment decision for that patient.

The Board of Medicine's role is to ensure that every physician practicing in the state meets requirements for safe practice. Its role is not to overturn evidence-based medical guidelines to appease the whims and political agenda of the state.

Sincerely,

Brittany Bruggeman, MD

August 5th 2022

Tom Wallace
Deputy Secretary for Medicaid
Florida Agency for Health Care Administration
2727 Mahan Drive
Mail Stop #8
Tallahassee, FL 32308
Dear Director Wallace,

I am an adolescent medicine physician, writing to express grave concern with regards to the rule that the Agency for Health Care Administration (AHCA) prohibiting coverage of gender-affirming care under the Medicaid program. Denying evidence-based, medically necessary standards of care to transgender adolescents constitutes a broad and sweeping discriminatory action by the State of Florida and its Medicaid program.

- Prohibiting gender-affirming care for children suffering from gender dysphoria runs counter to guidance from every major medical society, including the Florida Chapter of the American Academy of Pediatrics, the American Academy of Pediatrics, the American Medical Association, the American Psychiatric Association, and many more.
- It is my experience that children who receive evidence-based gender-affirming care and support experience sharply reduced incidence of mental health comorbidities including anxiety, depression, and suicidal ideation.
- The current standard of care and clinical guidelines for gender-affirming care—developed by the World Professional Association for Transgender Health (WPATH) and the Endocrine Society—are evidence-based, well researched, and widely accepted as the gold standard for the care of children and adolescents with gender dysphoria.
- Overriding the established standard of care for transgender youth cuts off

necessary treatment for transgender children and puts the physical and mental health of vulnerable children at risk.

- The Florida Department of Health study the state is using in its decision-making process fails to conform to established research methodologies and norms, as outlined in [this analysis](#) by the Yale School of Medicine.
- Physicians in all areas of practice should reject government's attempts to insert itself into the doctor-patient relationship and to enact one-size-fits-all rulemaking to the practice of medicine.

Sincerely,

Elizabeth Carreno Rijo, MD MPH FAAP FSAHM

Hello,

Please find attached a letter I wholeheartedly agree with regarding the preservation of the rights of children to access gender-affirming care in our state. Below are some of the highlights:

- Prohibiting gender-affirming care for children suffering from gender dysphoria runs counter to guidance from every major medical society, including the Florida Chapter of the American Academy of Pediatrics, the American Academy of Pediatrics, the American Medical Association, the American Psychiatric Association, and many more.
- Children who receive evidence-based gender-affirming care and support experience sharply reduced incidence of mental health comorbidities including anxiety, depression, and suicidal ideation.
- The current standard of care and clinical guidelines for gender-affirming care—developed by the World Professional Association for Transgender Health (WPATH) and the Endocrine Society—are evidence-based, well researched, and widely accepted as the gold standard for the care of children and adolescents with gender dysphoria.
- Overriding the established standard of care for transgender youth cuts off necessary treatment for transgender children and puts the physical and mental health of vulnerable children at risk.
- The Florida Department of Health study the state is using in its decision-making process fails to conform to established research methodologies and norms, as outlined in [this analysis](#) by the Yale School of Medicine.
- Physicians in all areas of practice should reject government’s attempts to insert itself into the doctor-patient relationship and to enact one-size-fits-all rulemaking to the practice of medicine.

I ask that you continue to allow physicians to be able to provide gender-affirming care to the children of our state for their physical, mental, and emotional well-being.

Dear Dr Diamond,

The American Academy of Pediatrics (AAP), a nonprofit organization representing 67,000 pediatricians dedicated to the health, safety and well-being of all children and the Florida Chapter of American Academy of Pediatrics, Inc (FCAAP), a nonprofit organization representing more than 2,600 pediatricians committed to serving all children across the state, writes to express our concern regarding the request from the Florida Surgeon General for the Florida Board of Medicine to develop new standards of care for the treatment of gender dysphoria.

Gender-affirming care is the widely accepted standard of care for treating transgender adolescents with gender dysphoria. Gender-affirming care is endorsed and recommended by the American Academy of Pediatrics;ⁱ the Florida Chapter of the American Academy of Pediatrics, Inc;ⁱⁱ the American Medical Association;ⁱⁱⁱ the American College of Obstetricians and Gynecologists;^{iv} the American College of Physicians;^v the American Psychiatric Association;^{vi} the American Psychological Association;^{vii} the American Academy of Family Physicians;^{viii} the American Academy of Child and Adolescent Psychiatry;^{ix} the Endocrine Society;^x the Society for Adolescent Health and Medicine;^{xi} the Pediatric Endocrine Society;^{xii} the World Professional Association for Transgender Health (WPATH);^{xiii} and many more medical organizations committed to providing the best evidence-based care.^{xiv}

WPATH and the Endocrine Society have developed well-researched and evidence-based standards of care and clinical guidelines for the care of children and adolescents with gender dysphoria. WPATH's Standards of Care for the Health of Transsexual, Transgender, and Gender-Nonconforming People, Version 7^{xv} and the Endocrine Society's Endocrine Treatment of Gender-Dysphoric/Gender-Incongruent Persons: An Endocrine Society Clinical Practice Guideline^{xvi} (both are herein referenced as "standards of care") are well recognized and accepted among the medical community as the gold standard for treating gender dysphoria.

Included in the Board's meeting agenda to discuss the development of new standards of care for the treatment of gender dysphoria is the June 2, 2022 Florida Medicaid: Generally Accepted Professional Medical Standards Determination on the Treatment of Gender Dysphoria report (GAPMS)^{xvii}. The AAP and FCAAP provided in-depth comments in opposition of both the GAPMS report and the proposed Medicaid rule to ban coverage of gender-affirming care. Our joint comments are included in our communication to the Florida Board of Medicine and we encourage you to review them. The GAPMS report, which serves as the evidentiary basis for the attempt to develop new standards of care, fails to satisfy even the basic tenets of scientific

inquiry and research.^{xviii} Experts from Yale University recently released a critical review of the GAPMS report and found:

- Contrary to the June 2 Report's repeated claims, medical care for gender dysphoria is supported by a robust scientific consensus, meets generally accepted professional medical standards, and is neither experimental nor investigational.
- The June 2 Report appears to be a scientific report, but its veneer hides a flawed analysis that ignores the scientific evidence and relies instead on pseudo-science, particularly purported "expert" reports that are biased, inexperienced, and full of errors. The claimed "expert" reports are written by authors whose testimony has been disqualified in court and who have known ties to anti-LGBTQ advocacy groups.
- Nothing in the June 2 Report calls into question the scientific foundations of standard medical care for gender dysphoria. The June 2 Report makes unfounded criticisms of robust and well-regarded clinical research and instead cites sources with little or no scientific merit, including journalism, a blog entry, letters to the editor, and opinion pieces.
- The linchpin of the June 2 Report is an analysis by two epidemiologists that claims to undermine the scientific evidence supporting medical care for gender dysphoria. Their analysis is extremely narrow in scope, inexperienced, and so flawed that it merits no scientific weight at all.
- The June 2 Report repeatedly and erroneously dismisses solid studies as "low quality." If Florida's Medicaid program applied the June 2 Report's approach to all medical procedures equally, it would have to deny coverage for widely-used medications like statins (cardioprotective cholesterol-lowering drugs taken by millions of older Americans) and common medical procedures like mammograms and routine surgeries.^{xix}

Adolescents with gender dysphoria face increased challenges in life compared to their cisgender peers. Bullying, discrimination, harassment, and a lack of social acceptance are issues adolescents with gender dysphoria deal with on a daily basis and all these issues lead to increased risks of suicide and other mental health conditions.^{xx} In a study of more than 1,000 transgender adolescents, transgender adolescents had higher odds of all suicide outcomes compared to cisgender adolescents, and were at greater risk for suicidal ideations and attempts compared to their cisgender peers.^{xxi} Additionally, in the first large scale (N = 120,670) study examining the relationship between transgender adolescents and suicide, the authors found that between 30-51% of transgender adolescents reported engaging in suicidal behavior, compared to between 10-18% of their cisgender peers.^{xxii}

By proposing an alternative standard of care, Florida is ignoring the broad consensus among the medical community and the weight of peer reviewed medical literature. We call on the Florida Board of Medicine to reject the call for the development of new standards of care and ensure that the existing evidence-based standards of care are allowed to be used to care for children and adolescents with gender dysphoria. Only by doing so will the health and well-being of children and adolescents with gender dysphoria in Florida be preserved.

Thank you for your consideration of our comments.

Sincerely,

A handwritten signature in cursive script that reads "Moira Szilaygi".

**Re: Human Rights Campaign Comments on the Surgeon General's July 2,
2022 Letter concerning gender affirming medical care**

Dear Dr. Diamond and Members of the Florida Board of Medicine:

On behalf of the Human Rights Campaign's more than three million members and supporters nationwide, we submit this comment in response to the letter from the Surgeon General of Florida recommending the creation of a standard of care that would ban or significantly curtail the ability of medical practitioners to provide standard and medically necessary gender affirming health care to minors.¹ As the nation's largest organization working on behalf of lesbian, gay, bisexual, transgender, and queer people, we are deeply troubled by this letter in which the Surgeon General disregards scientifically based standards set by numerous medical professional organizations including the American Academy of Pediatrics, the American Medical Association, and the Endocrine Society.² The creation of a standard of care in line with the Surgeon General's recommendations would cause confusion and chaos among medical professionals in the State as they attempt to comply with standards that contravene the majority scientific consensus. It would also potentially force many vulnerable young patients to either delay the start of treatment or suspend medically necessary care during the course of treatment. We implore the Board to disregard the unfounded recommendation by the Surgeon General of Florida or to ensure that any creation of a standard of care includes gender affirming healthcare as a viable treatment for medical practitioners to recommend and dispense in consultation with their patients and their families.

¹ Joseph A. Lapado, Letter to the Florida Board of Medicine, July 2, 2022, accessed July 28, 2022, at <https://www.documentcloud.org/documents/22050967-board-letter>.

² *Id.*

Denying access to safe, affirming, and age-appropriate medical care such as gender-affirming hormones or puberty-delaying medication is dangerous and can be life-threatening. There is a clear correlation between youth receiving gender-affirming care and a decrease in anxiety, depression, self harm, and suicidal ideation. A blanket denial of care by preventing medical practitioners from engaging in the practice would increase rates of adverse mental health outcomes among transgender young adults.³

Gender-affirming care for transgender youth and adolescents largely involves social transitioning – whereby a person adopts a name, pronouns, and gender expressions that are consistent with their gender identity. Additionally, youth are often supported by a host of medical practitioners in their social transition through therapy and later consultation regarding medical transition if the patient so desires it.⁴ Numerous studies have found that, after social transitioning, transgender youth report similar mental health levels to the general youth population, eliminating mental health disparities typically seen. “Transitioning socially should not only be viewed as a form of treatment, but can be understood as a possibility for children to explore their own individual developmental pathways.”⁵ It is clear that these non-medical elements of transitioning help increase positive health outcomes. As stated, healthcare supporting social transitioning is sometimes only one part of a transgender individual’s healthcare plan to live fully as their whole selves.

For some people, medical transition is necessary. Gender-affirming medical care encompasses hormone therapy, puberty blockers or other medical procedures. And to be done properly and safely, there must be close consultation with medical practitioners. According to Williams Institute, there are approximately 16,200 transgender youth (ages 13-17) throughout the state of Florida.⁶ A standard banning or severely restricting gender affirming care would outright prevent these individuals from receiving care for gender affirming procedures within the State of Florida. For example, many transgender individuals report having to leave their home state (Florida included) in order to receive gender affirming care as the closest provider of such care resides outside of state lines.⁷ A new standard of care banning or severely restricting gender affirming care would push transgender youth across the State to either: 1) leave to a different, more welcoming state, to receive gender affirming care as there would remain no practitioner within the state that could provide them with said care, 2) suffer the mental health consequences as described above due to an inability to transition (due to financial, employment, familial, or other

³ “Use of GAHT [gender affirming health treatments] was associated with lower odds of recent depression and seriously considering suicide compared to those who wanted GAHT but did not receive it.” Amy E. restriction preventing them from crossing state lines), or 3) leave the state permanently with (or potentially without) their families to a state that is more welcoming and able to provide them with the standard and medically necessary treatments they need. Additionally, a new standard of care may lead to either the de-licensing of medical professionals throughout the state for having provided such care or the moving of medical professionals throughout the state because of a desire to provide such care. This could leave the State with a shortage of licensed medical professionals.

A new standard to prevent medical professionals from providing gender affirming care not only restricts access to necessary medical care, it also prevents parents from making decisions in the best interest of their children. This new standard would also prevent doctors from making medically sound determinations based on widely accepted and vetted standards of care and from working with their patients on how to provide the best care possible tailored to the individual for fear of losing their job and their license to practice medicine in the State. In a study of over 160 medical doctors, “[o]verall, 85.7 percent of clinicians were willing to provide routine care to transgender patients.”⁸ Although this number is encouraging, “willingness is not necessarily equivalent to competence or the ability to provide high-quality, sensitive care.”⁹ It is imperative to ensure that medical practitioners are able to provide gender affirming care not only for the benefit of youth throughout the State, but also to ensure that those same practitioners are keeping up to date with the latest in treatments made available by the scientific community.

A new standard also ignores the fact that the medical establishment has already spoken on this matter. The American Medical Association, representing millions of doctors across the United States, points out that the majority of medical associations throughout the nation include gender affirming care as part of their own treatment standards noting that:

The AMA opposes any discrimination based on an individual’s sex, sexual orientation or gender identity, opposes the denial of health insurance on the basis of sexual orientation or gender identity, and supports public and private health insurance coverage for treatment of gender dysphoria as recommended by the patient’s physician....In addition, other medical associations, including the American Academy of Family Physicians, American College of Obstetricians and Gynecologists and American Psychiatric Association have stated that medically necessary transition-related care should be covered by insurance.¹⁰

Numerous fallacies underlie the Surgeon General’s letter recommending a new standard of care. The theory of rapid onset gender dysphoria has been debunked throughout the scientific and medical literature, and met with significant and substantial methodological critiques.¹¹ In fact, determining

treatment approaches (or, in this case, lack thereof) based on so-called rapid onset gender dysphoria would not meet the generally accepted professional medical standards determination, due to the lack of empirical support for this theory. This would make a new standard of care an outlier nationally. Indeed, in 2021, the American Psychological Association, the American Psychiatric Association, the Florida Psychological Association, and over 120 other medical associations issued a position statement calling for “eliminating the use of Rapid-Onset Gender Dysphoria and similar concepts for clinical and diagnostic application given the lack of rigorous empirical support for its existence and its likelihood of contributing to harm and mental health burden.”¹²

In addition, the overwhelming evidence supports the ability of medical professionals to provide gender affirming care due to the positive mental health impacts of treatments such as puberty blockers on transgender youth.¹³ For example, a systematic review of 13 studies found that receipt of puberty blockers had numerous positive psychosocial impacts, including “significant improvements in multiple psychological measures, including global functioning, depression, and overall behavioral and/or emotional problems.”¹⁴ Puberty blockers are both safe and fully reversible.¹⁵ According to the Endocrine Society, “Pubertal suppression is fully reversible, enabling full pubertal development in the natal gender, after cessation of treatment, if appropriate. The experience of full endogenous puberty is an undesirable condition for the GD [gender dysphoric]/gender-incongruent individual and may seriously interfere with healthy psychological functioning and well-being. Treating GD/ gender-incongruent adolescents entering puberty with GnRH analogs has been shown to improve psychological functioning in several domains.”¹⁶

‘Off label’ use does not mean experimental, illegal, or unsafe. Puberty blockers have been used safely and effectively with cisgender youth for decades under FDA approval, with minimal side effects.¹⁷ They have been used safely and effectively with transgender youth since the 1990s.¹⁸ As with puberty blockers, there is substantial evidence demonstrating positive mental health benefits associated with gender-affirming hormones, including lower rates of depression, anxiety, and suicidality.¹⁹ Any form of gender affirming care received by transgender youth is administered in consultation with medical and mental health professionals and their parents. The vast majority of transgender youth and adults remain consistent in their transgender identity.²⁰ Doctors must have the ability to choose safe and effective medical treatments for actual patients with actual health needs.

HRC reiterates our strong opposition to the Surgeon General of Florida’s letter recommending the creation of a standard of care banning or severely restricting the use of gender affirming care by medical practitioners. We urge the Board of Medicine to recognize the positive health benefits that gender-affirming care has on transgender individuals and the necessity of medical practitioners in that care. It is important to recognize that denial of transition-related care is damaging and has effects beyond access to gender-affirming medical procedures and medication, including resulting in a chilling effect on support for social transition and culturally sensitive healthcare for a person’s full range of medical needs. Medical professionals must be able to care for their patients using the full swath of care paths possible, not just those deemed politically acceptable by the government.

Testimony for FL Board of Medicine - 8/5/22

My name is Sujatha Prabhakaran and as a Florida physician practicing gender-affirming health care, I am here to express my opposition to the changes recommended for gender-affirming care. The Florida Surgeon General's recommendations are medically unsafe and cruel to transgender individuals and their families, and therefore must not be implemented.

I currently practice as an obstetrician-gynecologist in Sarasota, FL specializing in reproductive health care including supervising the initiation of a gender-affirming hormone therapy care program over five years ago. Since inception, the program has provided vital health care for over 3,000 patients, so I know firsthand the potentially devastating impacts that loss of care would have for transgender individuals.

Gender-affirming care is medically necessary and is often lifesaving for transgender patients. Blocking access to such care will increase the risk for suicidal ideation, suicide, depression, and anxiety for them.

Medical knowledge and compassion for each patient's individual circumstances must guide decisions about access to gender-affirming care. These medical decisions belong to individuals and their doctors. Yet, this proposal places itself between transgender individuals and the care they so desperately need. It is a dangerous intrusion into the practice of medicine and individuals' freedom.

I have personally treated transgender patients who came to us with severe depression and suicidal thoughts for years. They sought care with us after realizing they were not living as their true selves and that this might be the cause of their mental illness. A few months after being on gender-affirming hormone therapy, they began to see changes in their body that helped them feel more comfortable and happier in their body. They also noted that their depression and suicidal thoughts had gone away. If they had not received the care they needed, they almost certainly would be much less healthy today, and per their own admission might have committed suicide. This is just one of thousands of patients who would be hurt by this change.

This damaging recommendation will have tremendous and lasting negative effects on Floridians, affecting them at a time in their lives that are among the most personal and complicated. As a physician, it pains me to consider not providing my patients with the health care they need and desire to live their fullest life.

The standard of care recommended by the Florida Department of Health is not founded on science. Board of Medicine Chairman David Diamond and other board members, a group of professors and clinicians from Yale University, the University of Alabama at Birmingham and the University of Texas Southwestern, disputed the state's conclusions about treatments for gender dysphoria. They also said establishing a standard of care to prevent such treatments would violate legal protections "against discrimination and harm tens of thousands of Floridians."

We have an obligation to our patients, not politicians.

Please remember our ethical oath as physicians to do no harm. The LGBTQIA+ communities in Florida are also our valued patients and I urge you to oppose the standard of care recommended by the Florida Department of Health.

Sincerely,

Sujatha Prabhakaran, MD, MPH, FACOG

Re: Petition to Initiate Rulemaking Setting the Standard of Care for Treatment of Gender Dysphoria

Dear Members of the Florida Board of Medicine:

Physicians for Reproductive Health (PRH) urges you to reject the petition from the Florida Department of Health to initiate rulemaking banning gender-affirming care for young people in Florida. PRH is a physician-led, national organization working to improve access to comprehensive reproductive health care, including gender-affirming care. Our network includes physicians of all specialties from across the country, including physicians of multiple specialties in Florida, committed to meeting the health care needs of the patients they care for.

Gender-affirming care is safe, essential, life-saving health care that allows for transgender and non-binary people to be able to live their full and authentic lives. Leading medical organizations including the [American Academy for Pediatrics](#), [American Medical Association](#), [American College of Obstetricians and Gynecologists](#), [Endocrine Society](#), [Pediatric Endocrine Society](#) and [World Professional Association for Transgender Youth](#) support gender-affirming care for transgender and gender non-binary people.

Barriers to essential health care makes patients and our communities less healthy, and denies them access to the full range of the quality, compassionate, health care they deserve. Bans like these disproportionately impact transgender youth of color, indigenous transgender youth, and immigrant transgender youth – populations who already face immense discrimination and access barriers to health care.

As physicians, we know that access to supportive, gender-affirming care is vital for transgender and non-binary, especially youth. Transgender and nonbinary youth have an increased risk of depression and suicidal ideation compared to other young people, with recent studies finding that between two-thirds to 72% of transgender youth are depressed and half considered suicide. However, research consistently proves that when transgender and nonbinary youth are affirmed by people around them and have access to gender-affirming care, rates of depression and suicide drop significantly. A [recent study](#) found that transgender youth who receive gender-affirming care are 60% less likely to be depressed and 73% less likely to have thoughts of suicide or self-harm compared to those who do not receive care. Sadly, this same study revealed that youth who are not able to access care experience a two- to threefold increase in depression and suicidal thoughts – indicating that delaying hormones and puberty blockers may in fact worsen mental health symptoms. It cannot be overstated that gender-affirming care is safe, essential, necessary health care that promotes adolescents' health and well-being. Transgender and nonbinary youth should not be subjected to a forced, unwanted form of puberty, particularly when it comes at the expense of their dignity and health.

The April 2020 guidance from the Florida Department of Health opposing gender-affirming care for youth ignores medical and scientific evidence and makes false claims about the health risks of gender-affirming care. This guidance not only interferes with the patient provider relationship and interferes with a provider's best medical judgment, but it also opposes social transition for transgender youth.

Anti-trans Florida politicians want to not only intervene in private health care decisions, but also prevent transgender youth from using the name, pronouns, and gender presentation that conforms to their identity.

Banning access to care is clear government intrusion on personal decision making. The government should have no role interfering in private health care decisions, especially not decisions that dictate what a person's body should look like. Private medical and health care decisions should remain between the patient, and their trained, expert health care provider. These are personal, intimate decisions that people must be able to make for themselves. Patients need providers who will center their individual needs and provide individualized care – they do not need government control over their bodies. Gender-affirming care centers the interests and autonomy of the young person receiving care.

The Department of Health is out of step with the majority of Floridians. Over the past several years, public support for respecting the rights of transgender and nonbinary people has grown significantly, with large majorities of people across the political spectrum opposing discrimination against transgender people in health care and other parts of public life. Furthermore, discriminating against people based on their sexual orientation or gender identity is a violation of the non-discrimination provisions in the Affordable Care Act. No child deserves to be targeted by politicians for who they are. Instead of adopting a harmful rule to ban gender-affirming care for young people, the Florida Department of Health should listen to transgender people and the medical professionals who work directly with them, who understand the life-changing, positive impact of ensuring that they can access the gender-affirming care they need. Let transgender kids be who they are: kids who want to play, be with their friends and family, go to school, play sports, and access health care from compassionate, caring and competent providers.

The actions being undertaken by the Department of Health and its attempts to weaponize their authority is unprecedented and dangerous. I implore you, as The Board of Medicine, to exercise your professional judgement to reject the Department of Health's proposed rule. Transgender and nonbinary youth are depending on you to protect access to life-saving, safe, essential, gender-affirming health care. Everyone, including our young people, should be able to access the care they need. If you have any questions or would like additional information please reach out to Adrienne Ramcharan, Assistant Director of State Policy (aramcharan@prh.org).

Respectfully,

Jamila Perritt, MD, MPH, FACOG

Re: OPPOSITION to Petition to Initiate Rulemaking regarding Standards of Care relating to Gender-Affirming Care

Dear Dr. Diamond and Members of the Florida Board of Medicine:

On behalf of its nearly 3,500 constituents in Florida, American Atheists stands in opposition to the petition to initiate rulemaking the Board of Medicine (“Board”) is considering,¹ which would result in the denial of critical, life-saving gender-affirming care to trans Floridians. We urge the Board to vote against this rulemaking and refuse to adopt this dangerous and harmful proposed standard of care.² This unfounded and malicious proposal will intensify systemic discrimination against trans people, undermine their access to life-saving health care, and unconstitutionally infringe their right to freedom of expression. The proposal asserts scientifically inaccurate claims and makes baseless arguments in a clumsy attack on scientifically based and medically sound gender-affirming health care, even going so far as to limit an individual’s ability to socially transition. We urge you to reject Surgeon General’s Ladapo’s petition to adopt a new “standard of care” in accordance with the Agency for Health Care Administration’s (“Agency”) guidance.

American Atheists is a national civil rights organization that works to achieve religious equality for all Americans by protecting what Thomas Jefferson called the “wall of separation” between government and religion created by the First Amendment. We strive to create an environment where atheism and atheists are accepted as members of our nation’s communities and where casual bigotry against our community is seen as abhorrent and unacceptable. We promote understanding of atheists through education, outreach, and community-building and work to end the stigma associated with being an atheist in America. As advocates for the health, safety, and

¹ Florida Board of Medicine, Gender Dysphoria Discussion Materials and Petition to Initiate Rulemaking, published Jun. 28, 2022. Available at: https://ww10.doh.state.fl.us/pub/medicine/Agenda_Info/Public_Information/Public_Books/2022/August/08052022_FB2_Publicbook.pdf.

² Florida Agency for Health Care Administration, General Medicaid Policy (proposed amendment), Fla. 59G-1.050, published Jun. 17, 2022. Available at: https://www.flrules.org/Gateway/View_notice.asp?id=25979915.

well-being of all Americans, American Atheists objects to efforts to subordinate the health and safety of all to the religious beliefs of a few.

Medical experts have conclusively established that gender affirming care is safe, clinically appropriate, and medically necessary for many individuals that experience gender dysphoria.³ Furthermore, legitimate and objective medical professional associations, such as the American Academy of Pediatrics, the American Medical Association, and the American Psychiatric Association, have long supported this care.⁴ These and other professional associations have expressly denounced the Agency's guidance, upon which this petition relies.⁵ The requested rulemaking and proposed guidance is not rooted in medical science, but instead social and religious bias against trans people. It seeks to deny them well-founded and necessary care, regardless of the impact on their health and well-being. Every claim the Agency asserted to support its guidance prohibiting coverage of gender-affirming care, and which is subsequently being used to support this petition, is inaccurate and misleading. The Board can and should ignore this politically driven so-called "science."

The materials and petition falsely assert that puberty suppression "leaves too many questions as to its effectiveness and medical necessity, especially considering how many children decide against transitioning," and therefore it should not be prescribed as doing so will "deny opportunities for adolescents to adapt and become comfortable with their natal sex." This deceptive claim intentionally disregards several published studies across the globe that have proven that detransition is rare. For example, a 2021 study showed that of 17,000 transgender-identifying adults, only 13% detransitioned.⁶ In that study, of the 13% of individuals who detransitioned:

- Approximately 32% detransitioned due to pressure from community or social stigma;

⁵ Dawson, L., Kates, J., & Musumeci, M. (2022, June 13). *Youth access to gender affirming care: The federal and state policy landscape*. KFF. Available at: <https://www.kff.org/other/issue-brief/youth-access-to-gender-affirming-care-the-federal-and-state-policy-landscape/>.

⁶ Turban, J. L., Loo, S. S., et al. (2021). Factors leading to "detransition" among transgender and gender diverse people in the United States: A mixed-methods analysis. *LGBT Health*, 8(4), 273–280. <https://doi.org/10.1089/lgbt.2020.0437>

- Approximately 35% detransitioned due to parental pressure; and
- Only 2% (44 individuals) detransitioned due to “doubt around gender.”

Additional studies have shown that less than 2% of adolescents who underwent puberty suppression ceased treatment.⁷ In contrast, 78% of adolescents who received puberty suppression later surgically transitioned. Moreover, a 2021 study showed that of 7,900 transgender patients, only 77 patients (less than 1%) expressed regret, and many of those who did express regret did so as a result of lack of social acceptance.⁸

The materials and petition claims that there is no evidence to support providing gender-affirming medical care to trans people. This too is false, as there is overwhelming evidence demonstrating the positive impacts of gender-affirming medical care for those who need it. In fact, several studies have established that receiving gender-affirming care, such as hormone-replacement therapy, has significantly improved the mental and social health of trans people. In a study of 47 transgender youth who received gender-affirming hormones, these youth were 60% less likely to report depression and 73% less likely to report suffering from suicidal thoughts.⁹ Another relevant study showed that 83% of those who did not receive gender-affirming care experienced suicidal ideation and or engaged in self-harm.¹⁰ This is only a fraction of the robust research supporting gender-affirming care and confirming that it is medically necessary and appropriate health care for trans people.

Despite the overwhelming body of research supporting care for trans people, Surgeon General Ladapo, seemingly as a political extension of the DeSantis Administration, has sought to insert the Board of Medicine, and the entirety of the Florida government, into the relationships between trans patients and their doctors. The screening process and medical standards of care for trans people are well-established and medically conservative. In the event a doctor determines that it is in the best interest of their patient to provide gender-affirming care, that decision should remain with the patient, their parents if the patient is a minor, and the doctor. Instead, adopting a new standard of care denying affirming care would prohibit health care providers from acting in the best interest of their patients, regardless of their need or medical standards of care. Under other circumstances, failing to follow these standards would be considered negligent, opening the provider to liability, and yet that is what the petition seeks for all Florida health care providers.

⁷ Wiepjes, C. M., & de Blok, C. J. M., et al. (2018). The Amsterdam Cohort of Gender Dysphoria Study (1972–2015): Trends in prevalence, treatment, and regrets. *The Journal of Sexual Medicine*, 15(4), 582–590. <https://doi.org/10.1016/j.jsxm.2018.01.016>

⁸ Bustos, V. P., et. al. (2021). Regret after gender-affirmation surgery: A systematic review and meta-analysis of prevalence. *Plastic and Reconstructive Surgery - Global Open*, 9(3). <https://doi.org/10.1097/gox.00000000000003477>

⁹ Allen, L. R., et al. (2019). Well-being and suicidality among transgender youth after gender-affirming hormones. *Clinical Practice in Pediatric Psychology*, 7(3), 302–311. <https://doi.org/10.1037/cpp0000288>

¹⁰ Tordoff, D. M., et. al (2022). Mental health outcomes in transgender and nonbinary youths receiving gender-affirming care. *JAMA Network Open*, 5(2). <https://doi.org/10.1001/jamanetworkopen.2022.0978>

If adopted, this standard of care will cause immediate and irreparable harm. By denying basic health care services to trans people, the Board would subject trans and gender-diverse people to stigma and sanction government-mandated discrimination by health care providers. This will worsen the barriers to health care that trans people already face:

- 23% of trans and gender non-conforming people who informed health care providers of their gender identity were denied service altogether.¹¹
- Due to discrimination and disrespect, nearly 30% of trans and gender non-conforming people postponed or avoided medical treatment when they were sick or injured. Similarly, 33% of gender non-conforming and trans people did not seek needed preventative care.¹²

Instead of medical best practices, the origin of this proposed rulemaking traces to known anti-LGBTQ so-called “experts” and hate groups. One such “expert” relied upon by the Agency is the president of the American College of Pediatrics, a fringe anti-LGBTQ hate group that portrays itself as a mainstream professional organization.¹³ Another “expert” supporting this proposed rule is a deacon who has described an increase in trans identification as a “mass mutation.”¹⁴ A third “expert” supporting the proposed rulemaking has a history of ideologically biased research and anti-trans activities.¹⁵ In short, the guidance to support the adoption of a new standard of care is fueled by hatred against trans people, political opportunism, and religiously motivated disapproval of LGBTQ people rather than conclusive medical science. Adopting a new standard of care that limits gender-affirming care is unscientific and dangerous, and any authority that would adopt such a standard of care should be ashamed for letting itself be used as a political weapon to further a culture war at the expense of innocent lives.

Trans people already face significant stigma, and they are at higher risk for mental and physical harm as the result of not being able to access gender-affirming care. The vulnerable deserve to feel safe and supported by their State, not targeted for denial of health care. If passed, this proposed rulemaking would lead only to families fleeing the state to preserve the health and

well-being of their trans children, increased suicidality among trans children, discipline against doctors for trying to act in their patients' best interests, and rampant discrimination against trans people in the medical sector.

The petition for rulemaking is baseless, dangerous, and grossly discriminatory. The Board should not insert itself into the decisions between a patient, their parents, and their doctor, especially at the urging of "experts" whose only qualification is hatred against trans people. American Atheists strongly urges you to take a stand, reaffirm the integrity of Florida's health care system, and refuse to adopt a new standard of care limiting gender-affirming health care. Every patient, regardless of gender or gender identity deserves to receive adequate and medically necessary health care.

If you have any questions regarding American Atheists' opposition to the proposed rulemaking, please contact me at bwilliams@atheists.org.

Sincerely,

Brittany Williams

To Whom This May Concern,

Please find attached a letter I wholeheartedly agree with regarding the preservation of the rights of children to access gender-affirming care in our state. Below are some of the highlights:

- Prohibiting gender-affirming care for children suffering from gender dysphoria runs counter to guidance from every major medical society, including the Florida Chapter of the American Academy of Pediatrics, the American Academy of Pediatrics, the American Medical Association, the American Psychiatric Association, and many more.
- Children who receive evidence-based gender-affirming care and support experience sharply reduced incidence of mental health comorbidities including anxiety, depression, and suicidal ideation.
- The current standard of care and clinical guidelines for gender-affirming care—developed by the World Professional Association for Transgender Health (WPATH) and the Endocrine Society—are evidence-based, well researched, and widely accepted as the gold standard for the care of children and adolescents with gender dysphoria.
- Overriding the established standard of care for transgender youth cuts off necessary treatment for transgender children and puts the physical and mental health of vulnerable children at risk.
- The Florida Department of Health study the state is using in its decision-making process fails to conform to established research methodologies and norms, as outlined in [this analysis](#) by the Yale School of Medicine.
- Physicians in all areas of practice should reject government's attempts to insert itself into the doctor-patient relationship and to enact one-size-fits-all rulemaking to the practice of medicine.

I ask that you continue to allow physicians to be able to provide gender-affirming care to the children of our state for their physical, mental, and emotional well-being.

Sincerely,

Dear Dr Diamond,

The American Academy of Pediatrics (AAP), a nonprofit organization representing 67,000 pediatricians dedicated to the health, safety and well-being of all children and the Florida Chapter of American Academy of Pediatrics, Inc (FCAAP), a nonprofit organization representing more than 2,600 pediatricians committed to serving all children across the state, writes to express our concern regarding the request from the Florida Surgeon General for the Florida Board of Medicine to develop new standards of care for the treatment of gender dysphoria.

Gender-affirming care is the widely accepted standard of care for treating transgender adolescents with gender dysphoria. Gender-affirming care is endorsed and recommended by the American Academy of Pediatrics;ⁱ the Florida Chapter of the American Academy of Pediatrics, Inc;ⁱⁱ the American Medical Association;ⁱⁱⁱ the American College of Obstetricians and Gynecologists;^{iv} the American College of Physicians;^v the American Psychiatric Association;^{vi} the American Psychological Association;^{vii} the American Academy of Family Physicians;^{viii} the American Academy of Child and Adolescent Psychiatry;^{ix} the Endocrine Society;^x the Society for Adolescent Health and Medicine;^{xi} the Pediatric Endocrine Society;^{xii} the World Professional Association for Transgender Health (WPATH);^{xiii} and many more medical organizations committed to providing the best evidence-based care.^{xiv}

WPATH and the Endocrine Society have developed well-researched and evidence-based standards of care and clinical guidelines for the care of children and adolescents with gender dysphoria. WPATH's Standards of Care for the Health of Transsexual, Transgender, and Gender-Nonconforming People, Version 7^{xv} and the Endocrine Society's Endocrine Treatment of Gender-Dysphoric/Gender-Incongruent Persons: An Endocrine Society Clinical Practice Guideline^{xvi} (both are herein referenced as "standards of care") are well recognized and accepted among the medical community as the gold standard for treating gender dysphoria.

Included in the Board's meeting agenda to discuss the development of new standards of care for the treatment of gender dysphoria is the June 2, 2022 Florida Medicaid: Generally Accepted Professional Medical Standards Determination on the Treatment of Gender Dysphoria report (GAPMS)^{xvii}. The AAP and FCAAP provided in-depth comments in opposition of both the GAPMS report and the proposed Medicaid rule to ban coverage of gender-affirming care. Our joint comments are included in our communication to the Florida Board of Medicine and we encourage you to review them. The GAPMS report, which serves as the evidentiary basis for the attempt to develop new standards of care, fails to satisfy even the basic tenets of scientific

inquiry and research.^{xviii} Experts from Yale University recently released a critical review of the GAPMS report and found:

- Contrary to the June 2 Report's repeated claims, medical care for gender dysphoria is supported by a robust scientific consensus, meets generally accepted professional medical standards, and is neither experimental nor investigational.
- The June 2 Report appears to be a scientific report, but its veneer hides a flawed analysis that ignores the scientific evidence and relies instead on pseudo-science, particularly purported "expert" reports that are biased, inexperienced, and full of errors. The claimed "expert" reports are written by authors whose testimony has been disqualified in court and who have known ties to anti-LGBTQ advocacy groups.
- Nothing in the June 2 Report calls into question the scientific foundations of standard medical care for gender dysphoria. The June 2 Report makes unfounded criticisms of robust and well-regarded clinical research and instead cites sources with little or no scientific merit, including journalism, a blog entry, letters to the editor, and opinion pieces.
- The linchpin of the June 2 Report is an analysis by two epidemiologists that claims to undermine the scientific evidence supporting medical care for gender dysphoria. Their analysis is extremely narrow in scope, inexperienced, and so flawed that it merits no scientific weight at all.
- The June 2 Report repeatedly and erroneously dismisses solid studies as "low quality." If Florida's Medicaid program applied the June 2 Report's approach to all medical procedures equally, it would have to deny coverage for widely-used medications like statins (cardioprotective cholesterol-lowering drugs taken by millions of older Americans) and common medical procedures like mammograms and routine surgeries.^{xix}

Adolescents with gender dysphoria face increased challenges in life compared to their cisgender peers. Bullying, discrimination, harassment, and a lack of social acceptance are issues adolescents with gender dysphoria deal with on a daily basis and all these issues lead to increased risks of suicide and other mental health conditions.^{xx} In a study of more than 1,000 transgender adolescents, transgender adolescents had higher odds of all suicide outcomes compared to cisgender adolescents, and were at greater risk for suicidal ideations and attempts compared to their cisgender peers.^{xxi} Additionally, in the first large scale (N = 120,670) study examining the relationship between transgender adolescents and suicide, the authors found that between 30-51% of transgender adolescents reported engaging in suicidal behavior, compared to between 10-18% of their cisgender peers.^{xxii}

By proposing an alternative standard of care, Florida is ignoring the broad consensus among the medical community and the weight of peer reviewed medical literature. We call on the Florida Board of Medicine to reject the call for the development of new standards of care and ensure that the existing evidence-based standards of care are allowed to be used to care for children and adolescents with gender dysphoria. Only by doing so will the health and well-being of children and adolescents with gender dysphoria in Florida be preserved.

Thank you for your consideration of our comments.

Sincerely,

A handwritten signature in cursive script that reads "Moira Szilaygi".

Thank you for your service on this board. I attended today's meeting but had work responsibilities that kept me from being able to stay until the afternoon to provide a comment in person.

In preparation for this meeting started to review the over 1800 pages of documentation on the Medical Board's website. Obviously some group was paid handsomely to expound on why this panel should decide on the medical decisions of people they have never met.

I am willing to bet that if this Board tried, you could find 1800 or 18000 or even 180000 people willing to write 1 page each FOR FREE about how access to these therapies in question have positively affected them or their children PERSONALLY.

In fact, I know some portion of that record exists, as I **implore you to read Transitions of the Heart by Rachel Pepper**. It is an objective account unlike those 1800 pages living in the website.

It's truly unfortunate with all the issues, like the disciplinary issues and accounts of deplorable behavior I witnessed sitting in your hearing today, that need real problem solving, that pushing a discriminatory agenda is where this Board and our energies need to be focused. It's pretty clear there is an agenda being pushed for a course of action that really should be left to a patient, their physician and, for minors, the patient's guardian. The transrights issue we are taking about isn't something which needs to be legislated, it needs to be left to those intimately involved in the patient's life and protected under HIPAA.

We can all recognize that a person is more than the sum of their parts and must be treated as more than an X or Y chromosome.

Please don't discriminate against our citizens, even the minors. The lens of the future rarely looks back on those who discriminate favorably.

Thank you for your attention and good luck to all of us.

Sincerely a concerned parent and citizen.

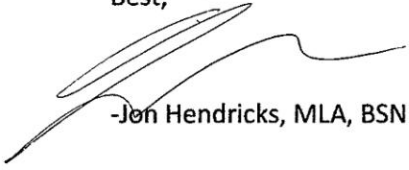

To the Florida board of medicine,

I understand that the surgeon general of the State of Florida has sent you a letter stating that under his view, gender-affirming care for treatment of gender dysphoria is something that the surgeon general of Florida wishes for the board of medicine to not endorse. I feel that this decision from the surgeon general is one of a politicized nature as the surgeon general has a track record of working with the state's governor in their quest to delegitimize vaccinations for COVID-19 and to instead promote illegitimate treatments for this disease.

The surgeon general vaguely states that there is not empirical evidence to suggest that treatment for gender affirming care is not of sound medical reasoning. Regardless, after performing a simple literature review, one can see that publications within the national institute of health database overwhelmingly suggest that gender affirming care is safe when prescribed in a clinical setting, and has the ability to improve the mental state of patients undergoing treatment for gender dysphoria. Moreover even though the surgeon general does not support the overwhelming literature and professional organizations that support gender affirming care (American association of pediatrics, world professional association for transgender health, the endocrine society, etc.), I would be hesitant to take medical advice from a person who sought to work with Governor Ron DeSantis to deed legitimize covid-19 vaccinations as well as to instead promote treatments for the disease that are not backed by credible empirical studies.

I implore the Florida board of medicine to not side with the politicized nature of the surgeon general's request, as I feel that this is simply an example of political posturing at the time when the governor is up for reelection. This is not a decision that is backed by evidence-based practice, empirical data, or even compassion for others. In effect, taking away gender affirming care from this population would be doing harm insofar as denying people access to treatment that has literally made their lives happier and in many instances prevented patients from completing suicide. As a nurse (recent BSN graduate), I will always fight for my transgender patients, as I would any of my other patients, to ensure that they have access to the care that they need to live a healthy and happy life.

Best,

-Jon Hendricks, MLA, BSN

Re: Florida State Medical Board Meeting About the Non-binding AHCA Report

After the state's move to ban coverage for all transgender medical treatments for Medicaid became inconclusive (no vote), they struck again. Now, they seek to directly attack doctors via the state medical board for providing gender-affirming care.¹ By doing so, they (again) put that care within the grasp "of ... [state] officials"—not "withdraw[n] ... from the vicissitudes of political controversy[.]" *West Virginia Bd. of Ed. v. Barnette*, 319 U. S. 624, 638 (1943). Like with the Medicaid policy proposal, they use the same report, which has been rebutted by experts. Scientific standing is not the only problem here. I wrote in July that the proposed Medicaid "policy ... 'raise[s] the inevitable inference that the disadvantage imposed is born of animosity toward the class of persons affected.'" Response to Gen. Medicaid Pol. Propos. (quoting *Romer v. Evans*, 517 U.S. 620, 634 (1996)). That quote still holds water; it is not frivolous nor redundant. Indeed, state actions tell you everything you need to know: they only restrict the minority. It is illogical and perverse—it makes no sense to fulminate against transgender treatments while they could be equally applied to non-transgender individuals. And while the state is playing with the law, they are playing with trans people's lives and their liberty. This mistake should not be repeated by the Florida Medical Board. Accordingly, the medical board should not make any new rules or adjustments vis-à-vis transgender healthcare.

Absent any hiatus, the state is moving quickly to push flagrantly undermining rules to restrict (in all ways possible) transgender healthcare. To be clear, this is not the only state action in this area. On April 20, 2022, the Department of Health announced its new (non-binding) guidance opposing everything from "[s]ocial gender transition" to "puberty blockers or hormone therapy[]" for adolescents. Fla. Dept. of H. 2022. *Treatment of Gender Dysphoria for Children & Adolescents*. *Contra* Human Rights Campaign Rebuttal 2022, 1 (the guidance "dangerously cherry-pick[s] select research to assert their claims" while simultaneously "ignor[ing] the vast majority of the literature" supporting such treatments). And in June, the state's Health Care Administrative Agency sent a 46-letter claiming that "gender affirming" treatments are not safe or effective in the

¹ The meeting is set for August 5, 2022. See Florida Board of Medicine. n.d. "Meeting Information." Florida - Board of Medicine. <https://flboardofmedicine.gov/meeting-information/>

absence of “available medical literature[.]” DeSantis, Ron, and Simone Marstiller. 2022. *Fla. Medicaid-Gen. Acpted. Pro. Med. Std. Determ. on the Treatment of Gender Dysphoria* (hereinafter “AHCA Report”); see Florida Administrative Register 2022, pg. 2462 (a proposed medicaid rule barring Medicaid coverage for all medical treatments corresponding to “Gender Dysphoria[.]”) (unpub. rule).² Although the meeting has already finished (July 8), there still has not been a final decision. In its most recent move—and not even a month later—it seeks to have a new meeting with the medical board, consistent with the request by the surgeon general. This is particularly chilling given the statutory authority the Florida Medical Board possesses, and now it’s not just Medicaid—it’s every trans person at risk. Today, the medical board is at the center of the stage in the middle of a scientific and constitutional calamity.

Under Florida law, the Florida Medical Board has substantial power, including “disciplinary action” against physicians. Fla. Stat. § 458.331. Below are a few reasons for disciplinary action, clearly applying to gender-affirming treatments in the state’s dogma of them being, *inter alia*, “experimental” and not safe. AHCA Report, 38.

(q) it shall be legally presumed that prescribing, dispensing, administering, mixing, or otherwise preparing legend drugs ... *inappropriately* or in excessive or inappropriate quantities *is not in the best interest of the patient* and is not in the course of the physician’s professional practice, without regard to his or her intent

(ee) prescribing, ordering, dispensing, administering, supplying, selling, or giving growth hormones, testosterone or its analogs ...

Id., at 458.331 (1) (q)(ee) (emphasis added).³

If a physician violates those statutes above, the punishment could be, for example, “[r]estriction of practice or license,” “[s]uspension or permanent revocation of a license[.]” or even “an

² <https://www.flrules.org/notice/Proposedinfo.asp?id=25979915>

³ Surgeries for transgender individuals (more modest in usage than hormones or hormone blockers) may be also found within chapter 458. See Fla. Stat. § 458.328 (1) (h) (“...The board shall impose a fine of \$5,000 per day on a physician who performs a procedure or surgery in an office *that is not registered with the department*”) (emphasis added). Since the state is seeking to outlaw all transgender treatments, *see supra* ¶2, it is unlikely that it would be registered with the department. Even if we could surpass all of these statutes, “[t]he board has authority to adopt rules pursuant to ss. 120.536(1) and 120.54 to implement the provisions of this chapter conferring duties upon it.” Fla. Stat. § 458.309 (1)

administrative fine[.]” Fla. Stat. § 456.072 (2) (b)(c)(d).⁴ The effect on the physicians is self-evident: many will be injured beyond just economic impairment. So too is the effect on transgender patients receiving (and needing) care. When treatment is diminished or stopped, the increase in the rates of suicide, suffering, and depression is not a mere question—it is a statement.⁵

The state’s actions today should not survive in the United States. When looking at the state’s actions relative to the AHCA Report, there’s no sheer concern about the “irreversible physical changes and side effects that can affect long-term health” related to treatments for gender dysphoria. 2. Nor could they: to this day, they have consistently failed to equally apply it to cisgender individuals, even when many treatments (as applied to cisgenders) are just as dangerous. *Compare* Fla. Dept. of Health guidance (opposing specifically gender-affirming care) *and* Florida Administrative Register 2022, 2462 (similar) *with* AHCA Report, 2–38 (similar). Indeed, “[i]f there is need to have [a] physician prescribe (and a pharmacist dispense) contraceptives, that need is as great for unmarried persons as for married persons.” *Eisenstadt v. Baird*, 405 U.S. 438, 450 (1972). Or, said another way, “[i]f there is a need to protect transgender youth from the purported risks of the banned treatments (there is not), then that need is as great for cisgender and/or intersex youth who receive the same medical treatments.” *Walker v. Marshall*, 2:22-cv-00167 (N.D. Ala. 2022), ECF 10, pg. 38 (hereinafter “*Walker*”). I will name a few examples. The state is fine with “chest surgery for [the] treatment of gynecomastia” as well as “chest-feminizing surgery” for non-transgenders. *Id.*, at 40. Similarly, gender dysphoria treatments, such as puberty blockers, “are also used to delay puberty in children with central precocious puberty[.]” *Id.*, at 39. The state says nothing about that. The same issue applies to hormone therapy: as for “nontransgender girls with primary ovarian insufficiency,” “hypogonadism,” and “Turner’s Syndrome,” for example, the state does not say anything about hormone treatment for those either. *Id.*, at 39–40. “[P]olycystic ovarian syndrome” may require testosterone blockers. *Id.*, at 40. Yet, the state bats no eye on blockers for that (nor any of the examples above)—even though apparently *all* medical treatments for gender dysphoria can cause “side effects that can affect long-term health[.]” AHCA Report, 2.

⁴ The medical board’s mission statement is far more candid: “The Florida Board of Medicine ... will license, monitor, discipline, educate, and when appropriate, rehabilitate physicians and other practitioners[.]” Florida Board of Medicine. n.d. Florida Board of Medicine - Healthcare Practitioner Licensing and Regulation. Accessed July 30, 2022. <https://flboardofmedicine.gov/>

⁵ See, e.g., Human Rights Campaign Rebuttal, *supra*, at 4–5 (listing six studies that demonstrate this); Olson, Kristina R. 2016. “Mental Health of Transgender Children Who Are Supported in Their Identities.” *Pediatrics* 137, no. 3 (March): 2015–3223 (stating that “[s]ocially transitioned transgender children who are supported in their gender identity have developmentally normative levels of depression and only minimal elevations in anxiety”—albeit better than not getting treatment or being “supported.”); *infra* ¶7 (*Amicus Curiae* brief)

There's no legitimate concern by the state about the quality of evidence either—and it would be almost impossible for the state to carry their burden of making an “exceedingly persuasive” justification. *United States v. Virginia*, 518 U.S. 515, 524 (1996). Beyond the purported concern about “side effects,” the report also claims there is “weak evidence supporting the use of puberty suppression, cross-sex hormones, and surgical procedures[.]” AHCA Report, 3. Thus, such treatments “are experimental and investigational.” *Id.* The public record demonstrates, however, that the state “tethers [transgender individuals] to sex stereotypes which, as a matter of medical necessity, they seek to reject.” *Kadel v. Folwell*, 446 F. Supp. 3d 1, 14 (M.D.N.C. 2020). As a threshold matter, “the State cannot carry its burden to justify the[ir] [state actions] based on purported concerns about the quality of the evidence concerning the treatment for two reasons: (1) the consensus within the mainstream medical community is that the treatment is effective, and (2) even if there were limitations in the data supporting efficacy of the care, that would not explain why only this medical care—when provided to transgender [individuals]—is singled out for a uniquely high standard of evidence.” *Walker*, 44. All mainstream medical organizations, such as “the American Medical Association, the American Academy of Pediatrics, and the Endocrine Society,” have deduced and affirmed that gender-affirming treatment “is safe and effective.” *Id.* Even experts from Yale are on the same train: “If Florida[] ... applied the June 2 Report’s [low-quality concern] approach to all medical procedures equally, it would have to deny coverage for widely-used medications like statins (cardioprotective cholesterol-lowering drugs taken by millions of older Americans) and common medical procedures like mammograms and routine surgeries.”⁶ McNamara, Meredith et al. 2022. *A Critical Review of the June 2022 Florida Medicaid Report on the Medical Treatment of Gender Dysphoria*, pg. 3 (hereinafter “AHCA Review Report”); see *id.*, at 16; see also *id.*, at 5 (gender-affirming care “has been vetted and approved by international bodies of experts based on the scientific evidence.”) The state has failed to do so and subjects transgender individuals to an unusual standard of evidence vis-à-vis their non-transgender counterparts. Therefore, there are no legitimate state interests.

⁶ To continue with the “low quality” concern, the state mentions it many times—even at the start. See, e.g., AHCA Report, 2 (“Studies presenting the benefits to mental health, including those claiming that the services prevent suicide, are either low or very low quality”). When readers surpass this deceptive language, however, they see that under the GRADE rating standards, even “low quality” studies “support a strong clinical treatment recommendation.” AHCA Review Report, 14; see Balshem, Howard, et al. 2011. “GRADE guidelines: 3. Rating the quality of evidence.” *J Clin. Epidemiol.* 64, no. 4 (Jan): 401-6. Randomized control trials would be considered “high quality” (AHCA Review Report, 13) while, conversely, observational proof, such as “studies [are] technically ranked as ‘low quality,’” *id.*, at 16 (citing Stone, Neil J. 2014. “2013 ACC/AHA Guideline on the Treatment of Blood Cholesterol to Reduce Atherosclerotic Cardiovascular Risk in Adults.” *Circulation* 129, no. 25 (June): S1-S45.) As stated above, medications, including statins and “common medical procedures like mammograms and routine surgeries,” rely on observational studies. AHCA Review Report, 3, 16 & n53. Thus, those studies are “low quality”—yet we don’t see the state sending a 46-page letter opposing any of those treatments, nor the other actions it has taken over the past couple of months. Either the state is hypocritical or it is discriminatory. It seems to be one or the other.

The state's dependence on faulty scientific findings does not rescue their claims. The state has sanctioned a reputedly "scientific report that so blatantly violates the basic tenets of scientific inquiry." *Id.*, at 2. It is "a document crafted to serve a political agenda." *Id.* In form and in effect, it endangers "adolescents with gender dysphoria access to medical interventions that alleviate suffering" by creating an unscientific report that spreads like a wildfire. Brief for the Am. Acad. Pediatr. as *Amicus Curiae*, p. 19, *Eknes-Tucker v. Ivey*, 2:22-cv-184-LCB-SRW (M.D. Ala. 2022). And when "research shows that adolescents with gender dysphoria who receive puberty blockers and/or hormone therapy experience less depression, anxiety, and suicidal ideation," the state merely ducks. *Id.*⁷ Hereunder, I will go over the major findings in the AHCA Review Report.

First, five attachments (by "experts") to the AHCA Report disregard medical guidelines for the treatment of gender dysphoria and instead "recommend against the use of such interventions to treat what is categorized as a mental health disorder[.]" 2. *Contra* Brief for the Am. Acad. Pediatr. as *Amicus Curiae*, 7–14 (20 major medical organizations listing the guidelines and affirming their effectiveness). However, the attachments could not be further afield. Not only do they go against the 20 major organizations listed above, but they also have underlying questions of bias and expertise. See AHCA Review Report, 6. Most notably, *none* are "peer-reviewed or published," a vital criterion by which scientific pieces may be publicly scrutinized. Nor do any of "the attachments provide a statement of funding and conflicts of interest." *Id.*, at 7. And *all* raise "flags" of bias. *Id.*, at 6. But first, turn to attachment E, which is by Quentin van Meter. He is the president of the American College of Pediatricians (ACP), a "political" organization "that opposes same-sex marriage, supports mental health providers practicing conversion therapy, and describes childhood gender dysphoria as 'confusion.'" *Id.*, at 7 (citations omitted); see *id.*, at n15, n16, n17. Meter has also been disqualified by a judge for being incapable of giving expert testimony about "the legal question of whether an adolescent transgender child should be administered puberty blockers and whether affirmation of an incongruent gender in a child is harmful or not[.]"⁸ Similarly, James Cantor (attachment D) in the report fares no better. There, "the Court gave

⁷ While "Cantor specifically notes that actual suicides are highly unlikely among gender dysphoric individuals, particularly trans-males[.]" the wall of medical experts (20 to be exact) seem to say otherwise. AHCA Report, 28. To be clear, "*more than one in three* transgender adolescents reported having attempted suicide in the preceding 12 months." Brief for the Am. Acad. Pediatr. as *Amicus Curiae*, 6 (emphasis added); see *id.*, at n15. And even if Cantor and the state are true, they miss the point: Suicide attempts are a risk factor for completing suicide. Bostwick, Michael. 2016. "Suicide Attempt as a Risk Factor for Completed Suicide: Even More Lethal Than We Knew." *Am J Psychiatry* 173, no. 11 (Nov): 1094–1100.

⁸ Caruso, Stephen. 2020. "A Texas judge ruled this doctor was not an expert. A Pennsylvania Republican invited him to testify on trans health care." *Pennsylvania Capital-Star*, September 15, 2020. <https://www.penncapital-star.com/government-politics/a-texas-judge-ruled-this-doctor-was-not-an-expert-a-pennsylvania-republican-invited-him-to-testify-on-trans-health-care/>

[Cantor's] testimony little weight because he admitted, *inter alia*, to having no clinical experience in treating gender dysphoria in minors and no experience monitoring patients receiving drug treatments for gender dysphoria.” *Id.*, at 8 (quoting Opinion and Order, *Eknes-Tucker v. Marshall*, 2:22-CV-184-LCB-SRW (M.D. Ala. 2022)). He could have been on the case because his “appearance in that case seems to have been funded by the Alliance Defending Freedom (‘ADF’), a religious and political organization that opposes legal protections for transgender people and same-sex marriage and defends the criminalization of sexual activity between partners of the same sex.” *Id.* (citations omitted); *see id.*, at n22, n23, n24. As for Attachment C (Romina Brignardello-Petersen & Wojtek Wiercioch), issues run the gamut, including inexperience. The first problem is quite simple—Brignardello-Petersen’s “only clinical experience appears to be in dentistry.” *Id.*, at 10.⁹ Apparently, we live in an alternate universe (“Florida”) where “dentistry” in lieu of endocrinology and mental health as applied to transgender care somehow passes as “expert.” Wiercioch, the other author, is a “postdoctoral fellow” who has “no prior research or clinical experience in” transgender care. *Id.* Indeed, the foregoing issues go against relevant guidelines; they require “expertise in the pertinent clinical content areas.”¹⁰ The study that the authors provide (Attachment C) is not peer-reviewed, nor are any of the studies in the attachments for that matter. As stated above, peer review is very important—it is not “merely window-dressing; they reflect bedrock commitments of the scientific method.” *Id.*, at 11. By failing to undertake basic peer-review, the authors (and most of the authors from the attachments) truncated ordinary procedures of scientific review. Furthermore, the authors include in their study a website called SEGM.org. *See id.* That citation crumbles upon examination; “the group’s website posts are not peer-reviewed or published, and its content is assembled by a small group of activists with few or no expert credentials[.]” *Id.* (quoting Boulware 2022).¹¹ Most notably, Brignardello-Petersen is connected to the group, having “conducted research” for them. *Id.*, at 8. The study provided by the authors suffers even more losses by further review. *See id.*, at 11–14 (evaluating the authors’ usage of certain rating systems and the absence of sufficient literature). Now, we turn to Patrick Lappert (Attachment F). Like Meter and Cantor, “evidence ... calls Lappert’s bias and reliability into serious question.” Memorandum Opinion and Order, *Kadel v. Folwell*, 1:19CV272 (M.D.N.C 2022), pg.

⁹ Brignardello-Petersen’s profile also states that she is a “Assistant Professor[of] Health Research Methods, Evidence, and Impact[.]” Brignardello, Romina. n.d. “Romina Brignardello Assistant Professor, Health Research Methods, Evidence, and Impact.” McMaster Experts. Accessed July 30, 2022. <https://experts.mcmaster.ca/display/brignarr>. But, as of July 30, 2022, her only contributions are in, *inter alia*, virology and epidemiology—both, again, inexpert for transgender care. *See id.*

¹⁰ Institute of Medicine, Board on Health Care Services, and Committee on Standards for Systematic Reviews of Comparative Effectiveness Research. 2011. *Finding What Works in Health Care: Standards for Systematic Reviews*. Edited by Alfred Berg, et al. N.p.: National Academies Press.

¹¹ Boulware, Susan D. 2022. “Biased Science: The Texas and Alabama Measures Criminalizing Medical Treatment for Transgender Children and Adolescents Rely on Inaccurate and Misleading Scientific Claims.”

27. The court order also observed that “Lappert has worked closely with ADF” and had been to conferences that “asked whether they would be willing to participate as expert witnesses.” *id.* (quoting ECF No. 209-2 at 90:13–91:13).¹² The issues listed above are not mere hypothetical concerns; they are serious barriers posed, such as conflicts of interest and biases. Worse, the authors as listed in the attachments never address or mention them—or list them as every “scientific” report is supposed to do. *See* AHCA Review Report, 7 & n13.

Second, the AHCA Report attempts to dismiss various studies. However, by doing so, they trip over their own feet in the process—another fatal mistake. Below is a non-exhaustive list of those failed attempts. To begin, turn to page 15 of the report. There, the Costa study “relies heavily on self-assessments” so apparently the results “are likely biased and invalid.” AHCA Report, 15. The report also claims that the “short-term period of the study” warrants condemnation. *Id.* These points lack merit for two reasons. First, the “self-assessments” are from a test called the Children’s Global Assessment Scale. It is well-documented, well-regarded, and accepted, and is relied upon for psychological research. AHCA Review Report, 17. The scale is thus “carefully constructed and psychometrically validated.” *Id.* Lastly, one cannot solely criticize a medical study—that is, in this study, about the efficacy of puberty blockers—without looking into the vast array of other studies because “[s]cientific knowledge is ... cumulative.” *Id.*, at 18. The AHCA Report blindly attacks “a single study and fails to acknowledge that the weight of the literature as a whole strongly supports the same results that Costa et al. report.” *Id.*, at 17–18 (emphasis deleted). Continuing on to the other studies, the AHCA Report on the Chen article deludes the reader by misrepresenting the article’s contents. *See* AHCA Report 15–16 (stating, by use of the article, that the “the effects of pubertal suppression warrant further study”).¹³ *But see* AHCA Review Report, 18 (The article “is not a substantive study of the effects of puberty blockers”). The article is “a consensus parameter[]”—a type of “structured methodology” that enables experts to create a “research agenda for future studies.” *Id.* Thus, those types of opportunities are simply to pick out ways to research subjects and techniques—not to be cited in such a narrow manner by the state. The review report says it perfectly: the article’s “statements are not indictments of puberty blockers—they are conventional acknowledgments of the value of further study that drives scientific inquiry and innovation.” *Id.* The AHCA Report separately cites a case in which they say “puberty suppression causes side effects, some of which have the potential to be permanent.” 16. Interestingly, the report says that these “indicate that Gn-RH is safe” and that the majority of the “side effects associated

¹² He has also stated that physicians “should be ‘criminally prosecute[d]’ for giving gender-affirming care. *Kadel*, at 27 (quoting ECF No. 209-2 at 52:4-18, 54:7–55:2, 57:8-15, 61:16–64:20).

¹³ (quoting Chen, Diane. 2020. “Consensus Parameter: Research Methodologies to Evaluate Neurodevelopmental Effects of Pubertal Suppression in Transgender Youth.” *Transgender Health* 5 (4): 246-257) (hereinafter “Chen et al”)

with Gn-RH are mild[.]” *Id.* One of the side effects the report digs into is “osteonecrosis.” *Id.* However, even it states that this side effect “is rare[.]” *Id.* From the state’s perspective, minor or moderate side effects (in its view, more solid than others) cause burdens—burdens that could be circumvented in toto if we strip away the right (and only the right) to gender-affirming care even though every medical organization opposes it. This is a strange way of looking at rights, and there is a good reason courts have not adopted this thinking. Further, it’s clear that gender-affirming care is not atypical for having specific side effects, so it makes no sense to only try to restrict and demean that care to a sole minority group. *See Walker*, 41–42 (rejecting the state’s concern of “risks” to justify banning gender-affirming care because there was nothing special tailored to those treatments).¹⁴

Third, the state again tries to negate the applicability of gender-affirming treatments to other treatments. Now, they try to assert that the “FDA did not approve [puberty blockers and hormone therapy] for treating gender dysphoria” and, as a result, it is classified as “off-label[.]” AHCA Report, 8. But the fact is, many drugs are used “off-label.” *See, e.g.*, AHCA Review Report, 20–21 (gabapentin is used off-label “for neuropathic or mixed pain”); (ketamine and fentanyl is used “off-label for pain relief”); (“[c]affeine is used off-label to treat apnea” including “phenobarbital is used off-label to treat neonatal seizures” in the NICU); (“pantoprazole is a proton pump inhibitor” and is also “used off-label in neonates with gastroesophageal reflux disease”); (“[o]ndansetron (Zofran) is used off-label for nausea and vomiting to prevent fluid loss”). As mentioned above, the state subjects transgender individuals to different standards of care in relation to their non-transgender counterparts. *See supra* ¶6.

Fourth, the AHCA Report claims that “the *majority* of young adolescents who exhibit signs of gender dysphoria eventually desist and conform to their natal sex[.]” 14 (emphasis added). Similar to Texas Attorney General Ken Paxton’s interpretations, the report uses the term “children” *Id.* “Actual scientific evidence on the course of gender dysphoria emphasizes the importance of distinguishing between prepubertal children and adolescents.”¹⁵ When the AHCA Report uses that

¹⁴ Also troubling, the letter cites studies that contradict its previous assertions, “in what looks like a circular firing squad.” *Equality Florida v. DeSantis*, 4:22-cv-0134-AW-MJ (N.D. Fla. 2022), ECF 81, pp. 13–14. *Compare* AHCA Report, 17 (“Prescribers ... de-emphasize that these drugs cause permanent physical changes and side effects that can lead to premature death”) with AHCA Report, 17 (the risk of long term effects are small, “most side effects associated ... are mild,” and “the authors indicate that Gn-RH is safe”) and Chen et al, 249 (“[s]uppressing puberty may reduce dysphoria and diminish risks for poor mental health in this population, thereby exerting *neuroprotective* effects.”) (emphasis added).

¹⁵ Boulware, Susan D. 2022. “Biased Science: The Texas and Alabama Measures Criminalizing Medical Treatment for Transgender Children and Adolescents Rely on Inaccurate and Misleading Scientific Claims,” p. 18 (hereinafter “Texas and Alabama Report”).

terminology, it gives a false sense “that most or all children *and* teens diagnosed with dysphoria will cease identifying with the gender not assigned at birth.” Texas and Alabama Report, 18. Of course, that is wrong. Rather, studies paint a different picture: “[A]dolescents who are diagnosed with gender dysphoria will persist in their gender identity[.]” *Id.*; *see id.*, n63, n64, n65. Although the resolving rate *is* higher in prepubescent children suffering from gender dysphoria, “standard medical protocols do not treat prepubertal children with drug therapy or ... surgery.” *Id.*, at 18; *see* Brief for the Am. Acad. Pediatr. as *Amicus Curiae*, 9. To defend its position, the state generally cites a study by Littman, but that goes awry.¹⁶ In the study, Littman “defines detransition as ‘discontinuing medications, having surgery to reverse the effects of transition, or both.’” AHCA Review Report, 22. This is obviously confusing because there are many reasons why people might want to stop medications. Applying her logic, her definition of a transgender individual could continue to be socially transitioned but be counted as a “detransition[er].” *Id.* Conversely, the state disregards important studies showing, *inter alia*, low regret and a detransition rate (findings were around $\leq 1\%$).¹⁷

Fifth (and lastly), the AHCA Report’s groundless statements about gender dysphoria being caused by “social and peer contagion.” 12. This so-called “peer contagion” in gender dysphoria may be caused by “rapid onset gender dysphoria[.]” *Id.* What is the pathology, or even the citations to back up this extraordinary claim? The former is not supported by any studies while the latter, is *her* study only. “Neither the American Psychiatric Association nor any other reputable professional organization” has actually validated ROGD. Texas and Alabama Report, 21. It could be because the study itself did not receive adequate feedback for it to be sufficient in the eyes of major organizations. The Texas and Alabama Report said

WPATH, among other authorities, has taken a skeptical view of Littman’s claim, and the study has been criticized for serious methodological errors, including the use of parent reports instead of clinical data and the recruitment of its sample of parents from anti-transgender websites. The journal of publication required an extensive correction of

¹⁶ Littman, Lisa. 2021. “Individuals Treated for Gender Dysphoria with Medical and/or Surgical Transition Who Subsequently Detransitioned: A Survey of 100 Detransitioners.” *Arch Sex Behav.* 50, no. 8 (Nov): 3353–69.

¹⁷ Bustos, Valeria et al P. 2021. “Regret after Gender-affirmation Surgery: A Systematic Review and Meta-analysis of Prevalence.” *Plast Reconstr Surg Glob Open.* 9, no. 3 (Mar); Danker, Sara et al. 2018. “Abstract: A Survey Study of Surgeons’ Experience with Regret and/or Reversal of Gender-Confirmation Surgeries.” *Plastic and Reconstructive Surgery* 6, no. 9S (Sept); Wiepjes, Chantal M., et al. 2018. “The Amsterdam Cohort of Gender Dysphoria Study (1972-2015): Trends in Prevalence, Treatment, and Regrets.” *J Sex Med.* 15, no. 4 (Apr): 582–90; *see also* Smith, Yolanda L. 2005. “Sex reassignment: outcomes and predictors of treatment for adolescent and adult transsexuals.” *Psychol Med.* 35, no. 1 (Jan): 89-99; Olson, Kristina R. 2022. “Gender Identity 5 Years After Social Transition.” *Pediatrics* 150, no. 2 (Aug).

the original Littman article because of its misstatements. Such a correction in reputable, peer reviewed academic journals is taken only when a panel of experts, in retrospect, came to recognize the methodological flaws of the original study and concluded that it would be unscientific to allow the originally published findings to stand.

Id., at 20–21.

Moreover, studies have rejected these notions of ROGD. When 173 youth arrived at Canadian gender clinics in 2022, they “found no evidence of rapid-onset dysphoria or social contagion” even when considering Littman’s hypothesis. AHCA Review Report, 24. And when another 173 youths were studied, they were also stumped with the same result: “no such correlations[]” materialized. *Id.*¹⁸ Data from the Williams Institute also supports those studies. The data simply “do[es] not show a massive wave of transgender identity even among teens.” *Id.* As of 2022, a study shows that 0.5% of adults and 1.4% of youth aged 13-17 identify as transgender (equivalent to 300,000 young individuals). *Id.*¹⁹ Collectively, the foregoing studies and resources join together to demonstrate the opposite of what the AHCA Report claims: there is no evidence of “rapid onset gender dysphoria” nor “social and peer contagion.” 12. Instead, it shows something else hidden under the cracked surface—stereotypes that transgender individuals “do not know[] their own gender identity and readily change their gender identity based on peer influence and social media.” AHCA Review Report, 24.

“[W]e are beyond the day when an [individual or] employer could evaluate [others] by assuming or insisting that they matched the stereotype associated with their group[.]” *Price Waterhouse v. Hopkins*, 490 U.S. 228, 251 (1989) (plurality op.). The state collapses under its own feet. “Nor is there an adequate remedy for preventable ‘life-long diminished well-being and life-functioning.’” *Whitaker v. Kenosha Unified Sch. Dist. No. 1 Bd. of Educ.*, 858 F.3d 1034, 1042 (7th Cir. 2017). When the state could eliminate discrimination, it chooses not to. The detrimental and irreparable effect is on the minority whom they have a compelling interest in protecting. *See Bd. of Dirs. of Rotary Int. v. Rotary Club of Duarte*, 481 U.S. 537, 549 (1987) (declaring the “State’s compelling interest in eliminating discrimination”); *Heart of Atlanta Motel, Inc. v. United States*, 379 U.S. 241, 252–53 (1964) (observing the systemic effects of discrimination); *id.*, at 274 (similar) (Black, J. concurring).

August 1, 2022
3641 NW 23rd Place
Gainesville, FL 32605

Dear Members of the Board,

In light of your recent guidance on the treatment of gender dysphoria for children and adolescents, as well as your Petition to Initiate Rulemaking on the same issue, I would strongly encourage you to at the very least issue guidance regarding another topic: infant male circumcision (circumcision).

I strongly believe circumcision is wrong and should not be permitted under Florida law. However, I only have a limited understanding of medicine, so I would highly encourage you to read this material about why it is wrong from a medical perspective, written by a highly qualified group of doctors: <https://www.doctorsopposingcircumcision.org/for-professionals/>. The medical case against it is comprehensive and overwhelming.

No medical association in the world recommends circumcision. Even the disreputable American Academy of Pediatrics cannot bring itself to issue a current statement on circumcision. The last statement it issued, in 2012, only states that families should be able to choose this for their children if they wish. No other medical association in the world takes a stance that is even remotely this pro-circumcision.

The scientific evidence supporting circumcision for alleged health benefits is incredibly weak. However, even if it were true, it would still not justify it. Circumcision is amputation of tissue and therefore must only be considered when conservative treatment for a diagnosed physical disease has failed. The vast majority of children do not have any diseases or conditions that would indicate the need for any treatment, much less circumcision. In addition, since the vast majority of circumcisions take place on minors who cannot give any consent, additional care must be taken. Proxy consent by parents is not sufficient.

The negatives of circumcision are numerous and obvious, but often denied. However, what is undeniable is that healthy tissue is removed. This by itself is enough reason for the procedure to be unethical. In no other circumstance is this considered acceptable in the state of Florida, and rightfully so. This is the main reason certain "gender affirming" procedures, such as castration and mastectomy, are unethical. The removal of healthy tissue, especially the genitals, especially from a child, should not be done. Either we live in a society which condones genital mutilation, or we do not.

Florida Statute 794.08 clearly and concisely bans female genital mutilation. This same protection should be provided to male children in Florida. It would be controversial, but the Department of Health has the authority to effectively ban circumcision. In addition to the Department's role in promoting the health of all Floridians, F.S. 458.331(1)(v) gives it the authority to establish standards of care. Requiring that informed consent be given by the patient on whom the circumcision is performed would eliminate almost all of the ethical problems with the procedure, and in my opinion be sufficient.

Your actions regarding circumcision would not follow the consensus in the United States medical community, but they would follow the consensus of the rest of the world. More importantly, it would be the moral and ethical stance to take. I applaud your recent actions opposing "gender affirming" care. You have been vilified, slandered, and threatened for these actions. Public opinion does not yet have quite the same negative view of circumcision as it does "gender affirming" surgeries, but that is rapidly changing. However, you should not base your decision upon public opinion in your decision making. Do what is right, not necessarily what is popular. Prove once more to the nation and the world that Florida is consistently dedicated to protecting the health and freedom of its citizens.

Sincerely,

A handwritten signature in cursive script that reads "Caleb Richard Duggan". The signature is written in dark ink and is positioned below the word "Sincerely,".

Caleb Richard Duggan

P.S. If you would like to watch a video lecture which gives a good overview of circumcision, I recommend this video: <https://youtu.be/XwZiQyFaAs0?t=264>.

MEDICINE BOARD
2022 AUG 18 AM 9:46

August 11, 2022

Dear Distinguished Members of the Board of Medicine,

I am writing this one letter to send to those of you who voted in favor of advancing the petition from the Florida Surgeon General for workshops and expert testimony on deciding the matter of care for transgender children and youth.

As a mom of a non-binary child, now a young adult, I am concerned there will be either a reduction of the current standard of care or a decision to disallow medical care such as hormone blockers for those transgender humans who are not yet considered an adult at 18. Gender affirming care is health care. Medical experts agree gender affirming care is medically necessary and can be life-saving. Gender affirming care helps youth who might otherwise kill themselves; that is a fact.

Why is there a need to create a separate standard of care for Florida when there is already a nationwide standard of care based upon the guidelines of several professional medical societies after years of research and vigorous scientific debate while taking care of patients to ensure harm is not done? Yet this care, **only this care**, is doubted and questioned by the current governor and surgeon general of this state.

Regarding the governor, we all know this attack is political and appealing to a base of voters with his eye toward a 2024 presidential run. The current surgeon general has shown himself to be on the fringe of the established medical associations on several health topics starting with the COVID-19 virus. The Florida Fact Checked information is not based on reality but bias and information taken out of context. (As a teacher, I am always explaining to my students about quoting without changing the meaning of the speaker.) What **is** blatantly false is stating "most children identifying as transgender will **detransition** following the onset of puberty." Current gender affirming care does not consist of "experimental and investigational medical treatments."

The speakers opposed to moving forward with changing or removing the current standard of care are living this and have lived it. The care they received was life-saving as many stated. One eloquent speaker toward the end of the discussion questioned why this matter is even before the members of the board when other types of standard medical practices are not questioned. It is just *this* about transgender care under the ruse of concern when it appears more along the line of transphobia. Doctors and patients are the ones who should do what is best. Supportive, loving parents are listening to their children and taking them for appropriate medical care and therapy. This is not abuse.

According to the Public Member List, there are two pediatricians on the board. I am surprised doctors treating children have not been guided by the existing standard of care for even one patient. Perhaps it is living in Milton and Tallahassee.

The speakers stating negative opinions and falsehoods were mostly those wearing Let Kids Be Kids stickers. They know nothing and are guided by ultra-conservative Christian religions, alarming non-news media, and conspiracy theories. Several people were spoken to for less than five minutes by someone wearing a sticker before they put on the sticker. It is doubtful they even

truly know one transgender person. One of those wearing a sticker went to a security person and asked him to move the person sitting near her! As at least one speaker opposed articulated, how can transgender kids "be kids" if they are forced to hide and deny who they are at the core based on their brains?

Trans (and non-binary) humans have always been here. They hid for decades, centuries even, desperate to live authentically and be seen.

I strongly recommend watching the following episode of *Through the Wormhole* on Discover+: *Are There More Than Two Sexes?* It is episode 3 of season 7.

This is directed at Dr. Diamond based on his comments, of which I took notes, just prior to the board members voting. I hope you were honest when you said this was *not about taking away* care. I hope it is to "ensure all" transgender youth in Florida get the "best care" and "care is given appropriately." That should not include removing life-saving hormone blockers for those kids prior to puberty. It should not remove hormone therapy for those past puberty. Social affirmation should not be stopped.

I beg you to listen to the experts such as Dr. Michael Haller, especially regarding debunking the idea that an increasing number of children are seeking puberty blockers or other medical interventions. Be mindful, these treatments are not handed out immediately like candy. Transgender children and youth go through therapy and are seen by physicians for many years. It is a journey taken by the transgender child and youth, usually with their parent(s) or guardian(s). Please obtain and carefully review all available data provided by medical experts involved with transgender care. Double-check sources to ensure the words are not taken out of context.

Regards,

A handwritten signature in black ink that reads "Wendy Peale". The script is fluid and cursive, with the first letters of "Wendy" and "Peale" being capitalized and prominent.

Dear Florida Board of Medicine-

While I know that you met yesterday and likely have made your minds up, I wanted to write to you in opposition to any proposed policy to limit or prohibit access to potentially lifesaving medical care for transgender youth. Here are some points you may wish to consider in your decision:

- Prohibiting gender-affirming care for children suffering from gender dysphoria runs counter to guidance from every major medical society, including the Florida Chapter of the American Academy of Pediatrics, the American Academy of Pediatrics, the American Medical Association, the American Psychiatric Association, and many more.
- Children who receive evidence-based gender-affirming care and support experience sharply reduced incidence of mental health comorbidities including anxiety, depression, and suicidal ideation.
- The current standard of care and clinical guidelines for gender-affirming care—developed by the World Professional Association for Transgender Health (WPATH) and the Endocrine Society—are evidence-based, well researched, and widely accepted as the gold standard for the care of children and adolescents with gender dysphoria.
- Overriding the established standard of care for transgender youth cuts off necessary treatment for transgender children and puts the physical and mental health of vulnerable children at risk.
- The Florida Department of Health study the state is using in its decision-making process fails to conform to established research methodologies and norms.

I hope that you make your decision with the patient's best interests in mind and that you do not succumb to political pressure. Thank you for your time and consideration.

Sincerely yours,

Mitchell E. Stern, MD

Subject: One-minute pediatric advocacy

Caroline Clark,DO

Please feel free to steal my email below and forward to bom.meetingmaterials@flhealth.gov. I attached the letter sent in this email as well. If you feel led to, please take 1 minute and forward this email and let's advocate to keep the state from deciding how we can care for our children in Florida.

Please find attached a letter I wholeheartedly agree with regarding the preservation of the rights of children to access gender-affirming care in our state. Below are some of the highlights:

- Prohibiting gender-affirming care for children suffering from gender dysphoria runs counter to guidance from every major medical society, including the Florida Chapter of the American Academy of Pediatrics, the American Academy of Pediatrics, the American Medical Association, the American Psychiatric Association, and many more.
- Children who receive evidence-based gender-affirming care and support experience sharply reduced incidence of mental health comorbidities including anxiety, depression, and suicidal ideation.
- The current standard of care and clinical guidelines for gender-affirming care—developed by the World Professional Association for Transgender Health (WPATH) and the Endocrine Society—are evidence-based, well researched, and widely accepted as the gold standard for the care of children and adolescents with gender dysphoria.
- Overriding the established standard of care for transgender youth cuts off necessary treatment for transgender children and puts the physical and mental health of vulnerable children at risk.
- The Florida Department of Health study the state is using in its decision-making process fails to conform to established research methodologies and norms, as outlined in [this analysis](#) by the Yale School of Medicine.
- Physicians in all areas of practice should reject government's attempts to insert itself into the doctor-patient relationship and to enact one-size-fits-all rulemaking to the practice of medicine.

I ask that you continue to allow physicians to be able to provide gender-affirming care to the children of our state for their physical, mental, and emotional well-being.

Subject: Act now to preserve health care rights for transgender children

FLORIDA BOARD OF MEDICINE TO CONSIDER PROHIBITING GENDER-AFFIRMING CARE FOR YOUTH

Act now to preserve health care rights for transgender children ...

Dear Rebecca M Plant,

Florida's children need pediatricians to act now ensure access to health care services free of government interference. The Florida Board of Medicine (FBOM) is scheduled to meet on **Friday, August 5**, and will consider establishing an alternative standard of care that conflicts with medical consensus for children seeking gender-affirming treatment.

This is the latest step in a series of efforts to block transgender youth from receiving appropriate, evidence-based medical care that started with the Florida Department of Health's April 20, 2022 [guidance](#) recommending against gender-affirming treatment of any kind for children and adolescents—including non-medical social transition. See FCAAP's statement [here](#).

On July 8, the Agency for Health Care Administration (AHCA) held a public hearing to consider a new rule prohibiting coverage of gender-affirming care under the Medicaid program (see the FCAAP/AAP joint [letter to AHCA](#)). During this hearing, the state heard testimony from "experts" from the American College of Pediatricians, a fringe organization classified by the Southern Poverty Law Center as an anti-LGBTQ [hate group](#).

This week, the FBOM will discuss enacting an alternative standard of care that could **limit or completely prohibit gender-affirming care for transgender youth in Florida**. See the FCAAP/AAP [joint letter](#) to FBOM Chairman David Diamond, MD.

How You Can Help

We are asking you to write to the FBOM in opposition to any proposed policy to limit or prohibit access to potentially lifesaving medical care for transgender youth. Here are some points you may wish to consider in your letter:

- Prohibiting gender-affirming care for children suffering from gender dysphoria runs counter to guidance from every major medical society, including the Florida Chapter of the American Academy of Pediatrics, the American Academy of Pediatrics, the American Medical Association, the American Psychiatric Association, and many more.
- Children who receive evidence-based gender-affirming care and support experience sharply reduced incidence of mental health comorbidities including anxiety, depression, and suicidal ideation.
- The current standard of care and clinical guidelines for gender-affirming care—developed by the World Professional Association for Transgender Health (WPATH) and the Endocrine Society—are evidence-based, well researched, and widely accepted as the gold standard for the care of children and adolescents with gender dysphoria.
- Overriding the established standard of care for transgender youth cuts off necessary treatment for transgender children and puts the physical and mental health of vulnerable children at risk.
- The Florida Department of Health study the state is using in its decision-making process fails to conform to established research methodologies and norms, as outlined in [this analysis](#) by the Yale School of Medicine.
- Physicians in all areas of practice should reject government's attempts to insert itself into the doctor-patient relationship and to enact one-size-fits-all rulemaking to the practice of medicine.

Please send your completed letters to born.meetingmaterials@flhealth.gov.

Thank you for your assistance as we continue to fight for equity in health care and equal rights for all children.

Dear Dr Diamond,

The American Academy of Pediatrics (AAP), a nonprofit organization representing 67,000 pediatricians dedicated to the health, safety and well-being of all children and the Florida Chapter of American Academy of Pediatrics, Inc (FCAAP), a nonprofit organization representing more than 2,600 pediatricians committed to serving all children across the state, writes to express our concern regarding the request from the Florida Surgeon General for the Florida Board of Medicine to develop new standards of care for the treatment of gender dysphoria.

Gender-affirming care is the widely accepted standard of care for treating transgender adolescents with gender dysphoria. Gender-affirming care is endorsed and recommended by the American Academy of Pediatrics;ⁱ the Florida Chapter of the American Academy of Pediatrics, Inc;ⁱⁱ the American Medical Association;ⁱⁱⁱ the American College of Obstetricians and Gynecologists;^{iv} the American College of Physicians;^v the American Psychiatric Association;^{vi} the American Psychological Association;^{vii} the American Academy of Family Physicians;^{viii} the American Academy of Child and Adolescent Psychiatry;^{ix} the Endocrine Society;^x the Society for Adolescent Health and Medicine;^{xi} the Pediatric Endocrine Society;^{xii} the World Professional Association for Transgender Health (WPATH);^{xiii} and many more medical organizations committed to providing the best evidence-based care.^{xiv}

WPATH and the Endocrine Society have developed well-researched and evidence-based standards of care and clinical guidelines for the care of children and adolescents with gender dysphoria. WPATH's Standards of Care for the Health of Transsexual, Transgender, and Gender-Nonconforming People, Version 7^{xv} and the Endocrine Society's Endocrine Treatment of Gender-Dysphoric/Gender-Incongruent Persons: An Endocrine Society Clinical Practice Guideline^{xvi} (both are herein referenced as "standards of care") are well recognized and accepted among the medical community as the gold standard for treating gender dysphoria.

Included in the Board's meeting agenda to discuss the development of new standards of care for the treatment of gender dysphoria is the June 2, 2022 Florida Medicaid: Generally Accepted Professional Medical Standards Determination on the Treatment of Gender Dysphoria report (GAPMS)^{xvii}. The AAP and FCAAP provided in-depth comments in opposition of both the GAPMS report and the proposed Medicaid rule to ban coverage of gender-affirming care. Our joint comments are included in our communication to the Florida Board of Medicine and we encourage you to review them. The GAPMS report, which serves as the evidentiary basis for the attempt to develop new standards of care, fails to satisfy even the basic tenets of scientific

inquiry and research.^{xviii} Experts from Yale University recently released a critical review of the GAPMS report and found:

- Contrary to the June 2 Report's repeated claims, medical care for gender dysphoria is supported by a robust scientific consensus, meets generally accepted professional medical standards, and is neither experimental nor investigational.
- The June 2 Report appears to be a scientific report, but its veneer hides a flawed analysis that ignores the scientific evidence and relies instead on pseudo-science, particularly purported "expert" reports that are biased, inexperienced, and full of errors. The claimed "expert" reports are written by authors whose testimony has been disqualified in court and who have known ties to anti-LGBTQ advocacy groups.
- Nothing in the June 2 Report calls into question the scientific foundations of standard medical care for gender dysphoria. The June 2 Report makes unfounded criticisms of robust and well-regarded clinical research and instead cites sources with little or no scientific merit, including journalism, a blog entry, letters to the editor, and opinion pieces.
- The linchpin of the June 2 Report is an analysis by two epidemiologists that claims to undermine the scientific evidence supporting medical care for gender dysphoria. Their analysis is extremely narrow in scope, inexperienced, and so flawed that it merits no scientific weight at all.
- The June 2 Report repeatedly and erroneously dismisses solid studies as "low quality." If Florida's Medicaid program applied the June 2 Report's approach to all medical procedures equally, it would have to deny coverage for widely-used medications like statins (cardioprotective cholesterol-lowering drugs taken by millions of older Americans) and common medical procedures like mammograms and routine surgeries.^{xix}

Adolescents with gender dysphoria face increased challenges in life compared to their cisgender peers. Bullying, discrimination, harassment, and a lack of social acceptance are issues adolescents with gender dysphoria deal with on a daily basis and all these issues lead to increased risks of suicide and other mental health conditions.^{xx} In a study of more than 1,000 transgender adolescents, transgender adolescents had higher odds of all suicide outcomes compared to cisgender adolescents, and were at greater risk for suicidal ideations and attempts compared to their cisgender peers.^{xxi} Additionally, in the first large scale (N = 120,670) study examining the relationship between transgender adolescents and suicide, the authors found that between 30-51% of transgender adolescents reported engaging in suicidal behavior, compared to between 10-18% of their cisgender peers.^{xxii}

By proposing an alternative standard of care, Florida is ignoring the broad consensus among the medical community and the weight of peer reviewed medical literature. We call on the Florida Board of Medicine to reject the call for the development of new standards of care and ensure that the existing evidence-based standards of care are allowed to be used to care for children and adolescents with gender dysphoria. Only by doing so will the health and well-being of children and adolescents with gender dysphoria in Florida be preserved.

Thank you for your consideration of our comments.

Sincerely,

A handwritten signature in cursive script that reads "Moira Szilaygi".

Hello,

I am a detransitioner, this is a video essay I made reflecting on the double mastectomy I had to treat my gender dysphoria, which was really just undiagnosed CPTSD. I wish the board of medicine to know the experience I, and many other young women have had with gender-affirming surgeries, which I illustrate some of the effects and nuances of here. I have been invited to speak at the upcoming public meeting in Florida, but due to the nature of hostility in such meetings, it would not be wise for my health to attend in person.

I hope you will watch this video and understand better the realities of these surgeries and the population receiving them.

https://www.youtube.com/watch?v=wdRQGrBogVU&list=LLykvjF1bAGJjgJMr_Xx9aaA

Thank you,
Laura

Dear Florida Board of Medicine,

I am writing to you today to demand that you reject the proposed guidance by Surgeon General Ladapo's Department of Health on Gender Dysphoria in Children and Adolescents.

The issued guidance by the Dept of Health and the studies used by this board are notably inaccurate and dangerous. As physicians – it is your responsibility to do no harm. As a government official, it is your responsibility to provide truthful information to create a more informed population. There are numerous peer reviewed articles that easily debunk politically and religiously motivated academic publications found in the Board's report on gender-affirming care. Unfortunately, this guidance and the cherry-picked studies by this board are nothing more than anti-transgender propaganda.

The nation's leading health organizations support gender-affirming care for transgender and gender non-conforming people -- including the American Academy of Pediatrics; the American Medical Association; The American College of Obstetricians and Gynecologists; The American College of Physicians; The American Psychiatric Association; The American Psychological Association; The American Academy of Family Physicians; The Endocrine Society; The Pediatric Endocrine Society; American Nurses Association; American Public Health Association; American Heart Association; National Association of Social Workers; World Medical Association; and The World Professional Association for Transgender Health, among others.

There is, in fact, overwhelming evidence to support the positive mental health impacts of gender-affirming medical care for trans youth - including in some of the very studies cited by the DOH and Board of Medicine. Prohibiting social transition is clear government intrusion on personal and parental decision making. Numerous studies have found that after social transition, transgender youth report similar mental health levels to the general youth population, eliminating mental health disparities typically seen. When transgender youth are affirmed by people around them, reported rates of depression and suicidality drop significantly. This rule will deny them this life-saving treatment.

I call on this Board to provide truthful information based on science and data as opposed to false statements based on prejudice and political agendas. The truth still matters and the evidence is clear: denying transgender youth the ability to transition is dangerous, abusive, and life-threatening.

Please reject this proposal and keep Florida safe for all.

Sincerely,
LaTrall Simon

Dear Florida Board of Medicine,

As a psychiatrist practicing in Miami for 40 years, I am writing to you today to demand that you reject the proposed guidance by Surgeon General Ladapo's Department of Health on Gender Dysphoria in Children and Adolescents.

(Ladapo has NO credentials in the field of transgender medicine. His California medical license is listed as delinquent, for failure to pay the renewal fee when it expired at the end of 2021, and the American Board of Internal Medicine site shows him as certified but NOT participating in the required maintenance of certification. He belongs to the fringe group "America's Frontline Doctors," which still endorses the debunked use of hydroxychloroquine for treating COVID-19.)

The issued guidance by the Dept of Health and the studies used by this board are notably inaccurate and dangerous. As physicians – it is your responsibility to do no harm. As a government official, it is your responsibility to provide truthful information to create a more informed population. There are numerous peer reviewed articles that easily debunk politically and religiously motivated academic publications found in the Board's report on gender-affirming care. Unfortunately, this guidance and the cherry-picked studies by this board are nothing more than anti-transgender propaganda.

The nation's leading health organizations support gender-affirming care for transgender and gender non-conforming people -- including the American Academy of Pediatrics; the American Medical Association; The American College of Obstetricians and Gynecologists; The American College of Physicians; The American Psychiatric Association; The American Psychological Association; The American Academy of Family Physicians; The Endocrine Society; The Pediatric Endocrine Society; American Nurses Association; American Public Health Association; American Heart Association; National Association of Social Workers; World Medical Association; and The World Professional Association for Transgender Health, among others.

Practice standards for treating any medical condition are determined by mainstream medical specialty societies whose members deal with those conditions and do not vary from state to state. They are NOT determined by maverick physicians pushing a political agenda.

There is, in fact, overwhelming evidence to support the positive mental health impacts of gender-affirming medical care for trans youth - including in some of the very studies cited by the DOH and Board of Medicine. Prohibiting social transition is clear government intrusion on personal and parental decision making. Numerous studies have found that after social transition, transgender youth report similar mental health levels to the general youth population, eliminating mental health disparities typically seen. When transgender youth are affirmed by people around them, reported rates of depression and suicidality drop significantly. This rule will deny them this life-saving treatment.

I call on this Board to provide truthful information based on science and data as opposed to false statements based on prejudice and political agendas. The truth still matters and the evidence is clear: denying transgender youth the ability to transition is dangerous, abusive, and life-threatening.

Please reject this proposal and keep Florida safe for all.

Sincerely,
David Tobolowsky

Dear Florida Board of Medicine,

I am writing to you today to demand that you reject the proposed guidance by Surgeon General Ladapo's Department of Health on Gender Dysphoria in Children and Adolescents.

The issued guidance by the Dept of Health and the studies used by this board are notably inaccurate and dangerous. As physicians – it is your responsibility to do no harm. As a government official, it is your responsibility to provide truthful information to create a more informed population. There are numerous peer reviewed articles that easily debunk politically and religiously motivated academic publications found in the Board's report on gender-affirming care. Unfortunately, this guidance and the cherry-picked studies by this board are nothing more than anti-transgender propaganda.

The nation's leading health organizations support gender-affirming care for transgender and gender non-conforming people --- including the American Academy of Pediatrics; the American Medical Association; The American College of Obstetricians and Gynecologists; The American College of Physicians; The American Psychiatric Association; The American Psychological Association; The American Academy of Family Physicians; The Endocrine Society; The Pediatric Endocrine Society; American Nurses Association; American Public Health Association; American Heart Association; National Association of Social Workers; World Medical Association; and The World Professional Association for Transgender Health, among others.

There is, in fact, overwhelming evidence to support the positive mental health impacts of gender-affirming medical care for trans youth - including in some of the very studies cited by the DOH and Board of Medicine. Prohibiting social transition is clear government intrusion on personal and parental decision making. Numerous studies have found that after social transition, transgender youth report similar mental health levels to the general youth population, eliminating mental health disparities typically seen. When transgender youth are affirmed by people around them, reported rates of depression and suicidality drop significantly. This rule will deny them this life-saving treatment.

Prohibiting social transition is clear government intrusion on personal and parental decision making. Numerous studies have found that after social transition, transgender youth report similar mental health levels to the general youth population, eliminating mental health disparities typically seen. When transgender youth are affirmed by people around them, reported rates of depression and suicidality drop significantly. This rule will deny them this life-saving treatment.

I call on this Board to provide truthful information based on science and data as opposed to false statements based on prejudice and political agendas. The truth still matters and the evidence is clear: denying transgender youth the ability to transition is dangerous, abusive, and life-threatening.

Please reject this proposal and keep Florida safe for all.

Sincerely,
Ted Battaglia

Dear Florida Board of Medicine,

I am writing to you today to demand that you reject the proposed guidance by Surgeon General Ladapo's Department of Health on Gender Dysphoria in Children and Adolescents.

The issued guidance by the Dept of Health and the studies used by this board are notably inaccurate and dangerous. As physicians – it is your responsibility to do no harm. As a government official, it is your responsibility to provide truthful information to create a more informed population. There are numerous peer reviewed articles that easily debunk politically and religiously motivated academic publications found in the Board's report on gender-affirming care. Unfortunately, this guidance and the cherry-picked studies by this board are nothing more than anti-transgender propaganda.

The nation's leading health organizations support gender-affirming care for transgender and gender non-conforming people -- including the American Academy of Pediatrics; the American Medical Association; The American College of Obstetricians and Gynecologists; The American College of Physicians; The American Psychiatric Association; The American Psychological Association; The American Academy of Family Physicians; The Endocrine Society; The Pediatric Endocrine Society; American Nurses Association; American Public Health Association; American Heart Association; National Association of Social Workers; World Medical Association; and The World Professional Association for Transgender Health, among others.

There is, in fact, overwhelming evidence to support the positive mental health impacts of gender-affirming medical care for trans youth - including in some of the very studies cited by the DOH and Board of Medicine. Prohibiting social transition is clear government intrusion on personal and parental decision making. Numerous studies have found that after social transition, transgender youth report similar mental health levels to the general youth population, eliminating mental health disparities typically seen. When transgender youth are affirmed by people around them, reported rates of depression and suicidality drop significantly. This rule will deny them this life-saving treatment.

Dear Florida Board of Medicine,

I am writing to you today to request that you reject the proposed guidance by Surgeon General Ladapo's Department of Health on Gender Dysphoria in Children and Adolescents. I am not trans, and I do not have family who is, but I have read much of the scientific research, and there are, without a single doubt people receiving this treatment who benefit from it. As long as that is the case, please let doctors and patients determine the best course of treatment.

Statements from the medical experts who conducted the studies cited in the Department's memo have established clearly and on the record that this rule is inconsistent with their research findings. This rule jumps beyond well-established peer-reviewed medical guidance and will have the impact of foreclosing life-saving options for Floridians.

Please use medical and scientific evidence, not because it is always right, but because it is the safest and best way we know how to move forward and save Floridian lives.

Please reject this proposal and keep Florida safe for all.

Sincerely,
Martin Powell

Dear Florida Board of Medicine,

I am writing to you today to demand that you reject the proposed guidance by Surgeon General Ladapo's Department of Health on Gender Dysphoria in Children and Adolescents.

The issued guidance by the Dept of Health and the studies used by this board are notably inaccurate and dangerous. As physicians – it is your responsibility to do no harm. As a government official, it is your responsibility to provide truthful information to create a more informed population. There are numerous peer reviewed articles that easily debunk politically and religiously motivated academic publications found in the Board's report on gender-affirming care. Unfortunately, this guidance and the cherry-picked studies by this board are nothing more than anti-transgender propaganda.

The nation's leading health organizations support gender-affirming care for transgender and gender non-conforming people -- including the American Academy of Pediatrics; the American Medical Association; The American College of Obstetricians and Gynecologists; The American College of Physicians; The American Psychiatric Association; The American Psychological Association; The American Academy of Family Physicians; The Endocrine Society; The Pediatric Endocrine Society; American Nurses Association; American Public Health Association; American Heart Association; National Association of Social Workers; World Medical Association; and The World Professional Association for Transgender Health, among others.

There is, in fact, overwhelming evidence to support the positive mental health impacts of gender-affirming medical care for trans youth - including in some of the very studies cited by the DOH and Board of Medicine. Prohibiting social transition is clear government intrusion on personal and parental decision making. Numerous studies have found that after social transition, transgender youth report similar mental health levels to the general youth population, eliminating mental health disparities typically seen. When transgender youth are affirmed by people around them, reported rates of depression and suicidality drop significantly. This rule will deny them this life-saving treatment.

I call on this Board to provide truthful information based on science and data as opposed to false statements based on prejudice and political agendas. The truth still matters and the evidence is clear: denying transgender youth the ability to transition is dangerous, abusive, and life-threatening.

Please reject this proposal and keep Florida safe for all.

Sincerely,
Hayley Dietrich

Dear Florida Board of Medicine

I am writing to you today to demand that you reject the proposed guidance by Surgeon General Ladapo's Department of Health on Gender Dysphoria in Children and Adolescents.

Care providers, doctors, and leading medical associations have been clear that gender-affirming care is safe, effective, and evidence-based, and that it's literally lifesaving.

The issued guidance by the Dept. of Health and the studies used by this board are inaccurate and dangerous. This guidance is nothing more than another tool for the Governor to express his opposition to transgender individuals' existence.

The nation's leading health organizations support gender-affirming care for transgender and gender non-conforming people, including the American Academy of Pediatrics; the American Medical Association; The American College of Obstetricians and Gynecologists; The American College of Physicians; The American Psychiatric Association; The American Psychological Association; The American Academy of Family Physicians; The Endocrine Society; The Pediatric Endocrine Society; American Nurses Association; American Public Health Association; American Heart Association; National Association of Social Workers; World Medical Association; and The World Professional Association for Transgender Health, among others.

Dear Florida Board of Medicine

I am writing to you today to demand that you reject the proposed guidance by Surgeon General Ladapo's Department of Health on Gender Dysphoria in Children and Adolescents.

Care providers, doctors, and leading medical associations have been clear that gender-affirming care is safe, effective, and evidence-based, and that it's literally lifesaving.

The issued guidance by the Dept. of Health and the studies used by this board are inaccurate and dangerous. This guidance is nothing more than another tool for the Governor to express his opposition to transgender individuals' existence.

The nation's leading health organizations support gender-affirming care for transgender and gender non-conforming people, including the American Academy of Pediatrics; the American Medical Association; The American College of Obstetricians and Gynecologists; The American College of Physicians; The American Psychiatric Association; The American Psychological Association; The American Academy of Family Physicians; The Endocrine Society; The Pediatric Endocrine Society; American Nurses Association; American Public Health Association; American Heart Association; National Association of Social Workers; World Medical Association; and The World Professional Association for Transgender Health, among others.

There is overwhelming evidence to support the positive mental health impacts of gender-affirming medical care for trans youth - including in some of the very studies cited by the DOH and Board of Medicine. Prohibiting social transition is clear government intrusion on personal and parental decision making. Numerous studies have found that after social transition, transgender youth report similar mental health levels to the general youth population, eliminating mental health disparities typically seen. When transgender youth are affirmed by people around them, reported rates of depression and suicidality drop significantly. This rule will deny them this life-saving treatment.

The Board must provide truthful information based on science and data as opposed to false statements based on prejudice and political agendas. The evidence is clear: denying transgender youth the ability to transition is dangerous, abusive, and life-threatening.

I urge you to reject this proposal.

Sincerely,

Cynthia Fisher

I urge you to reject this proposal.

Sincerely,

Yuisa Colon

Dear Board Members, thank you for your time,

I am a former “trans” kid.

As a child I was insistent, persistent, and consistent that I was a boy.

I have no doubt that if the option to take puberty-blockers and cross-sex hormones had been available, I would have done everything I could to obtain them, including threatening suicide, especially if I had others encouraging me to threaten suicide as children are today.

In the short-term I likely would have felt better.

Testosterone is a controlled substance. Like other controlled substances, it has high risks to health and well-being and has the potential for both addiction and abuse. Testosterone makes almost anyone who takes it initially feels a sense of euphoria. If I had taken it as a child it would have allowed me to completely dissociate from myself as a girl and create a new persona, someone who could pretend that the horrible trauma that triggered my gender dysphoria didn't happen to me.

When I first started taking it, it would have boosted my confidence and increased my energy and most importantly, I would have felt safer.

If I took testosterone, it would have been so much easier to pretend that I was not the little girl who was brutally sexually assaulted. A little girl who became convinced at the moment of the assault that I was not safe being a girl. That the only way I could keep it from happening again was by becoming a boy.

Despite feeling better in the short term, in the long term taking testosterone would have been profoundly damaging, potentially even more damaging than the sexual assault. I can't imagine the impact of being told by teachers, doctors, and other adults that I was born in the wrong body. That I was inherently flawed.

It would have reinforced all the mistaken beliefs I had that caused me to develop gender dysphoria in the first place:

That being a girl was bad.

That it was my fault that those men hurt me.

That my body was a mistake.

That it was too dangerous be a girl.

If I had been medically transitioned, I wouldn't have gotten the help I needed to work through my self-hatred and shame. I never would have realized that my transgender identity was a coping mechanism.

I am so thankful that my school psychologist put me on a healing path. I am grateful to other therapists who helped me understand that my transgender identity was a result of the sexual assault not because I was born in the wrong body.

I shudder to think at what my life would be like if I'd been encouraged to believe that I was a boy.

I would have lived my life hating myself.

Puberty blockers would have retarded my growth and development. Cross-sex hormones would have caused my otherwise healthy body to become dysfunctional. The combination of both puberty blockers and cross-sex hormones would have left me sterile.

Children who says they feel better because of puberty blockers and cross-sex hormones are likely telling the truth. In the short term, these interventions allow children to avoid the difficulties they are facing, whether that be grappling with internalized homophobia, struggling with autism, or trying to recover from a significant trauma.

We should not be giving children controlled substances in order to make them feel better. It is a horrible disservice to encouraging them to dissociate, to run away from their feelings, to run away from themselves and to take a drug that in the short term will help them to feel better by numbing their feelings but in the long term, permanently damage their bodies and in the long term, prevent them from getting the help that they need to understand the difficult feelings that they're having in the first place.

It is natural for children to do what they can to shut down difficult feelings which is why we work hard to stop children from using drugs and alcohol. We know that encouraging children to run away from their pain and struggles is not the solution even if it makes them feel better in the short term.

It is our job as adults to give children the message that no matter how intense and difficult their feelings are, they can work through them without dissociating from themselves to become a different person.

Because of loving, caring, and supportive therapists and teachers, I got the care I so desperately needed to process what happened to me.

Transgender activists often discount my story, saying I was never really transgender. They are right. I wasn't. And that is the point. Even though I was insistent, consistent, and persistent about being a boy, I wasn't a boy. Yet gender doctors admit that the only diagnostic criteria used to determine if a child should get puberty blockers, cross-sex hormones, and surgeries is if the child is insistent, consistent, and persistent with gender confusion.

It only takes one story like mine to show they are wrong. To show that children develop gender dysphoric feelings not because of being born in the wrong body, but as a coping mechanism.

The belief that a child can somehow be born in the wrong is a mystical view, not a medical view.

I have great respect for doctors. However, they have gotten it wrong in the past. We are still suffering from the consequences of the opioid epidemic, where doctors were told by pharmaceutical companies that treating pain with dangerous and addictive opioids was safe and effective. How many thousands of people died because doctors were following guidelines for pain management written by those who were profiting from the sale of opioids? How many people have wrestled with serious addictions after well-meaning doctors prescribed medications that they had been told were safe and effective only to find out later that they were misled by pharmaceutical companies willing to put dollars ahead of human lives?

The so called "treatments" for gender dysphoria that are being championed by activists will go down in history as being far worse than the opioid crisis unless regulation are passed to protect children from these experimental and harmful interventions. The only treatment proven to help manage and resolve gender dysphoria is therapy combined with allowing children to naturally progress through puberty.

Children struggling with confusion about their identity need love and support.

My teacher and therapist gave me the gift of time to heal and I am so incredibly grateful.

All children who are struggling with gender dysphoria deserve the same gift.

Thank you for your efforts to protect children from a dangerous ideology.

Erin Brewer

Billy Burleigh's Written Testimony to the Florida Board of Medicine

My name is Billy Burleigh and I used to be transgender.

As a child I had the reoccurring thought that, "God made a mistake, I'm a girl". I prayed before going to bed and, every time I prayed, I asked, "God, please make me a girl before I wake up". If I could have, I would have quickly chosen any path that would have transformed me into a girl.

In my early twenties, I sought help for the disconnect between my mind telling me I was a woman, and my body telling me I was a man. While going to therapy and doing my own research, the message I received was that I had to change my body to match my mind. After seeking any other path forward, I decided to take the therapists' and medical researchers' advice to change my body.

I started on a testosterone blocker and estrogen. My emotions were up and down, and my body was changing, but I was supposedly on this new road to happiness and that made me happy.

In my first surgery I had a penile inversion, an Adam's apple shave, and a brow shave. After the surgery, the doctor and nurses had difficulty stopping the bleeding from my new "vagina." My artificial vagina was packed with gauze and a sandbag was placed on my lower abdomen, but the bleeding did not stop. Later, mom told me that going into my hospital room was awful. The odor in the room was overpowering of stale blood. I received a blood transfusion and plasma and, eventually, the bleeding stopped. My two week stay in the hospital turned into a three week stay. But changing my penis to an artificial vagina required two surgeries, so about four months later I was back for part two, labioplasty. My money was low at that point, so I did not have any family or friends accompany me – I went through this second surgery on my own. I was desperate for the happiness I believed was ensured me.

After this, I had additional feminization surgeries, but no matter how many I had, every time I looked in the mirror, I saw a man staring back at me. I tried hard to resolve the conflict between my mind and my body but after seven years of trying, I had more problems at that point than I had when I started on the road of transition.

The bottom line is that the therapists and medical researchers were wrong – changing my body did not resolve my internal conflict and it did not make me happy, but what it did do was drain my financial resources and left a scarred body.

I have fully transitioned back to male, I am happily married, I have two beautiful stepdaughters, and I have peace of mind and body.

Lastly, I was a responsible adult and I made a horrible mistake. In hindsight, I am male and I was born into the right body. The therapists and medical researchers failed to help with my underlying problems. They identified me as transgender and they were wrong. How often are they wrong?

How were the therapists and medical researchers wrong?

I was led to believe that the cause of my gender dysphoria was, potentially, a birth defect - that my brain was washed in the wrong hormone and that the only path I had to happiness was to transition. This logic was wrong and it took me down the wrong path, but I did eventually find the right path to peace and freedom.

Later in life I heard it said that everyone has a need to be accepted, significant, and secure. Though I had not heard this before, I agreed with this statement, and I started thinking about how I had tried to satisfy these needs in my younger years. I had many problems as a child – I was very skinny, had a speech impediment, had learning difficulties, wasn't athletic, was sexually abused, and I didn't seem to fit in with the other boys. I did, however, seem to fit in well with the girls and I enjoyed playing with them more than I enjoyed playing with the boys. As a boy, I didn't feel accepted or secure, and I most certainly didn't feel significant. But if I were a girl, I believe I would have felt accepted and would have felt more secure. And, with my childhood distorted thinking, I thought I may have been more significant to my dad. In hindsight I see that I had several underlying problems that reinforced the false thought that I was a girl. The therapists never did explore these underlying issues, and my research on transgenderism failed to turn-up anything on these needs. The therapists and researchers, with respect to me, got it wrong.

I also learned that not all of our thoughts are actually our thoughts. Secular research and opinions on "What is a thought?" and "Where do thoughts come from?" seems to be in many different directions. The Bible says that they can ultimately come from God, ourselves, or the devil (and his minions). Here in the west, we are quick to dismiss the spiritual aspect of our well-being, but I had to dive into this spiritual component in order to find my freedom from this mental battle. Back in the first grade, I was standing in front of the school wondering where I belonged when the thought "God made a mistake, I'm a girl" came into my mind. From that point on, for decades, that was an intrusive reoccurring thought. I didn't know what to do with the thought; I didn't want the thought, and I did not share it with anyone, until I was having a breakdown and sought therapy in my early twenties. This started my road of transitioning to presenting as a woman.

The start of my road to transitioning back to male began when I gave my life to Jesus and started studying the Bible. I learned that we are all engaged in spiritual battles, whether we know it or not. The Bible talks about these battles, what we are up against, and about the provisions God has already provided to all of us, through Jesus, to overcome. My name is Billy Burleigh and I use to be transgender, but I am now a child of the Most High God; I was bought with a price and I belong to God. Knowing Who-I-Am makes a Huge difference!

The world has many ways, many means, of offering acceptance, significance, and security. However, the "ways" and "means" keep changing, just as the DSM has continued to change on what it says about transgenderism, or gender dysphoria, over the past many decades.

I believe that gender affirming therapy for any person of any age is wrong. I believe it is not gender dysphoria, but rather simply dysphoria. Per GoodTherapy.org, Dysphoria is defined as a state of generalized unhappiness, restlessness, dissatisfaction, or frustration, and it can be a symptom of several mental health conditions. As is my case, and as I have heard from others who have not de-transitioned and who have de-transitioned, there were many childhood issues that contributed to our dysphoria, and those issues were not explored nor dealt with in therapy. The media, the government, school systems, and other groups are telegraphing to children and teenagers that if they feel different, if they feel trapped in the wrong body, there is special help for them, that they will be embraced, helped, and protected. For kids who are struggling with many different issues, this is the wrong place to find acceptance, significance, and security – it does not cure, and it imparts lasting harm.

But as for me, Billy Burleigh, I am accepted, significant, and secure in Jesus of Nazareth, who is unchanging and who is a solid rock!

Thank you for your time today and for listening to my journey. I can make myself available later for questions. Thank you.

Addendum A to my testimony: When I was transitioning from identifying and presenting as a female back to male, I needed a medical document to change all my legal documents from Female to Male. Having a Phalloplasty would satisfy this requirement. Long story short – I asked the surgeon many times if I was a good candidate for this surgery and he assured me that I was. He said that I would be very happy with the outcome. I trusted him! He's a doctor, a surgeon, and he had my best interest in mind, or so I thought. Below are two pictures: the first is of my abdomen prior to the surgery and the second is about a year after the surgery. The surgery was so painful and the outcome horrified me. I later had the surgeon unfold the unsightly manmade penis and put the skin back onto my lower abdomen. The therapists and medical professionals say trust us, we care for you and we know what we are doing. Here again, the council I received failed me.

Before Phalloplasty

After Phalloplasty

Addendum B to my testimony: These are pictures of me at different times in my life:

- Me when I was 18, a senior in High School
- Presenting as female, about age ~35

- Presenting as female, about age ~34
- Transitioned back to male, married (that's Rachel), age ~52

Dear Mr. Vazquez:

I'm writing today to express my concern for the welfare of teenagers being subjected to mutilating surgery and potentially dangerous hormonal medications as part of "Gender Affirming Therapy." After review of available data, and deep reflection, I completely concur with the Department of Health's finding that these therapies are "experimental", and as such should not be conducted outside of IRB-approved research studies. Our approach should be a process of discernment, not abrogation of professional judgement to the ever-changing views of teenagers. We don't give 'fatness affirming therapy' to teens with anorexia nervosa, nor 'suicide affirming therapy' to teens calling for help following their suicide gestures. Why should we think 'gender affirming therapy' (GAT) must be the only option for children questioning their gender identity?

There remain legitimate questions about the possible narrow indications for GAT. Properly conducted clinical research is the only way to help answer at least the scientific questions that arise, especially as to long-term outcomes. Of course, 'science' is not equipped to address the ethical and moral considerations, and these overriding concerns are also deserving of vigorous and open debate.

Thank you for your courageous efforts to protect Florida's children.

Sincerely,

Richard H. Sandler, MD

Dear Mr Vazquez,

Please find a letter attached which we would like to submit into public record, in support of your plans to reform the treatment of gender dysphoria.

Thank-you.

Aaron Kimberly

Dysphoria without ideology

The Florida Board of Medicine
Paul Vazquez, Executive Director
4052 Bald Cypress Way, BIN C#
Tallahassee, Florida 32399

Paul.Vazquez@flhealth.gov

August 29, 2022

Dear Mr Vazquez,

I am an adult who has medically transitioned and is happy with my own transition. If I had been asked five years ago what I thought of childhood transition, I probably would have thought it was great. It's easy to look back on my experience of childhood onset gender dysphoria (GD) and imagine the benefits of having undergone childhood transition: If I'd been put on puberty blockers, I probably wouldn't have needed a double mastectomy and therefore wouldn't have scars. If I'd socially transitioned and started testosterone as a teen, then maybe my GD wouldn't have interfered with my social development as it did.

Despite these possible benefits that some may argue they would have experienced via childhood transition (which of course is no more than a thought experiment), I am now of a different mind: I strongly disagree with childhood transition. I'd like to explain to you how I've arrived at this conclusion.

As a young adult, I became a part of the lesbian community through which I met many very masculine lesbians and effeminate gay men. I began to understand my GD as somehow related to being gay and to the masculinizing effects of the Ovotesticular Disorder of Sex Development (DSD) which I was diagnosed with at age nineteen. Though I struggled with GD, I didn't give it

much more thought. In the butch/femme lesbian subculture, butches often use male nicknames and are referred to by male pronouns though, to be clear, no one is confused about the biological sex of butch lesbians. “Stone Butch” is a term for such women whose GD is so severe they can’t tolerate being touched.

Then, in 2006 I saw a documentary on mainstream TV about “trans kids” whose described experience of GD and cross-sex identification was a near exact reflection of my experience growing up. The documentary framed the experience of GD as: if you experience x,y, z, then it means you are a transgender person. So that was it! I thought, I must be a transgender person because I certainly had all of those experiences. Looking back, I can see that I had exhibited all the classic signs of GD, which I found to be confusing and distressing, since the age of three. Prior to seeing this documentary, I didn’t have language or a framework through which to understand my experience of cross sex identification. My GD wasn’t something I had discussed with anyone. But after seeing this documentary, it seemed to me that I finally had a framework to explain my heretofore confusing and distressing experience – I was “trans”! After this revelation, I booked an appointment at the local gender clinic where I was assessed for Gender Identity Disorder (GID) over a period of several months, and I was started on testosterone. I was assessed again by a clinical psychologist prior to having any surgeries done. I personally found the assessment process helpful, because it required me to consider things I hadn’t thought of, and prevented me from making hasty decisions. The changes to my body, from testosterone and a double mastectomy, did relieve my distress and disconnect with my body. However, it’s also been a very complicated emotional, psychological, social and physical process, which I believe requires a great deal of stability, maturity and support to navigate well.

In 2008, two years after my diagnosis and the start of my hormonal treatment, I became a registered nurse with a specialization in mental health. I worked in the mental health department at St Paul’s Hospital in Vancouver, Canada, for 10 years. Initially I worked in the Psychiatric Stabilization Unit and then in the Provincial Eating Disorders Program. In 2017 I moved to Kelowna, Canada, to help launch a multidisciplinary youth clinic. By 2019, about 25%

of the youth presenting to our clinic were trans identified and requesting medical interventions. The clinic physician was interested in providing medical interventions, but she didn't have the sessional time with our program to provide (what we'd assumed would be) lengthy assessments and care planning. Since assessment is one of my professional strengths, I offered to do intake assessments and coordinate the trans health services. I was excited to cross the table and learn about GD from a clinical perspective. Working within a multidisciplinary clinic seemed like an ideal setting to do whole person care, since we had access to primary care, psychiatry, counselling, housing services, parent supports, employment services and partnerships with more intensive mental health and social services.

I consulted with the Provincial Health Services Authority (PHSA), which provides oversight and clinical training for trans healthcare services throughout British Columbia. PHSA's team (Trans Care BC, TCBC) came out to Kelowna twice to do training for us. Additionally, I was doing weekly mentorship calls with them. During this training and mentoring process with TCBC, I started to become confused and concerned about the current state of trans healthcare.

TCBC's in-person training was best described as cultural sensitivity training. They presented the Genderbread man diagram, personal narratives, and coached us to use certain language. TCBC's training did not include any peer reviewed studies. Rather, their "literature" relied solely on community-based surveys. Shockingly, there was no mention of GD. Further, TCBC's website claims that one doesn't have to be trans to medically transition.¹

I was informed by TCBC that the purpose of assessments is strictly for the purpose of determining a patient's capacity to consent, and that assessment could be completed in a single visit, using a one-page checklist created by TCBC, found in their Primary Care Toolkit.² In British Columbia, minors may consent to treatment without parental permission, under our Mature Minors Act.

I asked TCBC for peer reviewed studies about GD, and psychotherapeutic models that are helpful for supporting those with GD. They didn't point me to a single study.

During mentorship calls and on the clinical listserv, I heard from other clinicians that they were telling parents that their child would die by suicide if the parents did not support their medical transition. I learned that one well known psychologist, who works with youth in the foster care system, had told an audience during a public presentation to lie about being suicidal to get what they wanted.³

I'd known some of these clinicians for many years because some of them were my care providers. My experience in trans healthcare as a clinician and my experience 15 years earlier did not mesh. Consequently, I became very confused about the nature and/or clinical meaning of "trans" or "GD" and why clinical practice in trans care had changed so much.

The youth I had been seeing at my clinic were often highly complex and very few of them seemed to have the same experience of GD that I did. Between Aug 2019 - Dec 2020, I saw 52 clients for hormone readiness assessments. Of these clients, 71% were natal females. Of these female clients, 8% identified as heterosexual. (The boys were all heterosexual or bisexual). Of the 52 clients, 19% had an ASD diagnosis. 29% had an ADHD diagnosis. 14% were involved with child protection services or were adopted, and 15% reported significant trauma. A single visit assessment seemed grossly insufficient, so I wanted to take my time with my clients, to do more thorough assessments, care planning, and provide education.

By getting to know my clients, I learned that some of the youth had been very lonely through childhood. Some admitted that they never had any GD as children. One teen girl in particular stands out in my mind. She had initially been brought to our clinic by her parents to start testosterone. She wanted to be a boy and had already socially transitioned. Then, one day her parents brought her in to see me again. She seemed embarrassed and said she was happier back when she was a girl. She was ambivalent, because she stated that she'd have to "grow her hair long and start wearing girl clothes". I informed her that she could have whatever hairstyle and wear whatever she wanted to as a girl and asked if she'd considered exploring what kind of girl she was. She lit up like it was Christmas morning and seemed very relieved. She never came back to start hormones.

Meanwhile, some of my friends who had medically transitioned 20 years ago were starting to open up about their transitions. One very much regrets her transition and now understands that her decision to transition had been motivated by childhood sexual abuse. The consequences of her transition have been considerable. Significantly, she's resigned herself to a life without a romantic partnership, since she's attracted to lesbians, but lesbians are not attracted to her, since she looks like a man.

I became so disturbed and confused by what I was seeing in trans care that I started digging into the medical literature for answers. Surely there was evidence to explain why thorough assessment and psychotherapy had been eliminated, and why GD is no longer being discussed among clinicians. I found no such evidence. What I found were 11 studies all saying that most young people with childhood onset GD desist by or through puberty.⁴ I also read through studies by psychologists Drs. Blanchard⁵, Bailey⁶, Zucker⁷, and Vasey⁸. The information I learned from these high-quality studies was overwhelming, and that sense of overwhelm led me to crash. No one had ever informed me about the three known pathways to GD, all outlined in the DSM-5:⁹

- (1) Late onset - Transvestic disorder with Autogynephilia
- (2) Early onset – highly correlated with homosexuality
- (3) GD related to a Disorder of Sex Development

The aforementioned body of work regarding GD not only makes 100% sense regarding my personal experience of GD, but it also maps onto what I've seen in the trans population over the past 20 years. We are not all the same. We have experiences, and different needs.

When I raised my concerns about the state of care being provided to trans identified youth within the system of care (TCBC, listserv etc), the response was drastic and swift: complaints were made to my employer, I was removed from the clinical mentorship mailing list, I was accused of using the listserv for anti-trans activism, our clinic was boycotted, and I was moved to another program within the organization. The attacks didn't stop there: A trans woman who

works TCBC, and two of her friends began a smear campaign on social media and called the head office of the organization I work for, in an attempt to get me fired. The accusation levelled against me was that I was “gatekeeping”, “spreading misinformation” and advocating for hatred against trans people.

These reactions (shunning, smearing, attacks on my livelihood) on the part of the members of the trans care system in BC, prompted me to create the Gender Dysphoria Alliance (GDA) in January 2021. My goal for the GDA was for it to act as a lightning rod for like-minded trans people who understand or want to understand themselves from an evidence-based clinical lens, rather than activist led narratives.

The GDA has had many different stakeholders such as parents of children and youth with gender-related distress, trans people, clinicians, detransitioners, teachers and journalists, reach out to us. They’ve all noted that they did not know where else to turn for evidence-based support and information on trans related issues. One teacher told us that 50% of her classroom of pre-teens identified as something other than “cis gender” but she was afraid that voicing concerns would be seen as transphobic.

I believe the clinical community has failed in its obligation to provide evidence-based care and education about what GD is.

Kids are being socially and medically transitioned without any regard to the desistance studies.

I believe there is a social phenomenon occurring that is attracting young, vulnerable people into trans identities. Dr Lisa Littman, in a preliminary study, named this phenomenon Rapid Onset Gender Dysphoria.¹⁰ The influence of social media and Queer theory activism, which is a deliberate attempt to blur our understandings of male/female and gay/straight, is confusing kids and recruiting them into a political movement that doesn’t care whether the kids have GD or not. To date, there is no other plausible explanation for why we are not only seeing many

more young people flooding clinics, but ***a completely new presentation of young people: girls with no history of childhood gender non-conformity.*** Historically, the only natal females who sought transition were butch lesbians who's reported experiences of GD fit the childhood onset pathway to GD. Furthermore, until the recent shift in populations presenting to gender clinics, females have always been the minority of those presenting with GD. The reason for this is threefold: (1) there are fewer lesbians than gay men, and even fewer butch lesbians. (2) women rarely have paraphilias like transvestic disorders, and (3) DSD related GD is rare. This new cohort of girls (and some boys) is not accounted for in our current evidence-based understanding of GD. This should prompt concern, pause and investigation by the medical establishment, not faster pathways to medicalizing them.

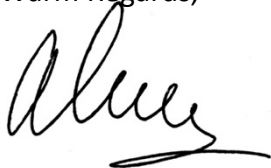

Knowing what I now know, I know I would have benefitted from the truth – that my GD is related to my DSD and sexual orientation.

I was lied to about the nature of my condition, and about my health and treatment options by the system. I will not participate in continuing that lie as a clinician.

I am very much in support of a return to evidence-based practices, including watchful waiting, psychotherapy, and comprehensive, whole-person assessment.

Thank-you Mr Vazquez, for your efforts to protect kids with one of the types of GD, as well as the kids who don't have GD, who would likely be harmed by hasty medicalization and misinformation.

Warm Regards,

Dear Chairman Diamond;

I WANT TO THANK THE BOARD FOR
Protecting minors from "Gender-Affirming"
Treatment. I AM GLAD THAT THE
BOARD RECOGNIZES CHILDREN WHO ARE
STRUGGLING WITH SEXUAL IDENTITY. NEED
COUNSELING NOT DRUGS AND SURGERY.

Sincerely Yours,

Robert P. Fernald

CAPT.

USAF (Ret.)

Dear Chair David Diamond,

We thank you and the state board for protecting minors from gender affirming treatments.

Our children and teens are not mature enough and this will protect them from making a decision they will regret later in life.

Thank you again and we are praying for you.

Sincerely,

Sandra Roberts

To: Vazquez, Paul <Paul.Vazquez@flhealth.gov>
Subject: Caring for children and youth with Gender Dysphoria

Dear Mr. Vazquez,

It has come to my attention that Florida will be having hearings about “gender affirmation care” vs a proper medical management of minors struggling with gender dysphoria.

I was a PICU nurse for over 15 years and am now the President of the Center for Bioethics and Culture. I have a keen interest in a “first do no harm” medical approach to minors who are unable to consent to permanent and harmful therapies.

As such, I’ve written and directed two documentaries on the subject:

Trans Mission: What’s the Rush to Reassign Gender?

The Detransition Diaries: Saving Our Sisters (release date Sept 19, 2022)

I wish to submit these films into the public record for the hearing.

Here are the links the film and trailer for the upcoming film.

<https://youtu.be/rUeqFoARKOA>

<https://youtu.be/NVhUoiXGWx8>

Can you confirm receipt of this email and if I’m allowed to do this?

Sincerely,

Jennifer Lahl R.N., B.S.N., M.A. (bioethics)

Dear Chair David Diamond

Thank you for prohibiting children + teens
from receiving hormone therapy or undergoing
"gender" surgery. Thank you for protecting
~~our~~ our kids. We are so
appreciative for standing for our
kids. God bless you and
keep up the good works.

Sincerely
Cristina R. Orozco

Dear

Chair David Diamond

Just A Note of Thanks for
standing AGAINST the Evil
confusion that is trying to
destroy this nations inheritance
Pray for you to continue to
stand for truth.

Sincerely

Christ
Hend

Dear Chairman Diamond,

Thank you and the Board so very much for voting to protect our minors from these horrible "gender-affirming" treatments.

May God bless you and your efforts to protect our children.

Sincerely,

Bonita Chase

CHAIRMAN DIAMOND -

THANK YOU FOR STANDING
STRONG AGAINST EXPERIMENTING
WITH THE CHILDREN OF
FLORIDA!!

BRYAN ROSENTHAL

Dear Sir,

This is to thank you as well as the state board for working so hard to protect our minors from gender-affirming treatments.

Your work and dedication are greatly appreciated.

We will continue to pray for you - God's blessings will abound -

Jody Kelly

Chairman David Diamond

Thank you and your team for your all
commitment in protecting our children.
It brings me great appreciation knowing
that we have someone like you and
your team can make a difference for
the better.

Rita Senquis

Dear Chairman Diamond,

Thank you for protecting of kids and families from these evil agendas trying to push into thing we don't want. Keep fighting this fight. I pray God strengthens you and protects you.

God bless you!

Sincerely,

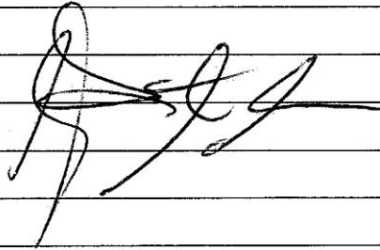

Robert Just

DEAR: CHAIR DAVID DIAMOND

THANK YOU FOR PROTECTING OUR MINORS

FROM THESE "gender-affirming"

TREATMENTS.

A handwritten signature in black ink, appearing to be 'R. S. J.', written on lined paper.

Dear David Diamond,

Thank you for protecting our
minors from these "GENDER AFFIRMING"

TREATMENTS.

Roger Banksen

Dear Mr Diamond,

Thank you and the
State Board for taking a stand to
protect our precious children from
gender-affirming treatments. We truly
appreciate your hard work and love
for our children. Keep up this great
fight.

Sincerely,

Parbatie Dial

Chairman Diamond

Thanks so much for standing
& protecting minors from gender-
affirming treatments. We appreciate
you helping to protect our children.

Jack Mat

Dear Chairman Diamond,

Thank you so much for all
you've done to protect our minors
from gender assignment
treatments.

We will continue to pray for
our state in this matter.

Sincerely,

Michelle Wolff

David Diamond,

Thank you for protecting our
minors from the gender -
affirming treatments.

Ernest & Adela Morgan

Dear Chairman Diamond,
Thank you and the
State board for protecting our
minors from the gender affirming
treatments.

Sincerely
Allen R. S.

Dear Chairman Diamond,

Thank you for protecting
minors from the "so called"
"gender affirming care".

We must protect our children
from this crazy ideology.
Children are born male or
female ~~and~~ determined by God and
we should not be doing life-altering
procedures or medicines. Thank you! Barry Webster

Dear Chairman Diamond,

Thank you for your work in
protecting minors from receiving
inappropriate gender treatments and
surgeries.

Sincerely,

Chris Roddy

Dear Chairman Diamond,

thank you so much for protecting our
youth from 'Gender-affirming' treatments.
God bless you, we are praying for you.

David + Teresa Sawyer

Dear David Diamond,

I am so thankful for you and
the state board for protecting
our minors from these "gender-
affirming treatments.

God bless you,

Louise Simmons

Dear Chairman Diamond,

Thank you for holding our stance on the protection of our minors from these treatments. We are greatly appreciative of your help in standing up for these rights for our children.

Sincerely,

Green D. Lee

Chair David Diamond,

Knows that our thoughts
→ Prayers are with
you. Thank you for
protecting our minors from
gender affirming

Thank you for advancing the
new rule prohibiting children
+ teens from receiving hormone
therapy.

M. Deber

Dear Chairman Diamond,

I wanted to take a moment to thank you + the State Board for protecting our minors from the horrific "gender-affirming" treatments!

God bless you as you continue to fight for the well-being of our children.

I'm praying for your continued success in these efforts!

Sincerely,
Kelli Banks

Dear Chair David Diamond

Thank you for protecting
our Minors from these
"gender-affirming" treatments
God bless you.

Kind regards
Mrs Laverne Brown

Dear Chairman Diamond,
Thank you the board's protecting
minors from so-called "gender affirming"
treatments.

I believe your decision reflects both
a moral + ethical outlook on this subject
and is just good common sense.

Our children should **(NOT)** be used as
experiments by special interest groups!
Keep up the good work! Kind Regards,
Cliff Evans

Chairman Diamond,

Thank you and the State board of
medicine for protecting our miners
from these "gender-affirming
treatment."

I appreciate all your hard work.

Sincerely,

Mrs. Stacy Nock
Ocoee Fl.

Dear David,

Thank you for protecting our rights from gender theory. It's really sad
that there is so much whining in some-sev. Hopefully it gets more
faded away.

Love, David,

David

Dear Chair David Diamond

I congratulate you and state board for
protecting minors from gender affirming
treatment.

Our children and teens are not mature
enough and this will protect them from
making a decision they will regret later
in life. Thank you so much.

Sincerely
James Roberts

Dear all,

I am a mom in California, a life-long Democrat. I am the parent of a son who at age 15 was convinced that he was a transgirl. He did not come by this belief organically. He was a rough and tumble boy who came to his identity after being cut from the high school baseball team. His dream. He was lost and started spending hours online and watching anime. He knew none of the girls in elementary school and in middle school he wondered how he would ever date girls because he had nothing in common with them.

He also decided he was trans with another boy from Boy Scouts. After he told us this we started seeing it everywhere.

As soon as he announced his trans identity, his mental health plummeted. He barely got out of bed. He lost 30 pounds. He started failing his classes at school. He was diagnosed with severe depression and anxiety. His online friends instructed him that his parents are abusive. His teacher in school also affirmed this belief and actively tried to help him move out of our safe home into a LGBT center.

My son is now 18 and moved out of our house while we were at work and we have no idea where he is.

Over and over, the media presents desperate trans-identifying children, abandoned by their families, but the hundreds of parents I know — parents like me — don't reject their gender questioning children. They reject us.

My son's first therapist offered a single option, immediately affirming his trans identity, insisting that we use his desired female name and pronouns. The therapist warned us that our son had a 44% chance of committing suicide if we did not celebrate our newdaughter. The 44% that the therapist quoted was lifted from a headline. The study it came from stated that this was an extreme overestimate, but this therapist had never bothered to read the study. Recent studies show the number to be magnitudes lower, and similar to rates for the comorbidities many trans-identifying children have.

As I watched my son change from a loving child to an unrecognizable kid — vicious, angry and sullen— my gut told me that the therapist was wrong. I read everything that I could on this new crop of teenagers that suddenly announce a trans-identity. Lisa Littman is spot on with her description of rapid onset of gender dysphoria.

I know that my story is not unique because I have heard 100s of stories like mine. The patterns are clear – these ROGD kids are into anime and cosplay. They spend too much time on social media. Many have internalized homophobia. They are socially awkward, intellectually advanced but emotionally immature, on the spectrum, have eating disorders, AND all of them have comorbid mental health issues that are not alleviated by gender affirming care. Forcing the affirmation model as the only treatment for gender dysphoria or incongruence will harm millions of children and youth in our country, leading them toward a lifetime of medications and surgery — treatments with no evidence base to support their safety or efficacy. Affirmation is not life-saving; it is life destroying.

Dear Paul Vazquez and the Florida Medical Board,

I urge you to create sensible and European-style regulations for care for gender-questioning young people under the age of 25, which is when science now knows the brain completes development.

[Finland](#) was the first country to do it, based on the evidence. They realize the importance of the age of 25.

This was followed by [Sweden](#) and the [UK](#).

The [exploding numbers of detransitioners](#) are the canary in the coal mine. Clearly young people are being socially influenced to identify as trans - even [France's National Academy of Medicine](#) realizes it, [as do clinicians who are themselves trans](#). A minority probably are, based on historical evidence, and probably a bit more than the past, given growing societal acceptance.

However, many are realizing they are not, with very costly consequences, including lifelong health problems, sexual dysfunction, and infertility.

Please read some of their testimonies here:

<https://nypost.com/2022/06/18/detransitioned-teens-explain-why-they-regret-changing-genders/>
<https://somenuanceplease.substack.com/p/some-reflections-on-the-hysterectomy>
<https://www.dailymail.co.uk/news/article-10953157/Man-suing-NHS-trans-surgery-regrets-bravely-waived-anonymity-share-ordeal.html>
<https://genspect.org/how-internalized-misogyny-contributed-to-my-transition/>
<https://www.newsweek.com/theres-no-standard-care-when-it-comes-trans-medicine-opinion-1603450>

And we don't even know how many detransitioners there are. One [recent study](#) says as many as 75%

of detransitioners don't return to their clinicians to tell them they are stopping their medicalization.

Please also read the testimonies of trans people who are very concerned about what is happening to children with undeveloped brains:

<https://www.newsweek.com/we-need-balance-when-it-comes-gender-dysphoric-kids-i-would-know-opinion-1567277>

<https://www.washingtonpost.com/opinions/2022/04/11/i-was-too-young-to-decide-about-transgender-surgery-at-nineteen/>

<https://bust.com/sex/195055-trans-man-gyneologist-advice-buck-angel.html>

Parents are understandably alarmed at what is happening to children: kids being influenced away from their families, [affirmed often in secret by schools](#) and friends, and then fast-tracked to medicalize by the medical establishment, some of them with clear monetary motives and no concern about ethics ([this one performed a double mastectomy on a 13-year-old girl](#) - in Florida!).

I urge you to set the standard in the United States - which will also make an impact beyond the US.

Thank you.

Greetings to all,

We are writing to The Board of Medicine because the mental health of our children is our most significant concern.

My husband and I have a combined mental health experience of almost 70 years. I am a psychotherapist who has had a mental health center for the past 21 years, serving our community with a team of over 20 professionals. My husband is a psychiatrist who holds medical licenses in 34 states and presently practices in 120 emergency rooms around the nation.

In the past 30 years in the field, I've had one adult male patient who had partially transitioned to be a female. My husband remembers having no more than 4-5 transgender cases in his career (none children) until about three years ago. Now, he sees 5-10 children with gender dysphoria per month in emergency rooms. In my clinic, not long ago, we received a phone call from a mother, and in that call, we identified ten preteen girls experiencing gender dysphoria—her daughter and four girls in her class, as well as five friends from another school. None of the clients who have come to us with gender dysphoria have presented with a history of childhood gender dysphoria. Instead, parents describe a sudden onset of their symptoms. This rapid onset is a clear picture of peer contagion. Historically, there has always been a small number of children who present with gender dysphoria, and 80% of them outgrow it.

Many say that the rise in gender dysphoria visits to mental health professionals like us has to do with increased acceptance which helps the clients not feel marginalized. However, we have not seen an increase in adults exploring transitioning. It is solely children seeking it. There is an increase of 4,400% in kids identifying with gender dysphoria, and we need the help of The Florida Board of Medicine not to harm these children permanently. Many psychotherapists explore other factors affecting the child's mental wellbeing, not affirm, and have found great success.

We can learn a lot from looking at the history of John Money, the psychologist who originally introduced terms such as gender identity, sexual orientation, and gender roles that are now adding to our current mental health crisis.

Money stated that pedophilia is not always pathological. He argued that there are affectional pedophilia and sadistic pedophilia. According to Money, affectional pedophilia was about having too much love for a child. Money had considerable research on sexual identity and the biology of gender based on the case of the Reimer twin brothers. One of the twins had a condition that was attempted to be corrected by circumcision. The procedure went wrong, and the boy lost his penis. Money suggested raising the boy as a girl, and the parents did. He often brought the two kids to his office to do therapy and show them how they needed to perform sex acts. Both twins killed themselves when they were in their 30s. In the 1960s, John Hopkins pioneered sex reassignment procedures, and in 1979 the clinic was closed because they realized that reassignment procedures did not bring happiness or any of the benefits they were looking to find.

Transitioning does not bring wholeness and happiness. We have already traveled those waters. Many young women who transitioned in adolescence later regretted it and de-transitioned. We can read about many of them. "What we focus on the longest grows the strongest" is a phrase I often use with my clients and students. Social media and academia are creating a climate that propagates gender confusion at unprecedented rates. They do it by putting pressure on young children to identify with a gender, introducing books about gender identity at an early age, and more.

Our children need the help of the Florida Board of Medicine to protect them and do no harm. Please do not allow the medical transition of minors with hormones, puberty blockers, or gender surgeries. Our current mental health crisis merits it. Our children deserve it.

Respectfully yours,

A handwritten signature in black ink, appearing to read 'B. Martinez-Penalver', with a stylized flourish at the end.

Dear Paul

I am a mother in The United Kingdom with a son who told me, age 14 that he was 'a girl' in June 2020. He wanted puberty blockers, cross sex hormones, name and pronoun change.

Currently and as of February 2022 he no longer believes himself to be the opposite sex and no longer wants hormones.

When he first told me, I was supportive and reassured him we would get through this together, he knows that I have several medically transitioned adult friends and could never be classed as 'transphobic'. Confusingly, I had never seen any behaviour from him that made me think he was *not* male.

I joined the parents forum of UK 'Children's Charity' Mermaids where I was informed: 'this is not a phase they grow out of', use his chosen female name and pronouns and see a doctor asap to arrange puberty blockers and to avoid our '*daughter*' self-harming or *worse*.

Strangely, I saw that the forum was receiving multiple new members every day, all like us and all the teenagers were saying exactly the same things, almost word for word. Many of them, like my son are somewhere on the Autism Spectrum and had started puberty earlier than their peers just before the isolation of Covid Lockdown. They had also accessed pornography at an early age. These similarities are key.

My husband and I looked at all the information available regarding this condition and found the description of 'R.O.D.G.' (Rapid Onset Gender Dysphoria). Studies and surveys showed that this was a phase, one that around 80% of teenagers grow out of **if** not affirmed in their belief, normal, talk

therapy can help, online influencers and social contagion play a big part in convincing vulnerable young teenagers their normal feelings of puberty mean something else.

We did not have a big confrontation. We spent more time together, never changed his pronouns or name and found a non-affirming therapist.

My son is happier than he's ever been, he got high marks in his exams this Summer, got a girlfriend, is enjoying his new college, plays guitar, meets up with friends and most importantly has a healthy body - his only body.

I have seen what happens to children who were given puberty blockers - they all go onto cross-sex hormones, it is a non-stop path. I have nightmares that we gave into the pressure at the beginning and pretended he was a girl like we were advised to. Thankfully we didn't sign our child up to stunted cognitive and bone development and a life-long medical reliance based on what he read on the internet.

Watchful waiting, the most cost-efficient response is actually the safest and most likely to lead to a happy child. Even socially transitioning them or altering pronouns helps to reinforce their feelings of being the opposite sex, remaining neutral is important.

Give these children **time** (2-3 years) not GnRH agonists, that were originally developed for adults with prostate cancer, endometriosis and uterine fibroids, and to chemically castrate sex offenders. Normal, talk therapy is a very helpful, safe space for them to discuss their feelings and any other issues with experienced professionals.

I know there is relentless pressure from lobby groups to recognise 'trans kids' but I know from experience that they are just kids going through the process of finding their identity. There is no such thing as 'the wrong puberty', natural puberty helps these young people find themselves.

Yours sincerely

J. Derbyshire

Dear Florida Board of Medicine

I am writing to you today to demand that you reject the proposed guidance by Surgeon General Ladapo's Department of Health on Gender Dysphoria in Children and Adolescents.

Care providers, doctors, and leading medical associations have been clear that gender-affirming care is safe, effective, and evidence-based, and that it's literally lifesaving.

The issued guidance by the Dept. of Health and the studies used by this board are inaccurate and dangerous. This guidance is nothing more than another tool for the Governor to express his opposition to transgender individuals' existence.

The nation's leading health organizations support gender-affirming care for transgender and gender non-conforming people, including the American Academy of Pediatrics; the American Medical Association; The American College of Obstetricians and Gynecologists; The American College of Physicians; The American Psychiatric Association; The American Psychological Association; The American Academy of Family Physicians; The Endocrine Society; The Pediatric Endocrine Society; American Nurses Association; American Public Health Association; American Heart Association; National Association of Social Workers; World Medical Association; and The World Professional Association for Transgender Health, among others.

There is overwhelming evidence to support the positive mental health impacts of gender-affirming medical care for trans youth - including in some of the very studies cited by the DOH and Board of Medicine. Prohibiting social transition is clear government intrusion on personal and parental decision making. Numerous studies have found that after social transition, transgender youth report similar mental health levels to the general youth population, eliminating mental health disparities typically seen. When transgender youth are affirmed by people around them, reported rates of depression and suicidality drop significantly. This rule will deny them this life-saving

treatment.

The Board must provide truthful information based on science and data as opposed to false statements based on prejudice and political agendas. The evidence is clear: denying transgender youth the ability to transition is dangerous, abusive, and life-threatening.

I urge you to reject this proposal.

Sincerely,

Asher Sochaczewski

To Paul A. Vazquez and the Florida Board of Medicine,

I want to support your move to restrict the so called "affirmative care" of children who identify as transgender. Around the age of thirteen, my daughter and several of her classmates came to the conclusion that they are transgender. When my daughter came out to us at fourteen, we were shocked as she had been a typical girl who had in no way demonstrated that she was unhappy with her body or the sex that she is. We are an educated, left leaning family (my husband is a professor) and have never embraced gendered social stereotypes. The boys in our family have long hair. Our eldest daughter is a lesbian in a loving relationship.

We thought that our daughter's distress should be explored and so made an appointment at a gender clinic. Outrageously, after one appointment, the "affirmative care" counsellor recommended that our young teen be put on experimental opposite sex hormones (ie. testosterone). We felt that was moving forward too quickly and I began to research everything I could about transgender teens. Four years later, I've made many eye-opening discoveries. I firmly believe that the recent outbreak of transgender identities in this new and different cohort of young people is the result of social contagion, as Dr. Erica E. Anderson (trans woman, and former president of the United States Professional Association for Transgender Health, and former board member of WPATH) has written here: https://www.sfexaminer.com/archives/opinion-when-it-comes-to-trans-youth-we-re-in-danger-of-losing-our-way/article_833f674f-3d88-5edf-900c-7142ef691f1a.html.

We must protect these young people from making irreversible medical and surgical changes on their bodies. You are well aware of the global shift regarding the transitioning of children and adolescents. Progressive countries such as Sweden, Finland, the UK and France have realized the harm that can come from the "affirmative care" model of treatment for trans kids and are now revamping their policies and programs for these patients. There are increasing numbers of detransitioners who are unhappy/angry with the healthcare they have received in the name of transgender care.

As a family we have not allowed our daughter to take testosterone though she begged that she needed it "for her mental health". Instead we have found a good psychologist who is helping our child deal with her anxieties. We are trying to educate our daughter about the realities of medical transition and how it is fraught with complications, both physical and psychological. We try to affirm her in her healthy body instead. She has recently stated that you don't need to take hormones to be trans. I hope that means she is backing away from medicalizing her perfect body.

Thank you for caring for and protecting the health of our children and youth. I support your search for the best treatment practices for these vulnerable kids. Please include mental health resources in your policies.

Sincerely,
Lavender Li

Dear Mr. Diamond.

Thank you for protecting
minors from gender-
affirming treatments.

Sincerely
Barbara Kliffel

Dear Mr Diamond

Thank you for protecting our minors from
from these "enders" offering treatments

Carol S. Muller

DEAR DAVID Diamond

I want to personally thank you for
looking out for the well being of all
Florida children by working to ban trans-
gender treatments for minors. Keep up the
fight & DON'T BACK DOWN!!

<Florida_Medical_Board_9_17_2022_Letter Form.pdf>

From the desk of : William J. Malone, MD, Endocrinologist, Twin Falls, ID

9/17/2022

Dear Chairman of the Board:

I'm an endocrinologist practicing in Twin Falls, ID, via Stanford University, NYU School of Medicine and Los Angeles County/University of Southern California Medical Center. I'm also a Board Member of a nonprofit international organization of clinicians and researchers which evaluates current interventions for gender dysphoria and promotes evidence-based care for children, adolescents, and young adults. I've published articles in The Journal of Clinical Endocrinology and Metabolism, The Lancet, Child and Adolescent Health, and Medscape on this subject. My views are my own, and do not represent the positions of any organization with whom I am affiliated. I am providing the following comments, annotated from public remarks I made recently to HHS, and copies of articles I have written on the topic of gender medicine, in the hopes the medical board will find them helpful as it deliberates next steps in gender care in the state of Florida.

1. Gender-affirmative care is a euphemism for a highly invasive treatment protocol for minors. To illustrate this point:

A 10-year-old feminine boy is teased for being gender-non-conforming, and determines that his interest in dolls and makeup indicates that he is transgender. Under the affirmative care paradigm, clinicians would have to affirm this child's belief and begin preparing him for transition starting with puberty blockers. Puberty blockers will halt his genital development—his genitalia will stay very small—prepubertal size, only slightly larger than infant sized genitalia. It will also stop accrual of bone

density, and alter his brain development, and impact the development of every part of his body in ways that we do not fully understand. In nearly 100% of cases, puberty blocked kids proceed to cross sex hormones. This means that puberty blockers should not be considered a pause button, nor stand-alone treatment. They represent the first step in a pathway of cross-sex hormones and possible surgeries that can cause permanent physical changes and sterility.

At around age 14, estrogen will be given, which results in the destruction of future sperm producing potential, rendering sterility. This young person will be dependent on estrogen life-long which will increase the risks of strokes and blood clots by several fold and may increase the risk of cancer.

At age 17, a surgeon will remove the pre-pubertal sized and non-functional testes. At age 18, a surgeon will create a neovagina from the penile tissue, but because the penis is the same small size that it was at age 10, a section of colon will need to be used. This neovagina may carry the odor of colon tissue, and will be susceptible to developing diseases of the bowel such as colitis. It is not clear whether this young person will ever experience sexual desire or be able to have an orgasm. What is clear is that the young person will never be able to reproduce and will face a life time of medical patient-hood.

Today, kids like the one I described are presenting in record numbers seeking sex reassignment. As many as 10% of youth identify as transgender. Affirmative care asks that children make life-changing decisions that carry irreversible consequences at an age when the ability to provide meaningful consent is questionable.

2. Interventions of such impact should only be provided when the evidence of benefit outweighs the risk of harm. In our highly politicized environment, it is claimed this is the case. However, every credible systematic review of evidence conducted to date—from the US to Finland to Sweden and the UK, has failed to demonstrate any lasting or credible benefits of these interventions while noting very significant risks. While the often-heard statement that “puberty blockers save lives” is catchy, and has been successful at shutting down dialogue, the statement has never been scientifically proven. Specifically, there is no evidence that puberty blockers reduce suicide rates in gender dysphoric youth.
3. Females who take testosterone have increased odds of developing heart disease. Other risks include: liver dysfunction, hypertension, vaginal atrophy, menopausal symptoms, and uterine pain. Irreversible masculinizing changes to the female body occurs -- deepening of the voice, facial structure changes, male pattern hair loss, enlargement of the clitoris. Males who take estrogen have increased risks of strokes and blood clots, as well as increased risks of male breast cancer.
4. Mastectomies remove healthy breast tissue from women, which prevents future breastfeeding, and can lead to scarring and permanent nerve damage.
5. Because of the low quality of evidence, no established standard of care for the treatment of youth with gender dysphoria currently exists. The World Professional Association for Transgender Health (WPATH) acknowledges that despite the misleading name, WPATH Standards of Care 7 and recently released 8 are also practice guidelines, not standards of care. Even the Endocrine Society’s guidelines admit that they “cannot guarantee any specific outcome, nor do they establish a standard of care”.

6. In the last 24 months, multiple guidelines have been developed by health authorities worldwide (UK, Sweden, Finland) which are increasingly divergent from US Guidelines regarding who should be treated, how they should be treated, when they should be treated, and whether medical interventions for minors can be ethically initiated outside of clinical trials.
7. Dr. Carl Heneghan, the Editor in Chief of the BMJ-Evidence Based Medicine division has written that the administration of puberty blockers and cross sex hormones to children and adolescents represents an “unregulated live experiment”. Dr. Christopher Gillberg, a Swedish psychiatrist and world’s expert in autism calls the current unregulated administration of puberty blockers and cross-sex hormones to children and adolescents the greatest medical scandal of modern medical times.
8. Unfortunately, the history of medicine has many examples of well-meaning interventions that resulted in widespread pain and suffering because they were not adequately studied prior to their adoption. Thalidomide and the recent opioid epidemic are such examples. Two decades ago, physicians were instructed, against their better judgment, to treat pain as the fifth vital sign and to liberally prescribe opioids. The short-term relief that patients experienced backfired into the biggest medical scandal of modern times, the current the opioid crisis. I, and great many of my physician colleagues are concerned that we are in the midst of a similar or perhaps even greater epidemic of harm directly resulting from physician actions, where there is no consensus as to how to determine medical necessity for treatment within a very large and diverse population of patients. The long-term medical harm at a massive scale will be unavoidable.

Sincerely,

A handwritten signature in black ink that reads "William J. Malone". The signature is written in a cursive, flowing style with a long horizontal stroke at the end.

William Malone, MD

Endocrinologist

COMMENTARY

Time to Hit Pause on 'Pausing' Puberty in Gender-Dysphoric Youth

William Malone, MD

September 17, 2021

Teens are identifying as transgender in record numbers. In 2017, [3-4 in 100 teens in the United States](#) reported that they are or may be transgender. A more recent 2021 study suggests that the rate of transgender identification among America's youth may be as high as [9 in 100](#). All of the major gender centers in the world have reported a several-thousand-percent increase in youth presenting with gender distress.

How do we reconcile these numbers with 2013 [data](#) reporting the prevalence of adult gender dysphoria to be a rare 2-14 in 100,000? Reflection is warranted because many US medical societies support providing youth who have transgender identification (over 1 million children and adolescents, using the latest estimates) with access to powerful endocrine interventions.

GnRH analogues (colloquially known as "puberty blockers") are now available at Tanner stage 2 of puberty — a threshold crossed by females as young as 8-9 years old. Cross-sex hormones and surgeries follow, and mastectomies are now available to children [as young as 13](#). Genital-altering surgeries, as well as the removal of the ovaries, uterus, and testes, can be obtained [as soon as a patient turns 18](#).

What's driving this massive increase in trans-identified youth? What are the risks, benefits, and uncertainties associated with hormonal and surgical interventions? Do such interventions improve the long-term psychological health of gender-dysphoric youth? How many will regret the irreversible changes made to their bodies during what may have been a temporary phase in their development?

We don't know the answers to these questions, but we need to figure them out before offering such interventions. Frontline clinicians — especially those working with youth — will not be able to remain on the sidelines of this issue for much longer. Each clinician considering writing a prescription for puberty blockers or cross-sex hormones, or generating a referral for surgery, will need to answer for themselves: *Just because I can, does it mean I should?*

What's Contributing to the Rapid Rise of Gender-Dysphoric Youth?

The etiology of the rapid rise of transgender identifications in young people is vigorously debated. Proponents of hormonal and surgical interventions for youth argue that the several-thousand-percent increase in the numbers of youth seeking gender reassignment is a reflection of more social acceptance of transgender identities, allowing more young people to "come out." But closer examination of this claim reveals several inconsistencies.

Because [adolescent](#) and young adult females now account for [6-8 in 10 of the presenting cases](#) (previously, prepubertal males were more common), one would expect a commensurate increase in the rate of transgender identification in older females. This has not occurred. In addition, [more than three quarters](#) of currently presenting cases have significant mental health problems or suffer from neurocognitive comorbidities such as [autism spectrum disorder or attention-deficit/hyperactivity disorder](#) — a much higher burden of mental health comorbidities than the historical cohort with gender dysphoria.

There is legitimate concern that these comorbid mental health conditions, as well as the influence of social groups and online immersion into transgender topics, may be playing a role in the rapidly growing rate of transgender identification among these particularly vulnerable youth.

The initial study [positing the theory](#) that social influence is playing a role in the increased incidence of "late" or adolescent-onset (vs childhood-onset) transgender-identified youth was harshly attacked by proponents of medical transitioning of youth, despite the fact that the study utilized [similar methods](#) used in other areas of health research. The study underwent an unprecedented second peer review and emerged with largely unchanged conclusions.

Since the study's publication, a [number of mental health clinicians working directly with gender-distressed youth](#) have corroborated a rapid onset of transgender identification among teens with previously gender-normative childhoods.

Pioneers in Gender Dysphoria Treatment Are Changing Course

Several European countries that were pioneers in pediatric medical transition are now reversing course toward far more caution after their own evidence evaluations failed to show that medically transitioning gender-distressed youth improves mental health outcomes. In Sweden, following [Karolinska Hospital's announcement](#) that it will no longer transition people under 18 outside of strictly regulated clinical trials, a number of other pediatric gender clinics followed suit and [made the same decision](#).

In the UK, Keira Bell — a young woman who was treated with "affirmative" hormonal and surgical interventions before detransitioning — brought a challenge against the national gender clinic. Her landmark case and the [UK High Court's original judgement](#) against the clinic have highlighted the urgency to reassess treatment approaches for the increasingly varied presentations of gender dysphoria in young people. As this article went to press, the UK's national gender clinic [won](#) its appeal against Keira Bell, meaning that doctors there will once again be able to decide whether their patients under 16 can properly consent to puberty blockers. Keira Bell said she is disappointed with this decision and will be seeking permission to appeal to the Supreme Court. She said the medical service had become "politicized," and added: "A global conversation has begun and has been shaped by this case. It has shone a light into the dark corners of a medical scandal that is harming children and harmed me. There is more to be done."

And the UK National Health Service (NHS) has already commissioned an [independent systematic review](#) of data, which concluded that the evidence of benefit of hormonal interventions in gender dysphoric youth is of very low certainty and must be carefully weighed against the risks. An [independent taskforce has also been convened](#) to reassess the country's approach to treating gender dysphoric youth.

Finland has arguably undertaken the biggest change of all. An early adopter of pediatric medical transition, researchers there noticed that adolescents who had mental health struggles at baseline [failed to improve after transition](#). The Finnish national Gender Identity Development services issued [new treatment guidelines in 2020](#) stating that psychotherapy, rather than gender reassignment, should be the first line of treatment for gender-dysphoric youth.

The leadership of America's medical societies have been slower to respond. Last month, the [Society for Evidence-Based Gender Medicine](#) applied to share information about youth gender transitions at the yearly meeting of the American Academy of Pediatrics (AAP). The application was denied without explanation, despite the fact that [80% of rank-and-file pediatricians](#) who voted on AAP resolutions days earlier endorsed a resolution calling for a reassessment of the evidence and more caution regarding gender transitions of minors.

The AAP leadership apparently ignored the resounding support for this resolution, but the clear message from that vote is that frontline pediatricians do not agree with the "one size fits all" approach of automatically affirming gender-distressed youth as transgender and proceeding to gender reassignment.

What We Know and Don't Know

There is now growing evidence that the "gender-affirming" model, based on the unproven assumption that gender reassignment is the best way to help gender-distressed youth, is not living up to its promise. This should not be surprising. Despite more than 50 years of experience with mature adult gender transitions, there is a lack of convincing evidence that transitions improve the psychological functioning of those with gender dysphoria, and studies on regret have been plagued by high dropout rates that prevent meaningful conclusions for practitioners and patients alike. Pediatric transitions are a much more recent phenomenon, with little to no quality data to guide decision-making.

We are witnessing a growing number of [vocal regretters](#) who underwent gender reassignment as teens and young adults under "gender-affirming" care protocols in recent years. A review of [stories on the subreddit r/detrans](#), which counts over 20,000 members (not all are detransitioners, as the forum is open to those fully detransitioned, partially detransitioned, desisted [those who identified as transgender for a period of time in their youth but no longer do], and questioning their transition) is flush with first-hand accounts of regret and should be mandatory reading for any clinician who is considering becoming a prescriber of gender-affirmative care.

Here is a brief outline of what we know — and more importantly, what we don't know — about the practice of medically transitioning minors.

- **Most cases of early childhood-onset gender dysphoria self-resolve.** [Eleven out of 11 studies](#) that followed the trajectory of gender-variant youth show that the most common outcome is natural resolution of gender dysphoria [around or after puberty](#). Among those diagnosed as having gender identity disorder, 67% no longer met the diagnostic criteria as adults; among those subthreshold for diagnosis, [93% were not gender dysphoric](#) as adults. Gender dysphoria in childhood is a far better predictor of future homosexuality than of future trans identity.

- **The future trajectory of people whose transgender identity emerged during or after puberty is entirely unknown.** No one has studied future trajectories of patients whose transgender identity emerged for the first time after the onset of puberty — a previously rare but now increasingly common presentation. Growing numbers of young detransitioners and desisters are precisely from this demographic, suggesting that a transgender identity that emerges in adolescence may not be durable.
- **Social transition does not improve mental health outcomes.** Recent studies show that while socially transitioned children can thrive in the short term, they **do not fare any better** than their non-socially transitioned dysphoric peers. It appears that **peer relations**, not the social transition status, predict mental health in gender-dysphoric children. We don't yet know the long-term trajectories of socially transitioned minors, but **emerging evidence** suggests that they may **be more likely to persist** with gender-related distress rather than outgrow it, as previously observed. This in turn necessitates decades of invasive and risky medical interventions. In fact, the Dutch researchers who pioneered the protocol used to medically transition minors (see Box) **explicitly and strongly discouraged** social transition of children and early adolescents.
- **Nearly 100% of children who begin puberty blockers will proceed to cross-sex hormones and surgeries.** The two main studies that have **evaluated the effects of puberty blockers** on mental health found **no improvements** or **improvements of marginal clinical significance**. Both studies are also at critical risk of bias due to the absence of control groups. **Four additional studies** looking at the mental health effects of puberty blockers were plagued by **design limitations** and also **failed** to show any convincing positive effects on psychological health. However, one effect of puberty blockers has been consistently replicated: **At least four studies show** that **virtually all of the children who start puberty blockers proceed to cross-sex hormones**. This suggests that rather than being a pause button, puberty blockers may serve as the "gas pedal" for gender transition.
- **Most of the long-term health risks are largely unknown.** No long-term studies exist of patients who underwent medical transition as teens or young adults. Therefore, our ability to assess risks vs benefits is limited. Puberty blockers have been demonstrated to **significantly impair bone health**, and it is not clear whether this will result in future osteoporosis. Cross-sex hormones are associated with **roughly 3-5 times the risk for heart attacks and strokes**, though long-term studies are of insufficient quality for accurate risk assessments. Other risks associated with these endocrine interventions will come to light as the practice continues to scale and as young people spend years and decades on these interventions. The risks to fertility are largely unknown, but it is almost certain that if puberty blockers are given at the early stages of puberty and followed by cross-sex hormones, sterility will result.
- **The medical pathway of "affirmative care" rests on a single Dutch study that is not applicable to the current populations of gender-dysphoric youth.** Most of the youth presenting for care today would have been explicitly disqualified by the original Dutch protocol, as most have significant mental health comorbidities and post-puberty onset of trans identities. This fact has been recognized by the principal investigators of the Dutch protocol itself, who have **recently begun to sound the alarm** about the **potential misapplication of their protocol** and who suggest that psychotherapy — rather than gender reassignment — is more appropriate for many of the currently presenting cases.

On Suicidality

The urgency to put gender-dysphoric youth through gender reassignment despite the dearth of evidence appears to stem from the notion that if we don't intervene medically and in short order, these youth will commit suicide. However, studies using quality data reveal a markedly different reality.

While gender-dysphoric youth do have elevated rates of suicidality, it's not uniquely high. In fact, it's **roughly similar** to the rate of suicidality found in populations of youth referred for other mental health conditions. Quality long-term studies that explored whether transition leads to reduced suicidality **have not been able to demonstrate** a reduction.

Medicine has a pattern of enthusiastically embracing unproven medical interventions, only to find out years or decades later that the harms from those interventions outweigh the benefits. We owe it to our patients to be transparent about the limits of our knowledge and the fact that the "affirmative care" pathway is largely irreversible.

When the benefits of an intervention have not been shown to outweigh the risks, medical ethics dictate that such interventions should not occur outside of clinical trials. We must not conflate medical care for gender-dysphoric youth with experimental and risky interventions that are based on low-quality evidence. It's time to hit pause on gender transitions for youth.

A Brief History of the Dutch Protocol

Before the mid-1990s, medical transition was primarily reserved for mature adults. However, noting the "[never-disappearing masculine appearance](#)" of many adult male transitioners, a team of Dutch researchers hypothesized that it might be appropriate to provide early intervention to a carefully selected group of adolescents before the irreversible physical changes of puberty occur.

To differentiate the majority of gender-dysphoric children who would outgrow their cross-sex identification by adulthood from the few who would probably not have resolution and would wish to transition later in life, the Dutch gender clinic designed a [rigorous screening protocol](#), with multidisciplinary teams closely following prospective candidates for several years.

To qualify for early intervention, the adolescents had to have had persistent and severe cross-sex identification from early childhood (cases of adolescent-onset trans identity were disqualified); the distress had to worsen during puberty; and the adolescents had to be free from any other significant mental health conditions. For qualifying adolescents, puberty blockers were initiated no earlier than 12 years of age, cross-sex hormones at 16, and surgeries upon turning 18. Ongoing psychotherapy was provided through the entire assessment and intervention period.

The Dutch team published the [final results](#) of their research in 2014. The authors reported that at the average age of 21 (approximately 1.5 years post-surgery), the young people were free from gender dysphoria and functioning well. Despite a postsurgical death from infection, several new diagnoses of metabolic illness, and multiple dropouts, the Western world enthusiastically embraced the early-intervention model. Concerningly, the only attempt to replicate the Dutch protocol outside of the Netherlands [failed to show any psychological improvements](#), and to date, no long-term outcome data are available for the cohort of the 55 treated Dutch adolescents.

These progressively irreversible interventions form the basis of the "Dutch Protocol." Currently, this protocol is being scaled in ways it was never designed for. For example, it strongly discouraged childhood social transition and did not transition adolescents with postpubertal onset of transgender identity or those with significant mental health comorbidities. Yet, treating such cases with the interventions outlined in the Dutch protocol is now common, and the age of eligibility for hormonal and surgical interventions has progressively lowered, with children as young as 8 now eligible to begin puberty blockers.

LETTER TO THE EDITOR

Puberty blockers for gender dysphoric youth: A lack of sound science

Dear Editor,

The medical transition of children and adolescents with gender dysphoria remains highly debated and there is significant divergence in policy internationally.¹⁻⁷ Mills and colleagues' review the interventions that comprise the "gender-affirmative" care pathway, an approach currently promoted by many medical organizations in North America.⁶⁻⁸ We strongly agree with the authors that pharmacists have a responsibility to "understand the evidence," and "place the well-being of the patient over any personal cultural beliefs."⁸ However, we think the use of evidence to support the authors' claim that gonadotropin releasing hormone (GnRH)-analogs are fully reversible and have been shown to improve mental health, requires critical appraisal.

GnRH-analogs have been used for decades to successfully delay the early onset of puberty in children with precocious puberty.⁹ While generally considered safe for this indication, recent concern about impacts on polycystic ovarian disease, metabolic syndrome, and future bone density, have been raised.¹⁰ Even less is known about the use of GnRH-analogs to halt normally timed puberty in youth with gender dysphoria; no long-term, longitudinal studies of GnRH-analogs for this indication exist.

Puberty-related hormones have wide ranging effects on brain structure, function, and connectivity.¹¹ Concerns have been raised that hormonal suppression of puberty may permanently alter neurodevelopment.^{2,11-13} The possible impact of puberty blockade on a young person's cognition has important implications for the decision to initiate exogenous cross-sex hormones and the capacity to give informed consent.¹⁴ Moreover, it has been suggested that pubertal suppression may alter the course of gender identity development, essentially "locking in" a gender identity that may have reconciled with biological sex during the natural course of puberty.¹³ Over 95% of youth treated with GnRH-analogs go on to receive cross-sex hormones.¹⁵ By contrast, 61-98% of those managed with psychological support alone reconcile their gender identity with their biological sex during puberty.¹⁶⁻¹⁸ This lack of evidence to support the durability of a transgender identification is conceptually consistent with significant psychosocial determinants of cross-sex identity, while the belief in immutable biological influences can best be described as a "current hypothesis."¹⁹

There are also concerns that GnRH-analogs may have irreversible effects on sexual function and bone development. In some youth

pubertal blockade at Tanner stage 2 followed by exogenous cross-sex hormones has resulted in a complete absence of adult sexual function.²⁰ Profound effects on future sexual function may even occur when puberty is paused and later allowed to proceed, since the precise timing of hormone exposure during the peripubertal window is a determinative factor in adult sexual function.²¹ Finally, several studies have found that the expected pattern of bone mass accrual during adolescence does not occur when puberty is halted.²²⁻²⁵ The long-term clinical consequences of failure to accrue normal bone mass are unknown.

Uncertainties about long-term risks of medical transition are often overshadowed by the most potent argument provided by advocates of the affirmative model: failure to affirm a young person's transgender identity may result in suicide. Suicidal ideation and self-harming behaviors have been found to be higher than age-matched peers, but comparable to nongender dysphoric youth referred for management of other mental health diagnoses.²⁶ However, the relevant question is whether affirmative care reduces suicide risk. Mills and colleagues' assertion that GnRH-analogs have been shown to decrease lifetime suicidal ideation stems from a nonrepresentative, low-quality survey of transgender adults that has been thoroughly critiqued by others.^{27,28} Moreover, their claim that these drugs are effective for other mental health outcomes is at odds with recent systematic reviews that concluded there is little change from baseline to follow-up in depression, anxiety, body image, gender dysphoria, or psychosocial functioning.^{2,12,29} A seminal Dutch case-series of children with early-onset gender dysphoria is cited to support the assertion that GnRH-analogs improve psychological functioning.¹⁵ The magnitude of posttreatment improvement in mental health outcomes in this study was small and of questionable clinical significance. Furthermore, the applicability of results to the most common demographic presenting today, that is, adolescent females with pre-existing mental health problems or neurodevelopmental conditions and no prior history of gender dysphoria, is questionable.^{4,30} A recent attempt to replicate the results of the Dutch study in the United Kingdom found no psychological benefit with GnRH-analogs, but treatment was associated with adverse effects on bone development.³¹

Multiple European countries that were pioneers in youth medical transition are now adopting a more cautious approach to the use of

GnRH-analogs and cross-sex hormones after their own evidence reviews failed to show mental health benefits and highlighted a profound lack of knowledge about harms. The UK's Cass review emphasized the paucity of data in their interim report stating, "it is important that it is not assumed that outcomes for, and side effects in, children treated for precocious puberty will necessarily be the same in children or young people with gender dysphoria."¹³ The NHS updated guidance on treatment of gender dysphoria removed statements about the reversibility of GnRH-analogs and now states, "little is known about the long-term side effects of hormone or puberty blockers in children with gender dysphoria."⁴ The Swedish Health Authority no longer offers GnRH-analogs to minors except in exceptional cases stating, "the risks of puberty suppressing treatment with GnRH-analogues and gender affirming hormonal treatment currently outweigh the possible benefits."³ Finland has severely restricted their use and now recommend psychotherapy as first-line treatment for gender-dysphoric youth.² Lastly, the French Académie Nationale de Médecine recently issued a press release stating, "great medical caution must be taken in children and adolescents, given the vulnerability, particularly psychological, of this population and the many undesirable effects, and even serious complications, that some of the available therapies can cause."⁵ Although puberty-blockers and cross-sex hormones will still be available, the Académie emphasized, "the greatest reserve is required in their use, given side effects such as impact on growth, bone fragility, risk of sterility, emotional and intellectual consequences and, for girls, symptoms reminiscent of menopause."⁵

In summary, we believe the authors' review does not present a balanced assessment of the evidence and betrays a bias toward uncritically promoting medical transition. The widespread methodological weaknesses in the research coupled with the lack of certainty that benefits outweigh harms, should raise questions about affirmation being positioned as the "standard of care" in the United States and Canada.²⁹ Patients and their families rely on pharmacists to resist ideological influence and communicate transparently. To this end, we call on Mills and colleagues to revisit their important review and provide a more nuanced discussion of the evidentiary basis for gender-affirming care.

No One Is Born in 'The Wrong Body'

William J. Malone, Colin M. Wright, and Julia D. Robertson

24 Sep 2019

5 min read

The idea that all people have an innate “gender identity” recently has been endorsed by many health-care professionals and mainstream medical organizations. This term commonly is defined to mean the “internal, deeply held” sense of whether one is a man or a woman (or, in the case of children, a boy or a girl), both, or neither. It also has become common to claim that this sense of identity may be reliably articulated by children as young as three years old.

While these claims about gender identity did not attract systematic scrutiny at first, they now have become the subject of criticism from a growing number of scientists, philosophers and health workers. Developmental studies show that young children have only a superficial understanding of sex and gender (at best). For instance, up until age seven, many children often believe that if a boy puts on a dress, he becomes a girl. This gives us reason to doubt whether a coherent concept of gender identity exists *at all* in young children. To such extent as any such identity may exist, the concept relies on stereotypes that encourage the conflation of gender with sex.

However, starting at a young age, children do tend to exhibit preferences and behaviors that we associate with *sex* (as distinct from *gender*). For example, male children display more aggressive behavior than female children. In addition, “cross-sex” behavior—or, more accurately, cross-sex stereotypical behavior—often is predictive of later same-sex attraction.

Can all of these findings be integrated? To start, just as sex influences the development of bodies, it also influences brains. There are in-utero differences in hormone exposures (male testosterone surges at eight weeks gestation, for example), and distinct developmental pathways are triggered based on the XX (typically female) or XY (typically male) chromosomal make-up of neurons. The integration of these sex-related and other developmental processes with environmental pressures gives rise to an individual’s unique personality and preferences.

It comes as no surprise then that population-based studies have demonstrated sex-related differences in personality and preferences that are independent of social influences. When social influences are weakened (in more egalitarian societies such as the Nordic countries of Europe), the sex-related differences in personality and preferences actually increase (the opposite of what one would expect if men and women were wired in an identical fashion). This suggests that as environmental pressures become relaxed, innate sex-specific preferences surface.

A closer look at personality traits shows that when data is analyzed in aggregate, there is a roughly 30% overlap between sexes, as schematized in the accompanying figure. The consequence of this overlap is that adolescent males who fall on the left end of the male (blue “masculine”) curve, and adolescent females who fall on the right end of the female (pink “feminine”) curve, will exhibit personality traits that diverge from the majority of other members of their own sex. In fact, due to the overlap of personality traits between males and females, *the personality traits of some females will be more “male-like” than those exhibited by some, or even most males’ and vice versa.*

In the case of an adolescent female whose behavior, personality traits and preferences are more “masculine” than most girls *and* most boys, she could be led to incorrectly conclude that she is really a male, born in the wrong body. That child’s parents could become confused as well, noticing how “different” their child’s behavior is from their own, or from that of their peers. In reality, that child simply exists at the end of a behavioral spectrum, and “sex-atypical” behavior is part of the natural variation exhibited both within and between the sexes. *Personality and behavior do not define one’s sex.*

There are approximately 40-million children in the United States between the ages of four and fourteen. The distribution curve above would suggest that roughly four-million of them have personality profiles that are “sex atypical,” but which are still part of the natural distribution of personalities within each sex.

The broad, but normal distribution of personality traits also explains studies showing a 28% concordance of transgender identity in twins. Twins have identical chromosomes, and so likely will have similar sex-related behaviors, as well as experience similar environmental influences in regard to those behaviors. Using twin adolescent males as an example: If their behaviors are at the “feminine” end of the male-typical distribution, they could both become confused as to what their behaviors and preferences mean about their sex.

In most cases, the thing that is now called “gender identity” likely is simply an individual’s perception of how their own sex-related and environmentally influenced personality compares to same and opposite sexed people. Put another way, it’s a self-assessment of one’s stereotypical degree of “masculinity” or “femininity,” and it’s wrongly being conflated with biological sex. This conflation stems from a cultural failure to understand the broad distribution of personalities and preferences *within* sexes and the overlap *between* sexes.

When a girl reports that she “feels like a boy” or “is a boy,” that sentiment may reflect her perception of how her personality and preferences compare to the rest of her peers. If the girl has an autism spectrum condition, she may even perceive “sex-atypical” behavior that does not actually exist, and thereby falsely self-diagnose as male even without experiencing any actual male personality traits.

It should be noted that these scenarios don’t apply to all cases of gender dysphoria, as many other triggers are described in the literature. But in most cases, counseling can help gender dysphoric adolescents resolve any trauma or thought processes that have caused them to desire an opposite sexed body.

Historical data suggests that about 0.5% of children develop gender dysphoria—distress caused by a perceived incongruence between one’s biological sex and gender presentation. Reinforcing studies in the medical literature show that, as children get older, childhood-onset gender dysphoria resolves (i.e. ends) in most cases. As two authors put it in a 2016 *International Review of Psychiatry* article, “the conclusion from these studies is that childhood GD [gender dysphoria] is strongly associated with a lesbian, gay or bisexual outcome and that for the majority of the children (85.2%; 270 out of 317 [studied individuals]) the gender dysphoric feelings remitted around or after puberty.”

Yet instead of offering counseling, medical professionals now are commonly telling children that they may have been “born in the wrong body.” This new approach, called “gender affirmation,” makes gender dysphoria less likely to resolve, pushing children down the path toward irreversible medical and surgical interventions. If aggressive transition options are pursued early in puberty, the combination of puberty-blocking drugs, followed by cross sex hormones, will result in permanent infertility.

The growing population of transgender-identifying high school students now is estimated to comprise about 2% of all students—a three-fold increase over the baseline 0.5% figure cited above. Many adolescents now are presenting to gender clinics, with some clinics seeing a 10-fold increase in new cases. Many of these adolescents have no history of childhood gender dysphoria. Higher rates of autism-spectrum conditions have been described in many of these adolescents, and the controversial “affirmation model” is being applied to this unstudied cohort as well. Not surprisingly, reports of transition regret, and de-transition, are growing in number.

To summarize, a lack of understanding regarding the distribution of sex-related personality and behavioral differences has led to confusion that impacts children who fall at the extreme tail-ends of the distribution, and who would be statistically more likely to grow up to be gay, lesbian or bisexual adults if allowed to experience uninterrupted puberty. Additionally, telling a child that he or she was born in the wrong body pathologizes “gender non-conforming” behavior and makes gender dysphoria less likely to resolve.

The fact is, *no child is actually born in the wrong body*. Adults should expand their understanding of what normal male and female behavior and preferences look like—which would lead them to appreciate that being male or female comes with a wider range of personalities preferences, and possibilities than old stereotypes would have us believe.

ORCID numbers: 0000-0001-6849-7285 (M. K. Laidlaw); 0000-0003-2831-6480 (Q. L. Van Meter); 0000-0002-1478-3355 (P. W. Hruz); 0000-0001-8678-0025 (A. Van Mol); 0000-0002-5150-292X (W. J. Malone).

Childhood gender dysphoria (GD) is not an endocrine condition, but it becomes one through iatrogenic puberty blockade (PB) and high-dose cross-sex (HDCS) hormones. The consequences of this gender-affirmative therapy (GAT) are not trivial and include potential sterility, sexual dysfunction, thromboembolic and cardiovascular disease, and malignancy (1, 2).

There are no laboratory, imaging, or other objective tests to diagnose a "true transgender" child. Children with GD will outgrow this condition in 61% to 98% of cases by adulthood (3). There is currently no way to predict who will desist and who will remain dysphoric. The degree to which GAT has contributed to the rapidly increasing prevalence of GD in children is unknown. The recent phenomenon of teenage girls suddenly developing GD (rapid onset GD) without prior history through social contagion is particularly concerning (4).

GnRH agonists are used in precocious puberty to delay the abnormally early onset of puberty to a physiologically normal age. The goal of PB in the healthy child, however, is to induce hypogonadotropic hypogonadism to "buy time" to confirm gender incongruence. In a study of PB in adolescents aged 11 to 17 years, 100% desired to continue GAT. They simply "bought" themselves lower bone density and the need for lifelong medical therapy (5).

Studies show that <5% of adolescents receiving GAT even attempt fertility preservation (6). Those started on PB at

Tanner stage II, as recommended by current guidelines, will be blocked prior to sperm maturation and ovum release. They will have no prospect of biological offspring while on HDCS hormones and continuing on to gonadectomy.

The Endocrine Society's guidelines recommend elevating females' testosterone levels from a normal of 10 to 50 ng/dL to 300 to 1000 ng/dL, values typically found with androgen-secreting tumors. The ovaries of women given testosterone correspond to those found in PCOS, which itself is associated with increased ovarian cancer risk and metabolic abnormalities (1). Venous thromboembolism risk is elevated fivefold in males taking estrogen (2).

The health consequences of GAT are highly detrimental, the stated quality of evidence in the guidelines is low, and diagnostic certainty is poor. Furthermore, limited long-term outcome data fail to demonstrate long-term success in suicide prevention (7). How can a child, adolescent, or even parent provide genuine consent to such a treatment? How can the physician ethically administer GAT knowing that a significant number of patients will be irreversibly harmed?

Hypothesis-driven randomized controlled clinical trials are needed to establish and validate the safety and efficacy of alternate treatment approaches for this vulnerable patient population. Existing care models based on

psychological therapy have been shown to alleviate GD in children, thus avoiding the radical changes and health risks of GAT (8). This is an obvious and preferred therapy, as it does the least harm with the most benefit.

In our opinion, physicians need to start examining GAT through the objective eye of the scientist-clinician rather than the ideological lens of the social activist. Far more children with gender dysphoria will ultimately be helped by this approach.

We agree with Walch et al that medical treatments should be based on scientific evidence rather than becoming political matters (1). However, Walch et al endorse a position statement by the Endocrine Society (ES) that is unsupported by the available evidence.

Walch et al endorse the ES position that puberty suppression (PS), cross-sex hormones (CSH), and surgeries are “effective,” “relatively safe,” and have been “established as the standard of care” (2). However, the ES clearly states that its practice guidelines “cannot guarantee any specific outcome, nor do they establish a standard of care” (3). The World Professional Organization for Transgender Health (WPATH) also acknowledges that despite the misleading name, WPATH Standards of Care 7 are also *practice guidelines*, not standards of care (4). Unlike standards of care, which should be authoritative, unbiased consensus positions designed to produce optimal outcomes, practice guidelines are suggestions or recommendations to improve care that, depending on their sponsor, may be biased. In addition, the ES claim of effectiveness of these interventions is at odds with several systematic reviews, including a recent Cochrane review of evidence (5), and a now corrected population-based study that found no evidence that hormones or surgery improve long-term psychological well-being (6). Lastly, the claim of relative safety of these interventions ignores the growing body of evidence of adverse effects on bone growth, cardiovascular health, and fertility, as well as transition regret.

Walch et al also endorse the ES position, claiming there is an established “durable biological underpinning” to gender identity (GI) (2). However, the first citation supplied by the ES for this position highlights contradictory studies and describes the biological origin of gender dysphoria

(GD) as simply a “current hypothesis” (7). The other citation describes GI as a “complex interplay of biological, environmental, and cultural factors” (8). Further, the concept of “durability” is challenged by the fact that most cases of GD in children naturally resolve by adulthood. It is precisely this lack of durability that should give pause to administering potentially harmful and often irreversible medical interventions to young patients with GD.

The ES position statement also overlooks a key fact that the existing body of evidence regarding treatment outcomes for GD was not only graded as “low quality,” but has been derived from a vastly different population than the one presenting with GD today. Currently, GD predominantly presents in adolescent females with no childhood history, in contrast to the prior predominantly male and childhood-onset GD presentation. It is not yet known whether this novel patient segment, which remains poorly understood and largely unstudied, will benefit or be harmed by hormonal and surgical interventions.

We concur with the 3rd ES position calling for more research. However, we are concerned that bias and politicization are preventing an honest scientific debate about interventions that carry lifelong implications for young people. There is a need for increased funding not only to better understand the natural history of this condition and its sharp increase in adolescent females, but also to help determine the optimal care of youth with GD.

In less than a decade, there has been a sharp rise in the numbers of young people presenting with gender dysphoria (GD). Today, the majority are adolescents, many with post-puberty adolescent-onset transgender histories, and suffering from mental health and neurodevelopmental comorbidities (De Vries, 2020; Zucker, 2019). Furthermore, there is controversy and heated debate in the literature on this topic (Dubicka, 2021). This lack of scientific consensus highlights the need for any published literature on the topic of GD to be carefully evaluated.

In this commentary, we critically examine a systematic review of the evidence for puberty blockers for GD youth that was recently published in this journal (Rew, Young, Monge, & Bogucka, 2021). Our aim is to highlight problems with this review that compromise its findings and conclusions.

Brief description of Rew et al.'s (2021) study

Rew et al. described undertaking a "critical" and "systematic" literature review on the topic of puberty blockers for GD youth. They identified nine studies for review and, on the basis of these, concluded that puberty blockers have "few serious adverse outcomes," and "several potential positive ones." Rew et al.'s abstract highlighted two key conclusions: the "potentially life-saving benefits" of puberty blockers; and a need for rigorous research. Their "implications," "conclusion," and "key practitioner message" sections appeared to claim that the literature supports the use of puberty blockers for the early puberty subgroup of GD youth.

Overview of our concerns

We agree with Rew et al.'s conclusion that more rigorous research is required in the area of management of GD in youth. However, in our view, their review suffers from methodological oversights, including the omission of relevant studies and suboptimal analysis of the quality of the included studies. As a result, the authors overstate the certainty of the potential positive outcomes and minimize the potential adverse outcomes of puberty blockers. Importantly, their statement, that a "positive

outcome" of puberty blockers is "decreased suicidality in adulthood," is a misinterpretation of a single cross-sectional study. This study's design was incapable of determining causation, and adult suicidality was not one of the measured outcomes (Turban, King, Carswell, & Keuroghlian, 2020).

Contrast Rew et al.'s (2021) conclusions with another recently completed systematic review of puberty blockers for GD youth, commissioned by England's NHS and conducted by The National Institute for Health and Care Excellence (NICE) (2020). The NICE review concluded that studies investigating the benefits or adverse effects of GnRH analogs (puberty blockers) were of "very low certainty using modified GRADE." They noted that any outcome differences that were found could have represented changes of "questionable clinical value," or, as the studies themselves were "not reliable," could have been "due to confounding, bias or chance." They suggest that if controlled studies are not possible, then reliable comparative studies are required.

These findings came just after NHS England suspended the use of puberty blockers for new patients under the age of 16, following the High Court's judgment that children so young could not consent to the unknown risks of these drugs. The Karolinska Institute in Sweden suspended the use of puberty blockers as treatment for GD youth outside of clinical trials following this review, citing multiple physical risks, including to bone development (Nainggolan, 2021). Finland also sharply curtailed the use of these drugs after their systematic review arrived at similar conclusions about the uncertain risk/benefit profile (COHERE, 2020).

We are concerned that Rew et al.'s review will mislead clinicians unfamiliar with the literature into prescribing puberty blockers to GD youth with confidence, when the only clinical stance supported by the evidence is that of extreme caution. This is also underscored by the fact that the research literature in this field is rapidly evolving. For example, a recently published study, that attempted to demonstrate the benefits of the Dutch puberty suppression protocol in the UK setting, failed to show any psychological benefit (Carmichael et al., 2021).

Limitations in study selection strategy

The review published by Rew et al. has important limitations that compromise its usefulness for clinical decision-making. Rew et al. identified only 151 potentially eligible studies, while the NICE review found 525 studies. One possible explanation for this could be their limited study search strategy. Another possible explanation is that Rew et al. did not conduct a comprehensive search so that, in omitting one of the largest electronic databases—EMBASE, they may have overlooked relevant evidence.

Notably, the final set of nine studies reviewed by Rew et al. is missing at least one key study on puberty blockers and psychosocial functioning (Costa et al., 2015), and two other studies examining the risks of puberty blockers on bone density (Joseph, Ting, & Butler, 2019; Klink, Caris, Heijboer, van Trotsenburg, & Rotteveel, 2015). It is unclear to us whether these studies were omitted due to the limited database search or whether the evaluators decided to exclude these studies, and if so for what reason. These three studies were all included in the NICE (2020) review. Although it has to be kept in mind that all the NICE reviewed studies' findings were assessed as "very low certainty," the Costa et al. study provided comparative evidence and found no significant difference in psychosocial functioning between a group of adolescents receiving puberty blockers plus psychosocial support, and a group receiving only psychosocial support, at eighteen months (the study end period) (Biggs, 2019). In addition, the Costa study was cited by the Finnish gender identity services in their policy change, which now recommends psychotherapy alone as first-line treatment.

Failure to adequately assess certainty of the study findings

It is our contention that the reviewers did not adequately assess the certainty of the reviewed studies' findings. For example, they used the Joanna Briggs Institute checklist to assess Turban et al. (2020), the study from which their message that puberty blockers reduce adult suicidality and have "potentially life-saving benefits" derives. This checklist can overemphasize whether studies report information and underemphasize the assessment of study validity. Below, we show how Rew et al. applied this tool to Turban et al. (2020), and the important study limitations it overlooked.

Was the exposure measured in a valid and reliable way? (Q3) Rew et al. answered "yes" to this question. We believe it should be "no." The exposure to puberty blockers was based on a self-report, with 73% of those respondents, who answered yes, claiming they began to use puberty blockers after the age of 18. It was noted that the respondents likely confused puberty blockers with other hormonal interventions (Biggs, 2020; D'Angelo et al., 2020). Although Turban et al. attempted to reduce the effects of this confusion by excluding certain participants from the sample, no adequate correction was possible. This introduced a significant risk of bias.

Were confounding factors identified and strategies to deal with them stated? (Q5, Q6) Rew et al. answered "yes" to both questions. We believe the answer to the latter question should be "no." For example, while one key confounding factor—prior mental health status—was indeed correctly identified by Turban et al., no strategy

was articulated to deal with it. When discussing their finding that puberty suppression is associated with lower lifetime suicidality, they acknowledged that "reverse causation cannot be ruled out: it is plausible that those without suicidal ideation had better mental health when seeking care and thus were more likely to be considered eligible for pubertal suppression" (Turban et al., 2020). This is one of the most serious limitations of the study, introducing a high risk of bias, and reducing the certainty of the findings.

In addition, while two questions ask about the subject selection criteria and whether the subjects and the setting were described in detail (Q1, Q2), these questions do not attempt to assess the impact of the sample composition. Affirmative ("yes") and "not applicable" answers to these questions, respectively, masked the fact that the study participants were not required to have a diagnosis of GD, and that the participant demographics were markedly different from the US population of transgender adults (D'Angelo et al., 2020), which negatively impacts the study's applicability/generalizability.

Rew et al. aggregated the answers to the checklist questions, with the Turban et al.'s study earning an 86% mark and a "good quality" rating. Even if we sideline the issue of any scoring inaccuracy, using such a simplistic scoring category is misleading since it implies that all questions are equally important, which is clearly not the case.

We also note, what appears to be, at least one error in Rew et al.'s assessment and reporting of study outcomes. In Table 2, they reported that Turban et al.'s positive outcome findings included decreased past-month psychological distress, past-month binge drinking, and lifetime illicit drug use. However, Turban et al.'s univariate analysis showed only one of these three outcomes, past-month psychological distress, showed any significant difference, and this significance disappeared once demographic variables were controlled for in the multivariable analysis.

A more rigorous tool to assess Turban et al.'s study would be ROBINS-I (The Risk of Bias of Non-randomized Studies of Interventions) (Sterne et al., 2016). This tool focuses on confounding, selection bias, classification and deviations from intervention, measurement of outcome, missing data, and selective reporting, and the extent to which the study design minimized biases and yielded trustworthy results. Given this, applying the ROBINS-I tool would find that the Turban et al.'s study is at a critical risk of bias.

Misleading statements regarding puberty blockers and suicidality

We are concerned that Rew et al.'s discussion of evidence about suicidality is unbalanced and misleading. Reading that puberty blockers had "positive outcomes [of] decreased suicidality in adulthood" will likely be understood as indicating causation. However, Turban et al. (2020), where this claim originates, noted that their study design did not allow for determination of causation, and "reverse causation" (individuals without suicidal ideation had better mental health and were more likely to be considered eligible for puberty blockers) was a plausible alternative explanation.

Further, there is a critical difference in meaning between "lifetime," and "adulthood." Not only does the

latter erroneously imply a pre-post effect (i.e., access to puberty blockers in childhood reduces suicidality in adults), which was not detectable in the study, but a measure of “adulthood suicidality,” which Rew et al. claim was impacted, was never included in the original study (Turban et al., 2020).

There is also unclear use of the term suicidality, which exaggerates the implication of Turban et al.’s findings. Suicidality is a broad term, which is comprised of suicide attempts, plans, and ideation, and indeed this was the manner it was used by Turban et al. It is also important to note that Turban et al. made no assessment of completed suicides. Turban et al. assessed six areas of suicidality (including recent and lifetime suicide attempts, recent ideation with plans, recent and lifetime ideation) and found no association between puberty blockers and suicidality measures on five of the six areas. The only association was with “lifetime suicidal ideation.” Of course, any suicidal ideation is concerning, but suicide attempts are generally considered of higher concern, in terms of suicide risk assessment, than suicidal ideation (Ryan & Oquendo, 2020).

Rew et al.’s inaccurate language further intensifies in the final sentence of their abstract, which described puberty blockers as “potentially life-saving.” This exaggerated claim is misleading, since there is no evidence to support it.

Absence of an appropriate process for making clinical recommendations

Finally, the authors appear to recommend the use of puberty blockers in the “key practitioner messages” box and in the “implications” section of their paper. Making recommendations requires not only evidence about benefits and harms on all health outcomes that are important for decision-making (which this review provides in a suboptimal way), but also considerations about patients values and preferences, ethics, acceptability, resources, costs, etc. (Andrews et al., 2013). All these considerations are balanced by making value judgments, which should be documented and reported explicitly and transparently. Rew et al. failed to do this, which, in our view, further undermines the credibility of their clinical practice recommendations.

Clinician reflections on the state of the GD literature

Rew et al.’s review illustrates a concerning trend, that we have observed in the GD literature, to overstate the evidence underpinning clinical practice recommendations for youth with GD. New publications reference prior ones with increasing and unwarranted confidence, and with the risk of misleading clinicians regarding the state of evidence. There is also a marked asymmetry in outcomes reporting: findings of positive outcomes of medical interventions are trumpeted in abstracts, while their profound limitations remain behind the paywall, thus, below the radar of busy clinicians.

Rew et al.’s paper demonstrates these types of issues. To start, the Turban et al.’s paper described a noncausal association between puberty blockers and “lifetime suicidal ideation,” carefully avoiding making a causal claim (although, arguably, implying it). Then, Rew et al., whose findings on suicidality are based solely on this Turban et al.’ study, rewrite this finding to create the strong

impression of causality—that puberty blockers reduce adult suicidality and are “potentially life-saving.” Subsequently, a recent Commentary and Editorial in the *Lancet* both directly state that puberty blockers reduce suicidality, and the latter adds the extraordinary claim that “removing these treatments is to deny life.” The only reference provided for these claims is the Rew et al. (2021) paper (Baams, 2021; *Lancet* editorial, 2021).

This resembles the game of “Telephone,” in which a message is whispered from person to person distorting the original meaning of the message. However, this is not a game, and these types of errors can cause harm. Clinicians relying on Rew et al.’s review are likely to misinform patients and families about the risk/benefit profile of puberty blockers. Can such patients really be considered as giving informed consent?

The clear signals emerging from the various reviews of the available evidence of the use of puberty blockers for GD youth are that there is very low certainty of the benefits of puberty blockers, an unknown risk of harm and there is need for more rigorous research. The clinically prudent thing to do, if we aim to “first, do no harm,” is proceed with extreme caution, especially given the rapidly rising case numbers and novel GD presentations. We must also, collectively, raise the bar on the quality of publications, in order to accurately educate clinicians and help patients make truly informed decisions that may impact for the rest of their lives.

Acknowledgements

The study received no external funding. Open Access fees were provided by the Society for Evidence-Based Gender Medicine. We would also like to thank the Society for Evidence-based Gender Medicine (SEGM) for providing access to several experts who helped shape this commentary and ensure its accuracy. Specifically, we would like to thank Dr. Romina Brignardello Petersen for contributing her methodological expertise; Dr. Michael Biggs for reviewing the accuracy of the claims relating to puberty blockers and suicidality made in this review, as well as relating to the developments in the United Kingdom; and to Ema Syrunik for her help with the preparation of this manuscript. The authors have declared that they have no competing or potential conflicts of interest.

Accepted for publication: 10 September 2021

The Karolinska Institute in Sweden, long considered gold-standard in providing transgender health care, no longer uses puberty blockers;⁶ nor does Finland promote their use.⁷ Additionally, a judicial review in the UK found puberty blockers to be an inappropriate option for most children younger than 16 years.⁸

We urge *The Lancet Child & Adolescent Health* to take this opportunity to engage with this issue, rather than publishing, in our opinion, inaccurate and careless Editorials.

We declare no competing interests.

Puberty blockers for gender dysphoria: the science is far from settled

The Editorial in *The Lancet Child & Adolescent Health*¹ stated that trans youth “have the same right to health and wellbeing as all humans”. However, what constitutes good health care for this population is far from clear based on the available evidence.

From the Editorial¹ and Baams' related Comment,² readers might perceive that administering gonadotropin hormone-releasing hormone (GnRH) analogues (also known as puberty blockers) to young people with gender dysphoria is a proven, life-saving treatment akin to giving insulin to type 1 diabetics. Baams' assertion that puberty blockers prevent suicidality can be traced to a paper by Turban and colleagues,³ which has been thoroughly critiqued by others,⁴ so instead we ask: what is the evidence that the benefits of puberty blockers outweigh the harms?

The statement that puberty blockers improve the mental health of young people with gender dysphoria stems from a seminal study by de Vries and colleagues in 2011.⁵ However, the population studied—ie, youth with gender dysphoria beginning in early childhood and no significant co-occurring mental health difficulties—markedly differs from the population today, which is characterised by post-pubescent young people reporting a trans identity for the first time, often in the context of significant mental health problems. This difference raises the question of whether this study is still applicable to the majority of currently presenting cases.⁶

Further, the magnitude of the post-treatment improvements in mental health was small. The depression (Beck Depression Inventory) scores

improved by around 3 out of 63 points, and the global function (Children's Global Assessment Scale) scores improved by around 4 out of 100 points, and other measures of psychological health had similar improvements of marginal clinical significance—or no improvement at all.⁵ Such modest gains have to be carefully weighed against the risks of puberty blockers to bone health and fertility, and the uncertainty of the long-term health effects of interrupting puberty.

The absence of a control group in de Vries's study⁵ made it impossible to determine whether the reported psychological improvements were related to the medical interventions or the psychological interventions that all study participants received (or other factors, such as time). A study of 14 young people with gender dysphoria who were rejected from puberty suppression due to “psychological or environmental factors” found that at follow-up 1–7 years after the original application, 11 of 14 did not feel any regret about not undergoing gender confirmation.⁷ This result is significant, because most youth who receive puberty blockers proceed to the full medical protocol of gender-affirming care; for example, one UK study⁷ showed that 43 (98%) of 44 patients aged 12–15 years proceeded to start hormone therapy after 3 years of taking puberty blockers. This same study, which to date is the only attempt to replicate de Vries and colleagues,⁵ found “no evidence of change in psychological function with GnRHa treatment”, including measures of distress and self-harm.⁸

There is growing acknowledgment worldwide that the practice of providing gender-affirming care for youth is far from settled science.⁹ A systematic review by UK's National Institute for Health and Care Excellence found that in youth with gender dysphoria there was “little change with GnRH analogues from baseline to

follow-up” in gender dysphoria, mental health, body image, and psychosocial impact. The study concluded that the reported psychological improvements are “either of questionable clinical value, or the studies themselves are not reliable and changes could be due to confounding, bias or chance”.¹⁰

All authors are board members of the Society for Evidence Based Gender Medicine. ME was a witness in the Keira Bell judicial review; his wife Susan Evans initiated the review and was a witness. Neither received any financial benefit from involvement in the case.

I am yet another mom with daughter who declared Transgender identity after medical trauma, covid isolation, excessive time online and followed a group of other girls who identify as such as well.

This has been two years and my fear is as she turns 18 she will freely dangerous and harmful medicalization.

Please hear parents voices as the transgender activists are more powerful and stronger.

Our kids need more mental health assistance and not affirmation. These kids need help mental health not medicalization.

Thank you.

Dear Mr. Vazquez and Board of Health,

I am writing regarding the efforts being taken to protect children, adolescents and vulnerable people from the one size fits all approach of affirmative care. I am a married mother (lesbian) and my wife and I are parents.

During the pandemic one of our children, 13, began to struggle with depression and announced a transgender identity. It was very challenging to find appropriate care for our son. We were fortunate that his pediatrician and psychologist were very experienced but it was obvious that they felt they could not be straight forward with us after our son announced a trans identity. Interpreting advice from these medical professionals was akin to communicating in a foreign language. However, they did make clear to my son they did not believe he should rush into transitioning. Neither doctor encouraged my son to socially transition or visit a gender clinic. Our son, however, was adamant that transitioning was what he needed to do, and that his life depended on it.

The school, operating on guidelines developed in conjunction with a local children's hospital, affirmed our son's transgender identity. We didn't know until months later that our child had been presenting as a girl at school and had changed his name and gender. When we contacted the school, they were operating in the dark regarding our son's mental health status. They agreed to revert to referring to our son by his birth name.

A couple of months later, roughly 2 years after announcing a transgender identity, our son quietly and suddenly told us he no longer saw himself as transgender. It is now 9 months later and our son continues to present as a young man. The last nine months have been challenging. As my son's depression improved he realized he pushed friendships away and spent his early high school years believing he was a trans girl. Returning to school where he presented as a girl has been deeply embarrassing. To say that we have been concerned would be an extreme understatement. What the school did in implementing a social transition without our knowledge endangered our son's life.

Social and medical transition, with children and teens should not be rushed.

What if we had taken our son to a gender clinic?

What if he had been put on a puberty blocker?

What if the school had continued to use my son's preferred name?

What if, instead of waiting patiently, we had followed our young teen's lead?

Teenagers should not be diagnosing themselves as having gender dysphoria and embarking on lifelong, irreversible changes. I truly hope knowledge of child and adolescent psychology and common sense drive the board's decision making process, and that Florida leads our nation in protecting gender distressed youth from harm.

Sincerely,

Amy Pellini

Good Afternoon

My name is Ritchie, I'm a detransitioner and I would like to have my testimony registered for the upcoming Florida Board hearing on 30/09/2022.

I would be grateful if you could acknowledge receipt of this.

Warm regards,

R.T Herron

<https://twitter.com/TullipR>

Written Testimony for the Florida Board of Medicine

Richard Trevor Herron 16/09/2022

Testimony

My name is Ritchie, I'm 35 years old and live in the United Kingdom, I represent a large group of male detransitioners whose voices have until now, been left unheard in the matter of Gender affirmation.

In 2014, despite having serious mental health issues, under the care of the United Kingdoms Gender Identity Clinics, I transitioned into a female identity at the age of 26. I adopted a woman's name, took an anti-androgen known as Zoladex Goserelin. I would later take Estradiol, a feminising cross sex hormone.

In 2018 I underwent major surgery called a penile inversion with scrotal graft. I had not initially intended to have surgery, I was unsure and weary. I quizzed medical professionals, they reassured me that complications were extremely rare but what I would be getting would more or less mimic a natal female's vagina.

I refused the surgery multiple times, putting it on hold until eventually being driven in 2017 to agree to be referred. During this time, multiple alarms were raised due to the state of my mental health and wellbeing. I had severe mental health issues and was abusing substances.

Despite this, I was permitted to have surgery and during which I experienced severe blood loss (1600ml), resulting in a blood transfusion days after surgery. My suture popped open days after surgery, which has left a gaping scar near the site. Inside, the passage way is narrow and numb, with only the prostate allowing partial pleasure. Climax is possible with great difficulty, however with a partner it is almost impossible due to the angle, structure and narrowness. Additionally, I left the hospital with a catheter and have been experiencing severe urethral constriction, which now requires constant medical attention.

Not long after surgery, I experienced intense regret. I blamed myself at first, then began bringing it up with the Gender Clinic, where instead of my regret being listened too, I was coached to believe this was a response to anaesthetic and related to my mental health rather than actual regret.

My trans identity was not up for question, it was a predesignated certainty and the idea of regret was constantly challenged and blamed on an obsessive compulsive rumination. I was then referred for treatment for Obsessive Compulsive Disorder, as they believed I was not experiencing regret but was instead suffering from a new manifestation of OCD.

Now years later, I continue to deal with incontinence and pain. My sexual function is but a fraction of what it was before transition. Even if I had not experienced those complications, the hormones have left me without a sex drive, low energy and short term memory loss.

As an adult, I am left ruined and shattered, with only myself to pick up the pieces. In doing so I have met with many 100's of others online who share the same reality, and the most concerning theme is; the younger a person starts hormones and has surgery; the worse the impact on wellbeing and health. I do not presume this is everyone's experience, but it is an experience that deserves to be heard. There are a sea of silent voices who are too ashamed to speak out, out of fear of losing their community, friends and being further socially alienated.

Many of us, myself included come from single parent households, experience varying degrees of autism and ADHD, OCD and experience major depressive, anxiety and cluster b personality disorders such as unstable personality and bipolar disorder. These issues were used as evidence of our trans status, but in reality, these are evidence of poor mental health. They are never resolved, but instead intensify with hormones and surgeries.

Whether the amount of people similar like me is low or not, irreversible damage is occurring under the name of medical care and it is your duty to ensure no harm is being done.

I hope the correct decisions are made.

Yours faithfully,

R.T Herron

"The State of Florida's Medical Board is meeting in a few days to discuss a new rule about "affirmative care." There is a good chance that this medical board will move to restrict these interventions in order to safeguard youth from harm.

I write to you to share my first hand experience for you to consider when weighing this issue.

I have seen first hand just how social contagion works with kids choosing gender dysphoria as a way to express their distress, in the same way that for example anorexia was spread through social contagion in the 90s. My daughter entered a school with a lot of trans kids and adopted a trans identity over the course of a week, and then we discovered she had been consuming the content of "trans influencers" online via social media during the pandemic. There was no "authentic self" blossoming - it was a mix of social pressure, confusion around puberty, questions around sexual preferences (is she gay? does that mean she has to be a man ?) and a cry for help around anxiety.

I reject the new gender ideology that is based on restrictive stereotypes and tells girls that if they are 'tomboys' they need to cut their breasts off, take testosterone and become infertile, and become men. My daughter was sucked into this ideology and her school were her cheerleaders, changing her pronouns and addressing her with a male name without our knowledge.

Like many kids, she has come out of her gender dysphoria now, thank goodness with her healthy body intact. Many kids aren't so lucky and there

is a huge industry waiting in the wings to make \$\$\$\$ off of these vulnerable kids. Schools are well intentioned but teachers are not licensed or trained to accompany children in this profound identity shift that is taking on a different gender. A gender doctor in BC Canada announces proudly that most of his 'clients' are kids who have come through the foster care system. A disproportionate number of these kids are neurodiverse.

I support the right of adults to change their gender identities but we have to acknowledge there is something going on here, with something like a 500% increase in young women now identifying as trans. Social media and the presence of trans activists promoting the ideology - and the interventions - is a huge part of this. As is this well meaning "inclusiveness" wave in schools and teaching kids they can choose their gender. We should be teaching them they can be whoever they want without having to change their gender. Let's expand the definitions of being a girl . I celebrate girls !

In the UK they have closed the Tavistock Gender Clinic and the lawsuits are beginning - young people whose bodies were changed without any deeper psychological analysis, who now want their breasts back, or their testicles, or their fertility. Canada where I live is behind the curve on this issue.

I submit my comments in support of a slow and cautious approach that leaves medicalization out of the equation. Gender Dysphoria is a genuine mental health condition which requires kind, listening mental health support, not "affirmation" and medicalisation.

Best regards ,

Alison Murray

Dear Paul A. Vazquez, J.D., Executive Director Florida Board of Medicine,

I am a parent of a 14 year old girl who identifies as transgender. I very much hope that the Florida Board of Medicine will lead the way on pushing back against gender affirmative care and am providing **comments in support of a slow and cautious approach that leaves medicalization out of the equation.**

Our daughter is not transgender: she is a natural tomboy who has recently latched on to this identity, as have several of her friends. I fully believe that if we did not live in the grip of gender ideology (which has infected our schools in California) my daughter would still identify as a girl and I would not be writing this letter. There are, after all, many ways to be a girl.

I was trained as a biological scientist and have been stunned by many people's willingness to actively deny the reality of biological differences between the sexes. I am adamantly opposed to the gender affirmation model and to the medicalization youth experiencing this condition. These models of diagnosis and treatment are not based on science or ethics and do not consider the long term health of this new trans-identifying population of teenage girls, many of whom are becoming collateral damage in the culture wars.

The UK recently commissioned a highly distinguished public health and pediatric expert, Dr. Hilary Cass, to reconsider the affirmative model. I grew up in the UK and while I've lived all my adult life in the US and am a US citizen, I continue to pay close attention to developments there and believe the US can learn from a recent report called the Cass Review interim report.

Please consider with care its findings, summarized below along with some relevant background.

What is the Cass Review interim report?

The Cass Review is an Independent Review of Gender Identity Services for Children and Young People. It was 'commissioned by NHS England and NHS Improvement in Autumn 2020 to make recommendations about the services provided by the NHS to children and young people who are questioning their gender identity or experiencing gender incongruence [1].' In March 2022, the Cass Review submitted an interim report to NHS England. This interim report '[set] out [the] work to date, what [had] been learnt so far and the approach going forward [2].'

Who is Dr. Hilary Cass?

Dr Hilary Cass was appointed by NHS England and NHS Improvement to chair the Independent Review of Gender Identity Services for children and young people in late 2020.

A former President of the Royal College of Paediatrics and Child Health from 2012-2015, Dr Cass recently finished a term as Chair of the British Academy of Childhood Disability (2017-2020).

Although retired from clinical practice, she remains an honorary Consultant Paediatrician at Evelina London Children's Hospital, Guy's & St Thomas's NHS Foundation Trust, where she was also previously Director of Education and Workforce.

Dr Cass is currently Chair of Together for Short Lives, and a Trustee for Noah's Ark Children's Hospice. She is also leading work on how to address the challenges for both families and professionals in supporting the rising numbers of children with complex medical conditions and disability.

Other recent roles include acting as the Senior Clinical Advisor for Child Health for Health Education England.

Prior to this Dr Cass held a range of senior education and management roles in NHS hospital trusts and was previously Head of School of Paediatrics in London. Her consultant clinical practice was as a tertiary neurodisability consultant from 1992 to 2018 in three very different specialist centres and she has published widely in this area.

In addition to her neurodisability practice, Dr Cass was closely involved in the development of paediatric palliative care services at Evelina London Children's Hospital.

Dr Cass was awarded the OBE for services to child health in 2015. She was also awarded an honorary fellowship by the Royal College of Nursing in 2015, and by RCGP in 2016.

Background

The United Kingdom has seen a significant increase in the number of children seeking help for distress in relation to their biological sex. Many school staff first started noticing the phenomenon of children – predominantly teenaged girls – wanting to change sex during the last decade.

In recent years, there has been a significant increase in the number of referrals to the Gender Identity Development Service (GIDS) at the Tavistock and Portman NHS Foundation Trust (para. 1.1).

From a baseline of approximately 50 referrals per annum in 2009, there was a steep increase from 2014-15, and at the time of the CQC inspection of the Tavistock and Portman NHS Foundation Trust in October 2020 there were 2,500 children and young people being referred per annum, 4,600 children and young people on the waiting list, and a waiting time of over two years to first appointment (para 3.10).

This surge in children seeking help for distress in relation to their sex is occurring in the context of an ongoing public debate around issues relating to sex, gender and gender identity.

Over the last few years, broader discussions about transgender issues have been played out in public, with discussions becoming increasingly polarised and adversarial. This polarisation is such that it undermines safe debate and creates difficulties in building consensus (para. 2.4).

No consensus

This being a new phenomenon, research is limited and no consensus exists (within the scientific community) about possible causes and most appropriate treatment options.

At primary, secondary and specialist level, there is a lack of agreement, and in many instances a lack of open discussion, about the extent to which gender incongruence in childhood and adolescence can be an inherent and immutable phenomenon for which transition is the best option for the individual (para. 1.7).

We must secure a balanced treatment of political issues, they must take a child-centred, evidence-based approach, and take care not to express personal beliefs in ways which could exploit pupils' vulnerabilities. We should not for example, present, as fact, childhood gender incongruence as an inherent and immutable phenomenon as this is a contested idea rather than an established evidence-based fact.

Low quality evidence

The Cass Review interim report acknowledges that '[over] the last few years, broader discussions about transgender issues have been played out in public, with discussions becoming increasingly polarised and adversarial' (para. 2.4). Many of us feel confused or conflicted about approaching the issues of sex and gender identity with adolescents. The above-mentioned rise in referrals to GIDS has been accompanied by an increasing number of news reports claiming that some teachers and/or schools are promoting the idea that gender identity supersedes sex. However, there is insufficient high quality, longitudinal data (relating to gender-questioning children) from which to draw robust conclusions. There is a notable gap in the evidence base pertaining to the surge in female teenagers seeking support from gender identity services.

Aspects of the literature are open to interpretation in multiple ways, and there is a risk that some authors interpret their data from a particular ideological and/or theoretical standpoint (para. 1.29).

Decisions need to be informed by long-term data on the range of outcomes, from satisfaction with transition, through a range of positive and negative mental health outcomes, through to regret and/or a decision to detransition. The NICE evidence review demonstrates the poor quality of these data, both nationally and internationally (para. 3.21).

It is also important to note that any data that are available do not relate to the current predominant cohort of later-presenting birth-registered female teenagers. This is because the rapid increase in this subgroup only began from around 2014-15. Since young people may not reach a settled gender expression until their mid-20s, it is too early to assess the longer-term outcomes of this group (para. 3.23).

Since the rapid increase in this group began around 2015, they will not reach late 20s for another 5+ years, which would be the best time to assess longer-term wellbeing (para. 5.10).

This is an area of research where no scientific consensus exists. Schools must be aware that any claims made about the reasons behind the increase in gender-questioning children are speculative and cannot be treated as established evidence-based facts.

Changing epidemiology

Early childhood gender dysphoria is not a new phenomenon. However, the existing literature on treatment and outcomes is largely based on early childhood gender dysphoria in male children. It may not apply to the current cohort of gender-questioning children who are older, predominantly female and often presenting with a range of neurodevelopmental and mental health co-morbidities.

In the last few years, there has been a significant change in the numbers and case-mix of children and young people being referred to GIDS (para 3.10).

This increase in referrals has been accompanied by a change in the case-mix from predominantly birth-registered males presenting with gender incongruence from an early age, to predominantly birth-registered females presenting with later onset of reported gender incongruence in early teen years (para. 3.11).

The mix of young people presenting to the service is more complex than seen previously, with many being neurodiverse and/or having a wide range of psychosocial and mental health needs. The largest group currently comprises birth-registered females first presenting in adolescence with gender-related distress (para. 1.10).

Much of the existing literature about natural history and treatment outcomes for gender dysphoria in childhood is based on a case-mix of predominantly birth-registered males presenting in early childhood. There is much less data on the more recent case-mix of predominantly birth-registered females presenting in early teens, particularly in relation to treatment and outcomes (para. 1.28).

Secondly, the cohort that the original Dutch Approach was based on is different from the current more complex NHS cohort, and also from the current case-mix internationally, and therefore it is difficult to extrapolate from older literature to this current group (para. 5.10).

The Cass Review interim report highlights the difficulties faced by clinicians responsible for making diagnoses and recommending treatment. Teachers are neither qualified nor capable of critically evaluating existing evidence. They must carry out their duties within statutory and non-statutory frameworks. This included ensuring that any necessary referrals are made as specified by their schools' safeguarding protocols.

Diagnostic overshadowing

Another significant issue raised with us is one of diagnostic overshadowing – many of the children and young people presenting have complex needs, but once they are identified as having gender-related distress, other important healthcare issues that would normally be managed by local services can sometimes be subsumed by the label of gender dysphoria (para.

4.10).

School staff must be clear that they are not qualified to offer students advice in this area. Moreover, the promotion of specific beliefs about the source(s) of gender-related distress could influence children's attitudes toward the diagnostic process before meeting with a clinically trained professional. Guidance from the Department for Education states that teachers "are in a position of authority and will typically be respected and trusted by the pupils they teach, giving their personal opinions greater weight and credibility. As a general principle, they should avoid expressing their own personal political views to pupils unless they are confident this will not amount to promoting that view to pupils [4]."

Affirmative vs developmental models

Broadly speaking, there are two approaches to treating children with gender-related distress: the gender-affirmative approach and the developmentally-informed approach. The gender-affirmative approach is based on the theory that a child's gender identity is innate. The developmentally-informed approach is based on the theory that a complex interaction of multiple factors underlie gender-related distress. The Cass Review interim report acknowledges that some clinicians report being under pressure to adopt a gender-affirmative approach.

Following directly from this is a spectrum of opinion about the correct clinical approach, ranging broadly between those who take a more gender-affirmative approach to those who take a more cautious, developmentally-informed approach (para. 4.15).

Some secondary care providers told us that their training and professional standards dictate that when working with a child or young person they should be taking a mental health approach to formulating a differential diagnosis of the child or young person's problems. However, they are afraid of the consequences of doing so in relation to gender distress because of the pressure to take a purely affirmative approach (para 4.20).

There is a spectrum of academic, clinical and societal opinion on this. At one end are those who believe that gender identity can fluctuate over time and be highly mutable and that, because gender incongruence or gender-related distress may be a response to many psychosocial factors, identity may sometimes change or the distress may resolve in later adolescence or early adulthood, even in those whose early incongruence or distress was quite marked. At the other end are those who believe that gender incongruence or dysphoria in childhood or adolescence is generally a clear indicator of that child or young person being transgender and question the methodology of some of the desistance studies (para. 5.8).

School staff are unqualified to evaluate the merits of these approaches. Moreover, they have an obligation to remain politically impartial. This means not supporting one approach over another.

Social transition

Social transitions (the act of treating children as if belonging to the opposite sex) are performed by some schools in England. A social transition is a powerful psychological treatment that affects a child's psychological development. Not only are school staff unqualified to judge the appropriateness of such interventions, the outcomes are poorly

understood.

Social transition – this may not be thought of as an intervention or treatment, because it is not something that happens within health services. However, it is important to view it as an active intervention because it may have significant effects on the child or young person in terms of their psychological functioning. There are different views on the benefits versus the harms of early social transition. Whatever position one takes, it is important to acknowledge that it is not a neutral act, and better information is needed about outcomes (para. 5.19).

Pressure

The Cass Review interim report acknowledges the pressures clinicians are under to adopt an unquestioning affirmative approach. Similarly, there is an acknowledgement that children are under pressure to identify with societal stereotyping. Schools cannot erase the pressures that children are under from, for example, social media and peers. However, teachers should promote acceptance for children's non-stereotypical behaviour (boys and girls exhibiting stereotypically 'feminine' and 'masculine' behaviour, respectively) and avoid reinforcing harmful stereotypes.

Primary and secondary care staff have told us that they feel under pressure to adopt an unquestioning affirmative approach and that this is at odds with the standard process of clinical assessment and diagnosis that they have been trained to undertake in all other clinical encounters (para. 1.14).

From the point of entry to GIDS there appears to be predominantly an affirmative, non-exploratory approach, often driven by child and parent expectations and the extent of social transition that has developed due to the delay in service provision (para. 1.18).

It is not the role of this Review to take any position on the cultural and societal debates relating to transgender adults. However, in achieving its objectives there is a need to consider the information and support that children and young people access from whatever source, as well as any pressures that they are subject to, before they access clinical services (para. 2.5).

We have heard that distress may be exacerbated by pressure to identify with societal stereotyping and concerns over the influence of social media, which can be seen to perpetuate unrealistic images of gender and set unhealthy expectations, especially given how long children and young people are waiting to access services (para 4.13).

These will be considered further during the lifetime of the Review and include: . . . The complex interaction between sexuality and gender identity, and societal responses to both; for example, we have heard from young lesbians who felt pressured to identify as transgender male, and conversely transgender males who felt pressured to come out as gay rather than transgender. We have also heard from adults who identified as transgender through childhood, and then reverted to their birth-registered gender in teen years (para. 4.14).

Safeguarding

Children with gender-related distress may pose specific safeguarding concerns. They have a higher incidence of comorbid psychiatric and/or developmental difficulties. Teachers need to be aware of possible harms such as breast binding or tucking (of male genitals). Children may

also be subjected to grooming and/or coaching, and encouraged to deceive parents, clinicians and teachers in order to secure particular outcomes such as clinical diagnoses of gender dysphoria. They may also be receiving cross-sex hormones from unregulated sources.

In addition, approximately one third of children and young people referred to GIDS have autism or other types of neurodiversity. There is also an over-representation percentage wise (compared to the national percentage) of looked after children (para. 3.11).

We have also heard about the distress experienced by birth-registered females as they reach puberty, including the use of painful, and potentially harmful, binding processes to conceal their breasts (para. 4.3).

Most children and young people seeking help do not see themselves as having a medical condition; yet to achieve their desired intervention they need to engage with clinical services and receive a medical diagnosis of gender dysphoria (para. 4.4).

We have heard that some young people learn through peers and social media what they should and should not say to therapy staff in order to access hormone treatment; for example, that they are advised not to admit to previous abuse or trauma, or uncertainty about their sexual orientation (para. 4.5).

We have heard about families trying to balance the risks of obtaining unregulated and potentially dangerous hormone supplies over the internet or from private providers versus the ongoing trauma of prolonged waits for assessment (para. 4.7).

Summary

There has been a huge increase in the number of children (predominantly female teenagers) seeking help for distress in relation to their biological sex. Research into this new phenomenon is limited. The lack of high-quality data from longitudinal studies together with the changing epidemiology means that no consensus exists about the possible causes for this recent surge in children wanting to change sex. Clinically trained professionals face difficulties in making diagnoses and recommending treatment. School staff who now affirm my daughter are neither qualified to evaluate existing research nor clinically trained. Therefore, they cannot judge the appropriateness of, for example, socially transitioning children. It is an intervention with poorly understood outcomes that affects children's psychological development. The Cass Review interim report outlines some of the specific safeguarding issues that surround gender-questioning children.

Thank you most sincerely for your time and consideration.

Yours sincerely,

Rachel Bordoli

Paul A. Vazquez, J.D.

Executive Director Florida Board of Medicine

BOM.MeetingMaterials@flhealth.gov

Dear Mr. Vasquez,

I am writing in regards to the proposed regulations on “gender-affirming” care currently under review in Florida. I am a California attorney who is watching gender issues closely across the US.

I believe I have the best interest of children in mind, not only because my 17-year-old daughter is obsessed with transition but also because I know 36 kids - organically from family relationships- who also self-identify as “trans.”

One of these children is my best friend’s son. Another is my sister-in-law’s daughter. The numbers defy logic. Sadly, most of the children I know are on the spectrum, including mine.

My child suffers greatly from depression and anxiety. I took her to a psychiatrist who immediately told my daughter and I that she would kill herself if she doesn’t get immediate gender medical care. Can you imagine someone saying that to your child?

I could write chapters on gender medicine and mental health but I’ll stick to my short letter. Please be rational when dealing with our kids’ health. They’re so precious and shouldn’t be experiments.

Best regards,

Avery Kennedy

Dear Florida Board of Medicine

I am writing to you today to demand that you reject the proposed guidance by Surgeon General Ladapo's Department of Health on Gender Dysphoria in Children and Adolescents.

Care providers, doctors, and leading medical associations have been clear that gender-affirming care is safe, effective, and evidence-based, and that it's literally lifesaving.

The issued guidance by the Dept. of Health and the studies used by this board are inaccurate and dangerous. This guidance is nothing more than another tool for the Governor to express his opposition to transgender individuals' existence.

The nation's leading health organizations support gender-affirming care for transgender and gender non-conforming people, including the American Academy of Pediatrics; the American Medical Association; The American College of Obstetricians and Gynecologists; The American College of Physicians; The American Psychiatric Association; The American Psychological Association; The American Academy of Family Physicians; The Endocrine Society; The Pediatric Endocrine Society; American Nurses Association; American Public Health Association; American Heart Association; National Association of Social Workers; World Medical Association; and The World Professional Association for Transgender Health, among others.

There is overwhelming evidence to support the positive mental health impacts of gender-affirming medical care for trans youth - including in some of the very studies cited by the DOH and Board of Medicine. Prohibiting social transition is clear government intrusion on personal and parental decision making. Numerous studies have found that after social transition, transgender youth report similar mental health levels to the general youth population, eliminating mental health disparities typically seen. When transgender youth are affirmed by people around them, reported rates of depression and suicidality drop significantly. This rule will deny them this life-saving treatment.

The Board must provide truthful information based on science and data as opposed to false statements based on prejudice and political agendas. The evidence is clear: denying transgender youth the ability to transition is dangerous, abusive, and life-threatening.

Stop discriminating against people for any reason. You are medically discriminating against these people.

I urge you to reject this proposal.

Sincerely,

Amy Bergey

Dear Paul A. Vazquez, J.D. (Executive Director Florida Board of Medicine)

I am a parent of a teenage old girl, who identifies as transgender. Our daughter is not transgender: she has struggled all her life with mental health challenges and with her social anxiety. We are constitutionally opposed to the affirmation model and with hormonal and surgical interventions. These are not based on science or ethics for this new population of teenage girls. A very vulnerable population.

Great Britain recently commissioned a highly distinguished public health and pediatric expert to reconsider the affirmative model in the United Kingdom. Please consider with care the findings of the Cass Review interim report.

What is the Cass Review interim report?

The Cass Review is an Independent Review of Gender Identity Services for Children and Young People. It was 'commissioned by NHS England and NHS Improvement in Autumn 2020 to make recommendations about the services provided by the NHS to children and young people who are questioning their gender identity or experiencing gender incongruence [1].' In March 2022, the Cass Review submitted an interim report to NHS England. This interim report '[set] out [the] work to date, what [had] been learnt so far and the approach going forward [2].'

Who is Dr. Hilary Cass

Dr Hilary Cass was appointed by NHS England and NHS Improvement to chair the Independent Review of Gender Identity Services for children and young people in late 2020. A former President of the Royal College of Paediatrics and Child Health from 2012-2015, Dr Cass recently finished a term as Chair of the British Academy of Childhood Disability (2017-2020). Although retired from clinical practice, she remains an honorary Consultant Paediatrician at Evelina London Children's Hospital, Guy's & St Thomas's NHS Foundation Trust, where she was also previously Director of Education and Workforce. Dr Cass is currently Chair of Together for Short Lives, and a Trustee for Noah's Ark Children's Hospice. She is also leading work on how to address the challenges for both families and professionals in supporting the rising numbers of children

with complex medical conditions and disability. Other recent roles include acting as the Senior Clinical Advisor for Child Health for Health Education England. Prior to this, Dr Cass held a range of senior education and management roles in NHS hospital trusts and was previously Head of School of Paediatrics in London. Her consultant clinical practice was as a tertiary neurodisability consultant from 1992 to 2018 in three very different specialist centres and she has published widely in this area. In addition to her neurodisability practice, Dr Cass was closely involved in the development of paediatric palliative care services at Evelina London Children's Hospital. Dr Cass was awarded the OBE for services to child health in 2015. She was also awarded an honorary fellowship by the Royal College of Nursing in 2015, and by RCGP in 2016.

Background

The United Kingdom has seen a significant increase in the number of children seeking help for distress in relation to their biological sex. Many school staff first started noticing the phenomenon of children – predominantly teenaged girls – wanting to change sex during the last decade. In recent years, there has been a significant increase in the number of referrals to the Gender Identity Development Service (GIDS) at the Tavistock and Portman NHS Foundation Trust (para. 1.1). From a baseline of approximately 50 referrals per annum in 2009, there was a steep increase from 2014-15, and at the time of the CQC inspection of the Tavistock and Portman NHS Foundation Trust in October 2020, there were 2,500 children and young people being referred per annum, 4,600 children and young people on the waiting list, and a waiting time of over two years to first appointment (para 3.10).

This surge in children seeking help for distress in relation to their sex is occurring in the context of an ongoing public debate around issues relating to sex, gender and gender identity. Over the last few years, broader discussions about transgender issues have been played out in public, with discussions becoming increasingly polarised and adversarial. This polarisation is such that it undermines safe debate and creates difficulties in building consensus (para. 2.4).

No consensus

This being a new phenomenon, research is limited and no consensus exists (within the scientific community) about possible causes and most appropriate treatment options. At primary, secondary and specialist level, there is a lack of agreement, and in many instances, a lack of open discussion about the extent to which gender incongruence in childhood and adolescence can be an inherent and immutable phenomenon for which transition is the best option for the

individual (para. 1.7).

We must secure a balanced treatment of political issues, they must take a child-centred, evidence-based approach, and take care not to express personal beliefs in ways which could exploit pupils' vulnerabilities. We should not, for example, present as fact childhood gender incongruence as an inherent and immutable phenomenon as this is a contested idea rather than an established evidence-based fact.

Low quality evidence

The Cass Review interim report acknowledges that '[over] the last few years, broader discussions about transgender issues have been played out in public, with discussions becoming increasingly polarised and adversarial' (para. 2.4). Many of us feel confused or conflicted about approaching the issues of sex and gender identity with adolescents. The above-mentioned rise in referrals to GIDS has been accompanied by an increasing number of news reports claiming that some teachers and/or schools are promoting the idea that gender identity supersedes sex. However, there is insufficient high quality, longitudinal data (relating to gender-questioning children) from which to draw robust conclusions. There is a notable gap in the evidence base pertaining to the surge in female teenagers seeking support from gender identity services.

Aspects of the literature are open to interpretation in multiple ways, and there is a risk that some authors interpret their data from a particular ideological and/or theoretical standpoint (para. 1.29).

Decisions need to be informed by long-term data on the range of outcomes, from satisfaction with transition, through a range of positive and negative mental health outcomes, through to regret and/or a decision to detransition. The NICE evidence review demonstrates the poor quality of these data, both nationally and internationally (para. 3.21).

It is also important to note that any data that are available do not relate to the current predominant cohort of later-presenting birth-registered female teenagers. This is because the rapid increase in this subgroup only began from around 2014-15. Since young people **may** not reach a settled gender expression until their mid-20s, it is too early to assess the longer-term outcomes of this group (para. 3.23). Since the rapid increase in this group began around 2015, they will not reach late 20s for another 5+ years, which would be the best time to assess longer-term wellbeing (para. 5.10).

This is an area of research where no scientific consensus exists. Schools must be aware that any claims made about the reasons behind the increase in gender-questioning children are speculative and cannot be treated as established evidence-based facts.

Changing epidemiology

Early childhood gender dysphoria is not a new phenomenon. However, **the existing literature on treatment and outcomes is largely based on early childhood gender dysphoria in male children. It may not apply to the current cohort of gender-questioning children who are older, predominantly female and often presenting with a range of neurodevelopmental and mental health co-morbidities.**

In the last few years, there has been a significant change in the numbers and case-mix of children and young people being referred to GIDS (para 3.10). This increase in referrals has been accompanied by a change in the case-mix from predominantly birth-registered males presenting with gender incongruence from an early age, to predominantly birth-registered females presenting with later onset of reported gender incongruence in early teen years (para. 3.11). The mix of young people presenting to the service is more complex than seen previously, with many being neurodiverse and/or having a wide range of psychosocial and mental health needs. The largest group currently comprises birth-registered females first presenting in adolescence with gender-related distress (para. 1.10).

Much of the existing literature about natural history and treatment outcomes for gender dysphoria in childhood is based on a case-mix of predominantly birth-registered males presenting in early childhood. There is much less data on the more recent case-mix of predominantly birth-registered females presenting in early teens, particularly in relation to treatment and outcomes (para. 1.28).

Secondly, the cohort that the original Dutch Approach was based on is different from the current more complex NHS cohort, and also from the current case-mix internationally, and therefore it is difficult to extrapolate from older literature to this current group (para. 5.10). The Cass Review interim report highlights the difficulties faced by clinicians responsible for making diagnoses and recommending treatment. Teachers are neither qualified nor capable of critically evaluating existing evidence. They must carry out their duties within statutory and non-statutory frameworks. This included ensuring that any necessary referrals are made as specified by their schools' safeguarding protocols.

Diagnostic overshadowing

Another significant issue raised with us is one of diagnostic overshadowing – many of the children and young people presenting have complex needs, but once they are identified as having gender-related distress, other important healthcare issues that would normally be managed by local services can sometimes be subsumed by the label of gender dysphoria (para. 4.10).

School staff must be clear that they are not qualified to offer students advice in this area. Moreover, the promotion of specific beliefs about the source(s) of gender-related distress could influence children's attitudes toward the diagnostic process before meeting with a clinically trained professional. Guidance from the Department for Education states that teachers "are in a position of authority and will typically be respected and trusted by the pupils they teach, giving their personal opinions greater weight and credibility. As a general principle, they should avoid expressing their own personal political views to pupils unless they are confident this will not amount to promoting that view to pupils [4]."

Affirmative vs developmental models

Broadly speaking, there are two approaches to treating children with gender-related distress: the gender-affirmative approach and the developmentally-informed approach. The gender-affirmative approach is based on the theory that a child's gender identity is innate. The developmentally-informed approach is based on the theory that a complex interaction of multiple factors underlie gender-related distress. The Cass Review interim report acknowledges that some clinicians report being under pressure to adopt a gender-affirmative approach.

Following directly from this is a spectrum of opinion about the correct clinical approach, ranging broadly between those who take a more gender-affirmative approach to those who take a more cautious, developmentally-informed approach (para. 4.15).

Some secondary care providers told us that their training and professional standards dictate that when working with a child or young person they should be taking a mental health approach to formulating a differential diagnosis of the child or young person's problems. However, they are afraid of the consequences of doing so in relation to gender distress because of the pressure to take a purely affirmative approach (para 4.20).

There is a spectrum of academic, clinical and societal opinion on this. At one end are those who believe that gender identity can fluctuate over time and be highly mutable and that, because gender incongruence or gender-related distress may be a response to many psychosocial factors, identity may sometimes change or the distress may resolve in later adolescence or early adulthood, even in those whose early incongruence or distress was quite marked. At the other end are those who believe that gender incongruence or dysphoria in childhood or adolescence is generally a clear indicator of that child or young person being transgender and question the methodology of some of the desistance studies (para. 5.8).

School staff are unqualified to evaluate the merits of these approaches. Moreover, they have an obligation to remain politically impartial. This means not supporting one approach over another.

Social transition

Social transitions (the act of treating children as if belonging to the opposite sex) are performed by some schools in England. A social transition is a powerful psychological treatment that affects a child's psychological development. Not only are school staff unqualified to judge the appropriateness of such interventions, the outcomes are poorly understood.

Social transition – this may not be thought of as an intervention or treatment, because it is not something that happens within health services. However, it is important to view it as an active intervention because it may have significant effects on the child or young person in terms of their psychological functioning. There are different views on the benefits versus the harms of early social transition. Whatever position one takes, it is important to acknowledge that it is not a neutral act, and better information is needed about outcomes (para. 5.19).

Pressure

The Cass Review interim report acknowledges the pressures clinicians are under to adopt an unquestioning affirmative approach. Similarly, there is an acknowledgement that children are under pressure to identify with societal stereotyping. Schools cannot erase the pressures that children are under from, for example, social media and peers. However, teachers should promote acceptance for children's non-stereotypical behaviour (boys and girls exhibiting stereotypically 'feminine' and 'masculine' behaviour, respectively) and avoid reinforcing harmful stereotypes.

Primary and secondary care staff have told us that they feel under pressure to adopt an unquestioning affirmative approach and that this is at odds with the standard process of clinical assessment and diagnosis that they have been trained to undertake in all other clinical encounters (para. 1.14).

From the point of entry to GIDS there appears to be predominantly an affirmative, non-exploratory approach, often driven by child and parent expectations and the extent of social transition that has developed due to the delay in service provision (para. 1.18).

It is not the role of this Review to take any position on the cultural and societal debates relating to transgender adults. However, in achieving its objectives there is a need to consider the information and support that children and young people access from whatever source, as well as any pressures that they are subject to, before they access clinical services (para. 2.5).

We have heard that distress may be exacerbated by pressure to identify with

societal stereotyping and concerns over the influence of social media, which can be seen to perpetuate unrealistic images of gender and set unhealthy expectations, especially given how long children and young people are waiting to access services (para 4.13).

These will be considered further during the lifetime of the Review and include: . . . The complex interaction between sexuality and gender identity, and societal responses to both; for example, we have heard from young lesbians who felt pressured to identify as transgender male, and conversely transgender males who felt pressured to come out as gay rather than transgender. We have also heard from adults who identified as transgender through childhood, and then reverted to their birth-registered gender in teen years (para. 4.14).

Safeguarding

Children with gender-related distress may pose specific safeguarding concerns. They have a higher incidence of comorbid psychiatric and/or developmental difficulties. They are also more likely to be looked after children. Teachers need to be aware of possible harms such as breast binding or tucking (of male genitals). Children may also be subjected to grooming and/or coaching, and encouraged to deceive parents, clinicians and teachers in order to secure particular outcomes such as clinical diagnoses of gender dysphoria. They may also be receiving cross-sex hormones from unregulated sources.

In addition, approximately one third of children and young people referred to GIDS have autism or other types of neurodiversity. There is also an over-representation percentage wise (compared to the national percentage) of looked after children (para. 3.11).

We have also heard about the distress experienced by birth-registered females as they reach puberty, including the use of painful, and potentially harmful, binding processes to conceal their breasts (para. 4.3).

Most children and young people seeking help do not see themselves as having a medical condition; yet to achieve their desired intervention they need to engage with clinical services and receive a medical diagnosis of gender dysphoria (para. 4.4).

We have heard that some young people learn through peers and social media what they should and should not say to therapy staff in order to access hormone treatment; for example, that they are advised not to admit to previous abuse or trauma, or uncertainty about their sexual orientation (para. 4.5).

We have heard about families trying to balance the risks of obtaining unregulated and potentially dangerous hormone supplies over the internet or from private providers versus the ongoing trauma of prolonged waits for assessment (para. 4.7).

Summary

There has been a huge increase in the number of children (predominantly female teenagers) seeking help for distress in relation to their biological sex. Research into this new phenomenon is limited. The lack of high-quality data from longitudinal studies together with the changing epidemiology means that no consensus exists about the possible causes for this recent surge in children wanting to change sex. Clinically trained professionals face difficulties in making diagnoses and recommending treatment. School staff who now affirm my daughter are neither qualified to evaluate existing research nor clinically trained. Therefore, they cannot judge the appropriateness of, for example, socially transitioning children. It is an intervention with poorly understood outcomes that affects children's psychological development. The Cass Review interim report outlines some of the specific safeguarding issues that surround gender-questioning children.

Thank you most sincerely for your time and consideration.

Yours sincerely,

Linda Grosse

Dear Florida Board of Medicine,

Thank you for taking up the vital question of regulating the so-called "gender-affirming" hormones and surgeries for young people.

My family has gone through so much trying to help our son who never showed any sign of gender confusion his entire life. It has been extremely difficult to find anyone that will help us without immediately saying that he is "transgender" and needs to be affirmed by everyone.

As parents of these children, we have seen some very well-meaning but misinformed doctors recommend these radical life-changing interventions sometimes on the first or second visit. The myth that our children are getting "assessments" is propagated widely, but no requirements have ever been clearly articulated about which child or young person distressed with their gender role will benefit vs will be harmed. This intervention sterilizes 100% of children if administered according to the Endocrine Society's recommendations.

Older adolescents can get hormones with no assessments at all, and have their healthy body parts amputated by eager surgeons on little more than self-declaration of "trans identity." Many of our children are gay and autistic and have come to believe their very real distress is explained by the fact that they are "transgender" and that hormones and surgeries will help. They do not. We have seen our children's mental and physical health plummet following "gender-affirmation."

We also encourage you to require exploratory psychotherapy and to issue a clear statement that psychotherapy for gender dysphoria is not conversion. Our children and families need safe non-invasive alternatives to radical experimentation known as "gender affirmation."

Thank you for doing what you can to regulate this experiment on our vulnerable children.

Dear Paul A. Vazquez, J.D.
Executive Director Florida Board of Medicine

I am the mother of a 28-year-old man, who has been identifying as transgender for the past six years. While there are undoubtedly various contributing factors responsible for the alarming increase in our youth and young adults being drawn to it, I ask that the Board of Medicine please consider that transgender ideology offers only a temporary reprieve to individuals experiencing psychological distress and more serious mental disorders. In my son's case, he was diagnosed with borderline personality disorder by a licensed Florida therapist when he was still in college. My son has loathed himself since he was in high school, and transgenderism is merely an escape from his self-hatred. He has also become anorexic. I knew he was extremely depressed, but I did not understand the severity of his disorder until it was too late to exercise any control over his treatment. It's hard for me to believe that my son was once a healthy, muscular, young man who was even an Eagle Scout. He began taking cross-sex hormones and his depression and anxiety worsened to the point that he dropped out of Florida State University and never completed his bachelor's degree in computer science. He has worked in minimum wage jobs consequently. He has refused to get therapy even though he acknowledges that the therapist, previously mentioned, was helpful.

My son, like so many other young people, has been persuaded by transgender activists that all his problems are due to him being "born in the wrong body". The problem is that there are now thousands of young people like him who have spent years trying to pass as the opposite sex only to realize that this ideology did not resolve their underlying psychological issues (just look at Reddit's Detrans group of well over 30,000 members). In fact, it did not matter how many changes they undertook (e.g., cross-sex hormones, orchiectomies, vaginoplasties, mastectomies), the euphoria of each change would wear off after a short while and they returned to feeling like they did not before the intervention.

This is the reason why European countries such as Sweden, Finland, France, and England have started to put breaks on puberty blockers, cross-sex hormones, and surgeries for minors. There are now several large studies that confirm that medical interventions did not alleviate the psychological distress and mental disorders of these unfortunate individuals. For example, one Swedish study found that the risk of suicide is actually 19 times higher in individuals after receiving a medical intervention. It also suggested that this is one of the reasons that so many of these individuals are

lost to follow-up. (I am assuming other parents will be sending you links to many relevant studies, but I can provide complete source citations if you are interested in reading more). I also want to share this suicide note left on Twitter in July 2015 from a young man who used the handle "Trans Malpracticed" (@Trans Malpr) and wrote that "I'll miss this beautiful, amazing world. I wanted to live a long, full life. Everyone dies someday. I love you. I want to apologize most to my parents. I let this destroy your healthy, promising child. I'm sorry. I'm so very, very sorry. Doc thought he was doing me favors, removing barriers I didn't even know... I didn't ask for favors, not when my life was at stake!" I can't tell you how terrible this makes me feel as the parent of a young man who has also been led down this same path. I can only pray that he will get the kind of behavioral health treatment he needs to realize that it is a mistake to try and change his body to deal with his distress.

In closing, I want to say thank you for giving parents and other relatives the opportunity to express our concerns about what has been happening to our families over the past several years. Transgender activists would have everyone believe that transgender individuals are the most marginalized in society, but it is really the families of these individuals who have been the most marginalized. We are treated terribly for affirming biology rather than pathology. It's simply awful knowing that this is probably the greatest medical scandal of our current era, and our culture isn't listening to us and there is little that we can do to prevent serious harm to confused youth who are experiencing severe psychological distress and mental illness.

Sincerely,

Julie Framingham

Dear Dr. Vazquez and Florida Board of Medicine members,

I am a parent of a 17 year old son who came out to me as transgender 3 years ago. He is one of the children that has "ROGD" - Rapid Onset of Gender Dysphoria, meaning coming out as trans "out of the blue" due to social contagion and mental illness. He has been very determined about taking cross sex hormones since day one he came out because he has been indoctrinated by the social media and trans activists that cross sex hormones will give him a new life and make him happy. He also believes that the health consequences such as infertile, sex function dysfunction, from medical transition are reversible.

Our family has been negatively impacted by his gender ideology. My relationship with him was very close before all this happened. However, as coached by his online "friends" and social media, he hates me and his family who disagrees with his gender identity and I'm one of them so he sees me as a stranger and enemy because I have been trying to do everything to prevent him from medical transition. Sadly I only have 6 months left before he turns 18 when he does not need parent consent to obtain hormone therapy. I live with extremely terrified feelings everyday because I know that I will not be able to do anything to stop him from harming his healthy body in 6 months. I am also horrified to even think that it will be too late when he discovers that medical transition did little to relieve his dysphoria and mental illnesses, but damages have already been made to his body permanently.

I am one of the parents in a parent support group where we parents all have similar stories about our kids who came out as trans. All of us support each other because we are not able to find trustworthy non-affirming therapists and doctors to help our vulnerable and naive kids. We are all facing a strong force of politicians, therapists, schools, friends and even family members that we need to affirm our kids and let them be the lead. When I told our pediatrician that my son identified as trans three years ago, her first reaction was referred us to a gender clinic, where the specialist affirmed my son in the first meeting and told us that we should support him to take cross sex hormones, without even asked any other questions regarding his mental health condition. Had I listened to the gender clinic and decided to let my son medicalize himself, my son would have been sterilized and there was no way back.

NO one is born in the wrong body and we all should accept who we are and should not do anything to damage our healthy body.

Respectfully,
Annie

Hello,

I am a pharmacist working in the US healthcare field. I strongly encourage the Florida Board of Medicine to restrict the misguided interventions aimed at "re-assigning" the gender of the youth in Florida.

Those who identify as transgender deserve holistic, evidence-based care that is in accordance with human reality and will offer them a real hope at happiness and fulfillment. None of this can be found in the attempts of medical providers to assist in "transitioning" of their patients.

Please restrict these practices to protect the youth in Florida and prevent the healthcare field from turning into a trade of goods and services, rather than retaining its essential mission of healing and "doing no harm" to individuals.

Thank you,

Angela

I beg you to ban "Affirmative Care" for minors. I am the father of an adult child who suffers from Rapid On-Set Gender Dysphoria and who started down this path as a teenager. Over the past several years, counselors, doctors, college professors, and college administrators did not question my child's gender confusion.

I believe "Affirmative Care" should be banned for all ages. The only long-term study that followed all participants showed that those who medically transition are 19 times more likely to commit suicide than those in the general public. Authors of a recent study had to correct their conclusions to accurately reflect that data showed there is no evidence that puberty blockers, cross-sex hormones, or gender-affirming surgeries improve mental health.

We desperately need professionals to stand up and stop this insanity. The brain doesn't completely mature until a person is at least 25 years old. Yet minor children are being allowed to make decisions that will affect them for the rest of their lives while counselors, doctors, and school administrators ignore the wishes and directions of parents.

All of the procedures considered "Affirmative Care" are experimental. None are being tracked and no long-term research is being conducted following any of these procedures; therefore, we will never know the depth of how devastating the outcomes are. At this point, we can only rely on the testimony of the tens of thousands of detransitioners. The common theme among them is that they were led/coerced down the path of medical transitioning. Once they realized they had made a mistake, the same people who encouraged them viciously turned their backs on them, including the doctors and mental health professionals.

Once again, I ask that you ban "Affirmative Care" for gender-confused minors.

Thank you,
Derek Faulk

Dear Dr. Vazquez and Members of the Board,

I am a practicing pediatric general surgeon in St. Petersburg.

I do NOT support alteration of secondary sexual characteristics with medications or surgical procedures for minors with gender dysphoria. Evidence for such treatments is poor, the long-term outcomes are unknown, and the harms may well outweigh any benefits. Altering normal anatomy and physiology for minors, who are unable to understand the long-term implications of such decisions, is ethically problematic.

I DO support access to appropriate mental health care and counseling for minors suffering from gender dysphoria.

Please contact me if there are any questions.

Respectfully,
Christopher Snyder, MD, MSPH

Thank you for taking up the vital question of regulating the "gender-affirming" hormone and surgeries for our children.

I am a parent of one of these children, we've seen some well-meaning but misinformed doctors, therapists, and other adults recommend these radical life-changing interventions. I know in my family's case my 13 year old daughter was offered Testosterone at our first visit to a prestigious gender clinic within a 2 hour visit, with NO follow up to her personal therapist.

As we, her parents, declined this intervention my daughter thought she would die, because of on-line influence of the internet's pushing the suicide narrative. That was years ago now, and she hasn't died of suicide she in fact now believes her parent's have her back and tell her the truth of medical interventions that would lead to long term effects and sterilization. She is close to now desisting and living as the woman she was born as.

We encourage you to require explorator psychotherapy and issue a clear statement that psychotherapy for gender dysphoria is not conversion. Our children need safe non-invasive alternatives to radical gender theory which is an experiment on children or adults as there is no long term studies.

Thank you for doing what you can on this dangerous experiment on vulnerable children
Beth

To The Florida Board of Medicine,

I am writing in regards to the upcoming meeting to determine the implementation of regulations related to "sex-based medicine". I implore you, in the name of sanity and reason, to **VOTE FOR STRICT REGULATIONS** in regards to so-called "sex-based medicine". Particularly when it comes to children and patients under the age of legal consent (18 years of age).

I am sure that your inbox is being flooded with misguided physicians, parents and patients who are pleading just the opposite and in a spirit of charity I will assume that they are doing so from a place of love and care for those poor individuals who truly struggle with gender dysphoria. However, as I stated, they are misguided. As physicians we rely on objective facts, science, logic and reason in our practice of medicine to best care for our patients; when we fail to do so, we do a disservice to our patients and our profession. While the concept of objectivity is one that has largely been abandoned by the mainstream culture, it is imperative that we as physicians do not follow suit. It is quite simply the case that neither facts, logic or reason undergird the concept of "gender affirming care" or gender ideology at large. Instead, it is a movement that is based solely on subjectivity and appeals to emotion. In fact, the strongest argument put forward by those who support "gender affirming care" amounts to little more than emotional blackmail, "They'll hurt themselves if we don't let them transition". While this might seem like a compelling impetus to comply with the wishes of the underaged patient and their parent; it does not take a vivid imagination to conceive of numerous similar scenarios in the varied fields of medical practice where we as physicians would never acquiesce to similar threats. So why do we blindly accept them when they are placed under the aegis of "sex and gender"? Instead of cowing to the loudest voices in the room, we as physicians ought to allow ourselves to be guided by reason and ask if there are not alternative treatment strategies we might investigate. Surely, we are not limited to radical and unalterable surgical procedures or experimental drug regimens which thwart natural human development.

The proponents of "gender ideology" are very skilled at the conflation of words and terms in order to obfuscate these issues. The truth is that the term "gender" has no place in the medical vocabulary. Gender is a property of language as it pertains to those which utilize masculine and feminine forms of words (Spanish for example). Sex is a property of human beings. Physicians treat human beings, not words and human beings have a sex not a gender.

A sex that can be objectively determined by biologic characteristics, namely the presence of the Y chromosome. The belief that an individual is a member of the opposite sex, despite all objective scientific evidence to the contrary, is not in accordance with reality. It is false. It is a false belief. Should an individual persist in this belief, it would be a fixed false belief. A fixed false belief is known as a delusion. You don't treat delusions by indulging in them.

Thank you for your consideration and I once again implore you to **VOTE FOR STRICT REGULATIONS** in regards to so-called "sex-based medicine".

The Florida Medical Board is considering several issues relating to medical transition for minors suffering from gender dysphoria.

This is a very medical complex issue often overshadowed by gender issue driven politics. Regardless of ones personal beliefs it is clear that the medical and psychological aspects of medical/hormonal transition in minors has not been studied objectively. Neither the short term or longer term effects are known.

We do, however, know that medical transitions in adults are associated with number of medical problems and complications-some of which are not reversible. Children and young adults would be expected to be even more susceptible.

I would urge the Florida Medical Board to proceed slowly and cautiously on permitting medical transitions for minors who have been "diagnosed" as gender identity issues

Thankyou

Dear Members of the Florida Board of Medicine,

I am a pediatrician in the Central Florida area and have practiced for 28 years. I am gravely concerned that “Affirmative Care “ is detrimental to the children of Florida. In all my years of practice, I have never had any discussions with parents regarding their children’s gender identity until the past 2 to 3 years. This explosion of gender dysphoria came out of nowhere and is very much a socially driven issue. I know that some children truly struggle with gender dysphoria, but for most, it is transitory.

Children during development go through many stages of trying to define who they are, where they fit into their family, society and their own bodies. There is a natural progression and struggle in all these areas. Giving a child the power to make a life altering decision at such a young age is malpractice! Most children end up comfortable with their gender. The few that don’t, can as adults with full knowledge undergo gender reassignment.

We need to be compassionate and provide psychological support for these children as they struggle, but affirming their decision and providing them medical intervention that is irreversible is maleficence. We are called as physicians to “First Do No Harm“ as stated in the Hippocratic Oath.

I strongly encourage the Florida Board of Medicine to protect the children of Florida from this misguided , detrimental Affirmative Care model.

Sincerely,

Gregory J. Coffman, M.D
Vice Chair Orlando Health Physician Associates
Department of Pediatrics

To whom this may concern,

As a practicing physician, I believe it is detrimental to children, especially those under 13, that they be protected from so-called gender-affirming care. Most children do not know what they want to do with their lives, how could they possibly understand all the risks associated with long-term and permanent changes with gender-affirming care, especially surgical ones.

It is in their best interest to not assume that they have the full capacity of an adult to make such a life-changing decision, where the data is still unclear of how many of these transition treatments have benefited them, whether that be meta-analysis or prospective studies.

Peace be with thee,
HP

I am horrified to see that trusted doctors, psychologists and psychiatrists are promoting the idea that children are born in the wrong body. This is quite clearly a recent trend with many children suddenly rejecting their gender and wanting to appear as the opposite. Where is the evidence of these kids that were suicidal about their gender in the history books? Why do these children only have a certain personality type? It is not healthy to affirm these kids without question and promote a lifestyle of surgeries and cross sex hormones. Many of the kids have autism or complex mental or emotional issues and should not be pushed into permanently altering their bodies. Look at the companies promoting trans as a lifestyle and will benefit from the huge sums of money involved.

A child believing they are 'trans' is more like being anorexic than being gay, with gay being a sexual preference and trans involving sterilization and amputation of healthy body parts. Most questioning kids will, if left alone, come to accept their birth gender. On Reddit chat boards alone there are 38,000 destransitioners and the number increases weekly.

Please uphold the spirit of 'first, do no harm' and stop automatically affirming children who are too young to vote, drink alcohol or drive, yet are guiding medical professionals into butchery.

Julie Angus
Concerned parent.

Dear Paul A. Vazquez, J.D. ,

>

> I am the parent of a teen who became confused about his gender a few months after covid first hit. However, we did not find out about his "new" identity until last year. My child never showed any signs of gender confusion in his childhood. He was what we call the typical boy who loved everything that had to do with boys. He loved playing outdoor and getting dirty. Never showed any distress with the clothes he wore and always loved playing with boy toys (cars, trucks, trains, etc). His gender confusion came after the amount of time he spent on the internet during covid lockdown.

> In the last year we have tried helping our child by removing social media and blocking certain sites from his phone and computer. We also tried finding him a therapist. However, after doing some research and speaking with other parents who are in this same situation as us, we came to the conclusion that no therapist is better than a bad one. You see, once the gender topic comes up, therapist and other specialists now put everything else aside and just focus on that. Then they send kids/young adults to a gender clinic where they are placed on crossed-sex hormones and then have irreversible surgeries. But of course you know all that. That is now what these children and young adults need. We need stop putting them into a path of irreversible damages.

> A lot of this children suffer from anxiety, depression, ADHD, autism, and bullying. Some were sexually assaulted and have not been able to speak about it.

> Our child, for example, was a victim of bullying while he was in middle school. Sadly we did not find about it until he no longer attended the school and he refuses to tell us what happened to him.

> Although we do not affirm his new identity, we love our child and nothing will ever change that. We worry about him and his future if he continues on this path. For now, he has only come out to his closed friends at school who celebrate his new identity and affirm him. Friends of which most are also calling themselves trans or non-binary.

>

> I don't understand how professionals like yourself are blinded by what is happening out there. In the past few years, we have seen an enormous increase of children identifying as trans, specially after covid lockdown. Children are being told that if they feel a certain way, it is because they were born in the wrong body. What kind of nonsense is that? This ideology makes it seem like we walk into a store that sells infant parts and we put them together just like we do with the Mr. Potato Head toy. It's ridiculous. We all know no child is born in the wrong body.

>

> I ask you, actually I beg you to please put a stop to this medical malpractice happening with children and young adults. We need you to create a rule that will prevent doctors from bring able to prescribe experimental puberty blockers, cross sex hormones and perform any type of gender affirming surgeries such as double mastectomies, vaginoplasty or phalloplasty on minors. Below you will find reasons why we need to put a stop to this.

>

> - There is a lack of high-quality rigorous evidence surrounding these treatment procedures, which make them experimental in nature since the long-term consequences of these drugs being used on children/teens are relatively unknown. There is also a lack of debate among medical professionals in this area because doctors that speak out against these treatments being used on children are silenced. Alternate treatment options are not being considered or even presented at this point in medicine. It appears activism has infiltrated our medical community on this issue and biological reality is being ignored.

> - The side effects we are aware of often times lead to the sterilization of these individuals and the loss of any future sexual function when puberty blockers are used.

> - Children and teen brains are not fully developed until age 25 and therefore they cannot give informed consent because they don't have the ability to fully understand the consequences of these treatments. Parents are also not

being given the full picture and all treatment options available to them like the watchful waiting approach. They are being told to only affirm or their child will commit suicide. They are also not told that through the watchful waiting treatment approach, many of these children, upwards of 80%, would resolve their distress during or shortly after puberty. There is also no evidence that medical transitioning children actual improves mental health outcomes.

> - Proper assessments are not being done and there is little to no safeguarding in place before a child is placed on a medical pathway. Many of this new cohort of children/teens do not even meet criteria for gender dysphoria, yet they are being treated medically for the “feeling” in their mind that they should be the opposite sex. They are experiencing normal discomfort with their pubescent body, but are being convinced that any amount of discomfort with their body is an indication that they are “transgender.” There is currently no coherent definition of the word transgender in the medical field.

> - Co-morbid issues are being unchecked and unresolved in the name of gender affirming care and patients and parents are being told that medical transitioning will fix their child’s distress.

> - We are now seeing the population of detransitioners increase every day because they come to the realization that medical transitioning did not fix their pain and many are stating their co-occurring mental health issues were ignored or not explored.

> - Medical organizations and associations are blindly adopting guidelines from WPATH without doing a proper review of the evidence being used for these guidelines. These guidelines are being pushed as actual standards of care, which is a gross misrepresentation of what these guidelines are. Further, professionals that are speaking out against these guidelines or advocating for a review of existing literature are silenced through gaslighting or simply ignored as in the case of the American Academy of Pediatrics.

> - Other countries like the UK, Sweden, Finland and France are re-evaluating these medical treatments for children because they have done a rigorous review of existing literature and research and have come to the conclusion that the risks do not outweigh the benefits in children and there is just so much we don’t know about the long-term consequences of these irreversible interventions. These countries have either stopped medical transitioning minors or are advocating for great caution when medically treating children for gender dysphoria. They are all stating mental health treatment should be the first line of defense, which is not currently happening in the US.

> - Despite what the media reports, these surgeries are occurring on children. Many hospitals state openly they are performing double mastectomies on children ages 16 and up and sometimes as young as 15, as stated in the new WPATH guidelines that were set to be released this month. In addition to the pediatric gender clinics in Florida hospitals providing these medical interventions, there are many private plastic surgeons, OBGYN offices, private endocrinologist offices and pediatricians prescribing puberty blockers, cross sex hormones and operating on minors. They claim parents give consent, but should a parent be allowed to consent to experimental medical treatments for their child for a mental health issue? Should parents be able to consent to amputating healthy body parts for their children and taking away their fertility and ability to have a child as an adult?

>

> Again, I ask you to please help put a stop to this by creating a rule that will protect our children from being used as experiments.

>

> Sincerely,

>

> J.C.

>

Dear Paul A. Vazquez, J.D.

Executive Director Florida Board of Medicine

I am a parent of a 19 year old girl, and a 23 year old young man who identify as transgender.

Our daughter is not transgender: she and more than a dozen of her school mates transitioned at the same time. This is adolescent social confusion.

My son has been hospitalized with mental health issues before falling for the trans-fix all cure for struggle- you can leave it all behind in a new body! In fact he was given estrogen not 6 months after his second of two hospitalizations for psychosis last year, in which he stopped all meds and refused psychiatric follow up and with no checking in with his history or other health care providers. We were in fact not 3 weeks before in an hour long appt with his primary urgently seeking mental health care and looking at the possibility of bi-polar or schizophrenia that emerges in your men typically at this age. The affirming care does not care about this if you want hormones and surgeries you can just have them. This is harmful. This is malpractice.

We are constitutionally opposed to the affirmation model and with hormonal and surgical interventions. These are not based on science or ethics Great Britain recently commissioned a highly distinguished public health and pediatric expert to reconsider the affirmative model in the United Kingdom. Please consider with care the findings of the Cass Review interim report. This shift toward evidence based ethical practice will be coming to America.

What is the Cass Review interim report?

The Cass Review is an Independent Review of Gender Identity Services for Children and Young People. It was 'commissioned by NHS England and NHS Improvement in Autumn 2020 to make recommendations about the services provided by the NHS to children and young people who are questioning their gender identity or experiencing gender incongruence [1].' In March 2022, the Cass Review submitted an interim report to NHS England. This interim report '[set] out [the] work to date, what [had] been learnt so far and the approach going forward [2].'

Who is Dr. Hilary Cass

Dr Hilary Cass was appointed by NHS England and NHS Improvement to chair the Independent Review of Gender Identity Services for children and young people in late 2020.

A former President of the Royal College of Paediatrics and Child Health from 2012-2015, Dr Cass recently finished a term as Chair of the British Academy of Childhood Disability (2017-2020).

Although retired from clinical practice, she remains an honorary Consultant Paediatrician at Evelina London Children's Hospital, Guy's & St Thomas's NHS Foundation Trust, where she was also previously Director of Education and Workforce. Dr Cass is currently Chair of Together for Short Lives, and a Trustee for Noah's Ark Children's Hospice. She is also leading work on how to address the challenges for both families and professionals in supporting the rising numbers of children with complex medical conditions and disability.

Other recent roles include acting as the Senior Clinical Advisor for Child Health for Health Education England.

Prior to this Dr Cass held a range of senior education and management roles in NHS hospital trusts and was previously Head of School of Pediatrics in London. Her consultant clinical practice was as a tertiary neuro-disability consultant from 1992 to 2018 in three very different specialist centers and she has published widely in this area.

In addition to her neuro-disability practice, Dr Cass was closely involved in the development of pediatric palliative care services at Evelina London Children's Hospital.

Dr Cass was awarded the OBE for services to child health in 2015. She was also awarded an honorary fellowship by the Royal College of Nursing in 2015, and by RCGP in 2016.

Background

The United Kingdom has seen a significant increase in the number of children seeking help for distress in relation to their biological sex. Many school staff first started noticing the phenomenon of children – predominantly teenaged girls – wanting

to change sex during the last decade.

In recent years, there has been a significant increase in the number of referrals to the Gender Identity Development Service (GIDS) at the Tavistock and Portman NHS Foundation Trust (para. 1.1).

From a baseline of approximately 50 referrals per annum in 2009, there was a steep increase from 2014-15, and at the time of the CQC inspection of the Tavistock and Portman NHS Foundation Trust in October 2020 there were 2,500 children and young people being referred per annum, 4,600 children and young people on the waiting list, and a waiting time of over two years to first appointment (para 3.10).

This surge in children seeking help for distress in relation to their sex is occurring in the context of an ongoing public debate around issues relating to sex, gender and gender identity.

Over the last few years, broader discussions about transgender issues have been played out in public, with discussions becoming increasingly polarised and adversarial. This polarisation is such that it undermines safe debate and creates difficulties in building consensus (para. 2.4).

No consensus

This being a new phenomenon, research is limited and no consensus exists (within the scientific community) about possible causes and most appropriate treatment options.

At primary, secondary and specialist level, there is a lack of agreement, and in many instances a lack of open discussion, about the extent to which gender incongruence in childhood and adolescence can be an inherent and immutable phenomenon for which transition is the best option for the individual (para. 1.7).

We must secure a balanced treatment of political issues, they must take a child-centred, evidence-based approach, and take care not to express personal beliefs in ways which could exploit pupils' vulnerabilities. We should not for example, present, as fact, childhood gender incongruence as an inherent and immutable phenomenon as this is a contested idea rather than an established evidence-based fact.

Low quality evidence

The Cass Review interim report acknowledges that '[over] the last few years, broader discussions about transgender issues have been played out in public, with discussions becoming increasingly polarized and adversarial' (para. 2.4). Many of us feel confused or conflicted about approaching the issues of sex and gender identity with adolescents. The above-mentioned rise in referrals to GIDS has been accompanied by an increasing number of news reports claiming that some teachers and/or schools are promoting the idea that gender identity supersedes sex. However, there is insufficient high quality, longitudinal data (relating to gender-questioning children) from which to draw robust conclusions. There is a notable gap in the evidence base pertaining to the surge in female teenagers seeking support from gender identity services.

Aspects of the literature are open to interpretation in multiple ways, and there is a risk that some authors interpret their data from a particular ideological and/or theoretical standpoint (para. 1.29).

Decisions need to be informed by long-term data on the range of outcomes, from satisfaction with transition, through a range of positive and negative mental health outcomes, through to regret and/or a decision to detransition. The NICE evidence review demonstrates the poor quality of these data, both nationally and internationally (para. 3.21).

It is also important to note that any data that are available do not relate to the current predominant cohort of laterpresenting birth-registered female teenagers. This is because the rapid increase in this subgroup only began from around 2014-15. Since young people may not reach a settled gender expression until their mid-20s, it is too early to assess the longer-term outcomes of this group (para. 3.23).

Since the rapid increase in this group began around 2015, they will not reach late 20s for another 5+ years, which would be the best time to assess longer-term wellbeing (para. 5.10).

This is an area of research where no scientific consensus exists. Schools must be aware that any claims made about the reasons behind the increase in gender-questioning children are speculative and cannot be treated as established evidence-based facts.

Changing epidemiology

Early childhood gender dysphoria is not a new phenomenon. However, the existing literature on treatment and outcomes is largely based on early childhood gender dysphoria in male children. It may not apply to the current cohort of gender-questioning children who are older, predominantly female and often presenting with a range of neurodevelopmental and mental health co-morbidities.

In the last few years, there has been a significant change in the numbers and case-mix of children and young people being referred to GIDS (para 3.10).

This increase in referrals has been accompanied by a change in the case-mix from predominantly birthregistered males presenting with gender incongruence from an early age, to predominantly birthregistered females presenting with later onset of reported gender incongruence in early teen years (para. 3.11).

The mix of young people presenting to the service is more complex than seen previously, with many being neurodiverse and/or having a wide range of psychosocial and mental health needs. The largest group currently comprises birth-registered females first presenting in adolescence with genderrelated distress (para. 1.10).

Much of the existing literature about natural history and treatment outcomes for gender dysphoria in childhood is based on a case-mix of predominantly birth-registered males presenting in early childhood. There is much less data on the more recent case-mix of predominantly birth-registered females presenting in early teens, particularly in relation to treatment and

outcomes (para. 1.28).

Secondly, the cohort that the original Dutch Approach was based on is different from the current more complex NHS cohort, and also from the current case-mix internationally, and therefore it is difficult to extrapolate from older literature to this current group (para. 5.10).

The Cass Review interim report highlights the difficulties faced by clinicians responsible for making diagnoses and recommending treatment. Teachers are neither qualified nor capable of critically evaluating existing evidence. They must carry out their duties within statutory and non-statutory frameworks. This included ensuring that any necessary referrals are made as specified by their schools' safeguarding protocols.

Diagnostic overshadowing

Another significant issue raised with us is one of diagnostic overshadowing – many of the children and young people presenting have complex needs, but once they are identified as having gender-related distress, other important healthcare issues that would normally be managed by local services can sometimes be subsumed by the label of gender dysphoria (para. 4.10).

School staff must be clear that they are not qualified to offer students advice in this area. Moreover, the promotion of specific beliefs about the source(s) of gender-related distress could influence children's attitudes toward the diagnostic process before meeting with a clinically trained professional. Guidance from the Department for Education states that teachers "are in a position of authority and will typically be respected and trusted by the pupils they teach, giving their personal opinions greater weight and credibility. As a general principle, they should avoid expressing their own personal political views to pupils unless they are confident this will not amount to promoting that view to pupils [4]."

Affirmative vs developmental models

Broadly speaking, there are two approaches to treating children with gender-related distress: the gender-affirmative approach and the developmentally-informed approach. The gender-affirmative approach is based on the theory that a child's gender identity is innate. The developmentally-informed approach is based on the theory that a complex interaction of multiple factors underlie gender-related distress. The Cass Review interim report acknowledges that some clinicians report being under pressure to adopt a gender-affirmative approach.

Following directly from this is a spectrum of opinion about the correct clinical approach, ranging broadly between those who take a more gender-affirmative approach to those who take a more cautious, developmentally-informed approach (para. 4.15). Some secondary care providers told us that their training and professional standards dictate that when working with a child or young person they should be taking a mental health approach to formulating a differential diagnosis of the child or young person's problems. However, they are afraid of the consequences of doing so in relation to gender distress because of the pressure to take a purely affirmative approach (para 4.20).

There is a spectrum of academic, clinical and societal opinion on this. At one end are those who believe that gender identity can fluctuate over time and be highly mutable and that, because gender incongruence or gender-related distress may be a response to many psychosocial factors, identity may sometimes change or the distress may resolve in later adolescence or early adulthood, even in those whose early incongruence or distress was quite marked. At the other end are those who believe that gender incongruence or dysphoria in childhood or adolescence is generally a clear indicator of that child or young person being transgender and question the methodology of some of the desistance studies (para. 5.8).

School staff are unqualified to evaluate the merits of these approaches. Moreover, they have an obligation to remain politically impartial. This means not supporting one approach over another.

Social transition

Social transitions (the act of treating children as if belonging to the opposite sex) are performed by some schools in England. A social transition is a powerful psychological treatment that affects a child's psychological development. Not only are school staff unqualified to judge the appropriateness of such interventions, the outcomes are poorly understood.

Social transition – this may not be thought of as an intervention or treatment, because it is not something that happens within health services. However, it is important to view it as an active intervention because it may have significant effects on the child or young person in terms of their psychological functioning. There are different views on the benefits versus the harms of early social transition. Whatever position one takes, it is important to acknowledge that it is not a neutral act, and better information is needed about outcomes (para. 5.19).

Pressure

The Cass Review interim report acknowledges the pressures clinicians are under to adopt an unquestioning affirmative approach. Similarly, there is an acknowledgement that children are under pressure to identify with societal stereotyping. Schools cannot erase the pressures that children are under from, for example, social media and peers. However, teachers should promote acceptance for children's non-stereotypical behaviour (boys and girls exhibiting stereotypically 'feminine' and 'masculine' behaviour, respectively) and avoid reinforcing harmful stereotypes.

Primary and secondary care staff have told us that they feel under pressure to adopt an unquestioning affirmative approach and that this is at odds with the standard process of clinical assessment and diagnosis that they have been trained to undertake in all other clinical encounters (para. 1.14).

From the point of entry to GIDS there appears to be predominantly an affirmative, non-exploratory approach, often driven by child and parent expectations and the extent of social transition that has developed due to the delay in service provision (para. 1.18).

It is not the role of this Review to take any position on the cultural and societal debates relating to transgender adults. However, in achieving its objectives there is a need to consider the information and support that children and young people access from whatever source, as well as any pressures that they are subject to, before they access clinical services (para. 2.5). We have heard that distress may be exacerbated by pressure to identify with societal stereotyping and concerns over the influence of social media, which can be seen to perpetuate unrealistic images of gender and set unhealthy expectations, especially given how long children and young people are waiting to access services (para 4.13).

These will be considered further during the lifetime of the Review and include: . . . The complex interaction between sexuality and gender identity, and societal responses to both; for example, we have heard from young lesbians who felt pressured to identify as transgender male, and conversely transgender males who felt pressured to come out as gay rather than transgender. We have also heard from adults who identified as transgender through childhood, and then reverted to their birth-registered gender in teen years (para. 4.14).

Safeguarding

Children with gender-related distress may pose specific safeguarding concerns. They have a higher incidence of comorbid psychiatric and/or developmental difficulties. They are also more likely to be looked after children. Teachers need to be aware of possible harms such as breast binding or tucking (of male genitals). Children may also be subjected to grooming and/or coaching, and encouraged to deceive parents, clinicians and teachers in order to secure particular outcomes such as clinical diagnoses of gender dysphoria. They may also be receiving cross-sex hormones from unregulated sources.

In addition, approximately one third of children and young people referred to GIDS have autism or other types of neurodiversity. There is also an over-representation percentage wise (compared to the national percentage) of looked after children (para. 3.11).

We have also heard about the distress experienced by birth-registered females as they reach puberty, including the use of painful, and potentially harmful, binding processes to conceal their breasts (para. 4.3).

Most children and young people seeking help do not see themselves as having a medical condition; yet to achieve their desired intervention they need to engage with clinical services and receive a medical diagnosis of gender dysphoria (para. 4.4).

We have heard that some young people learn through peers and social media what they should and should not say to therapy staff in order to access hormone treatment; for example, that they are advised not to admit to previous abuse or trauma, or uncertainty about their sexual orientation (para. 4.5).

We have heard about families trying to balance the risks of obtaining unregulated and potentially dangerous hormone supplies over the internet or from private providers versus the ongoing trauma of prolonged waits for assessment (para. 4.7).

Summary

There has been a huge increase in the number of children (predominantly female teenagers) seeking help for distress in relation to their biological sex. Research into this new phenomenon is limited. The lack of high-quality data from longitudinal studies together with the changing epidemiology means that no consensus exists about the possible causes for this recent surge in children wanting to change sex. Clinically trained professionals face difficulties in making diagnoses and recommending treatment. School staff who now affirm my daughter are neither qualified to evaluate existing research nor clinically trained. Therefore, they cannot judge the appropriateness of, for example, socially transitioning children. It is an intervention with poorly understood outcomes that affects children's psychological development. The Cass Review interim report outlines some of the specific safeguarding issues that surround gender-questioning children.

Thank you most sincerely for your time and consideration.

Yours sincerely,

Kathleen

I would be happy to discuss this further with you.

I am a Florida resident and I am totally against any transitioning of minors in Florida as regards the medical community. We ask for a ban on gender-affirming care for minors.

Please record my comments against any gender-affirming surgeries or "health care" for minors.

Thanks,
Neal

Dear Florida Board of Medicine,

We thank you for taking up the vital question of regulating the so-called "gender-affirming" hormones and surgeries for young people.

As parents of these children, we have seen some very well-meaning but misinformed doctors recommend these radical life-changing interventions sometimes on the first or second visit. The myth that our children are getting "assessments" is propagated widely, but no requirements have ever been clearly articulated about which child or young person distressed with their gender role will benefit vs will be harmed. This intervention sterilizes 100% of children if administered according to the Endocrine Society's recommendations.

Older adolescents can get hormones with no assessments at all, and have their healthy body parts amputated by eager surgeons on little more than self-declaration of "trans identity." Many of our children are gay and autistic and have come to believe their very real distress is explained by the fact that they are "transgender" and that hormones and surgeries will help. They do not. We have seen our children's mental and physical health plummet following "gender-affirmation."

We also encourage you to require exploratory psychotherapy and to issue a clear statement that psychotherapy for gender dysphoria is not conversion. Our children and families need safe non-invasive alternatives to radical experimentation known as "gender affirmation."

Thank you for doing what you can to regulate this experiment on our vulnerable children.

To The Florida Board of Medicine,

September 19th 2022

The profession of Medicine is the profession that seeks to restore the bodily integrity of the human person when illness or injury has caused this integrity to be compromised. This is what I do daily as an Emergency Medicine Physician. I also help facilitate the healing of persons psyche when they are damaged from trauma and illness as well. I participate in this process by employing tried and true methods of restoring wholeness to the human person that have been subjected to peer review and scientific scrutiny.

Gender ideology is an ideology and not medicine. Ideology that seeks to destroy the bodily integrity of the human person by removing or diminishing normal functioning parts of the human person is the antitheses of medicine and should not be allowed to tout itself as medicine. It is ideology that hopes to use the tools of medicine to diminish and not restore the human persons integrity without subjecting itself to broad based peer review.

From the time of Hippocrates to today it has been well understood that castration of a male, as was the custom in some ancient cultures and even amongst some peoples until recently does not make a female but makes a Eunuch. The same could be said for mutilation of female genitalia. This does not make a male but a traumatized female. The subjection of children to any of these experimental practices would be a gross violation of the fiduciary responsibility of physicians to preserve and restore bodily integrity to patients. How can a child possibly participate in a decision that will alter their body permanently when the very thought is being seriously questioned across the globe. Look at events in England and Sweden who have been at this experiment for longer and have not found it to be the panacea they had hoped for. Assisting in this ideology by adopting laws to facilitate its practice should be considered a dereliction of due diligence.

Sincerely,

Michael Page, MD

Holland, Michigan

Subject: Oppose Gender Affirmative treatments that lack sufficient evidence base in science not ideology
Date: Tuesday, September 20, 2022 12:56:29 PM

[You don't often get email from rich_florentine@yahoo.com. Learn why this is important at <https://aka.ms/LearnAboutSenderIdentification>]

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

My name is Dr. Richard Florentine, MD.

I am a licensed board certified physician of Internal Medicine in Massachusetts. I am writing to you about my strong concerns about the attempt in your state to advance the practice of “gender affirming care” for vulnerable patients with gender dysphoria despite the lack of good quality evidence on the benefits of this method of treatment and it's highly likely life- long and irreversible harm to vulnerable, young children and adolescents who do not have adequate brain maturation to be able to give fully informed consent.

The impetus for this push for “gender affirming care” seems to be mostly motivated by ideology and politics rather than medical facts and supportive evidence based proposals. This is very DANGEROUS for the practice of medicine and for some of the most vulnerable patients in our society. This practice needs to be halted until further study and adequate and well designed studies can protect these vulnerable children from a profit driven, ideologically dominated medical complex which is NOT founded on a sufficiently sound high quality evidence base to support it's claims. High quality evidence is required of every other kind of medical practice. The even more vulnerable children with gender dysphoria should not be subjected to irreversible harm to their bodies and brains without the usual medical practice of extensive study of new treatment possibilities.

The ideological foundations of this type of proposed medical care was proposed by Dr. John Money at Johns Hopkins University in Baltimore, whose experiment on an unfortunate male patient, David Reimer, who was not intersex but had a damaged penis from a botched circumcision, and was raised by his parents, at the recommendation of Dr. Money, as a girl. His treatment included both surgical and hormonal interventions to ensure that he would develop female-typical sex characteristics. This conformed with Money's theory that gender was a social construct that could be altered by the conditions under which a child was raised. However, the attempt to conceal from the child what had happened to him was not successful—the child self identified as a boy. Eventually, with the guidance from his psychiatrist, his parents informed him of what had happened to him at birth and he decided to reverse the hormonal and surgical interventions that had been performed to feminize his body. He continued to be tormented by his childhood ordeal and took his on wife at the age of 38.

David 's life story is an example of the harm wrought by theories that gender identity can socially and medically be reassigned in children.

Previous medical literature had shown that in young male patients (the majority of the cases of GD) (in the past) with prepubescent gender dysphoria showed a high rate of natural resolution with 61-98% of the children reidentifying with their biological sex during the experience of their own puberty with psychological support. (work of Zucker).

Currently there has been a complete reversal of this pattern of gender dysphoria with a NEW (?Epidemic) form of non childhood initiated gender dysphoria in genetic adolescent girls, which has increased by 5000%. In addition, many of these patients have comorbid conditions such as autism/ASD and Attention Deficit/ Hyperactivity Disorder. The reasons for this new phenomena has not been fully explained. But since the recent introduction of “gender affirming treatment” on this subgroup of patients, has lead to 100 % of these patients have pursuing "gender transition" treatments.

In the US, the thrust for this kind of “gender affirming care” has been ideologically motivated, with an effort to

“silence’ all debate or oppositional voices.

In Europe, however, there has been a movement at reassessment after the leading Gender Identity Development Service, called Tavistock and Portman Trust’s Gender Identity Development Service clinic in London were closed after a “damning report on ideological malpractice”. On July 29,2022, the World’s Largest Pediatric Gender Clinic was shut down due to Poor Evidence , Risk of Harm and Operational Failures. These concerns have also been recognized increasingly in Western Europe, where more thorough medical records are kept, Thus Sweden has made the decision to no longer offer gender transition to minors outside of clinical trials. Finland has also now sharply restricted eligibility for gender transition to minors with a classic, early childhood onset gender dysphoria and no mental health comorbidities, and has stated that “psychotherapy” should be the first line of treatment.

At the Federal level of the USA, the US continues to assert that “gender-affirming” care is safe and effective, despite the findings of multiple systemic reviews of evidence that found that the benefits of gender transition are highly uncertain while the risks may be significant. Specifically, the Endocrine Society’s treatment guidelines for gender-dysphoric youth are followed, a minor’s future sterility is likely. Other health risks include compromised bone health, brain development, cardiovascular complications and a number of other, as yet unknown risks.

For these and other reasons, I strongly urge you to oppose supporting medical treatments that are not sufficiently evidence based, especially when irreversible harms is great and informed consent is not possible.

Sincerely yours,

Richard Florentine, MD
Massachusetts

Dear Florida Board of Medicine,

As a current medical student and future physician, I firmly believe that "gender-affirming care," when defined as providing chemical and surgical methods of transition to children and adolescents, are not only harmful, but unproven and experimental treatments that should not be available to minors. The evidence-based medicine is clear: there are negative short- and long-term psychological, emotional, social, and medical consequences of these so-called therapies. I strongly urge you to carefully evaluate the available science before making any decisions which have irreversible effects on Florida's youth, and to prevent harm to children.

Sincerely,

Sarah E. Toates

Paul A. Vazquez, J.D.
Executive Director
Florida Board of Medicine

Dear Florida Board of Medicine,

I am not a doctor or psychologist, I am a parent, a mom.

There's no stronger instinct than a parent's need to protect his or her child.

Last year, a California woman fought off a mountain lion—with her bare hands. Why? Because the predator was dragging away her 5-year-old son. She heard a commotion, ran outside and immediately began punching the mountain lion. It fled, and she saved her son's life.

The Florida Board of Medicine must use its authority to protect children and adolescents from misinformed and dangerous actions and must allow its members to render evidence-based professional care. Minors cannot provide informed consent to irreversible and unknown harms of so-called "gender affirmative" medical treatments and surgeries. Gender confusion and body dysphoria require psychoeducation while comorbid psychopathology may require psychotherapy and psychopharmacology. "Puberty-blocking" drugs are misrepresented as "reversible pause buttons" while interfering with growth, sexual development, fertility, and multi-system functioning. The meteoric expansion of gender clinics is a preventable medical scandal in the making.

What is the treatment doing, other than sterilizing people; placing them at increased risk of various cardiovascular problems, osteoporosis, and cancers; destroying their sexual response; and limiting their future dating and partner pools?

Transgenderism is an ideology that values artificiality, medical experimentation, image obsession, and mutilation; and devalues health and self-acceptance.

Worse, promoting and protecting content that encourages gender transition can lead

to irreversible harm. The chemical and surgical interventions used for gender transition cause health problems like cardiovascular disease, reduced bone density, and, ultimately, sterilization. They don't even improve mental health in the long run: Those who surgically transition are 19 times more likely to commit suicide than their peers, and teen suicide rates are found to be higher in states where minors can access these interventions with greater ease.

You're assuming these kids need these medical interventions. The evidence does not support this. Every evidence review has found the evidence behind these interventions to be low quality, meaning you can't predict outcomes reliably (in particular if the intervention will help). Maybe kids who are trans identifying shouldn't be given these surgeries and drugs this young, as it's not clear when it is temporary or not (kids before puberty in the past, if not socially transitioned, grew out of it most of the time, and older people have found in many cases that their trans identification stemmed from being gay, depression, separation anxiety, being on the spectrum, trauma, etc.). That is why many countries are actually protecting "trans" kids by not rushing them to permanent dangerous interventions until they understand themselves better--that is, not giving them puberty blockers (which seem to almost always lead to taking hormones), hormone and surgeries, except in very very special cases, and in research settings. Trans identification is poorly understood and in many cases temporary. This is not at all like being gay. This isn't a right wing issue, it's a medical issue. You can look at the Cass Review in the UK, the French National Academy of Medicine, Finland, Sweden...the US has gone anti-science.

Stop the affirmation only policy. There is no biological test for gender identity disorder, it is a mental disorder. No one is born in the wrong body. "Born in the wrong body" is like saying one was born with the wrong liver, heart, kidney, brain, or other organ. It's just not possible, and thinking one is born in the wrong body is a mental illness, and "gender affirming medicine" does not solve a mental illness. It does no long term good and is purely and simply abuse (child abuse if practiced on minors) and should be stopped!

The message we must send to our children is that we do not need a label. We do not need irreversible medication. We do not need surgery. We are fine just the way we are.

Thank-you, and Do No Harm!

Sincerely,
Laurie Samuelson, 65 year Florida resident

Dear Florida Board of Medicine members,

It has come to my attention that you are reviewing the regulations for **youth transition** and the **informed consent process**. As a parent, a tax-payer and Doctor of Education, I strongly request that you limit puberty blockers, surgeries, and any other hormone therapies for children. These medical procedures do not correct the real issues, which are mental health related. Issues of fitting in, being accepted and loving themselves cannot be satisfied with surgery. These children need a stringent therapy program. In addition, children often say things they don't understand, or mean and often regret. When my daughter was young, she wanted to be Cinderella, but I knew she would grow out of that and she did. I did not go and get surgery to make her look like Cinderella. They are extremely impressionable, and unable to fully understand the lifelong impacts of these decisions. It is very apparent the adults in their lives are also in need of therapy and are not acting in the best interest of these children. Gender is a feeling, Biology is a fact. Please use your authority to save these children from a lifetime of pain and confusion. These children should be given coping mechanisms to help them through adolescence and the awkwardness that comes with it. Once they turn 18, they should be free to decide on surgery.

Thank you very much for your time.

Hello, I am a certified/licensed anesthesia provider in Ohio and also a devout Catholic and member of the Catholic Medical Association. I understand that the State of Florida is soon going to be considering regulations for "youth transition" and the "informed consent process".

The destruction of a person's reproductive organs is not health care and only fuels a lie, namely that a person can become something other than what Almighty God has destined them to be. It is simply not possible to transition to a new gender by cosmetically changing reproductive organs with medicine and surgery. We all need to stand up and say "no" to this ridiculous fad we are going through.

You probably have read the story by Hans Christian Anderson, "The Emperor's New Clothes". In this story, everyone in town believes a lie and by not speaking up and promoting the truth this farce continues. It is the innocent child that finally stops the madness: "the king is naked !!" We need to all get our heads out of the sand and speak up: "TRANSGENDER MEDICINE IS NOT HEALTHCARE !!".

I would be happy to discuss this issue on the phone.

Best regards,
~Matt

Dear Florida Board of Medicine Members,

I am writing to encourage you to not legalize "gender affirmation surgery" for children, in Florida. Children need time for full neurologic development before making decisions regarding this surgery, unless they were born with a chromosomal disorder of sexual development. Then, the decisions of surgery should be made in the best interest of the child, with parental consent. These guidelines would help prevent unnecessary surgeries which may be made because of peer or societal pressures. Thank you for your consideration.

Dear Board Members,

I stand with the Catholic Medical Association (CMA) to voice my support for regulating sex-based medicine practices in the state of Florida in light of medical evidence and the highest ethical standards that safeguard the dignity of each human being. I especially support restricting “gender-affirming care,” which seeks rapid gender transition for children and adolescents. Now is the time to set things right and an example for the rest of the country. Now is the time to return to medical evidence, parental authority in their children’s healthcare, and to protect children and adolescents from barbaric mutilation and puberty suppression being pushed in the name of political ideology.

Sincerely,
Tyler Tominello
Medical Student
Catholic Medical Association (CMA)

Dear Charmon Diamond,
Thank you and State Board for protecting our
miners from these gender-affirming treatments.

Sincerely,
A. Brown

Chairman David Diamond

I greatly appreciate all the hard work and commitment that you have done in protecting children and the righteousness of God.

It's through your unwavering perseverance that there is hope for the future.

I am writing to voice my strongest possible objection to any medical treatment for people under 18 for "transgenderism" under the guise of "gender-affirming care."

This is an ideologically-driven abomination. It's medical malpractice and needs to be immediately outlawed. No child can consent to any of this:

Puberty blockers are NOT a "temporary pause button." Puberty blockers cause: infertility, chemical castration in sex offenders, are being used off-label with no studies on safety or efficacy, cause stunted growth, reduced brain size, IQ & cognition, osteopenia, osteoporosis, bone fractures & lifelong reduced bone density, an INCREASE in anxiety/depression/suicidal ideation, micropenis in males, just to name a few.

All of this transgender nonsense is being funded by pharmaceutical billionaires. Young girls are having their healthy breasts cut off before they can vote, legally sign a contract or join the military or buy a drink. Girls are having their healthy uteruses & ovaries removed. Boys are having their testicles & penises cut off. It's barbaric and sickening and the state of Florida has a LEGAL & MORAL responsibility to stop it and protect these vulnerable children from predatory doctors, surgeons and their mentally ill parents.

Trans medical care should be outlawed for people under age 25, when the brain is fully formed. The drinking age is 21. Because kids don't have the mental ability to have good judgment and weigh consequences. Please stop this to the oldest age possible.

The most notorious butcher surgeon in the country butchers children in FL, Sidhbh Gallagher, MD, of Gallagher Plastic Surgery. She needs to lose her license in FL. FL needs to outlaw the practice of doctors advertising these surgeries to children on social media, if you legally can. Dr. Gallagher does this better and more than anyone on Facebook & Instagram.

Thank you for doing this.

Best regards,
Ms. Donine Henshaw
Tucson, AZ 85718

Sincerely,

Donine S. Henshaw, M.A.

Good morning,

I am writing today to send my strong encouragement to the Florida Board of Health in the matter of the regulation and restriction of pediatric gender affirming care. I am writing as the mother of an ROGD teen girl, and as a Registered Nurse of almost 20 years.

In the past 5 years, I have watched as more and more young people, mostly young women have declared a trans identity. I see this in my practice both as an emergency RN and as a Forensic Sexual Assault Nurse Examiner. The girls that are identifying this way are largely suffering from childhood trauma, autism, and other mental health issues, and many of them are typically gender nonconforming, lesbian or bisexual, and somewhat socially awkward, with difficulty fitting in with their peers.

This is my experience with my own daughter as well. Autistic, recovering from a childhood sexual assault, depression, anxiety, an eating disorder, and desperate for acceptance from the peers that have tormented her for her entire school career. She never showed any signs of gender dysphoria or discomfort with her natal sex until her middle school introduced a unit on gender identity. Shortly after that, every single one of her friends began identifying as some letter under the LGBTQ+ umbrella and she herself declared a non-binary identity. This was almost four years ago, and my own daughter has since declared that she is a lesbian, bisexual, back to lesbian, and now demanding the use of her preferred pronouns. I have always loved and supported my children. I am what you would call a classic liberal, I campaigned for marriage equality and have a son who is gay. I told my daughter that I will always love and support her, but that I didn't know what non-binary meant, as there are two sexes and a billion+ different ways to express oneself. My daughter's mental health has steadily declined since she made this identity declaration, and she has spent the past 3 months in various treatment facilities after two suicide attempts. Affirming her, using preferred pronouns, telling her she is separate from her body will not help her. She needs therapy to work through her trauma, coping skills to deal with life's hardships, treatment for her anxiety and depression, and a healthcare system that does not misdiagnose her autism as transgenderism.

I have grave concerns as an RN about the use of puberty blockers in children, and I am horrified at the number of photos I see circulating on social media of young girls post double mastectomy. Even worse, I am appalled at the number of physicians who have taken to using social media as a way of advertising double mastectomies and genital reconstruction surgeries to children.

I have serious concerns that basic medical ethics are being overlooked, and I am shocked that my own professional organizations have stayed silent. Although it is not law, the Nuremberg Code is the gold standard for medical ethics regarding human experimentation and it is the framework used to teach nursing students about ethical issues in institutions across this country. The Nuremberg Code states that a patient must be able to give informed consent to any treatment for it to be considered ethical. There are no long term clinical trials on the use of puberty blockers in otherwise healthy children for extended periods, and the short term evidence points to issues with cognitive development, bone loss, osteoporosis, brain swelling, vision loss, and so much more. These effects are permanent and not reversible, as the public has been told.

There are no long term clinical trials on how children who have been effectively sterilized during puberty do in the long term in regards to mental health, but we do know that the suicide rate for transgender individuals, contrary to popular belief, is much higher approximately 7-10 years post transition, indicating that this is not in any way a form of suicide prevention as the public has been told.

There are no long term clinical trials on the use of wrong sex hormones long term and the impacts this has on every other body system. The public has been told that transgender individuals have a much shorter lifespan than the average American, and we are told this is because of high suicide rates and transphobia, but the fact that some of these people have destroyed their bodies by taking years of wrong sex hormones is always, conveniently, left out of the discussion.

With every issue listed above, how can we even begin to say that parents and children are being given appropriate information, or that they could even begin to give informed consent? There are far too many unknowns to consider any of this informed, and as the lawsuits of the detransitioners start to roll in, we will see how well that holds up in court.

It seems that medical providers have stopped following evidenced based guidelines in pursuit of activist interests, and the harm being done is impacting our most vulnerable population, our children. As a healthcare professional, I am ashamed of my colleagues for perpetuating these lies about this so called gender affirming care, and as a mother I have lost all trust in the healthcare system. I will no longer use a primary care provider for myself or my family, CVS minute clinic check ups all around when necessary, otherwise I manage from home. I have no faith or trust in the medical community anymore. I do not trust activist physicians or nurses who are so eager to throw away evidence based practice and ethics in search of gaining internet or social media fame, or to make a name for themselves.

As an RN, I am called to provide holistic care to all of my patients, to facilitate healing of body, mind, and spirit. How can I do that when society is pushing a ridiculous notion that somehow a person's body is separate from their mind and spirit and physicians who seem to have lost their ability to think critically are endorsing such a notion?

As a mother, I am called to advocate for and protect my child at all costs, how am I to do that when unethical physicians disregard every concern I have or somehow label me bigoted and non affirming for expressing these concerns? As a mother, I look to physicians to assist me in maintaining my children's physical and mental health, not to brainwash them into thinking humans can magically change sex, or that all of their mental anguish will be solved by elective cosmetic surgeries and procedures.

I am appalled and disgusted by the behavior of social media activist physicians, I believe that the medical transitioning of children is the largest medical scandal of all time, more so than lobotomies, thalidomide, or Tuskegee. I am begging you today, as both a nurse and a mother, to be the first of what will hopefully turn out to be a landslide of reasonable medical agencies, to restore sanity and urge caution in performing unnecessary elective procedures on minors that will not solve their mental health issues, only turn them into lifelong patients dependent on the medical and pharmaceutical industry for survival.

Please help return the focus of healthcare to HEALTH, not identity politics, not customer service, not political activism.

Thank you for your consideration,

Elizabeth N.G. Watson RN, BSN, PHN

I hope I'm in time to to stop your voting to give you my thoughts so you may make an objective decision. I am writing as a concerned voter who wants you to know that I believe this is NOT your decision to make! Consulting with a minor without their parents present goes against everything our Country is built on. By changing legislation to allow doctors the ability to council, prescribe medication to, or help minors to change their appearance because the minor may think they are something else will be opening doors that will hurt others in the future.

Examples:

1. This could change laws regarding under age sex, let's say a 15 yr old and someone who is 18. Right now Parents can have the 18 year old arrested. The fact that this piece of legislation is excluding the parents may take the parents rights away for all future events!
2. How will pornography is look in legal system if this piece of legislation passes?

These questions do need to be asked because children shouldn't be making major decisions about their bodies alone, without parents present or parental consent. Our uniformed police officer's across the United States cannot question minors without their parents present, so why would this be any different? And if you change this will you be changing this protection for our children?

Thank you,

Jeanne Southard

Dear Florida Board of Medical Practice,

I understand that the Florida BOMP is considering regulation of transgender medical practice.

My concern is that National Medical Associations and the current practice standards have adopted an unproven and experimental approach to transgender treatment called "affirmation" as opposed to an evidence based and scientifically grounded approach to the treatment of the diagnosis of "gender dysphoria."

I support the Florida BOMP adopting a scientific and evidence-based regulation of the treatment of gender dysphoria.

Medical atrocities are being committed on youth and young adults in the name of a transgender ideology that has no basis in science. Florida can lead the nation by joining the United Kingdom and other European countries that are beginning to recognize the affirmation model coupled with medical intervention as truly harming people. My best wishes to you if you take this on. Transgender activists will attack the reliance of science and evidence supported medicine for treatment of gender dysphoria and transgender persons mercilessly. Good luck.

Sincerely,

David Musielewicz

Hello,

My name is Heather Elizondo Vega. I am a member of both the American Academy of Pediatrics and the Christian Medical Dental Association. I am board-certified through the American Board of Pediatrics in both General Pediatrics and Adolescent Medicine.

I learned from the president of the CMDA that you all were allowing comment through 20 September 2022 regarding the issues surrounding gender-affirming medical care, particularly for youth. Thus, I am writing to you in response to that.

First, I would like to express my concern that your organizations did not make this information (about the inquiry) publicly available. I only learned because I met with the CMDA President at a recent conference. I am disappointed that there was not any sort of mass e-mail sent out from either the Dept of Health or the Board of Medicine about this opportunity for comment through 20 September 2022. Thus, I am concerned that you are going to receive a skewed representation of the population of Florida physicians due to many individuals being unaware of the opportunity to comment at this time.

I have mixed opinions regarding the medical care for youth to provide "gender affirmation". I have heard the arguments on both sides. I do very much have ethical and medical concerns about gender-affirming medical interventions. However, at the same time, I cannot support a state-wide ban on such services. Here is how I came to that conclusion: I am concerned that children are rushing into treatment too early. I am also concerned about longterm ramifications such as irreversible physical attributes that, in some cases are later regretted, and I am particularly concerned about infertility. However, I also support individual autonomy and parental rights to make decisions for their children.

I think that there need to be protections put into place to ensure that children are evaluated by a qualified mental health professional over a period of time before they enter into any sort of gender-affirming medical treatment. Perhaps, some sort of extra protections such as having a child meet with two independent mental health providers for consensus would be a good idea. Secondly, there should never be a situation in which a child receives gender-affirming medical interventions without parental consent.

Again, while I do have ethical and medical concerns about gender-affirming medical care, I think that the decision should be left to the patient/parent/medical provider/psychological provider group, should be individualized, and should be made with much discussion in relationships. I am generally

opposed to the idea of outright government bans, as this becomes an infringement upon patient rights and parental rights.

Meanwhile, as I do have concerns about the medical ramifications of gender-affirming medical care, I think we need to support long-term studies regarding the risks and benefits. I would support a Florida-wide education campaign to help the medical and lay community to know that there is more to this argument than suicide prevention. Most studies and policy statements that have been made by the “major medical organizations” discuss gender-affirming medical care in the context of either suicide prevention or prevention of patients seeking “street drugs”. The voices of the counterpoint are not loud enough or widespread enough. We need more education to the medical and the lay community about the reality that there is a lack of long-term data regarding suicide prevention and regarding the rates of persistence versus desistence. More information is also needed by the medical and lay community about fertility considerations, particularly since most teens who identify as transgender do not make attempts to preserve their fertility before entering treatment, whereas it is my understanding that the rates of adults who identify as transgender who desire fertility is much higher.

So, ultimately, I would like to advocate for more education, a strong policy regarding the need for parental consent, and a strong policy regarding the need for a high-quality psychological intervention before entering into decisions about gender-affirming medical interventions. But, because of my concerns about the politicization surrounding this issue as well as infringements upon individual and parental rights, I cannot support an outright ban on such services for youth in Florida nor can I support any sort of criminalization of either parents who undertake this treatment for their children or of medical providers who provide such services. Generally speaking, medical decision-making is best left between patient/parent/provider and best left out of the government’s hands. However, if the Department of Health and the Florida Medical Board are concerned about the ethical and medical concerns related to this issue, as am I, I would whole-heartedly support a stronger education campaign for both the lay and medical community so that everyone has a better understanding of both the pros and the cons of such treatment.

Thank you for your consideration.

Sincerely,

Heather

Good morning,

As a medical doctor board-certified in General Preventive Medicine and Public Health and concerned for the true health of children, I want to give my professional recommendation that the Florida Board of Medicine **not** support any gender-affirming actions, rapid gender transition or other putative gender-altering interventions on children as these actions do not constitute care, medicine or evidence-based practice.

Best,
John W. Kieffer, MD, MPH

I am writing to urge you to adopt these measures to protect children from dangerous medical transitioning through prohibiting both informed consent and banning Puberty Blockers, Wrong/Cross-Sex Hormones and all surgeries related to gender transition.

As you are aware the use of Puberty Blockers, wrong-sex hormones, and surgeries such as double mastectomies and penectomies are all experimental with no long-term studies. Research shows that there is no shown improvement in mental health as a result of any of these procedures. Minors do not have the capacity to make lifelong decisions, especially when the decision could sterilize them. This is evident by the number of detransitioners coming forward and telling their stories about their regret over medically transitioning. Their numbers are growing rapidly, but most are too afraid to speak up. .

My daughter suffers from Rapid On-Set Gender Dysphoria, ROGD, and has all the typical traits of this phenomenon. Her college pushed and aided her down the path of transitioning. Sadly, she estranged herself from us in the spring of 2020. That July she started taking wrong sex hormones. In April of 2021 she travelled to Florida and had a double mastectomy at the age of 22. A 22-year-old does not have the capacity to truly understand the lifelong implications of such a decision. Yet much younger children are being allowed to make such decisions and that is unacceptable and child abuse.

I am the Indiana leader of Parents of ROGD Kids and a leader a Christian support group. I spend a lot of time speaking with parents dealing with a child that suddenly comes out as Trans. All of the children have the usual traits of ROGD such as trauma or mental health comorbidities. Most of these children are still minors. The parents are scared to death and don't know where to turn. Trying to find a therapist that won't affirm their child's belief they were "born in the wrong body" is almost impossible. The schools are ignoring their parental rights. Even more frustrating, doctors are affirming their child in front of the parents.

When I give presentations, the audience is shocked when they find out the only provider of gender care for minors in Indiana is Riley Children's Hospital in Indianapolis. Up until two years ago, Dr. Sidhbh Gallagher was on staff at Riley and the Eskenazi gender clinic. She would post pictures on Facebook of herself posing with young woman right after she had amputated their healthy breasts. As I'm sure you are aware, she relocated her practice to Florida. She now includes posts on TikTok where she refers to herself as the "Tit Wizard" and the procedure as "Teetus Deletus" and "Yeet the Teets".

Dr. Gallagher is just one example of the many mental health and medical professionals acting in unethical manners and, instead of being reprimanded, are being applauded. It is mind boggling that we have come to a place where it is acceptable to ignore mental health history, cut off healthy body parts, and inject dangerous off label drugs, which are creating lifelong medical patients. Worse yet, these so-called professionals are turning their backs on the individuals who now regret what they were coerced into doing to their bodies.

I ask that you adopt these guidelines and protect our children from these experimental, unproven, and dangerous procedures. Let Kids be Kids.

-

Thank you for your time.

Justine Mercedes

Dear Board of Medicine

I am a Florida licensed physician writing this letter in support of the rulemaking request by Surgeon General Joseph Ladapo. As you are aware, the data upon which gender affirming care has been recommended is of low quality and there is no objective high quality data that would justify the expense or the known risks of this path that sets up these patients for a lifetime of medical problems.

The explosion of new adolescent girls who are seeking these treatments is a social contagion that is being fueled by predatory clinicians and we need to put an end to this in Florida.

Dear Members of the Florida Board of Medicine:

I understand you are evaluating the need for regulation of gender-related health care. Based on my experience with my own trans-identified child plus extensive reading on this topic, I believe regulation is badly needed.

When my child came out as trans I interviewed a couple dozen therapists in search of one who would do a thorough assessment and standard psychotherapy with my child. All I could find were therapists who believed in immediately affirming a child's trans identity. I finally found a therapist in another state who my child could see online. I have had to pay out-of-pocket for this treatment, but it has been worth every penny. Over time my child has built a trusting relationship with this therapist; my child's anxiety has decreased; her confidence has increased; she is no longer pursuing medical transition; and her relationship with us has improved immensely. Simply affirming her trans identity would not have fostered this growth.

When I began researching medical transition treatments, I was truly stunned to learn about the types of treatments being offered to children and young people. The female body has not evolved to process large amounts of testosterone. Doctors consider high testosterone levels in girls with polycystic ovary syndrome to be dangerous, but testosterone magically becomes safe and therapeutic as soon as a girl declares a trans identity. Doctors tell athletes that using anabolic steroids will damage their cardiovascular systems but now hand out the original anabolic steroid, testosterone, freely to girls and young women. Minors are receiving double mastectomies because they don't like their bodies. Many if not most adolescents go through periods of disliking their bodies, but we used to let them grow out of that discomfort instead of cutting them up. Traditionally, doctors have been very reluctant to perform hysterectomies on women under 35 because it can increase the risk of stroke, bone loss, heart attacks, and urinary issues, but now hysterectomies are okay for young women as long as they identify as transgender. Phalloplasties should simply be banned based on their complication rate, but women whose prefrontal cortices are not yet fully developed can get them. It seems that in the realm of gender medicine, all common sense, conventional wisdom, and medical knowledge fly out the window, and anything goes. It truly feels like the wild west.

I hope you will follow the lead of the United Kingdom where the National Health Services is conducting a thorough review of the scientific literature around transition treatments and plans to revamp their pediatric gender services based on their findings.

Please regulate gender medicine for the sake of our children, adolescents and young adults.

Sincerely,

Susan Nagel

Hello! I am a family medicine physician from Nebraska and am writing to encourage you to take a strong stand for the youth of your state as you consider regulations regarding sex based medicine. Rapid gender transition therapy is child abuse. The medical and evidence-based studies of these methods demonstrate both short and long term harm of these interventions and they should not be allowed. Psychosocial support models, which other countries are moving back to after seeing the negative effects of surgical and hormonal "therapies", are safer and offer our children the opportunity to grow and mature as they are intended. Always consider the Hippocratic oath in which medical professionals vow to "first, do no harm". These therapies are most certainly causing harm to the young people being subjected to them.

Thank you for your consideration and leadership.

My name is Mark Casebolt

I am a general surgeon in Ocala, Florida

I am writing to you because I am concerned about upcoming recommendation concerning surgical alteration of external sexual characteristics for minors who suffers from gender dysphoria.

As a father of 4 grown children, I have a hard time believing that any minor has the mental acuity and emotional maturity to make such a monumental and irreversible decision.

With the evidence being inconclusive I do not see any compelling reason to recommend that the surgery be done. I would err on the side of conservative management.

I think the decision about gender altering surgery should only be made after an individual reaches the age where they have the emotional maturity to make such a decision.

Where is the harm in having them wait?

Paul Vazquez, JD, Executive Director
Florida Board of Medicine

Dear Director Vazquez,

I am writing as a concerned physician and surgeon to encourage the Florida Board of Medicine to restrict the use of hormonal and surgical therapies to treat gender dysphoria in children.

Despite the popular narrative, there are no high-quality, long-term studies that show that the mental health state or suicide rate is any different following transition of children. The fact that many of these irreversible treatments are currently being proposed for and even administered to children who have barely reached the age of puberty is unconscionable.

In fact peer-reviewed studies show that a “watch and wait” approach to gender dysphoria in children will result in a realignment of gender identity with biological sex in up to 85% of these same children.

Even the revered Tavistock Center in the United Kingdom has been forced to close its doors and cease treating children with gender dysphoria for a variety of reasons, including the health staff felt under pressure to adopt an ‘unquestionably affirmative approach.’”

I believe it is premature to move forward with such experimental therapy without the informed consent of these children, who very commonly will begin down an irreversible path which many will regret. We owe our children more than this. Please continue to urge caution and withhold such experimental therapy from our precious children.

Thank you.

Dear Members:

I am concerned about the youth transition and informed consent process being considered by the Florida Board of Medicine.

"Gender-Affirming Care," including rapid gender transition for children and adolescents, is neither caring nor affirming. Medical and evidence-based studies show that significant short and long term harm is done by such interventions.

Let your vote be guided by reason and truth, not emotions. Vote NO for "Gender - Affirming Care."

To Members of the Florida Board of Medicine:

As the Board seeks to understand the evidence, efficacy and the ethics of gender care - and in particular the "affirmative approach" involving hormonal and surgical transition - I am compelled to submit my comments.

I'm a liberal and a Democratic, a social worker by profession, and the mother of a 16-year-old girl who has been caught up in the trend of young girls suddenly embracing a transgender identity. I supported (and still support) gay marriage, I applaud and stand for peoples' rights to express their chosen sexual identity, and, I support people to live, including to physically transition *if they are adults who have considered the pros and cons over a period of time*, as the gender they feel expresses their "true" selves.

I am, however, dismayed that the school curriculum in this country, apparently along with the American Academy of Pediatrics, endorses the unscientific notion that gender is "an internal sense" and not a biological reality. Please see [here](#), [here](#), and [here](#) for more information. The number of girls claiming a transgender identity has [skyrocketed](#) in recent years.

The summer that my daughter turned nine, we moved across the country from New Jersey to California so my husband could start a new job. Until then we had been a family who had limited internet contact to less than two hours a day, (again, as per recommendation of the AAP, who we formerly thought of as a reliable resource for health and children).

When we moved, without school in session, and with fewer friends and social outlets in our new town, our daughter turned to more time on the computer. When she took up coding via the MIT-organized website Scratch.org, I figured if she was going to spend more time online, at least it would be "educational". Several weeks later, our daughter announced "I've realized I'm transgender". My husband and I were confused, as there was no indication at all of these thoughts until she said this. Although we were confused, we were not alarmed. Why would we be? Kids are impressionable. They "try on" different identities as part of their development. Over the years, my daughter presented herself as depending on the days, a kitten, a bunny, and a ballet dancer.

As we met more people in our new town, I was astonished to discover that other adults, including my daughter's new pediatrician and her schoolteachers, were not only eager to embrace my daughter's 'transgender identity', but they were disapproving when I commented that I thought this was a phase. While we were happy, we told our daughter and anyone else who would listen, to have our daughter dress however she wanted, cut her long hair, even call

herself a different name since she "hated" her own name...this did not, we reiterated, mean that she was actually a boy.

The pediatrician, who had met my daughter once, insisted on "respecting my daughter's gender identity" and proceeded to call her by a boy's name my daughter had chosen for herself. I then switched to a different pediatrician, who repeated the need to "respect and support" my daughter's sudden, seemingly random, recognition that she was "actually a boy". She also recommended that my 9-year-old attend support groups for transgender children, run by the local lgbtq center. They had support groups for parents too, so that the parents could "learn to embrace the transition".

Meanwhile, in the wake of her newly found trans identity, my daughter's mental health became severely compromised. She (ten years old now) was diagnosed with depression. She started cutting herself. She spoke of thoughts of suicide, that she thought would disappear if she could only be medically transitioned to be a boy.

When we approached mental health practitioners (a first, then a second, then a third!) they all repeated that not affirming my child's gender identity was putting her at a higher risk of suicide. The second one was actually the person to introduce my child, without my knowledge, when I was out of the room, to the idea of puberty blockers. All three of them said some version of "would you rather have a dead daughter or a live son"?

In brief, after five years of insisting she "knows herself", pleading for puberty blockers, and attempting several times to have professionals convince us, her parents, of the need for medicalization...she stopped. It wasn't sudden. First she grew her hair out a little longer. She got interested in lip gloss. She read graphic novels and books about what we used to call "tomboys". Over time, she has thought this through for herself and now realizes she was, in her words, "confused." If we had succumbed to the pressure (and that is indeed what we felt - pressured!) of doctors, school counselors, mental health professionals, and other parents who barely knew our child., all of whom insisted that my child knew best...my child would already have been on a path to medical transition. Some effects of this transition (her voice, facial hair) would be irreversible. Her fertility, at age 10, would have been compromised...perhaps permanently.

I know (too many) parents that have experienced almost exactly the same circumstances as did our family. In some cases, their kids were older and the parents were unable to intervene in medical decisions. In some cases, CPS was called in by school officials who thought the parents were damaging their children by not 'affirming their gender identity'

And in some cases, as often happens, their kids matured and changed their minds. After all, we now know the brain is not fully developed into one's mid-20's. If my daughter was 25 when she first announced her trans identity, I probably would have considered it a more measured declaration. I'm glad we questioned her at nine.

I implore the members of this board to carefully consider the potentially disastrous consequences of allowing children (and adults who don't have much history with them) to make life-changing medical alterations.

Thank you for your consideration of this matter.
Rina Davis

Greetings,

I am writing to you as a parent of a trans-identified child, who did not have any discomfort with their biological sex until being exposed to information regarding gender identity on the internet. Our child is intellectually gifted and on the autism spectrum. It is well known that children on the spectrum are at greater risk of being emotionally manipulated by peers and adults. I believe that the confluence of social media and normal adolescent insecurity during the pubertal process is creating a perfect storm among our youth who are just trying to make sense of the world. Parents like me are counting on the grown-ups in the room to look at the evidence, and to recognize the social contagion that is before us.

So called "gender affirming care" sounds like an altruistic endeavor, however what that care involves is chemical castration with puberty blockers, followed by wrong sex hormones, which leaves an individual sterile and most likely without the ability to have full sexual function. Surgically, for females, it involves the removal of healthy breast tissue, and after a few years on testosterone, the removal of the reproductive organs. For males, it involves the removal of the testicals and an inversion of the penis to create a pseudo-vagina, which is really just an open wound that requires constant maintenance to keep the wound from closing. These are not life "affirming" or life saving procedures, they are life altering, permanent changes that will create a lifetime of frustration for individuals who will no longer be able to experience sexual pleasure. It also creates individuals who are dependent on synthetic hormones for the rest of their life. The pharmaceutical companies stand to make huge profits off of vulnerable people. This is the second dope sick of our time.

This is a psychic epidemic that has been perpetuated by propaganda that children are being exposed to not only on the internet, but also within schools across our nation with the teaching of the pseudoscientific concept of gender identity. This is a faulty belief system that people can be born in the wrong body based on regressive, sexist stereotypes. It is not bigoted or transphobic to denounce this concept.

One of the big lies around this movement is the risk of suicide. I hope you and your fellow physicians understand that this is a false, misleading and emotionally manipulative lie. There is a long term study from another country that shows the suicide rate actually increases by nearly 20 percent after people have medicalized.

More and more detransitioners, individuals who no longer believe they are the opposite sex, are starting to come forward to tell the stories of how they have been harmed, and currently it seems that the medical community and our governmental institutions are treating them like an anomaly. The truth is their numbers are growing because a different cohort of individuals are being "affirmed" without any safeguarding or long term psychoanalysis to unpack an individual's ideations. We are at risk of pathologizing childhood.

Please be brave in renouncing these unethical, and unscientific practices.

Respectfully,

Chris, a concerned parent

Dear Florida Board of Medicine,

Thank you for questioning the regulation of so-called "gender-affirming" hormones and surgeries for young people. I can guarantee that this is one of the most important issues of our lifetime.

As a parent of one of these children, I have seen some very well-meaning but misinformed doctors recommend these radical life-changing interventions sometimes on the first or second visit. The myth that our children are getting "assessments" is propagated widely, but no requirements have ever been clearly articulated about which child or young person distressed with their gender role will benefit vs will be harmed. This intervention sterilizes 100% of children if administered according to the Endocrine Society's recommendations. Even with an older child, there is often social dysmorphia and extreme OCD that should be addressed before anything having to do with gender is even talked about. My son is one of those older youth who was coerced into going on hormones and eventually ending up with an orchiectomy. The physicians and mental health "experts" did not fix his social anxiety or his TOCD. He is in a much worse place than he has ever been in. We are really struggling right now and worry every day about his mental state.

Older adolescents can get hormones with no assessments at all, and have their healthy body parts amputated by eager surgeons on little more than self-declaration of "trans identity." I suspect that my child may be gay with autistic traits and has come to believe his very real distress is explained by the fact that he is "transgender" and that hormones and surgeries will help. They will not. I have seen my child's mental and physical health plummet following "gender-affirmation."

I also encourage you to require exploratory psychotherapy and to issue a clear statement that psychotherapy for gender dysphoria is not conversion. Our children and families need safe non-invasive alternatives to radical experimentation known as "gender affirmation."

Thank you for doing what you can to regulate this social experiment on our vulnerable children. I believe that this is going to go down as the largest medical scandal ever in the history of bad medicine. It's time to pick a side. I hope you pick the side of children.

Thank you,

Connie Hahn

Dear Members of Florida Health Board:

Good morning , and I hope this email finds you and your families in good health and spirits. I am dropping a very short note to encourage you not to adopt any rapid processes of so called gender affirmation procedures or chemical processes. As we all know, the published research and personal empirical experiences regarding these procedures is less than optimal and many sources and personal experiences tell us that these procedures cause tremendous harm with some irreversible effects. The complication rates after surgical transformation has led to multiple readmissions for an abnormally high rate of postoperative morbidity. The rates of suicide have been reported to escalate over 400% compared to a control group. Our hospital systems can not handle this growing number of easily preventable morbidities and mortalities. These patients require very careful selection of these patients with clear informed consent of these complications. The other item to consider is the fact that informed consent should clearly state that these procedures and drug treatments do not change the genetic code of the individual and as thus, the claim that they change the gender of the individual is false and misleading. In addition, there are many, many potential side effects we do not know such as the rates of specific hormone sensitive cancers and the destructive nature of long term hormone treatment on the musculoskeletal system. I have personally seen numerous patients who are currently receiving hormone blocking and stimulating treatment for gender dysphoria and most have severe changes within their major joints such as knees, hips and shoulders. Yet, none of them have had any informed consent that this is a known and probable side effect with irreversible damage.

Thus, I am asking you to adhere to the basic principles of informed consent and ensure that all of the patients undergoing these procedures are properly informed of the potential risks (there are hundreds) as well as the published benefits (which there are none) so we can treat these precious individuals with the respect they deserve.

May God continue to bless all of you and the important work you do everyday.

To whom it may concern,

I understand the doctor who pioneered some of the gender surgeries no longer supports such interventions because it did not resolve the psychological challenges that he had hope to remedy through such radical interventions. It seems grossly irresponsible to allow such interventions to occur on children. Please be guided by sound science and not ideology.

Fr. Glenn Kohrman, B.S.M.E., M.S.M.E., MDiv., MA

To whom this may concern:

I am pediatric GI physician in Illinois and have evaluated patients since 2020 for side effects following hormone treatment for gender transition services that were provided by Gender Clinics elsewhere. Some of the side effects included migraine headaches, intractable vomiting, intractable diarrhea, and chronic abdominal pain. These symptoms got worse as the hormone doses increased. These symptoms were not present before hormone treatment. Parents reported that despite signing a consent form, they were not aware that these were the potential side effects of hormone treatment.

All the patients I have evaluated have a history of mental illness, physical or sexual abuse, or being bullied at school. Many of them are having family discord with parents going through separation or divorce. Many of the patients did not feel that the mental illness, bullying, abuse or family discord received adequate attention or treatment.

Parents stated that teachers and principals told them that the children wanted to identify as the opposite gender and that the parents have to support their wishes. Parents felt bullied into accepting their child's wishes rather than being given an opportunity to talk to their children without interference from teachers or principals.

I hope that you will take my shared experience into consideration as you consider sex-based practice of medicine in Florida.

Sincerely,
Katrina Nguyen, MD

Florida Board of Medicine Members

I am writing to you today to voice my concerns about the current state of affirmative only health care for transgender youth and young adults in the United States. I am not an activist. I wish to convey my thoughts on this matter as a mother of a biological son who identifies as a female. I am a democrat. I do not see this as a right vs left issue despite what the media and trans activists would like you to believe.

The problem that I see with the current affirmative only trans healthcare for youth and young adults is that doctors seem to think there is only one approach and that approach leads their patients down a medical path that they will need to follow the rest of their lives. This one size fits all approach is immediate affirmation only, socially and medically with little regard to the individual patient's health background and childhood social history. There is little to no psychotherapy for these individuals before approving cross sex hormone medication. Trans activists call any sort of psychotherapy conversion therapy. This is absolutely wrong! Psychotherapy is meant to explore the underlying reasons that a child declares he or she is trans and help guide the patient and their family in making the right decision for each individual. Many of these trans identified children and young adults are neuro-diverse. They have histories of ASD, ADHD, OCD, are socially awkward, have poor executive function skills, have slow processing speeds, have sensory integration issues and/or trauma. Still others will grow up to be homosexual and identify as trans due to internalized homophobia. Yet others are influenced by friend groups, social media and teachers. There are many ways into identifying as trans and there should be many options for these patients of how to deal with their feelings instead of just one path that will make them a medical patient for the rest of their lives.

Sweden, Finland and the UK have recently restricted hormone therapy and surgeries for transgender youth because studies have shown that the risks outweigh the benefits for most patients. Studies show that left alone to mature, many trans identifying youth (65-80%) will re-identify as their birth sex. Misinformation, is all that lay people and some doctors know due to the media and trans activists. My hope is that the Florida Board of Medicine can realize that they have the power to do what is best for patients and their families. Patients and their families need to be fully informed of all possible side effects and complications of cross sex hormones and surgeries. They do not need to be rushed into medical care. They need a thoughtful well managed plan of care that includes mental health exploratory therapy. They need the truth that these young people are not at higher risk of suicide. They need to be aware that there are no long term studies to prove that transition is the best option to all. They need to be followed for several years throughout their childhood and adolescence to assess their mental health and their feelings about being trans. Cross sex hormones should only be given under the guidance of strict clinical trials. Cross sex hormones are not benign. Genital surgeries are permanent. Patients need to be followed for a prolonged time after transition also ... 20 years or more. Please do your diligence and research and discuss with the trans doctors of Sweden, Finland and review the Cass Report on Tavistock of the UK to understand why they have pulled back on the affirmation only treatment. Those countries have been doing transitions for much longer than the United States and we should learn from them.

Gender non-conforming youth and young adults are very vulnerable. They deserve love and respect. They deserve to explore their nonconformity without risking permanent damage to their body. Families deserve to do what they feel is best for their children and young adults without fear of being called transphobic or being accused of abuse. After all parents know their kids best of all. Doctors need to discuss all options with patients and their families, the pros, the cons, and potential complications and life altering experience. Surgical procedures and cross sex hormones should never be promised to fix the patients feelings. They should never be promised to make their life better. Doctors need to inform patients about all the potential complications and not be driven by money. This is a person's life that you hold in your hands and you should First Do No Harm!

**Sincerely,
Sandi Allison**

You don't often get email from cioffi@prodigy.net. [Learn why this is important](#)

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

Dear Sirs, I hope this email finds you well and in good health.

My name is Alfred Cioffi. Academically, I have a Doctorate in Bioethics (Gregorian U, Rome) and a Doctorate in Genetics (Purdue U). I am an Associate Professor of Biology and Bioethics at St. Thomas University, Miami Gardens, Florida.

In re. teenagers and gender transitioning, a few points to consider:

First, it is well known that the vast majority of gender questioning self-resolves as children transition through the teen years into adulthood. This is within the range of normal psycho-sexual development.

Second, teens -like any of us- are also influenceable by peer pressures and beliefs; but teens generally more influenceable, due to their immature mind.

Third, many parents do not necessarily possess in-depth knowledge of human psycho-sexual development. Therefore, when one of their children tells them that they want to "transition" -perhaps because his/her best friend at school is transitioning-, parents may feel pressured to allow their child to transition too, but without realizing the full life-long implications of this.

Fourth, it has also been published that the suicide rate of transitioned people is at least 15x higher than those who do not transition. I know that Drs. Mayer and McHugh's data (Johns Hopkins) has been challenged and disputed -it starts getting ideological. Even so, even if it's only twice or three times the background suicide rate, that is sufficient reason for pause. And, we can't just keep blaming societal non-acceptance for the discontent, since there's plenty of acceptance in society today.

Fifth, since a full transition is essentially irreversible (loss of genitalia and therefore fertility), we really should wait at least until adulthood, when the person, on average, will have a more mature mind to make this drastic decision. Repressing puberty artificially on teens is cruel, abusive and ethically unjustifiable. Teens deserve at least the chance to finish their biological sexual development before considering this issue.

In sum, I ask you to please refrain from allowing teens to transition, and from parents consenting to their children's transition. This is an extremely serious decision, and should be strictly adult fare.

Respectfully submitted,

Alfred Cioffi, SThD, PhD

Dear Doctors,

As a practicing physician, I appreciate the opportunity to testify about these matters. Many young people clearly suffer in their experience of sexuality. And, of course, well-meaning people want to help.

But regardless of how one conceives of gender, that person IS male or female, as defined by genotype, a biological reality.

Therefore, both common sense and scientific data tell us that infusing non-physiological hormones or surgically altering the body is NOT a solution for distress.

No pre-adult could possibly give proper informed consent to permanent sterilization or to the permanent alteration in body image, giving rise to a shocking rate of suicide and depression.

It is no wonder that Europe has put the brakes on all of this.

Please do whatever you can to exercise prudence in limiting such irreversible medical practice on our vulnerable young people.

Thank you so much.

Sincerely yours,

N. Joseph Schrandt, M.D.

Dear Members of the Board:

I entered the medical profession in 1963 and at age 80 am still practicing as medical director of a large hospital in South Florida and an associate Dean at our local medical school. Prior to this, I have delivered thousands of babies and have first hand experience of the family unit with children. Mothers have never told me they were faced with such issues. It's a known fact that the great majority of these children with these thoughts, normally outgrown them. I must say I am highly disappointed that members of our esteemed profession would even consider such atrocities as any gender transformation procedures on our children.

Moreover, enacting such atrocities, without input from geneticists, endocrinologists, pediatricians, psychiatrists, and most importantly, the parents, makes this tantamount to medical misconduct and child abuse. Yes, that thump you just heard was Hippocrates turning over in his grave.

Therefore, I urge the Board to oppose any such legislation. Thank you in advance for analyzing the issue and voting your conscience. Our noble profession needs to adhere to our basic principle "primum non nocere" (do no harm).

Dear Sir / Madam

I am writing as parent of a teenager who began to question their gender during the 2020 pandemic. My daughter was 15, had no prior history of gender confusion, but had experienced social anxiety and had been bullied at high school. She experienced a traumatic (possibly sexual) incident with her boyfriend and began to identify as transgender soon afterwards. He also began to identify as transgender at the same time along with a close circle of their friends. All of these teenagers, including my daughter, developed mental health issues during the school lockdowns and were struggling in multiple ways. Some parents have been using the new names and pronouns and others have been proceeding more reluctantly, but all of us love our children and want the best for them.

My daughter has since been diagnosed with high-functioning autism and has been gradually improving in her mental health. Her ex-boyfriend has now desisted and returned to identifying as his birth Sex.

I strongly believe that for many teenagers, their gender-exploration is not an organically-arising awareness that requires adults to immediately agree and affirm an identity. It is something that arises from emotional pain and can be peer-influenced.

These young people require compassion and support that affirms them as valuable and loved human beings, but there should be no rush to cement a transgender identity.

My daughter is currently happy dressing in a gender non-conforming way and has received CBT counselling to help her manage her black-and-white thinking patterns. She is 17 now, and I believe it is right to safeguard her from damaging her future fertility and sexual-functioning by taking opposite-sex hormones. This would be irresponsible in my opinion.

Huge numbers of gender-questioning teenagers are autistic - why on earth does anyone think autistic young people ought to be sterilised and have mastectomies? I am looking to my daughter's longer term health and am very happy for her to be dress as she wishes and be gender non-conforming.

I would urge the state of Florida to safeguard young people's bodies and provide ethical and evidence-based medical care.

Yours sincerely
Coral Lancaster

[Learn why this is important](#)

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

Dear Sirs and Madams,

As a member of the Catholic Medical Association and a practicing Urologic surgeon who specializes in men's health, I fully understand that gender dysphoria is a real condition. Patients with gender dysphoria truly suffer, and they all deserve compassion and effective, evidence based treatment. Some adults with gender dysphoria may elect to alter their bodies with hormones and surgery; as adults, this is their prerogative. The use of hormonal manipulation and surgery that permanently, drastically changes the body is not appropriate, however, in children and minors.

The use of hormones such as testosterone and puberty blocking drugs is increasingly advocated to "affirm" the feelings of gender in minors. Surgery is also advocated to change the outward appearance of these young patients. The undeniable fact is that chemicals and surgery do not, can not, and never will change a child's gender. Their sex chromosomes are fixed. They are male or female, and that is not mutable.

If the use of drugs and body altering surgery cannot truly change a child's sex, can they cure gender dysphoria? The medical literature tells us the answer is "no". An extensive review of research papers from 1946- 2017 has been published in the journal Pediatrics. The authors found that drugs and surgery do not appear to resolve gender dysphoria in children. Studies also show the changes to their bodies brought on by hormonal manipulation and surgery do not meet most of these children's hopes and needs. What medical evidence does show, is that when treated with appropriate, caring counseling 85-90% of minors with gender dysphoria will ultimately resolve these feelings and no longer identify with the opposite sex. Further, it is fact that some of these children who have been "transitioned" are regretful and wish to return to their original body. That they can not is a tragedy. The human brain and emotional self take years to fully develop; to assert that a child can truly know he or she would be more comfortable assuming the appearance of the opposite sex and undergoing permanent, life altering treatment is not supported by evidence and is foolhardy.

Since there is a lack of robust, long term medical research that proves puberty blocking drugs, hormones, and irreversible, so-called gender reassignment surgery actually cure gender dysphoria in minors, they should be avoided. Time, therapeutic counseling, and if the parents wish, pastoral and religious counseling, are the best treatments. Florida's legislature should act to protect these vulnerable patients by passing and advancing to Governor DeSantis legislation preventing the use of puberty blockers, hormones, and body altering surgery in minors with gender dysphoria.

Some people who received this message don't often get email from camamn2@gmail.com. [Learn why this is important](#)

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

To Members of the Florida Board of Medicine:

The current trend in the country, and in mainstream medicine has been to push for hormonal "treatment" that alters pubertal development in children who, for whatever reason, are experiencing gender dysphoria. There is furthermore a trend toward pushing for surgical alteration of children who identify themselves as the opposite of their biological sex. This is a very concerning development.

As a pediatrician, my goal has always been to DO NO HARM. There is good evidence that 80-95% of children who experience some gender dysphoria will not have persistence of this problem past adolescence, if they are left alone, or get appropriate counseling for any mental health problems. Children are not capable of understanding the long term effects of puberty blocking hormones or surgery, and therefore cannot give appropriate informed consent to these procedures. The use of these procedures leaves these children with long term side effects, including sterility. Even transgender affirming groups have questioned these treatments, as they are beginning to see the harm done both physically and psychologically to individuals who have undergone these procedures.

An exhaustive review of the evidence was published in the Fall 2016 issue of The New Atlantis. The entire article would give you a much better picture of the state of research in this area at that time. Further studies are ongoing, but it is very important to look very carefully at methods, as many of the studies have been very biased, or have been so small as to be statistically insignificant. Decisions regarding these issues should be based on solid scientific evidence, not emotion. I quote the summary conclusion from part 3 of this study. (pp112-113):

"The scientific evidence summarized suggests we take a skeptical view toward the claim that sex-reassignment procedures provide the hoped for benefits or resolve the underlying issues that contribute to elevated mental health risks among the transgender population. While we work to stop maltreatment and misunderstanding, we should also work to study and understand whatever factors may contribute to the high rates of suicide and other psychological and behavioral health problems among the transgender population, and to think more clearly about the treatment options that are available." There is a further, more lengthy conclusion to the whole article that follows.

Rather than pushing medical therapies fraught with unwanted side effects and dangerous long-term risks (some quite dangerous to long term health), and disfiguring and irreversible surgical procedures, particularly on children and adolescents whose brain maturity precludes them from being able to truly anticipate the long term consequences, it would be much better to address the serious mental health challenges that some of these children face, and to guide them to an

appropriate but much safer solution to their problems.

I sincerely hope that you will choose to do what is truly best for children: to provide compassionate care for all, regardless of sexual orientation, but to refrain from procedures that are harmful from both a physical and psychological standpoint.

Sincerely,

Anne M. Nealen, M.D., F.A.A.P., F.A.C.P.

To whom it may concern,

I have been a Board-certified Pediatrician for over two and a half decades. I have never been so disturbed by a policy involving the pediatrician population as I am now with the "Gender transition affirming treatments".

The great Psychologist, Dr. Erik Erikson's theory on the stages of psychosocial development categorizes the very stage of a child's development in question (12-19 years old), as the transition years. His theory states that the crisis this age group faces is questions about Identity vs Inferiority. Erikson states a favorable outcome is when the adolescent can see himself or herself as a unique and integrated person. An unfavorable outcome is when the adolescent has confusion over who and what one really is.

I am tired of seeing kids make life long, permanent decisions due to their irrational, developing brain, as they mitigate this transient stage of life. It should be a criminal offense if mature, board certified, adult physicians are allowing a "child" to determine their gender. I am not naïve to believe this is not a challenging time for kids, but if parents would step in and reaffirm their children for who they are and covered them in love and NOT have a child make "adult" decision, this crisis would blow over. In addition, couple parental support with intense psychosocial therapy for a year or so and then readdress the issue.

I am embarrassed to be associated with a profession who is allowing mutilation of our future. As scientists, our profession deals with "evidence-based" practices. Where is the data that shows the mental, emotional, and physical stability of a child ten years from now, who had been mutilated, is stable, happy, and contributing to society.

This "Gender transition affirming treatment "is CHILD ABUSE.

I tell the parents, that if a child cannot decide that eating vegetables is good for their health, how can I trust their future gender to an adolescent?.

I know I am not living in the twilight zone.

Dr. Bonita Jude, MD, FAAP,

As a practicing physician, I am strongly against "gender affirming care". These interventions destroy our children by subjecting them to often irreversible medicines and surgeries at a time when children are vulnerable and easily influenced. There is no science to support it - the studies that are available are extremely poorly designed and do not show any benefit, while causing great harm physically and psychologically. I am completely against these practices and strongly urge you to oppose them.

To whom it may concern,

It seems as though there are shortcuts taken and children are being rushed into transitions, why?

I agree with the State of Florida's Medical Board's proposed new rule to restrict affirmative care interventions on children.

Are the following questions being asked and/or answered?

- Why are parents being rushed and pressured into making these life changing decisions for their children?
- What are the long term effects from the numerous drugs, is this being studied?
- Are the Children's full range mental-health issues taken into consideration before the decision is made?
- Do the doctors and/or staff feel pressured to adopt an "unquestioning affirmative approach"?
- What are the long term effects from the numerous surgeries associated with this, is this being studied?
- Research?
- Science?
- How much money is being made from this?

These are CHILDREN, made in the image and likeness of God.

Thank you for bringing this to light.

Sharon Merritt.

Dear colleagues,

I am a physician for 21 years and never in my mind I thought I was going to I had to write an email to protect the rights of children.

It is absolutely insane what's going on now. We are physicians, we protect life, we protect innocence. And we do not act on crazy movements.

There is no role for Florida to allow for any children or adolescents to have access to any form of castration. This is not medicine. This is not align of our Hypocratic oath. This is wrong!!

I am absolutely against it and I hope this is now allowed in Florida!

Respectfully

To Whom It May Concern :

I am very worried about our young people and the so called gender affirming care. As we all know , young people is still growing and developing. Why causing sterilizations , castrations and mutilations; all permanent bodily changes , when it is well known , that about 80% might change their mind ! Our Children need to know the truth about this figures , what are they doing to their bodies, and what impact that might have in their lives later on. Studies show that about half of the patients with gender dysphoria suffer from mental illnesses, and treating the mental illness (depression, adjustment disorders , etc,) may resolve the gender dysphoria too . One out of five patients , regret having surgery after gender reassignment or transition. Science tells us is not right , is not good medicine for our Children , then let's protect them and help them ! Let's have them informed of this staggering figures ; talk to their doctors, their therapists , their families, their ministers , other patients that had gone through same experiences. Let's have them grow , develop ,mature and them with all this information make the best decisions.

Sincerely

Dr. Janette Serrano de Malavet

I am writing as a practicing central Florida family physician. I was not aware until this weekend that the board was seeking public comment on proposed legislation for Gender Transition Affirming Treatments. My concern is specifically for treatments (medical/hormonal and especially surgical) for gender reassignment for individuals under the age of 18. These treatments can be permanently life altering and the decision is being made by or for young people under the age of 18. Is it really possible at this young stage in their life that they can truly be making a fully informed consent about a very adult decision? This is not to say I think we should deny help and support to children and teens struggling with their sexual identity. But I do not think this drastic step is necessary before they are fully of age and even then pursued only with careful and thoughtful informed consent.

Thank you,
Heidi L. Zimmerman, MD

Good evening Florida Board of Medicine,

As a physician licensed in Florida for over thirty years I was happy to learn that the Board of Medicine has decided to address medical and surgical treatments for patients with gender dysphoria. Florida's approach to the recently ended Covid-19 pandemic was reassuring to me because it was evidence-based. I saw news reports about how Governor DeSantis and Dr. Ladapo read studies in the peer-reviewed infectious disease and epidemiology journals to help formulate the appropriate response to the pandemic from the state health agencies. Our health leaders were able to correctly identify that our older patients were at highest risk and warranted the most aggressive preventative and therapeutic methods. Similarly, our youngest patients were at the least risk from the virus but at greatest risk from the side effects of the mitigating strategies that kept them socially isolated and uneducated.

A similar evidence-based approach is warranted for our patients with gender dysphoria. Sadly, the conversation about what appropriate care is has been dominated by a very small but very adamant and very vocal group. I have listened to the arguments about so-called "gender affirming care" and find them lacking in scientific evidence. There really aren't any studies that show that medical hormonal therapy or plastic surgery improve the outcomes for patients with gender dysphoria. I recall that in 1979 the Johns Hopkins Hospital stopped performing what was then called sex reassignment procedures because the psychological outcomes and more importantly the suicide rates were the same in groups that received and didn't receive the surgery.

Our newest Supreme Court Justice, Ketanji Brown-Jackson, has been

roundly mocked for stating that she could not define a woman because she was not a biologist. However, the ridicule is misplaced. She correctly realizes that gender is biological. That certainly has been the understanding of biologists, physicians and ordinary people forever. Now we are being told by that small, loud group that we can be whatever gender we feel we are. That just isn't true. Many people who share my science-based view are routinely bullied, mocked and cancelled. That doesn't make my view any less true.

There is nothing that a physician can do to change someone's gender. Stating otherwise is an affront to medical science. The only possible gender-affirming care is to tell a boy that he is a boy and a girl that she is a girl. Anything else is a disservice to patients suffering from gender dysphoria and makes me question whether those physicians should be allowed to practice our medical profession.

We have seen over the past few years a spike in the number of patients who announce that they are of the opposite gender. The prevalence is particularly high in teenage girls. Rather than being offered psychotherapy, most of these patients are directed to irreversible hormone therapy, plastic surgery and sterilization. Parents consent for fear of losing their child to suicide. The stories of regret grow each day. Thousands of children are harmed each year by treatments to which they cannot adequately give informed consent.

As you deliberate what the appropriate policies should be for Florida's physicians I encourage you to study the evidence. I encourage you to pursue a policy of "First, do no harm." I encourage you to allow scientific debate and not buckle to the demands of the loudest in the room. I encourage you to require appropriate psychiatric and psychological treatment to patients suffering from gender dysphoria before allowing irreversible treatments. And finally, I encourage you to follow the science. It's hard to believe that the discovery of DNA is less than seventy years old. And yet, we seem to have understood the reality of our genetically determined gender for far longer.

Eugenio Erquiaga, MD

It is a crime to mutilate children this way and also your job in your positions to prevent undue harm to our children in regards to these processes. It shouldn't be about the money and business side of these lucrative and surgical procedures. Please restrict all misguided interventions and protect the youth of your state from unnecessary and lifelong harm.

There is scientific evidence that the human brain doesn't stop growing and decision making isn't mature until age 25.

I'm not sure what is wrong with the parents and adults in this convoluted process, but it's worth further scientific investigation- don't you think?

Mrs. Marcia Vandermus

Dear Sirs ,

The issues regarding youth transition and informed consent are very concerning for medicine. In the medical practice where we struggle to do what is best for children, we can not ask children and their parents to consent to medications and procedures that will cause the young patients irreversible physical and mental harm. A child and a teen are unable to consent to these types of treatment as they do not have the cognitive capacity or experience to know what it truly means. The permanence of the operations and the lifelong hormonal treatment is not something to experiment with in children. Most children who suffer from gender dysphoria will outgrow it by the time they complete puberty. The best treatment is good mental health services that can actually diagnose the root cause of the situation which in some cases may be early schizophrenia or child abuse. The parent relies on the medical personnel to honestly tell them the truth of what is known about the risks and benefits and many are consenting based on the fear their child will commit suicide. They are not told that there is no evidence that these treatments/procedures decreases the risk of suicide. Countries where they have been doing transgender care for much longer than we have, have not seen a decrease in the suicide rate nor a decrease in the mental health issues of this fragile population. These countries have also stopped doing teen and early childhood medical/procedural treatments as they have seen the lack of good outcomes. In view of the scientific information available now, these treatments are a violation of the Hippocratic Oath. It is experimentation on children which mutilates their normally functioning sexual body parts and medicalizes them for life.

Here are some statements that are well footnoted with scientific references from the American College of Pediatricians which support my statements.

<https://acpeds.org/topics/sexuality-issues-of-youth/gender-confusion-and-transgender-identity/deconstructing-transgender-pediatrics>

<https://acpeds.org/position-statements/gender-dysphoria-in-children>

Please do not allow treatment and procedures which harm the minds, bodies and souls of our future citizens and medicalize them for life. Children and their families deserve better than costume transitions which will affect their future ability to live healthy lives and to have children if they desire to be a parent.

Thank you for your time deciding this matter. I know we are all trying to do what is truly best for children.
Sincerely,

Mary M Nave, MD, FACP

To whom it may concern:

I am writing as a board-certified obstetrician/gynecologist who is opposed to the proposed gender-affirming care. This is especially harmful to the youth, who need our protection as medical professionals from this social phenomenon. The claim that gender affirmation is the only thing that can prevent these teenagers from committing suicide is not backed-up by the best available data.

As a physician, I have treated several patients who identify as transgender and the phenomenon is becoming increasingly common. Spending some time talking with these patients, several things become apparent. Firstly, these people need to be treated with love and respect and gentleness, just like all of us. Perhaps even more so, as these patients frequently struggle with feelings of anxiety and lack of self-worth. Secondly, these people often possess a deep sense of incompleteness – and the sense that their completeness and happiness are just around the corner. If only they could attain the “next thing”, hormonal treatments, surgical management, or wide societal acceptance, then they would finally feel whole.

Contrarily, however, the best available evidence suggests the opposite is true. In a study published in 2011, a cohort of 324 patients who underwent “sex-reassignment surgery” were examined over a 30-year period. They were found to have an increased incidence of inpatient psychiatric treatment, criminal activity, cardiovascular disease, and perhaps most shockingly, a rate of suicide 19.1 times more likely. Notably, the suicidality of these patients did not manifest until about 10 years postoperatively. None of the studies suggesting that surgical management results in improved psychiatric status look at long-term outcomes.

In fact, almost all of the data suggesting cross-sex hormone treatment and surgical gender reassignments actually benefit patients are low-quality and poorly powered. Indeed, the Centers of Medicare and Medicaid, in a document defending its decision to not have a national policy covering these treatments, stated, “the quality and strength of evidence were low due to mostly observational study designs with no comparison groups, subjective endpoints, potential confounding...small sample sizes, lack of validated assessment tools, and

considerable lost to follow-up”.

The largest study to date looking at the effects of transgender surgical procedures and cross-sex hormone administration was published in the *American Journal of Psychiatry* in 2019. Based on data obtained from Sweden (the country that seems to have the widest acceptance of, and treatment for, gender dysphoria), there is no improvement in mental health with the administration of cross-sex hormones over time. Furthermore, completed suicides were not even tracked in this study, which is apparently the very reason why we as a society must urgently mutilate and sterilize our children.

I hope everyone in positions of power will carefully and objectively consider these issues, rather than being swayed by political influence or passing trends.

Sincerely,

Jason Phillips, MD FACOG
Department Head, Obstetrics and Gynecology St. Vincent's Clay
President, Jacksonville Catholic Medical Association

Hello Mr. Vasquez,

I am writing with respect to the issue of the Florida Board of Medicine's consideration of regulating gender affirming care.

I am a parent of two teenagers. I live in California. I was a lifelong Democrat until my youngest child, now age 17, was swept up by gender ideology at age 13.

I beg the Florida Board of Medicine to regulate this area of what is nothing short of medical experimentation on our youth.

My daughter was by all accounts a happy and typically developing young girl with traditionally feminine interests. She is gifted and highly creative. Up until the 7th grade, she showed absolutely zero signs of wanting to be something other than a girl.

At the point puberty started, we saw a massive change in her demeanor, her academic performance, her manner of dress and hygiene, and much more. She did not want to discuss puberty in any way, shape or form with me. At the start of 8th grade, she fell into a deep depression, began failing most of her classes, stopped showering or caring for her appearance, began wearing baggy clothes. We immediately sought counseling for her and she was put on antidepressants for both anxiety and depression. We still do not understand the source of these issues - they seemingly came out of nowhere.

She then came out as "non binary" to us, which we really didn't understand. As her parents, we love her unconditionally, and told her as much. She asked us to call her by they/them pronouns and did not want to be referred to as our daughter. She asked to bind her breasts. She stated she wanted to have her breasts removed as soon as it was feasible.

I researched "how to support a non binary child" on Google. What I read scared me: article after article told me I must affirm my child's new identity or she would likely commit suicide. On the fifth page of Google search results, I found a site that presented a contrary view: a view that outlined for me that thousands of girls were coming out in this manner, all very similar to my own, with no history of dysphoria. It talked about the dangers of breast binding, puberty blockers, and hormones. It educated me that mastectomy might not be the only surgery my daughter might pursue: if she came out as a "full boy" we could expect to be asked to approve a genital surgery. All of this sounds horribly wrong to me.

Little did I know that by this point, her school and her friends and everyone around her had already been calling her a different name and pronouns for at least a year. It was all hidden from us. I took her for educational psychological testing. She has no ADHD/ADD, no autism,

nothing but a high level of giftedness and a risk for bipolar disorder.

Instead of maturing into a different worldview and embracing her developing body as she moved through puberty, my daughter has become more entrenched by the day with this idea that she was born in the wrong body. She may go away to college next year, and I cry at the thought that as soon as she leaves our home, she will head immediately to Planned Parenthood and do all of the things that we as parents could never in our right minds approve. She is going to jeopardize her health, and she will have no idea how this might permanently impact her future.

We have had extreme difficulties finding therapists who can explore the source of her body hatred, and her anxiety and depression, who don't jump to affirmation or push us to affirm. I haven't taken her to a pediatrician in 3 years because I'm afraid she will talk to the physician privately and ask for these treatments. I have spent the last four years immersed in the science on this. I cannot understand how our country is not just allowing, but encouraging and celebrating the interruption of normal puberty, administration of cross sex hormones, or "affirming" surgeries when so many of these children have either physical or mental health comorbidities or both.

There are no long-term studies on the effects of these treatments on adolescents. We know that 80% of youth desist out of dysphoria or a trans identity IF they are not placed on a medical pathway. So why would we rush them down that very pathway? You can read the stories of detransitioners whose lives and health have been seriously damaged by having been rushed to these treatments with no safeguarding. In the state of Florida, you have a plastic surgeon, Dr. Gallagher, who advertises "yeeting the teets" and glamorizing mastectomies as easy as getting one's nails done. It is so dangerous to be manipulating vulnerable youth in this manner and taking away the opportunities they have as adults to have normal sex lives, bear children, and not be injecting cross-sex hormones into their bodies for the rest of their lives.

If these policies were regulated, fewer devastating mistakes might be made. Fewer lives might be ruined. The FL BOM can't save my daughter, but you can save hundreds just like her. Please, save our children.

Sincerely,
Maria Gray

Dear Mr Vazquez

I am a physician and member of the Catholic Medical Association, board certified in internal medicine, pulmonary disease and critical care. I am well versed in evidence based medicine having been an author or coauthor on over 60 papers or poster presentations presented at medical meetings. In that capacity I am writing to comment on the Florida Board of Medicines policy considerations for gender transition therapy for Children.

In short the board should regard this at best as experimental therapy that is potentially dangerous and has almost no medical evidence in its favor.

It is known that the puberty blocking drugs are associated with a number of complications. For example there are changes in bone mineral density that may be associated with increased osteoporosis risk as noted here

[Bone Development in Transgender Adolescents Treated With GnRH Analogues and Subsequent Gender-Affirming Hormones - PubMed \(nih.gov\)](#)

The package insert for these drugs includes risks for psychiatric disturbance, seizures and pseudotumor cerebri. (a disorder in which the intracranial pressure of the cerebrospinal fluid around the brain is increased, and which if untreated can cause blindness.)

There are basically no long term well controlled studies for this off label use of puberty blockers to treat gender dysphoria. Still less is there evidence for cross hormone therapy.

Surgical treatments such as mastectomy, or phalloplasty, penectomy and the rest of it are associated with permanent sterility, loss of sexual function and surgical wound complications.

The evidence such as it is supporting such treatments is mostly produced by transgender activists who have created their own medical journals to publish in. It is rather as if a pharmaceutical company created its own journal to publish its own pivotal trial data. This would obviously reflect unacceptable bias.

At the very least the physicians and activists defending this kind of treatment in children who do not show long term, well controlled data, with hard endpoints have no business proceeding to subjecting children to a therapy they can not themselves consent to. Obviously the consent to the extent their is consent would be through a guardian and it is not clear the guardian would be acting in the child's best interests where they to subject them to therapy with so little scientific support and obvious known risks.

If doctors do proceed with this, the legislature should life the statue of limitations on any negligence claims resulting from injury related to subjecting the kids to this, and any claim related to lack of informed consent should be automatically escalated to a gross negligence claim , because the unless a child and guardian were told this is very poorly studied the advocates of this kind of medical intervention are being dishonest.

Thank you

Michael DePietro MD
Hockessin Delaware

I am a grandparent of a 16 year old girl, who identifies as transgender. She might be a lesbian, but she is not transgender. She has struggled with mental health issues. My family is opposed to the affirmation model and hormonal/surgical interventions for my granddaughter. Historically, teenage females are plagued by social contagion issues including anorexia, bulimia, and cutting. We believe our granddaughter has been caught up in this latest social contagion like many other teens. She has always struggled socially, and gender ideology with its social justice aspect, has proved to be the answer for her to longing to belong and have friends. Nearly 25% of kids in her high school have recently claimed a trans identity.

Research is limited, and no consensus exists within the scientific community about possible causes of gender dysphoria and the most appropriate treatment options. We must secure a balanced treatment of political issues, which must take a child-centered, evidence-based approach, and take care not to express personal beliefs in ways that could exploit vulnerabilities. We should not for example, present childhood gender incongruence as an inherent and immutable phenomenon, as this is a contested idea not an established evidence-based fact.

The number of people who regret transition is unknown. Most who “desist” simply stop treatment and do not report their desistance to their providers. According to the ever-increasing numbers of people involved in online forums and groups of detransitioners, they do not have support from the medical or transgender communities. Many say they did not fully understand the magnitude of side effects, adverse outcomes, and risks involved in their transitions.

The human brain is not considered fully developed until approximately 25 years of age. According to psychological developmental stages of children and teenagers, forming identity is an important process. Erik Erikson’s psychosocial developmental stage of ‘Identity vs Role Confusion’ speaks perfectly to the normalcy of teens questioning their identities. Self-exploration is a normal part of growing up for everyone. The problem with claiming a trans identity is the irreversible damage that can be done with medical and surgical interventions. Children and teenagers are unable to provide true informed consent for such treatment. They are unable to fully understand the lifelong consequences of these decisions. Please consider this and protect children from irreversible damage. When they are adults who can provide true informed consent, they can make these decisions for themselves.

Thank you most sincerely for your time and consideration.

Dear Sir, Madame

I am a retired Pediatrician that continue to practice in the state of Florida as volunteering for the poor. In my long years of practicing Medicine in three different continents! I believe that the issue of Youth transition and the Informed consent process is a very complex sensitive subject to reach a solution for.

Our role as Physician is to do "NO HARM", do our best to focus on the well being not only of our children, but also parents, relatives, friends, society & the world. In order to reach an agreement between those who are not for and those who are for this above issue, we must analyze well the detrimental consequences that will impact the children, & the families of the world.

As we all know well that the maturity of the human brain occur at the age 24 -25 . Why do we want to mislead ourselves blindly by following our children desires & thoughts ? Adults are to be responsible of showing the right path to their children not the opposite. Can a parent give his car key to a twelve years old and tell him go and drive my car to get some groceries? The answer is No of course. The child brain is not mature yet. The car is not a toy. Also! In our legal system, judging the children whether delinquent, thieves, murderers, criminals etc... is quite different than the procedure for adults. Why that? Because they are Children /Youth/Not mature yet .The media effects on the children was very well studied and how it cause harm to our children. Recently a study done about "IGD " Internet Gaming Disorder" associated with anxiety, insomnia, isolation, social dysfunctional behavior, violence and academic failure. Isn't the media? Well all of us see well how the media can be harmful to our children embedding in their pure brain fantasies that are not fruitful or productive or even realistic about the outcome. Unfortunately the media doesn't show the irreversible damage and harm they can trigger with this fashion. The media shows them clearly that everything is okay, everything is good for you, it is the normal, it is okay to do so and so. Is this the right thing to follow ?Is this good for our children? The answer is No. There is no supervision or guidance. There is lack of educating our children about all these ideas early in their life before they get exposed to the wrong unnatural ones.

Some medical studies showed for a fact that the rate of Anxiety, Depression & suicides are at a higher % in those transgenders ? Is that what we want for our families? the answer is No. Children have the right to live their childhood with their normal brain. It's okay for a boy to play with a doll ? or a girl to play with a truck? What's wrong with that? is it harming anyone? Children have the right to explore, they will find their way. It doesn't mean they are suffering ? Children are our future. They are our most precious gifts of Life. Lastly, for their well being we advice them no alcohol until 21 years old, we can do as well and tell them no transition until you mature and your brain is fully developed my child.

Thank you for reading my mail. May God guide you in the " No Harm" Path.

Best Regards,

Marcelle G. Habib, MD

Subject: Transgender issue in FL - email deadline tomorrow please help out

I would like to request help (a brief email) from each of you, as pediatricians,
regarding **TRANSGENDER ISSUE in FL:**

I. FL BOM is meeting Sept 30 to discuss a new rule about "affirmative care"
(gender-affirming care) and what changes need to be implemented;

specifically, the areas of the transgender issue being focused on are:

- 1- Youth transition
- 2- Informed consent process

***** TOMORROW Tues. Sept. 20 is the deadline to send a brief email
for the FL BOM** to consider your input about regulation of the practice of medicine
to protect children/ FL citizens. You can address one or both of these areas.

***** PLEASE SEND YOUR CONCISE EMAIL TO BOTH OF THESE EMAIL ADDRESSES:**

- * 1- Paul.Vazquez@flhealth.gov
- * 2- BOM.MeetingMaterials@flhealth.gov

II. In-person expert, patient and parent testimony are also needed at FL BOM hearings;
(register at meeting; 3 minutes max speech);

- Sept.30: 8 am to 12 noon in Tallahassee; FL BOM Rules Committee workshop to gather info
to help craft a rule regulating gender care

- Oct 6; 4-6 pm (may end later) in Tampa; FL BOM 's Rules Committee second meeting
- Oct 7; 8 am to 5 pm in Tampa; full FL BOM meeting to discuss and possibly vote on
any rule brought for the from the Rules committee

Thank you in advance for your input !

Appreciate any feedback; please forward to like-minded colleagues who might be also interested to help;
I am very sorry for the last-minute notice!!

Diane Gowski, MD
727-480-7574. if any questions or concerns
dianetg@aol.com
=====

((note; if you would like to send me a bcc copy of your email, for feedback to me to update please do so
)

Subject: Parental concern about medicalization of minors
Date: Saturday, September 17, 2022 2:48:40 PM

[You don't often get email from florence.begole@icloud.com. Learn why this is important at <https://aka.ms/LearnAboutSenderIdentification>]

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

Good afternoon Mr. Vazquez

I am writing to express my concern as a parent and teacher regarding the medicalization of minors (particularly those with rapid onset of gender dysphoria).

My own teenage daughter , caught up in the social media promoted trans ideology now wants to take testosterone (a class 3 drug) in addition to getting a mastectomy and eventual phalloplasty. The devastating , permanent effects of testosterone are now known from testimony and physical evidence of more and more de-transitioners. We know a youth's brain is not fully developed until the age of 25. Permitting such medicalization of minors is unconscionable. As a parent and teacher, I ask you to protect this generation of children.

Sincerely

Florence BeGole

Comments to the Florida Department of Health and Florida Board of Medicine on the “Affirmative Care Model” and Standards of Care for Youth Gender Transition

Catherine Saxbe, M.D., Diplomate, American Board of Psychiatry & Neurology

The following professional comments are based on medical understanding of the neurological and endocrine development of the human body, the healthy psychosocial development of the adolescent, and the presentations, manifestations, and treatments of psychological distress, including depression and dysphoria. None of the conclusions are informed by personal opinion, a political, moral, social, or religious agenda; but are strictly in the interest of determining the best, evidence-based medical care for youth expressing gender dysphoria or gender incongruence. The recommendations in this statement are the result of an extensive review of relevant published research and over a decade of clinical experience as a child and adolescent psychiatrist and child advocate.

“Gender Dysphoria” is a relatively new diagnostic term in the American Psychiatric Association’s Diagnostic and Statistical Manual of Mental Disorders, fifth edition (DSM-5). In editions prior to 2013, the diagnosis “Gender Identity Disorder” described patients with fantasies of and prolonged insistence on being or becoming the opposite sex, and experiencing emotional distress over the discrepancy between one’s natal sex and one’s desired sex. Gender dysphoria recasts the disorder not as inner psychological conflict but as a de facto difference in “assigned” sex and subjective gender identity. This is also referred to as “gender incongruence”.

The White House, The Department of Justice, and the Department of Health and Human Services have recently promoted the practice of “gender-affirming care” in opposition to “conversion therapy”.

“My Administration must safeguard LGBTQI+ youth from dangerous practices like so-called “conversion therapy” — efforts to suppress or change an individual’s sexual orientation, gender identity, or gender expression — a discredited practice that research indicates can cause significant harm, including higher rates of suicide-related thoughts and behaviors by LGBTQI+ youth.”¹

The above description of conversion therapy is misleading and inaccurate. Conversion therapy has traditionally meant intervention to “treat” homosexual orientation and convert same-sex

¹ Executive Order on Advancing Equality for Lesbian, Gay, Bisexual, Transgender, Queer, and Intersex Individuals, signed by President Biden on June 15, 2022

attraction to opposite-sex attraction. It is indeed harmful, as the above White House Executive Order states. Radical gender identity theory activists and lobbyists who drafted the Executive Order have reclassified standard psychotherapeutic approaches to gender dysphoria with supportive therapy and exploring the origins of the gender-questioning feelings as so-called “conversion therapy”. Patients may present with self-loathing and self-rejection resulting in depression and dysphoria. Gender dysphoria is dissatisfaction with how one’s body is made and develops, a rejection of one’s own physical self and a yearning - often obsession - to become the opposite sex. Since biological sex is coded in our cells, it cannot be changed. What could be more of a *conversion* than giving exogenous hormones to force the body to resemble the opposite sex? Only an approximation to the appearance of the opposite sex can be achieved, through lifelong ingestion of cross-sex hormones, organ removal, and cosmetic surgeries. This extreme medical intervention has direct effects and side effects that must not be undervalued and are often irreversible.

While puberty blockers used to halt early (precocious) puberty have been shown to be reversible, no such studies exist for puberty blockers administered to stop normally timed puberty. . . they may harm bone development, may permanently alter the brain, and that it is not yet known how they affect other vital organs, all of which undergo significant structural changes during uninterrupted puberty.²

“Gender-affirming care” for children and adolescents sounds like a wholly positive term because caregivers (parents, therapists, and doctors) want to affirm the validity of adolescent distress and alleviate it. However, the “affirmation” in this treatment approach is agreement with the patient's belief that incongruent gender identity is the sole source of their dysphoria and that the patient is actually the opposite gender, or even the opposite biological sex, though no treatment can change the X and Y chromosomes present in the body’s cells. The female and male biological sexes are not equivalent to gender identities of feminine and masculine, though this distinction is frequently confounded.

The medical model of so-called gender-affirming care is to start children in puberty at Tanner Stage II (typically from 9 to 12) on “puberty blockers” which chemically interfere with the natural, normal, and healthy development of puberty. The theory is that puberty-blockers (chemical castration of males and chemical menopause for girls) “buy time” or “pause puberty” for these distressed children to figure out which gender they “really” are. However, by blocking the normal development of puberty, the endocrine process which plays the essential and primary role in

² <https://segm.org/fact-checking-gender-affirming-care-and-young-people-HHS>

coming to terms with sex and gender, is prevented. Puberty blockers do not freeze time. Children continue to grow and time moves on, but powerful chemicals have arrested the psychological and biological evolution that their bodies are programmed to begin. After the profound effect of puberty arresting drugs, children who've thwarted their development will very likely not identify as their biological sex nor typical gender because the exogenous hormones they've received have severed that physiologic relationship. Following off-label high dose synthetic hormones, the majority of patients, encouraged by gender-affirming therapists and doctors, begin cross-sex hormones^{3,4} (girls take high doses of testosterone and boys take high doses of estrogen) so that girls grow beards and hairy arms and legs, their voices deepen, their jaw and facial features widen to look more masculine, their vaginal tissue desiccates, and they may become infertile. The changes wrought by high dose hormones on the developing body are mostly permanent.

Suppression of puberty with gonadotropin-releasing hormone agonist analogs (GnRHa) in the pediatric transgender patient can pause the maturation of germ cells, and thus, affect fertility potential. Testosterone therapy in transgender men can suppress ovulation and alter ovarian histology, while estrogen therapy in transgender women can lead to impaired spermatogenesis and testicular atrophy⁵

These patients may next choose to have cosmetic surgeries to amputate breasts and harden the lines of their facial bone structure to appear more masculine. In boys on estrogen, their penis remains childlike, sperm production never starts or stops, and they may grow breast tissue. Cosmetic surgeons add breast implants to natal males and shave their jaw bones and Adam's apple to approach the appearance of the opposite sex so that they can "pass" as their non-biological sex. Some trans-feminine patients may amputate their penises and scrotum, and plastic surgeons may construct a pseudo "vagina" out of tissue taken from the colon. Girls on testosterone may develop (non-functional) micro-penises after puberty blockers and cross-sex hormones cause the clitoris to enlarge. However, since they have not developed these secondary sex characteristics naturally and require lifetime hormones to maintain the appearance but not the function, they are unlikely to experience orgasm ever in their adult lives. Females on cross-hormones are at greater risk for heart disease (double that of men) and bone loss as well as other complications. Males with high estrogen levels are at higher risk for depression, deep vein thrombosis and pulmonary embolism, diabetes, and other complications.

⁴ de Vries ALC, Steensma TD, Doreleijers TAH, Cohen-Kettenis PT. Puberty Suppression in Adolescents With Gender Identity Disorder: A Prospective Follow-Up Study. *The Journal of Sexual Medicine*. 2011;8(8):2276-2283

⁵ Cheng, et al, 2019:<https://pubmed.ncbi.nlm.nih.gov/31380227/>

Pro-“affirmative care” providers cite a statistic that this intervention saves lives by preventing suicide in transgender teens. They quote a suicide risk as high as 41% or more for those with gender dysphoria who do not transition.⁶ This is not evidence-based, has never been shown in a double-blind controlled study, and a careful reading of the statistical analysis of the scant articles that cite this figure reveal the actual risk factor to be much lower. The oft-touted claim that puberty blockers reduce suicide has quite simply not been shown. There is no established, causal relationship. When it comes to gender dysphoric children, there is little evidence that medical transition decreases suicide rates.⁷ There are also conflicting published conclusions about the benefit vs. risk ratio in treating children with puberty blockers and in 2019 the National Health Services in England commissioned a full scale, evidence based review of the current treatment, led by pediatrician Dr. Hilary Cass, and known as the *Cass Review*.

The context for the commissioning of this broader review was the weak evidence base underpinning the current practice of prescribing gonadotropin-releasing hormone analogues to pause puberty in children and young people with gender dysphoria, as well as the uncertainties about the subsequent prescription of cross-sex hormones.⁸

The assertion that such a radical intervention on a healthy child is life-saving is a reflection of misleading but persistent misinformation and is repeated by doctors, medical societies, and politicians, despite lacking evidence-based support. A long-term Swedish study found post-operative transgender people have “considerably higher risks” for suicidal behavior, and a study in the *European Journal of Endocrinology* showed that suicide rates among post-surgical transgender male-to-females were 51% *higher* than the general population.^{9,10}

A prominent study published by the *Journal of the American Psychiatric Association* erroneously claiming that medical transition alleviated suicidality was corrected to clarify that it demonstrated “**no** advantage of surgery” in this regard.¹¹ The false statistical conclusions in that study had been used to manipulate parents into consenting to hormones and surgery for their minor

children under threat that withholding transition would lead their children to commit suicide. This study and others with similar inaccurate conclusions have been the basis for states to dub any withholding of transition aimed treatment - so-called “gender-affirming care”, which includes social transition, to be considered child abuse. The state of Maryland has removed children from parents and legal guardians who do not use a child’s preferred pronouns under the auspices of a hate crime and child abuse.

There is one approach to childhood onset gender dysphoria that has been the standard of care for decades and practiced by clinicians and that is to without medical intervention and provide supportive therapy in a watchful waiting approach.¹² The majority of childhood onset gender dysphoria resolves by adulthood, is not correlated by suicide rates higher than other mood disorders in children, and in most cases results in a same-sex orientation. So, returning to the Executive Order to fight conversion therapy, “gender-affirming care” is thwarting the natural process by which homosexual teens come to terms with themselves as accept themselves for who they really are, without the influence of lifelong cross-sex hormones that lead to sexual dysfunction and infertility. In openly homophobic governments such as Saudi Arabia and Iran, homosexuality is a crime punishable by death, and sex-reassignment treatment with hormones and surgery is considered a cure and subsidized by the state. They are true victims of “conversion therapy”.

Medical gender transition is not quality health care. It does not improve physical health; it deteriorates it. Despite claims to the contrary interventions to approximate the appearance of the opposite sex do not improve mental health, but instead encourage a depressed patient’s belief that the or she was made in the wrong body, and promises an outcome that is impossible. In psychiatry and psychology, the goal of treatment for self-loathing and self-rejection is self-love and self-acceptance, not affirmation of perceived defects requiring risky surgeries, lifelong hormones, and amputation of healthy, especially developing, body parts.

In our society, we have laws that recognize the immaturity and lower accountability of minors. These laws are to protect them and others from harm. For example, driver’s licenses, voting, tattoos, and other elective procedures for underage citizens are limited by law. It is a well-established truth, verifiable by neuroanatomy and behavior, that impulse control and long term planning by adolescents is impaired compared to adults. The pre-frontal cortex commands executive functioning (reasoning, problem solving, comprehension, impulse control, creativity,

¹² D’Angelo, R., Sylulnik, E., Ayad, S., Marchiano, L., Kenny, D.T. & Clarke, P. (2021). One Size Does Not Fit All: In Support of Psychotherapy for Gender Dysphoria. *Arch Sex Behav* 50: 7-16

and perseverance) and does not fully develop until age 25. All of those qualities are essential in giving truly informed consent for a combination of radical medical procedures to impose on a 9 to 12 year old who may have idealized ideas of what it means to be the opposite sex. They can't possibly know nor project what infertility and permanent anatomical changes will mean to their 25, 35, and 65 year old selves.

It is normal, natural, and common for pre-teens and teenagers to have a sense of invincibility, passionate conviction, and high risk tolerance. They are undergoing an important psychological process known as individuation, which is typified by extreme emotions, parental (and to some degree, societal) rebellion, rapidly shifting displays of self-expression from clothing to make-up to hobbies to music and peer groups, and experimentation with their personae, emerging sexual identities, and coming to terms with their developing bodies. To lock in a gender-questioning eleven or twelve year-old child to a concretized "gender identity" defies everything known about child development. Going through discomfort and negative self-regard is part of growing up. Emotional resilience as an adult comes through the destabilizing and re-stabilizing developmental stages of maturation and experience. Authentic selves are not fully formed at Tanner Stage 2. This is a time of significant transition characterized by self-consciousness, anxiety, awkwardness, and emotional lability. One does not need to be a mental health professional to know this. The stages of psychosocial development, from infancy to old age, first described by Erik Erikson in the 1940s and still taught in psychiatry, psychology, social work, and counseling education, defined adolescence from ages 12 to 18 as a time of Identity vs. Role Confusion. It is when adolescents explore a sense of self. It is not when a sense of self is finalized, but when the journey begins in earnest. This social and emotional development is derailed by the use of puberty blockers at the moment when the influence of natal hormones is key. It is typical, normal, and developmentally appropriate for children during this stage to be confused about who they are and who they are becoming, and to cycle through various "identities" in order to mature and discover who they are and want to be. This observable child-to-young-adult process is recognized by various rites of passage and modes of expression in every culture on Earth. It is a global human experience examined by endocrinologists, psychologists, psychiatrists, neurologists, pediatricians, sociologists, anatomists, philosophers, writers, lawmakers, educators, and other chroniclers of development. This is precisely the age when the medico-socio-politico gender-identity concept of "affirmative care" is meant to be implemented. And it is a potential disaster for gender-questioning children biologically and psychologically. During this

phase, social acceptance and social interactions reach a pinnacle of importance, and the parental influence recedes. Social groups determine in large part the self-expression and self-worth of individuals in a peer group. In recent years, as gender identity theory is discussed and promoted among younger audiences via schools and social media, teachers, parents, and mental health providers have observed groups of peers socially transition together to opposite sex pronouns, and seek gender-affirming medical care as a result of peer influence and social relationships.¹³

Stages and phases of adolescent angst often have generational expressions, such as an epidemic of anorexia in the 1980s and 1990s, replaced by a high rate of cutting behaviors in the 2000s and 2010s, and now a widely observed gender dysphoria. Children around the country who still believe in Santa Claus are being transitioned socially by parents who view atypical gender behavior (girls who refuse to wear dresses) as confirmation of a mismatch in gender identity and biological sex. This social trend is a major public health phenomenon and needs serious scholarly research to understand what has been a several thousand percent increase in youth presenting with gender dysphoria, compared to fifteen or twenty years ago.

Conclusion

I strongly urge parents, professionals, and the state of Florida to reject the theory of this “affirmative-care model”, to respect and allow the normal physical, psychological, and neurological development of adolescence, and to treat dysphoria and depression with compassionate, supportive therapy, and/or appropriate medications that do not alter one’s intrinsic physiology and anatomy. When troubled teens reach the age of legal maturity, or better, neurological maturity at age 25, they may decide for themselves what medical interventions they would like to pursue if they have persistent gender dysphoria - many will not - and their adult selves will be in better place intellectually and emotionally to give truly informed consent.

Dear Dr. Vazquez and others:

Please see my comments related to transgender interventions on minors.

I am a parent of a child who had thought she was trans, but changed her mind.

Respectfully,

Erin Friday, Esq.
Co-Lead Our Duty

C. Erin Friday, Esq.
California

September 16, 2022

Florida Board of Medicine

I am an attorney in California, a life-long Democrat who voted for same-sex marriage and a mother of two. I am the parent of daughter who at age 13 was convinced that she was a trans boy. She did not come by this belief organically. She was indoctrinated by an older trans-identifying girl and people she met online. She was influenced by TikTok, Youtube, Instagram and Twitter. She came to her identity after spending hours online during the COVID lockdown. She was sent porn by groomers — homemade porn by her minor groomer friend, as well as Hentai — anime porn with gender bending themes, incest and sadomasochism. She listened to erotica read aloud on Youtube. She was taught how to dissociate from her body and was encouraged to sell provocative pictures to a sugar daddy online, being told that it's really not her body that she is showing because she is actually a boy.

I watched as close to 50% of her girl scout troop -7/16— came out as trans or non-binary.

As soon as she announced her trans identity, her mental health plummeted. She barely got out of bed. Brushing her teeth was a feat. She copied her older trans-identified friend and limited her calorie intake. She imitated this girl and others online — cutting her hair, dying it different colors, donning binders, piercing her nose, decorating her room in a goth motif. She started failing her classes at school. She was diagnosed with severe depression and anxiety. Her online friends instructed her to distance herself from me — to hate me. They told her to call me by my first name, to state that I was just her birth mom and that I am a bigot since I wouldn't accept her trans-identity. She was coached on how to emancipate and run away to an LGBTQ shelter. At their instruction, she was told to kick me head in.

Over and over, the media presents desperate trans-identifying children, abandoned by their families, but the hundreds of parents I know — parents like me — don't reject their gender questioning children. They are coached to reject us. This is a cult-like method- remove those who love and care from the person.

My daughter's first therapist offered a single option, immediately affirming her trans identity, insisting the we use her desired male name and pronouns, and treat her as a boy. The therapist warned us that our daughter had a 41% chance of committing suicide if we did not forget our little girl, and celebrate our new son. The 41% that therapist quoted was lifted from a headline. The study it came from stated that this was an extreme overestimate, but this

therapist had never bothered to read the study. Recent studies show the number to be magnitudes lower, and similar to rates for the comorbidities many trans-identifying children have. We went through a number of other therapists all who affirmed or would not take my daughter on as client because of “conversion therapy” laws.

As I watched my daughter change from a loving child to an unrecognizable kid — vicious, angry and sullen— my gut told me to swim upstream, ignore all of the medical providers. I quit my law practice and read everything that I could on this new crop of teenagers that suddenly announce a trans-identity. Lisa Littman is spot on with her description of rapid onset of gender dysphoria.

I pulled my daughter from the public school, that without parent input, changed her name and sent CPS to my home when I complained. I took away her phone and all social media. I fired the therapist. After rejecting many other mental health providers who would also only affirm and had no interest in my daughter’s addiction to porn or her depression and anxiety, I finally found one willing to explore the causality of her trans identity. I worked tirelessly to show her how amazing her natural body is, how periods are a part of life and discomforts are part of the human condition. I showered her with love and compassion and took all of her daily vitriol, enduring her insults hours on end.

I am happy to say that after about 2 years of love and support, my daughter is now comfortable in her body. She joined the track team, wore a ballroom gown at her uncle’s wedding and spent the summer in a bikini. Had I followed the myopic and unscientific affirmation model, my little girl, would have had her breasts removed and her body pumped with testosterone. This is the affirmative model.

As a lead of a parent of a Rapid On set of Gender Dysphoric Kids support group, I know that my story is not unique because I have heard now 100s like mine. When new parents onboard — which they do almost every week — I can predict their stories whether they have a son or a daughter. The patterns are clear — these ROGD kids are into anime and cosplay. They spend too much time on social media. Many have internalized homophobia. They are socially awkward, intellectually advanced but emotionally immature, on the spectrum, have eating disorders, AND all of them have comorbid mental health issues that are not alleviated by gender affirming care. Forcing the affirmation model as the only treatment for gender dysphoria or incongruence will harm millions of children and youth in our country, leading them toward a lifetime of medications and surgery — treatments with no evidence base to support their safety or efficacy. Affirmation is not life-saving; it is life destroying.

The parents of desisted kids know that once the companion mental health issue resolves, so does the gender dysphoria. Dysphoria is the manifestation of the mental issue, similar to anorexia. People who overeat and look to surgery for the quick fix, still need to resolve what the root cause of their over-indulgence in food.

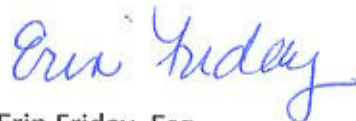

I no longer take my daughter to a pediatrician for the school sports health forms. You see, our pediatrician who knew her since she was born, changed her name to be male without my permission – just following orders - was her excuse. I will never recover from my disdain towards the medical community for failing my daughter and not only abandoning my family, but pushing her towards a delusion.

We, parents, in this space can clearly see the social contagion, the marketing to our kids, and the indoctrination of the schools. Sex-ed curriculum hits the kids 3 times with a the false statements that we have a gender-essence – that one can have a brain of a male and body of female. These kids “acquire” gender dysphoria, they do not have it. We are sterilizing a generation of children.

In closing, I help detransitioners and other parents caught in the web. I know how the gender ideology is ripping apart families and leaving regret in its wake. I have read every study on this issue – likely 3 times over – the science does not support pumping bodies with cross-sex hormones. I have yet to meet a well-adjusted “trans” person, I live in San Francisco. More studies aren’t needed, they are there. Surgeries do not alleviate body dysphoria. Age is the greatest predictor of tubal ligation regret. (40% of women under the age of 24 will regret tubal ligation.) Puberty blockers harmed a number of young girls who used them for precocious puberty. 19% suicide rate POST-surgery and transition. Mental health issues are not cured by plastic surgeries. None of this is new. What is new, is that we have changed biological reality and we have decided that somehow maturation related to gender identity (which is fluid per the ideologues) is the exception to the rule that most humans mature at age 25, with no basis in science. Actuaries understand maturation – this is why kids cannot rent a car until 25, or rent a vacation home.

Had I sent my daughter to a gender clinic, she would be preparing for a life as a medical patient even if she detransitioned. No one is born in the wrong body.

Respectfully,

Erin Friday, Esq.

Hello, I am writing today as a parent as well as a physician. I have two teenage children, one is currently identifying as transgender. I can tell you my child is not anxious or depressed (her psychiatrist agrees), she is certainly not suicidal. I doubt that many of the growing numbers of similar children are. They are just kids. They copy each other (and internet peers), they look for attention, they get confused, and they definitely make mistakes.

I have been in leadership positions and I know how difficult it is to say no when colleagues want to expand privileges or services. I know how there is frequently more dissenting voices for what is wrong for our patients, than for what is really right; remember our creed is first "Do no harm"

The fact remains that any minor person simply does not understand enough about life, interpersonal relationships, or their future to make medical decisions that will affect the rest of their lives. Today's kids may seem more savvy and grown up because they are exposed to a lot, but seeing things and internalizing the meaning to our lives and future are very different. We all understand teenage invincibility, car accidents, fashion fads and certain phases. Why don't we see how hormones and surgery are setting most of these kids up for potential disaster?

The U.K., Sweden and Norway have all closed gender clinics and have stopped offering gender medicine to minors.

We seem to have no trouble recognizing that Tourette's and Dissociative Identity disorder are being spread via social media, with a similar 2000-4000% increase in diagnosis rate. Yet no one is willing to say that social media has anything to do with the burgeoning number of "transgender youths".

There is also a growing epidemic of detransitioners. These people are truly depressed and suffering. And they have no voice, they receive vitriol and hate. Let's not add to their numbers. They all say that they felt happy **while pursuing** transition, which is expected when one has goals to set, work toward and attain; but that once they got there, they found it did not actually solve any of their problems and in fact created new ones.

The best data available actually shows the highest suicide rates among transgender people at 8-10 year POST transition. If we wait that long our problems will truly be epidemic and epic.

The most reliable data we have say that about 80% of kids with gender dysphoria will desist before adulthood.

Please, let us not pathologize normal variation of gender expression into something unacceptable that has to be changed through life long treatment. We are telling future gay adults and tomboys and not so masculine boys that they are not ok the way they are. This will lead to an actual psychological crisis. How many of us nerdy doctors would have been led down the same path when we were kids?? Where would we be now?

An argument used for early transition is better physical outcomes down the road. However, most actual transgender ADULTS do not feel that waiting has impacted their results. Further, early treatment does not allow sufficient development of genitalia to provide tissue for good outcomes. As far as secondary sex characteristics hormone manipulation will make changes no matter when

they are started.

Physicians should be the voice of reason in society, not contributors to and creator of psycho-social pathology. We can support our youth with love and guidance and encouragement. We can lay out future potential options. Many parents who are advocating for transition for their children have been frightened into believing there is only one answer, they are frightened and feel that supporting their child means going along with anything. Early treatment may be beneficial for a very small number of individuals but the vast majority of kids presenting as transgender today will be hurt by it. Parents consult the internet and it is very hard to find more than one answer on the internet. Even I initially fell for the idea that my child might need hormones and feared for my child's well being. I was distraught due to cognitive dissonance; it did not feel like the right thing but I was told it was the right thing. After many lengthy discussions with my child and many hours of research I have a far better understanding of what is actually best for my child; even when she does not. But this is a lot of parenting in general is about, guiding kids to adulthood when they will be ready to make decisions for themselves.

My personal phone is 352-267-3770. I would be happy to answer any questions. Thank you for your time and attention to this matter most critical to our youth and their futures.

I am an Aunt in Florida, a life-long Democrat. My nephew at age 15 was convinced that he was a transgirl. He did not come by this belief organically. He was a rough and tumble boy. He was socially awkward. He was lost and started spending hours online and watching anime. He knew none of the girls in elementary school and in middle school he wondered how he would ever date girls because he had nothing in common with them. He also decided he was trans with another boy from Boy Scouts. After he told us this we started seeing it everywhere.

As soon as he announced his trans identity, his mental health plummeted. He barely got out of bed. He lost 30 pounds. He started failing his classes at school. He was diagnosed with severe depression and anxiety. His online friends instructed him that his parents are abusive. His teacher in school also affirmed this belief and actively tried to help him move out of our safe home into a LGBT center.

My nephew is now 18 and moved out of their house while they were at work and they have no idea where he is. Over and over, the media presents desperate trans-identifying children, abandoned by their families, but the hundreds of parents I know — children like my nephew's parents — don't reject their gender questioning children. They reject them.

My Nephew's first therapist offered a single option, immediately affirming his trans identity, insisting that his parents use his desired female name and pronouns. The therapist warned them that their son had a 41% chance of committing suicide if they did not celebrate their new daughter. The 41% that the therapist quoted was lifted from a headline. The study it came from stated that this was an extreme overestimate, but this therapist had never bothered to read the study. Recent studies show the number to be magnitudes lower, and similar to rates for the comorbidities many trans-identifying children have. The suicide statistic is higher after transitioning.

As I watched their son change from a loving child to an unrecognizable kid — vicious, angry and sullen— my gut told me that the therapist was wrong. I read everything that I could on this new crop of teenagers that suddenly announce a trans-identity. Lisa Littman is spot on with her description of rapid onset of gender dysphoria.

I know that my story is not unique because I have heard 100s of stories like theirs. The patterns are clear — these ROGD kids are into anime and cosplay. They spend too much time on social media. Many have internalized homophobia. They are socially awkward, intellectually advanced but emotionally immature, on the spectrum, have eating disorders, AND all of them have comorbid mental health issues that are not alleviated by gender affirming care. Forcing

the affirmation model as the only treatment for gender dysphoria or incongruence will harm millions of children and youth in our country, leading them toward a lifetime of medications and surgery — treatments with no evidence base to support their safety or efficacy. Affirmation is not life saving - it is life destroying.

Paul A. Vazquez, J.D., Executive Director

Florida Board of Medicine

I am writing to ask that you carefully consider the [exponential rise](#) of gender dysphoria and trans identification in young people, particularly teen girls beginning in 2015. As an academic, I have spent the last 18 months studying this phenomenon, and although there is much left to be answered, I concur with health policy analysts in [Finland](#), [Sweden](#), [UK](#) and [France](#) as well as prominent concerned figures of [WPATH](#) & [USPATH](#) that the affirmation model of care currently in place is ushering many young people to seek irreversible medical treatment for what may be transitory distress. As the [Cass Report](#) highlights, there are many etiological pathways to and out of gender dysphoria. Gender dysphoria is not prima facie evidence of being transgender as demonstrated by the growing [narratives](#) of those who have [detransitioned](#); trauma, internalized misogyny and homophobia, peer/social contagion, and being on the autism spectrum, for example, can lead to dysphoria. Further several studies have shown that sexuality may be related to the experience of [gender dysphoria, as 60-90%](#) of those with childhood gender dysphoria align with their biological sex and grow up to be LGB. It is imprudent and unethical to treat these youth with irreversible treatments without letting them fully understand their sexuality.

We need to [uncouple LGB from T in order to understand](#) why affirmation and conversion therapy bans may be an [impediment to sound psychological support](#) for gender dysphoria. We need discussion of the ethics around [informed consent](#) for medical treatment that is based on poor quality evidence. We need legislation that support parents who love and want the best for their children. The current state of affirmation medicine triangulates families and leaves young people particularly vulnerable.

I support the practice of Dialectical Behavioural Therapy and open-ended psychotherapy for youth with gender dysphoria. I support the more traditional “watchful waiting” approach that takes into account what we know about gender dysphoria and child and adolescent development. I support a family centered approach where the rights of parents, who know their children, and long-term well-being are centred. We do not know enough about the potential risks and benefits of hormonal and surgical treatments. Considering that our brains do not fully mature until the mid 20’s, and it is impossible for an adolescent to fully

understand the risk to future fertility and sexual function. Given that these treatments are poorly researched, these irreversible treatments should not be available to those under the age of 25.

I implore you to be prudent in your decisions.

Best regards,

C. K. Moruzi, Msc., PhD.

Chan Kulatunga-Moruzi, M.Sc, Ph.D

To: Paul A. Vazquez, J.D. Executive Director Florida Board of Medicine Paul.Vazquez

I am a child advocate parent member of Cardinal Support Network of Ohio. We are a volunteer network of families of gender confused children and young adults who are suffering. We love our kids. We support any protections put in place that would align with science and evidence-based care of children who suffer from gender dysphoria. Ohio also needs to protect minors from the experimental practices of the gender clinics. We hope that this Florida resolution will encourage the Ohio Medical board to investigate the medical harms happening in our own clinics and separate themselves from WPATH members associating with this organization that has been radicalized by activists, creating a billion dollar industry and state sponsored child abuse.

1. There is absolutely no scientific evidence that you can be born in the wrong body and the burden of proof sits on the shoulders of every gender clinic director the hospitals that employ them, not the parents.
2. State medical boards should protect minors from unnecessary interventions that have become popular and mainstream, and as we witness a growing media induced social contagion of teenage girls with low self-esteem desiring bilateral mastectomies marketed as top surgery by clinics and public hospitals.
3. The majority of these children resolve their issues and accept their bodies after natural puberty is complete and do not pursue transition as adults. Many of them would grow up to be gay, lesbian or bisexual adults.
4. These interventions on minors have NOT met the lowest GRADE of evidence common in every other area of medicine for minors. Finland, Sweden, France and other countries have stopped transitioning children.
5. Detransitioners, those that regret these decisions are telling their stories and we are concerned for our own children's futures. We need to listen and learn from detransitioners and protect them.
6. There is a drastic imbalance between the benefits and harms of these procedures. The recommendations of gender clinics lack any long-term study and rely on adult biased surveys when treating children.
7. We do know that the majority of youth who are given supportive non-medical resources resolve their issues with gender identity, even some gender clinics state this on their websites for years prior to the drastic intervention changes taking place.
8. There is no way to know who will benefit from transition and who will be harmed. Parents who want watchful waiting are looked down upon by clinics as unaccepting and even transphobic.
9. The state medical board should stop the grooming of our children into believing anyone can be born in the wrong body. We have human sexed bodies, defined in every cell of our body as male or female. Removing reproductive organs does not change this reality. Neutering a male child does not make him female. We believe we are victims of medical malpractice. Of the 580 parents who have completed our survey:
 - A. 80% of their children are female, mostly between the ages of 12-21 (average = 14)
 - B. 67% had one or more friends come out at the same time (average = 3)
 - C. 55% had a formal mental health diagnosis prior to "coming out" as transgender (most common diagnoses were anxiety, (74%), depression (65%), ADHD (30%) and ASD (16%))
 - D. 70% reported their child had experienced a major stressful event prior to onset of GD (e.g. death or divorce of parents, suicide of friend or sibling, sexual or physical trauma, or received serious medical diagnosis)
 - E. Parents overwhelmingly reported that social transition had a negative effect on their child's socialization, emotional wellbeing and family relationships.

10. These clinic directors have stated without evidence, that unless parents go along with these unnecessary interventions, our kids will kill themselves. Many parents go along against their better judgment and are coerced into social and medical interventions. It's not their fault.
11. Parents are concerned about medical malpractice with regards to misdiagnosis and surgical errors resulting in the creation of lifelong medical patients. Our children have normal endocrine systems that are being destroyed by wrong sex hormones.
12. Allowing children as young as 4 to self-diagnose as transgender and accepting delusion as true by any adult is just one element of malpractice. Hospitals can be held liable for injuries caused by doctors. In order to be accredited, every hospital has to have rules in place that protect the safety of patients. Evidence based care has been replaced by activist-based care and these clinics partner with activist groups (HRC, GLSEN, PFLAG, Living With Change and Planned Parenthood). These groups promote misinformation and profit from the gender industry. In Ohio as an example there are 7 gender wings in these Children's hospitals.
13. It is important to note that the new WPATH guidelines include doing eunuch surgeries on minors and believe this is an identity that needs to be supported with surgeries. WPATH has been dropped by Finland as it has been radicalized by activists.

Nationwide's Director's Statements, 2021 Pride Podcast , Dr. Liebowitz, Thrive Director

WPATH Adolescent Chapter Lead of the 8th Addition standards of Care is your typical, radicalized gender clinic director. He assisted in writing the new WPATH guidelines that include surgeries for eunuch identities. He has treated over 2,000 patients. **These are some of the many troubling statements he believes in.**

"We have to go on what the young person bases their experience on... and that (it) is actually a good thing for everyone, which eliminates gender boxes and which eliminates just 2 gender boxes and it allows young people to be authentic no matter how they express themselves. It's important to affirm without questioning it is a phase. It's okay to validate without.

Curricula should include gender identity and sexual orientation. I know there is curricula that schools can turn to such as GLSEN, HRC are developmentally appropriate and it benefits all youth and all families.

Referring to natural puberty calling it "irreversible puberty". Nationwide Director states: **"As a child gets older for young adolescents as their body starts to go through irreversible puberty if you think about it by definition for a transgender person going through the puberty that is not associated with their gender identity can be pretty devastating."**

And **(natural puberty) that leads to really irreversible, devastating outcomes** for the rest of their lives that can be very challenging to undo should a transgender person go through their first puberty, and go through a second puberty, parents often tell me how difficult one puberty is let alone 2, therefore, we ascribe to using puberty blockers which is a medicine that halts puberty. It is largely reversible.

We are suppressing puberty to buy time for that young person to be older and become more mature and better able to be in a place to make decisions about more irreversible treatments which include the gender affirming hormone treatments such as testosterone or estrogen.

What gender affirming hormones would do for a more mature adolescent is they would produce the affects that would create a puberty of the gender associated with their desired assigned sex at birth. So, for example, in a transgender boy, it would deepen their voice, it would create a perhaps facial hair in the future, it would perhaps change their muscle mass in a way that is more consistent with the secondary characteristics of boys or men.

And for a transgender girl, **estrogen would create a development of breasts, it would create a softening of their skin, redistribute fat in a way that is more typical of women**

The decisions on surgery are largely based on emotional maturity of the young person, how long that they have been experiencing their own gender dysphoria, how impaired their life is as a result of not obtaining surgery

(NOTE FAILURE RATES OF THESE SURGERIES ON THE REFERENCE PAGE)

(Surgery) is more likely to be recommended for a person who is still a minor would be a top surgery or a chest reconstruction, masculinization surgery, for a transgender boy simply because for a boy who has been living as a boy (57:43), and on testosterone for years at this point and their entire life identity is being perceived as the gender they identify in." The WPATH guidelines and are currently revising since the evidence and research have been evolving since the last guidelines were issued in 2011.

Because they are receiving gender affirming medical care, them to be expected to use a bathroom that a cisgender kid needs to accept it and include cisgender students as well.

The more we talk the more we normalize and the more we can act and support all kids.

It is important for a pediatrician to **meet with them alone** and ask them in an open-ended way that does not presume that the faith-based organization is harmful but what religion and spiritually means to them and how the institution they are going to makes them feel as far as comfort around gender roles, gender identity and sexual orientation.

We are seeing higher rates of suicide in this group, it's not inherent in this group. There is research on anxiety, depression and being transgender that is contingent on family support.

Family acceptance and support is helpful in reducing negative outcomes in transgender youth.

We should be screening for sexual orientation, gender identity and gender expression alongside mental health challenges in everyone and not make assumptions. This should be introduced as young as a child is able to speak a language by not enforcing that a child has to be a certain way.

We start with less irreversible going up to more going up to irreversible depending on emotional maturity and age. **We follow WPATH Standards**

Dr. Liebowitz stated seeing 1,000 patients in 2020 alone.

Cincinnati Children's Transgender Clinic Summary

Since 2013, Cincinnati's Trans Clinic has been aggressively transitioning over 2,000 children referencing an adult transgender survey as proof that if you do not actively transition your child, that child will be homeless or commit suicide later in life. Cincinnati Children's transgender clinic, court custody against parents, **the director stated that 100% of the patients were candidates for medical interventions for gender affirmation.**

It is funded by a transgender lobby, Living with Change (LWC). The founders are publicly transitioning their own biological son presenting a conflict of interest, donating \$2 million from sales of sex toys (Pure Romance), sells breast binders to young girls and legal name changes for minors as "gender affirmation".

Dr. Conard stated "it's not my job to worry about these kids' adult lives and the long-term effects, I am just trying to get them through puberty alive" Parents in CSN have reported that the gender clinic staff typically ask: "Would you rather have a dead son or an alive daughter?" when they question these drugs, such as testosterone for females, a Class A controlled substance with many risks and not approved by the FDA for this purpose.

Admits testosterone is given to biological females and for puberty suppression: Leuprolide acetate is an injection given monthly or quarterly. Histrelin is an implant that lasts 12 to 18 months. The choice, Conard said, depends on how, or if, insurance will pay for the treatment. **In puberty suppression, the child does not develop functioning sperm or eggs. If the child wants to have biological children, then the child must progress through a normal puberty to get mature sperm or eggs for preservation and then go on the suppressing hormones. When an older transgender adolescent has already gone through puberty, the clinic offers the possibility of sperm or egg preservation before starting the gender transition with hormones. "But that's hard for a 15- or 16-year-old to think about," Conard said.**

detrans female

Your story, and that of my own and others if why I fight so hard against the toxic positivity of this movement by the lgbt. We need mental healthcare, not hormone shots. I wish you all the best

detrans female

This is a great perspective to have! I really appreciate it. You're right that it's proof we thought we were doing what was best for us. When I started transitioning, pretty much no one talked about regret or detransition, and a lot of people even insisted it didn't happen at all. Instead I only heard stories of people who went decades suppressing their dysphoria just to eventually transition anyway and wishing they had done it sooner, so I understandably thought it would last forever. Thank you so much <3

I am so sorry for how you are feeling right now. I know that things like your voice are difficult to accept (I still struggle with accepting mine at times..) and even though you may not be able to sing at the pitch you'd like it shouldn't stop you from singing in general. I'm not good about following through with it usually but there is also voice training for at least speaking voice... I understand how you feel about not getting to experience being a young woman I definitely feel the same on that as I came out as trans at 13, started T at 14 and had a mastectomy at 16 and a legal name change.. lived that way until around age 21 when I realized the mistake of it all. It is hard and it's hard not to want to relive those times without the alterations we had made to our bodies and life to fit what we wanted at the time. All we can do is try to support each other here and keep moving forward. Buy and wear the things that make you feel pretty, if you're worried about your hair right now then maybe some wigs would be an option for you or some extensions or something.. I would speak with someone who does hair who might be able to help on that. May even be some products that would help with the hairline.

I wish the best for you. You are not alone.

September 15, 2022

Dear Florida Board of Medicine,

My daughter has been seriously harmed by the gender medical community in California where we live, and she has been encouraged to pursue irreversible medical treatments including testosterone therapy and the removal of her female organs/hysterectomy.

Our story is similar to many other families, but it has been devastating for our child and our entire family. Our daughter told us she was confused about her gender identity during the first summer of the pandemic, in August of 2020. We reached out to parents and therapists in our community and everyone, following the Gender Affirming Care initiative, told us how they affirmed their daughters and took them to support groups and the Gender Center.

Our daughter had already been struggling for a long time with serious depression, anxiety and she is autistic. She became so obsessed with the idea of removing her female body parts that she resorted to hitting herself in the stomach with full force, pulling her hair out and breaking things. She told us if we wouldn't get her a hysterectomy she would give herself one, realizing this meant she would cut herself open and she would die. We tried to find her help from therapists, but she was so agitated and hysterical that she really couldn't get benefit from talk therapy. We went to a doctor to get help with stopping her period and the doctor told her that if we would consent, she could get a hysterectomy. My daughter cannot forget these words and she plays them over and over in her head. She is not rational and cannot be soothed or comforted.

We had to call 911 and take our daughter to the psychiatric emergency room twice over the past year after she fell apart and couldn't recover from her obsessive

thoughts about removing her female body parts. She was put on a 5150 hold the second time because she was a threat to herself and others. She also had to go to a psychiatric hospital for a 6 week stay to stabilize this summer.

I am asking you, Florida Board of Medicine to please consider changing the age of consent for gender medical treatments to at least the age of 25. Children should not be told by doctors that they can surgically remove healthy body parts as a way to feel better about themselves.

Thank you,

William Mahon

September 15, 2022

Dear Florida Board of Medicine,

I am the mom of a child in Northern, California who has been harmed by the Gender Affirming Care model and who has been encouraged to pursue harmful medical interventions including Testosterone therapy and a Radical Hysterectomy by medical practitioners at UCSF Pediatric and Adolescent Gender Center and UCSF Division of Gynecology.

My request to the Florida Medical Board is that the minimum age for gender-related medical interventions be changed to 25 since it is widely documented by the scientific community that maturation of the prefrontal cortex, responsible for executive functioning and critical decision making in the adolescent brain, is not accomplished until the age of 25.

The development and maturation of the prefrontal cortex occurs primarily during adolescence and is fully accomplished at the age of 25 years. The development of the prefrontal cortex is very important for complex behavioral performance, as this region of the brain helps accomplish executive brain functions. - ["Maturation of the Adolescent Brain," Pub Med](#)

Here's my story. My daughter is now 16 years old. She is autistic and has co-existing serious mental health conditions including acute anxiety and clinical depression, making her extremely vulnerable.

When my daughter became confused about her gender identity in the summer of 2020, she was encouraged by Internet influencers to take immediate action to change her body. The gender affirming care model told us as parents that we had to support her. Her first request was to medically suppress her period using hormones. Our pediatrician was able to help with this initially, but my daughter's high level of distress about break through bleeding, which inevitably occurs with menstruation suppression, led us to speak to UCSF Child and Adolescent Gender Center via telehealth. My daughter was so distressed that she struggled to focus on any of her preferred interests or activities, including school, leaving the house, interacting with peers or

basic self care. During this time, my daughter continued her obsessive Internet research on the topic and became fixated on the solution of demanding a radical hysterectomy to remove her ovaries, uterus, fallopian tubes and external female genitals. The pediatric nurse at the UCSF Gender Center referred us to an OBGYN at UCSF for support with the menstruation management and because she was known to be reassuring to distressed kids.

During the consult with the UCSF doctor, my then 15 year old daughter was told that Testosterone therapy would “induce amenorrhea” or effectively suppress her period. I objected and stated my concerns about my daughter’s significant development delays due to Autism and her inability to make informed decisions for herself in addition to her extreme emotion dysregulation, tendency to become aggressive and her anxiety and clinical depression. The doctor already had this history on my daughter, so I believe it was unethical to discuss this treatment option with my daughter. The doctor also discussed with daughter the opportunity to get “gender affirming gynecologic procedures,” and told her that while surgeries were usually done on people over the age of 18, she could get a radical hysterectomy if she could get her mom to consent. This offer from a UCSF doctor has been the single most harmful aspect of the gender affirming care model for my daughter. Her obsessive fixation on getting me to consent to surgery at a young age has lead her to extreme dysregulation, school refusal, self harming behavior and multiple psychiatric hospitalizations.

My daughter has been hospitalized twice at the psychiatric emergency rooms in Northern California after she decompensated into self-injurious behavior while obsessively demanding a radical hysterectomy. She was placed on a 5150 hold after the second psychiatric hospitalization and stayed in a psychiatric hospital for 7 days. Later that month she was transported to a Psychiatric Hospital for a 6 week stabilization stay.

Many Autistic children share common traits that make them uniquely vulnerable to the gender ideology and to the suggestion by medical professionals that they will experience immediate relief from irreversible medical interventions. For Autistic kids who have often felt marginalized in the classroom, in their communities and even at home, their blame is often directed inward toward their bodies, and the suggestion of changing their bodies to find relief is very powerful. Hallmarks of Autism include rigid, black and white thinking, challenges with understanding the social world, tendencies toward [perseveration](#) and difficulties with regulating emotions, to name a few. The prevalence of co-borbid mental health issues among Autistics is widely documented, with extremely high rates of ADHD, anxiety and depression. While each of these issues can be challenging to manage in themselves, the combination of ASD qualities with additional issues such as impulsivity and difficulty shifting attention, and unhealthy thinking patterns that emerge from anxiety and depression, can lead to extreme dysregulation and explosiveness. When combined with an obsessive fixation

on medical interventions, these co-borbid mental health conditions make it impossible for a child to think rationally.

Parents are often blindsided by [Rapid Onset Gender Dysphoria](#) when it shows up in their young teenage children. Most kids will move on through this phase of identity exploration if we don't make it concrete for them. Parents deserve to know there are other ways to support our kids rather than buying into the 'affirm and medicalize' model currently in place in our country. Our children were not born in the wrong bodies and no one in the medical community should be saying they were.

Thank you for considering this perspective.

Respectfully,

Karen Mahon

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

Here is my story and I now know I am not alone. I live in California but grew up in Florida. My teen daughter suddenly came out as trans 1 ½ years ago. There is a life pattern and a path to transness that is almost comical to hear. This is NOT normal. Many of these trans identifying teens are girls. This is new. They fit into a pattern identified as ROGD. Read Dr. Lisa Littman's [studies](#) because they are spot on. These teens are the average age of 16 when they come out. They have struggled with mental illness their entire lives. They have been bullied as children. They have struggled socially to fit in their entire lives. They never mentioned gender or sex as ever being an issue their entire lives. They hung out on Youtube or other social media that lean heavily on algorithms to suggest the next thing to watch. They often came out as lesbian a year prior. And as we now know, they are often on the Spectrum. And then they dropped a bomb on our house that we're still trying to dig out from.

Here's what else is going on in our lives: We seek help and we're only told of the 'affirming' therapists. We're put on waiting lists because there aren't enough therapists. After months of waiting, we take whatever therapist we can find. They tell us to 'trust the process.' We see things moving too fast but realize too late that we're caught in an agenda that we want no part of. Some of us still don't realize this. We're told our teen will kill themselves at any moment if we don't give them medical treatment right away. The endocrinologist creates a disease to list in our teen's medical chart to treat them with testosterone so the insurance will cover treatment. Our child has no such disease and yet, it's on her chart: "Unspecified Endocrine Disorder". Meanwhile, they fail to point out to us that our child is suffering from severe to extreme anorexia (we were told our child just needed to 'gain some weight') when in a rational medical world, they would have been immediately hospitalized. The severe anxiety that the therapist didn't treat at all before referring us to the gender clinic gets worse. We want what is best for our child but medically torturing our child while not first acknowledging and addressing these severe mental health issues first is medical malpractice. And we go on. Eventually, we wake up and seek care at several eating clinics to help treat our daughter. All of them affirm. None of them know how to treat eating disorders caused by Autism. So we stay at home, suddenly becoming medical experts ourselves because we can no longer safely seek care for our daughter within the medical establishment. We are now seeking life outside of the US. It is not safe to take your child to the doctor anymore. It's that simple. How on earth did we come to this?!

Please stop the medicalization of trans children. Many of these children are often girls who have many co-morbidities such as eating disorders, depression and anxiety that often have simply manifested due to undiagnosed or diagnosed Autism. It is often the autism that is speaking, not because they were 'born in the wrong body.' We all know it is physically impossible to be 'born in the wrong body.' Everyone is born simply biologically male or female with a tiny contingent of people who are intersex. Children reach true maturity at age 25 and we know that children on the Spectrum often lag behind with maturation, which is closer to 30. Parents are being turned away as not trustworthy when they are the ones who know their own children. The 4000% increase in girls identifying as trans should not be normalized, especially when 48% of the patients at Tavistock were considered on the Spectrum. Medicalizing these children with cross sex hormones and puberty blockers will likely lead to surgery and it will lead to infertility. It will also make their co-morbidities amplified. This we can see early signs of and yet, trans centers are not fully explaining this to the families who enter these clinics. The 'affirmation only' model is pushing these vulnerable children and families into a future life being tied to the medical industry. They will make a fortune off of these children. As a parent, I'm appalled that I can no longer take my child to a doctor and trust that they won't push them towards this ideology. We are looking into leaving the US now because the entire industry has been co-opted and I now trust no doctor. None!. I've been burned four times already in the past year by 'affirmation only' care. Please, please heed parents warnings and stop this insanity. There will be reckoning one day on all of this but in the meantime, so many families are suffering as are these children.

Paul A. Vazquez, J.D.
Executive Director
Florida Board of Medicine

Dear Executive Director,

I am writing to you as a parent of an autistic child. My son has been thoroughly indoctrinated to believe that all his social problems will be solved by changing sex. He reads the propaganda printed by gender clinicians and believe hormones and surgeries to be completely safe. Due to his autism he doesn't see the harms. How will he feel when he's had irreversible hormones and surgeries and realises he's still socially awkward? I plead with you to protect vulnerable children like my son.

Kind Regards,
Jane Clarke

To Whom It May Concern

I am writing to express my deep concerns about the current state of affirmative care for gender questioning youth and adolescents.

I am the mother of an 18 Year Old daughter who decided 3 years ago - completely out of the blue - that she was "trans". Her entire circle of friends also identified as trans. It has made our life a living hell. After she decided she was trans, her mental state plummeted. She became depressed, anxious, suffered panic attacks and began cutting herself. She also suffered from suicidal ideation.

The pediatrician I took her to just before she turned 16 told me to affirm her or she would suffer harm. In March 2020, one clinic asked me if I wanted a dead daughter or living son. My husband and I were not having it. We found a good psychologist who specializes in body dysmorphia and she treats kids who claim to be trans or "born in the wrong body". That made perfect sense because when she was placed in my arms at 13 months old, she was only 15 lbs. She didn't cry and couldn't even hold a bottle, let alone crawl. She was subsequently seen by world renowned orphan specialist, Dr. Jane Aronson, who diagnosed her as a failure to thrive baby and said we got her "just in time." Her toddler years were filled with night terrors and flashbacks. At 8 years old she told us that a piece of her heart was missing and she needed to know who she was.

The psychologist has diagnosed our child with pre-adoption trauma, depression, anxiety and suicidal ideation. One year later she confirmed that our child is not transgender. She's just fearful of her future, has abandonment issues, and needs to focus on what she does well outside of her gender space. One of our daughter's friends started testosterone in 2019. She went off to college last year and had to come home. She has decided she is not trans after all and has declared herself to be "non-binary" and changed her boy name to a gender neutral one.

Our daughter has been diagnosed with borderline personality disorder this year. We have never affirmed her male identity and were able to convince her highschool and most of the adults in our lives to not affirm her. We see some improvement in her self esteem and are told that this may take a while for her to work through, but as long as she works at therapy, she will have the tools needed to cope with her issues. We believe in watchful waiting and not medicalization for children. Puberty blockers and cross-sex hormones have too many harmful side effects and we refused to be complicit in what we see as experimentation with children's bodies. I have personal experience with Lupron which we used during IVF in the 90's and had to stop because it gave me a heart rhythm issue that I am still dealing with today. When I was in my 20's I was put on the Pill to deal with painful menstrual cycles. After one month, I was rushed to a specialist in NYC, Dr. Porges, who told me that I was on the verge of a heart

attack or stroke and he cautioned me that hormones, regardless how low the dose, were a danger to me. So I know what hormones are capable of doing to an adult body.

Last year I spoke to a mother whose 15 Year old gender dysphoric/autistic daughter was diagnosed with osteopenia after two years on puberty blockers. The doctors strongly urged her to continue with testosterone. She refused. Today her daughter is mentally better and showing signs of desistance.

My husband and I (and we are Liberals by the way) support a slow and cautious approach that leaves medicalization entirely out of the equation. We have seen no good reason why children should be allowed to self-identify - before their brains are fully formed - and placed on a path of medical misery. History will not look kindly on what was done to this generation of vulnerable youth.

Thank you for reading this.

Sincerely,

Robert and Kathleen (Dooley) Breslin

September 14, 2022

Dear Florida Board of Medicine,

I am writing to you regarding the needs of children and teenagers who struggle with gender dysphoria. As you may know, some children begin experiencing gender dysphoria as early as age 3. For others, gender dysphoria suddenly appears in adolescence. In either case, there are usually many underlying reasons why children and teenagers report discomfort with their biological sex.

As a marriage and family therapist for the past 27 years, and as someone who has educated on gender identity for nearly 20 years, I want to emphasize to you the importance of directing these children and their families to get the help that they are needing – psychological help for the root issues – rather than simply treating surface symptoms with experimental medical treatments. For children who begin experiencing gender incongruence by the age of three, there are often attachment issues that need to be addressed. For adolescents who define themselves as transgender, though not previously demonstrating gender incongruence, there are usually other issues. Often these adolescents and teenagers with no prior history of gender incongruence have other emotional, relational, or mental health issues. These individuals often encounter cultural messages encouraging cross-gender behaviors and identities, and for some of these young people, adopting a transgender identity becomes a welcome distraction from their emotional or mental turmoil. Many teens become fixated on a transition as a solution to all of their problems. Without proper psychological intervention, they develop tunnel vision around transitioning, and as they find encouragement from culture and even the medical establishment, their obsession grows until they finally begin taking steps. Unfortunately, however, years after transition these young people are likely to find that their emotional, relational, and/or mental health issues remain, and the transition did not resolve their problems. Many will regret the transition and feel even more hopeless and suicidal after accomplishing their goal of transition and finding they are still as depressed as they were years earlier, before embarking on their journey of hormones and surgery.

As a therapist, I have assisted children and teens in exploring their underlying issues, addressing the deeper needs, and making peace with their biological sex. As one who understands the root issues, I am writing to ask you to recommend therapy instead of hormones to these very confused individuals who are unhappy in their own skin. They often have attachment issues, trauma, family dynamics, and other issues to work through. If they are to become truly healthy and productive adults, they need encouragement to deal with root issues rather than move down an impossible path of trying to change their biology. These children and teens need help addressing their *psychological* make-up not changing their *biological* make-up.

Thank you for considering the deeper issues and needs of these children,

Julie Hamilton, Ph.D., LMFT

Good afternoon,

I heard that the Florida Board of Medicine is meeting to consider regulations regarding the practice of gender medicine.

As a concerned parent living in the state of Georgia, I wanted to briefly share my family's experience with my now 16 yr old daughter as it relates to affirmative care.

In 2020 our daughter told us she thought she was trans and wanted us to use different pronouns than she/her, consider allowing her to wear a binder, and consider the use of testosterone or puberty blockers. At 14, she was already well into the stages of puberty, so halting that for what was described as feeling like she was born in the wrong body felt dangerous. In addition, what we knew as her parents was that she had been sexually abused by a teenage neighbor two years prior, just as she was starting puberty. Touched in sensitive areas, she now wanted to bind those areas and ultimately make them disappear. As parents we felt like this was a coping mechanism to deal with the trauma from the abuse. Why would she want to be a girl if girls are abused?

My husband and I decided not to use her preferred pronouns and not to allow the use of binders or testosterone. She was not happy with us for a year and a half, but she was confident in our love for her and the strong relationship that we had with her. Fast forward to June of 2022 when she went to a father-daughter camp still thinking she was trans. Halfway through the week she, by herself with no prompting from my husband, came to the realization that she had been discounting her value as a girl. She arrived home to tell me that the trans identity was a coping mechanism for the abuse, but while she was within the coping mechanism she couldn't admit that that is what it was all about. Now, she is free from this belief and is growing in her confidence as a female.

Imagine if we had taken her to a doctor or gender therapist who took her at her word of being born in the wrong body. She could have been put on a path to body mutilation. Imagine waking up and realizing that it had been a coping mechanism, but it was too late bc she had already taken too many steps to reverse where she was. We are so thankful that did not happen. We are so thankful we decided to encourage her to wait. We always knew it was a coping mechanism, but to her we said wait bc you never know how you might feel a few years down the road.

We believe this is the only "affirmative care" approach that should be allowed for these kids. We affirmed the struggle that she was going through. We affirmed our love for her. And now we still have our daughter, with her body and mind completely intact and experiencing a

freedom she had not experienced for the last 4 years since the abuse.

Our hope is that our story can help other parents advocate for their children, because maybe they know of something in the child's history that might be contributing to their desire to change their gender. And our hope is that our story can encourage the Florida Board of Medicine to seriously consider the dangerous effects of blindly affirming these kids who need adults to help them become healthy instead of affirming their ultimate demise.

Sincerely,
Heather Duffie
Georgia Parent

Hi -

I am the parent of a 15 year old daughter who has been identifying as a boy for a year and a half now. Our daughter's announcement came out of the blue 9 months into lockdown here in New Jersey and with no previous identity issues.

I would like to write to urge you to recommend using the utmost caution, setting guardrails around this issue. We are loving parents of 2 older children too, both of whom are in college now. We were pushed to agree to medicalization very quickly. Our daughter was said to be a good candidate for puberty blockers after 1 visit to a psychiatrist. We zoomed into a "trans parent support group" where we were told that our child should be in charge (who was 13 at the time). We were urged to make an appointment with an endocrinologist, just to investigate. We did that and within 15 minutes were being shown a puberty blocker that could be implanted which was described as "totally reversible" and "safe". (blockers are not safe or reversible- I will leave others to tell you why) We left that appointment after I accused the doctor of violating her hippocratic oath. This was 6 months into our child's new identity. We were warned by all that if we didn't affirm our child and medicalize immediately our child had a good chance of suicide. That suicide statistic is a lie.

In the time since then we have cycled through a number of psychiatric nurses. Our child takes focallin for ADHD and sertraline for anxiety and depression. I am always suspicious of clinicians as they are always referring up to the endocrinologist and surgeon. We fear a clinician will call CPS on us for not agreeing to medicalize our teen. There is a disconnect. The psychologists don't deal with the medicalizing so won't take responsibility for what happens if a child medicalizes unnecessarily (and they don't know the medical risks) and the doctors/surgeons will say they aren't the ones making the assessment. It's kind of like do it yourself gender medicine- with children/teenagers driving the bus and big pharma and the many gender clinics getting rich. The trans activists are masterful at marketing. Please lurk on the Trevor Project. Go in and pretend to be a 14 year old who thinks they might be trans. You will see how they "help" the kids and encourage them to hide things from their parents. Unfortunately it is very hard to get up to speed on this quickly. If I had been up to speed we never would have gone to that endo who devastated my family. I have spent more than a thousand hours researching this and think this is the scandal of the century, worse than the scandal which was the lobotomy and satanic panic/recovered memories/multiple personality disorder. They ask parents to sign informed consent because it is considered experimental medicine. Think about that. They want parents to consent to experimental medicine being practiced on their children. This medicine will sterilize the child and in many cases leave them without sexual function. They don't know what puberty blockers do to the brain. It is a human rights violation in plain sight. No adult can or should consent to this for a child!

Please recognize that gender identity is more of a religion (unfortunately being taught in public schools here in NJ) . It is not a sexual orientation and shouldn't be conflated with being gay or lesbian. In fact, lots of LGB people are waking up to this and feel that gender medicine

is harming children and teens who would grow up to be gay or lesbian otherwise. Our teen is still ID'ing a boy but no longer wants blockers. We continue to support and love her - and even use her chosen name. I avoid pronouns. There are countless stories of detransitioners. There is a detrans subreddit with 38,000 in it now. That's a lot of medical harm and evidence that identity is fluid. We will wait and see. There is a 4000-5000% increase in teenage girls showing up at gender clinics in the last 10 years. Does that make sense? Thanks for listening. I wrote more than I thought I would. I am happy Florida is considering what is best for children and parents. Please question what trans activists and large charitable organizations say the truth is.

Sincerely,
Kathryn Handelman

The Florida Board of Medicine must use its authority to protect children and adolescents from misinformed and dangerous actions and must allow its members to render evidence-based professional care. Minors cannot provide informed consent to irreversible and unknown harms of so-called “gender affirmative” medical treatments and surgeries. Gender confusion and body dysphoria require psychoeducation while comorbid psychopathology may require psychotherapy and psychopharmacology. “Puberty-blocking” drugs are misrepresented as “reversible pause buttons” while interfering with growth, sexual and brain development, fertility, and multi-system functioning. The meteoric expansion of gender clinics is a preventable medical scandal in the making.

Dear Board of Health,

I am asking as a parent that the Florida Medical Board listen to the testimonies of detransitioners and consider that "gender-affirming" medical care crystalizes an identity, that without the committing aspect of medical intervention, many more transgender identifying persons would likely have desisted fully and physically intact. Unfortunately, the affirmative approach in general is not in anyway neutral -it tends to push a child toward a path of medicalization without allowing for the child to change their mind easily.

I know this well because I have a daughter who identified for a year as a boy at her school and did not feel like she could change back to being a girl for fear of the social ramifications. It was too embarrassing and difficult for her. We decided to move for year for her to go back to being a girl -her biological sex and she agreed to try this in her new environment. She now understands that she is simply a girl with boy interests. What was once called a tom-boy. But in today's "gender-affirming" environment, she was genuinely confused by all the information she was receiving online and in her school. The move and ability to go back to her true self identifying with her biological sex-helped to pull her out of her confusion and she is now thriving. Unfortunately, most families are not able to take such drastic measures to support their child. We think that if she would have stayed, she would have continued to be severely confused.

Most importantly, through this experience, which rocked our entire family, we have now learned of the flood of detransition's coming out of this gender-affirming care approach. We believe that 100% of children deserve to go through puberty and into adulthood with their fertility intact and their brains and bodies unaltered by synthetic hormones. It is developmentally appropriate for children to experiment with different identities. But the "gender-affirmative" model solidifies these otherwise transient identities. An intact body that has gone through a biologically appropriate puberty is a human right that all children deserve. Yet we know that the current model of "gender-affirming" care causes many cases of regret and detransition. These are children whose fertility, bodies, voices, breasts, and penises, and wombs have been sacrificed to allow others to supposedly "truly transgender kids" to receive care that is really nothing more than a medical experiment.

We need to find a way to support kids who identify as transgender without shaming them and

yet without any medical intervention. I believe this is possible and many adult transgender persons testify to the gratitude they felt by a cautious approach that centered around their mental health needs being met and a process that allowed them to be sure that the decisions they were making as an adult were the right ones for them.

We also need to have exploratory therapy available to all children impacted with gender-identity issues and to not conflate this with "conversion" therapy. This should be made available and also be a requirement before any adult medical care.

Thanks for taking the cautious approach that honors your oath to "First, Do No Harm".

Sincerely, Kierstin Swanson

Hello I'm writing as a parent of two children who have undergone medical gender transition.

Recent years have shown an explosion in the numbers of young people who claim a transgender identity and medical and surgical interventions which are irreversible and potentially serious.

The Florida Board of Health must use its authority to protect children from misguided, misinformed, and dangerous interventions. Children deserve careful, evidence based, quality care at all times. It's past time for an open, honest, rigorous debate centering children rather than political or activist agendas.

There is not a single shred of evidence that interventions such as puberty blockers, cross sex hormones, surgeries, or even social transition improve long term mental health, or that they decrease suicide risk. On the contrary, the best studies show the worst outcomes.

Search the Cochrane base, and you will find that there is no quality evidence for these interventions. More study is desperately needed. In the meantime, these children deserve open, unbiased exploratory therapy to help them deal with underlying co-morbidities.

Thank you for your attention to this matter. I hope that you will courageously stand for children such as mine and so many others.

Warmly, Lynn Chadwick.

As the Florida Board of Medicine meets to consider regulations around gender medicine, I am writing to express my strong support for a slow and cautious approach that does not medicalize our kids for the rest of their lives.

There is serious risk of harm to our vulnerable youth in the so-called “affirmative care” model, which includes puberty blockers, surgery, and cross sex hormones. And there is an absolute shocking lack of medical knowledge about the outcomes of this “one-size fits all” type of treatment plan. See this editorial in the BC Medical Journal: <https://bcmj.org/letters/informed-consent-gender-questioning-youth-seeking-gender-affirmative-care-complex-issue>

Based on systematic reviews of the literature, Sweden, Finland, France, and the UK have concluded that the risks outweigh potential benefits and now tightly regulate medical interventions for youth under 18, in favor of psychological treatments. The interim report of the UK’s Cass Review outlines some of these concerns.[2]

Medical professionals are bound to “do no harm”, and I applaud the courage of the Board in assessing the current state of gender medicine and ensuring that it does not harm our kids.

My daughter has expressed discomfort in her body, and school officials have lied and hid from us her efforts to socially transition. We are her parents and we love her unconditionally, as most parents do. Any social transition counselling (which is simply a first step towards irreversible medicalization of children) and medical interventions must require parental knowledge and consent.

Some people think that parents are causing harm if they do not support medicalization of their children, when in fact the reverse is true. It is important that parents are not cut out of the discussion by school and medical personnel, because maintaining a strong and healthy connection to family is crucial and in the best long term interest of the child. A loving parent can support their child through their feelings of gender dysphoria, while at the same time not supporting irreversible medicalization.

I encourage you to also consider data on the sharp increase in the number of adolescent girls presenting gender dysphoria. This could point to a social contagion for which medicalization of these girls would be a terrible and irrevocable outcome.

Also, the increasing numbers of desisters and detransitioners shows that gender identity changes - which makes permanent medical treatment so very harmful. See Littman L.

Individuals treated for gender dysphoria with medical and/or surgical transition who subsequently detransitioned: A survey of 100 detransitioners. Arch Sex Behav 2021;50:~~3353-3369~~.

Instead of the so-called “affirmative care” model, I support less invasive and non medical treatments such as watchful waiting, treating underlying psychiatric conditions and exploratory therapy. These treatments are more individualized to each person, and do not harm the child permanently. Treating underlying causes is especially important when you consider the high percentage of kids experiencing gender dysphoria who have autism.

Dear BOM Meeting,

I am pleased to see you are considering implementing regulations regarding the practice of gender medicine.

I have a son who believes he is a woman. If he is pressed into gender reassignment surgery without any and all medical professionals making sure he knows the full ramifications and risks around this experimental procedure, then the medical profession will open itself up to serious consequences for their actions. Equally if he is given powerful drugs to facilitate his transition process without fully informed consent of the full range of side effects that have the potential to cause him harm, again the medical professionals who neglect to do this open themselves up for litigation.

My son is under 18 years of age and he is aware of proper procedure as far as informed consent is concerned and he is also aware of the process of gathering evidence to support him if he is harmed by not being given full disclosure and fully informed consent.

I am sure more and more youth are realising they need to take precautionary measures as they see their peers in the transgender community suffering when they were not fully informed and as a result had no idea what they were really allowing doctors to inflict on them; a life long condition that has robbed them of many healthy aspects of their lives without any way to hold these medical professionals to account. So youth are now learning how to gather information they are given in preparation for any possible harm that occurs so that they can take this information to court to not only get recompense but to ensure case law is created to protect others.

However this can all be avoided if competent and thorough regulations are put in place around this issue.

The medical profession that is capable of giving prescriptions and performing operations, need to be the last step after serious in depth counselling that includes informing the patient of any potential harm of allowing doctors and other professionals to prescribe powerful drugs and/or to carry out experimental operating procedures.

Regulations need to cover this aspect thoroughly so that anyone involved in the care of youth with transphobia or any other gender related condition are made fully aware of their responsibilities and the ramifications for them if these responsibilities around patient care are neglected. If this is done then doctors and clients dealing with gender issues of any kind will be in a much safer and more caring environment with professionals taking the care that is seriously lacking in some negligent medical practises.

The regulations put in place need to state the step by step procedures health professionals need to follow to ensure client and medical professional alike are protected.

Eg

1. Ensure the client has had in depth counselling with a counsellor who will help them question if this is the right path for them.
2. Ensure the client has written examples of what potential side effects can occur with any prescription for hormone treatment (puberty blockers, testosterone, progesterone etc) before they give their consent so there is no doubt that they have been fully informed
2. Ensure the client has written examples of what potential side effects can occur with any operational procedure before they give their consent so there is no doubt that they have been fully informed

Kind Regards

To the Florida Board of Medicine:

I am so very grateful that you are closely examining this difficult topic of gender affirming care for young people. As a pediatrician, I have seen several children and teens in recent years struggling with gender dysphoria and the numbers are increasing.

When I first started seeing these patients, I would typically refer such a patient to the local gender clinic, assuming they would receive a full evaluation, including mental health assessment, before initiating any kind of medical treatment. Over time, however, I have come to realize that the default approach of gender affirming care is simply that— just to affirm. Meaning to simply take at face value whatever the child says about their own gender, regardless of age, history of gender incongruence, state of mental health, other diagnoses (such as autism), or the perspective of their parents. I attended a talk a few months ago by Diane Ehrensaft, Director of Mental Health for the UCSF Gender Center and one of the main proponents of gender affirming medicine, and this is how she described the major tenets of this approach (bolded below and verbatim from her slide):

- **Gender variations are not disorders; there are infinite pathways of gender; cisgender is only one of many; each gender pathway is positive; no one pathway is privileged over another**
- **gender is not fixed at a moment in time, but is a lifelong process**
- **co-occurring psychological issues, if present at all, are typically related to interpersonal and cultural reactions to a child, not internal pathology**
- **therefore, pathology more likely lies in the culture rather than in the child**
- **essential therapeutic tenet: it is not for us to say, but for the children to tell**

While it may sound reasonable from a social justice perspective to say all gender pathways are equally valid, what that often translates into in practice is that kids are rather quickly medicalized (meaning puberty blockers, cross sex hormones, and/or surgery) sooner rather than later, and often with very little exploration of any possible underlying issues. In fact, such exploratory therapy is often discouraged by gender-affirming doctors/therapists as 'conversion therapy' -- because if all possible genders are equally valid, regardless of one's natal biology, and we should accept whatever the child says at face value, then it logically follows that any therapeutic exploration is unnecessary 'gatekeeping'.

I personally find this very troubling-- the 'natural history' of gender dysphoria prior to the last decade was that most kids who felt gender dysphoric as young children would get past it once they hit puberty (puberty itself is often the cue which facilitates that process-- making puberty blockers much more significant than just the pause button it is claimed to be). Many studies have shown these kids with childhood onset gender dysphoria often turn out to be gay later, some go on to be cis, and a small minority do continue to be trans into adulthood. So to me, what makes sense is to leave those kids alone and allow them to come to terms with their bodies over time if that's possible, rather than "overtreating" what even proponents admit may be a temporary or 'fluid' condition. I don't think it's "transphobic" at all to "privilege" the pathway which allows the child to keep all their original body parts and avoid irrevocable consequences (like possible sterility) and a lifetime of mandatory medication. Moreover, how can such a young person possibly understand the potential consequences of what they are 'agreeing' to-- among others, the potential risks of not being able to have an orgasm, a biological child, or not being able to breastfeed? Indeed the rapidly growing number of detransitioners suggests that many of these young people truly did not understand the implications of such decisions (the detrans subreddit-- <https://www.reddit.com/r/detrans/> -is now up to over 38,000 members and full of heartbreaking stories).

Of course many of the kids being seen now do not have childhood onset gender dysphoria-- more commonly these days gender dysphoria shows up near puberty, without signs noted earlier in childhood. This has been dubbed 'rapid onset gender dysphoria' (ROGD) and is a radically different phenomenon (not just with age of onset, but also that it affects mostly natal girls; childhood onset historically affected mainly natal boys), but these types are often completely conflated. The reason this matters so much is because the original Dutch study (on which the whole approach of gender affirming care is based) consisted of only 55 kids with only childhood onset GD; there really is NO long term follow up data on outcomes for this new population of older ROGD kids. The Dutch study also specifically excluded any kids with mental health diagnoses, though the population currently presenting itself for care has been shown to have 2-3 times the risk of various mental health problems (anxiety, depression, self harm, etc). This again calls into question whether the Dutch protocol should even be applied to them. And if it doesn't apply, then there is truly minimal evidence to support current practice. Indeed this is exactly what many other countries around the world have concluded, leading them to step back from gender affirming care in the last year (e.g. UK, France, Sweden, Finland).

Despite the concurrence of the AAP with gender-affirming medical care, there are clearly serious problems with the current approach and more long term research is urgently needed. Every U.S. gender clinic should be collecting data on the various interventions received by all of their patients, as well as outcomes with respect to physical and mental health over time, including an attempt to determine outcomes for those who don't return to the clinic.

I believe it is the responsibility of all physicians, especially pediatricians, to keep always foremost in our minds the long term best interest of our young patients and

their families. Medical guidelines should not be driven by activists or political factors, but by medical considerations and scientific evidence. Until we have more definitive data, I believe our staunch commitment as physicians to 'first, do no harm', prescribes a pause to the medicalization of gender dysphoria in youth.

Sincerely,
Paula Brinkley, MD, MPH, FAAP
Berkeley CA

Dear Florida adults

I am from the UK and we have been struggling with our children being caught up in this social contagion.

It's a terrible choice to push young children down a medicalised path without trying talking therapies or watchful waiting.

86% of children desist. Puberty blockers and hormones for children are so dangerous and cause long term damage.

Don't let it ruin your Floridian children who are beautiful and confused. No one is born in the wrong body. I strongly feel children should not be pushed down the affirmation path.

Love your children as they are

I recommend you read this

[76% of referees to The Tavistock & Portman Gender Identity Service \(GIDS\) are adolescent girls, and we also know from The Tavistock's statistics that 48% either have a diagnosis of, or show traits of Autism. 1](#)

Adults are there to protect children not to lead them into irreversible harm. Adolescence is a time of exploration, impulsivity, and search for identity. Biological sex is real. Gender Ideology has no basis in science. These are Facts.

Please lead the USA, adopt a cautious, slower and safer approach to treating children with gender questioning.

That affirmation, social transition, smothering the voices of mothers. and irreversible medicalization is the only treatment given to kids lost is insanity.

Please protect our children.

Mother of 15 year old daughter who thinks being a boy will solve the sexual trauma she experienced as child.

Dear Paul A. Vazquez, J.D.

Executive Director Florida Board of Medicine

I am the uncle of a teenage old girl, who identifies as transgender.

My niece is not transgender: she has struggled all her life with mental health challenges and

with her social anxiety.

We are constitutionally opposed to the affirmation model and with hormonal and surgical interventions. These are not based on science or ethics for this new population of teenage girls. A very vulnerable population.

Great Britain recently commissioned a highly distinguished public health and pediatric expert to

reconsider the affirmative model in the United Kingdom.

Please consider with care the findings of the Cass Review interim report.

What is the Cass Review interim report?

The Cass Review is an Independent Review of Gender Identity Services for Children and Young People. It was 'commissioned by NHS England and NHS Improvement in Autumn 2020 to make recommendations about the services provided by the NHS to children and young people who are questioning their gender identity or experiencing gender incongruence [1].' In March 2022, the Cass Review submitted an interim report to NHS England. This interim report '[set] out [the] work to date, what [had] been learnt so far and the approach going forward [2].'

Who is Dr. Hilary Cass

Dr Hilary Cass was appointed by NHS England and NHS Improvement to chair the Independent Review of Gender Identity Services for children and young people in late 2020.

A former President of the Royal College of Paediatrics and Child Health from 2012-2015, Dr Cass recently finished a term as Chair of the British Academy of Childhood Disability (2017-2020).

Although retired from clinical practice, she remains an honorary Consultant Paediatrician at Evelina London Children's Hospital, Guy's & St Thomas's NHS Foundation Trust, where she was also previously Director of Education and Workforce.

Dr Cass is currently Chair of Together for Short Lives, and a Trustee for Noah's Ark Children's Hospice. She is also leading work on how to address the challenges for both families and professionals in supporting the rising numbers of children with complex medical conditions and disability.

Other recent roles include acting as the Senior Clinical Advisor for Child Health for Health Education England.

Prior to this Dr Cass held a range of senior education and management roles in NHS hospital trusts and was previously Head of School of Paediatrics in London. Her consultant clinical practice was as a tertiary neurodisability consultant from 1992 to 2018 in three very different specialist centres and she has published widely in this area.

In addition to her neurodisability practice, Dr Cass was closely involved in the development of paediatric palliative care services at Evelina London Children's Hospital.

Dr Cass was awarded the OBE for services to child health in 2015. She was also awarded an honorary fellowship by the Royal College of Nursing in 2015, and by RCGP in 2016.

Background

The United Kingdom has seen a significant increase in the number of children seeking help for distress in relation to their biological sex. Many school staff first started noticing the phenomenon of children – predominantly teenaged

girls – wanting to change sex during the last decade.

In recent years, there has been a significant increase in the number of referrals to the Gender Identity Development Service (GIDS) at the Tavistock and Portman NHS Foundation Trust (para. 1.1).

From a baseline of approximately 50 referrals per annum in 2009, there was a steep increase from 2014-15, and at the time of the CQC inspection of the Tavistock and Portman NHS Foundation Trust in October 2020 there were 2,500 children and young people being referred per annum, 4,600 children and young people on the waiting list, and a waiting time of over two years to first appointment (para 3.10).

This surge in children seeking help for distress in relation to their sex is occurring in the context of an ongoing public debate around issues relating to sex, gender and gender identity.

Over the last few years, broader discussions about transgender issues have been played out in public, with discussions becoming increasingly polarised and adversarial. This polarisation is such that it undermines safe debate and creates difficulties in building consensus (para. 2.4).

No consensus

This being a new phenomenon, research is limited and no consensus exists (within the scientific community) about possible causes and most appropriate treatment options.

At primary, secondary and specialist level, there is a lack of agreement, and in many instances a lack of open discussion, about the extent to which gender incongruence in childhood and adolescence can be an inherent and immutable phenomenon for which transition is the best option for the individual (para. 1.7).

We must secure a balanced treatment of political issues, they must take a child-centred, evidence-based approach, and take care not to express personal beliefs in ways which could exploit pupils' vulnerabilities. We should not for example, present, as fact, childhood gender incongruence as an inherent and immutable phenomenon as this is a contested idea rather than an established evidence-based fact.

Low quality evidence

The Cass Review interim report acknowledges that ‘[over] the last few years, broader discussions about transgender issues have been played out in public, with discussions becoming increasingly polarised and adversarial’ (para. 2.4). Many of us feel confused or conflicted about approaching the issues of sex and gender identity with adolescents. The above-mentioned rise in referrals to GIDS has been accompanied by an increasing number of news reports claiming that some teachers and/or schools are promoting the idea that gender identity supersedes sex. However, there is insufficient high quality, longitudinal data (relating to gender-questioning children) from which to draw robust conclusions. There is a notable gap in the evidence base pertaining to the surge in female teenagers seeking support from gender identity services.

Aspects of the literature are open to interpretation in multiple ways, and there is a risk that some authors interpret their data from a particular ideological and/or theoretical standpoint (para. 1.29).

Decisions need to be informed by long-term data on the range of outcomes, from satisfaction with transition, through a range of positive and negative mental health outcomes, through to regret and/or a decision to detransition. The NICE evidence review demonstrates the poor quality of these data, both nationally and internationally (para. 3.21).

It is also important to note that any data that are available do not relate to the current predominant cohort of later-presenting birth-registered female teenagers. This is because the rapid increase in this subgroup only began from around 2014-15. Since young people **may** not reach a settled gender expression until their mid-20s, it is too early to assess the longer-term outcomes of this group (para. 3.23).

Since the rapid increase in this group began around 2015, they will not reach late 20s for another 5+ years, which would be the best time to assess longer-term wellbeing (para. 5.10).

This is an area of research where no scientific consensus exists. Schools must be aware that any claims made about the reasons behind the increase in gender-questioning children are speculative and cannot be treated as established evidence-based facts.

Changing epidemiology

Early childhood gender dysphoria is not a new phenomenon. However, **the**

existing literature on treatment and outcomes is largely based on early childhood gender dysphoria in male children. It may not apply to the current cohort of gender-questioning children who are older, predominantly female and often presenting with a range of neurodevelopmental and mental health co-morbidities.

In the last few years, there has been a significant change in the numbers and case-mix of children and young people being referred to GIDS (para 3.10).

This increase in referrals has been accompanied by a change in the case-mix from predominantly birth-registered males presenting with gender incongruence from an early age, to predominantly birth-registered females presenting with later onset of reported gender incongruence in early teen years (para. 3.11).

The mix of young people presenting to the service is more complex than seen previously, with many being neurodiverse and/or having a wide range of psychosocial and mental health needs. The largest group currently comprises birth-registered females first presenting in adolescence with gender-related distress (para. 1.10).

Much of the existing literature about natural history and treatment outcomes for gender dysphoria in childhood is based on a case-mix of predominantly birth-registered males presenting in early childhood. There is much less data on the more recent case-mix of predominantly birth-registered females presenting in early teens, particularly in relation to treatment and outcomes (para. 1.28).

Secondly, the cohort that the original Dutch Approach was based on is different from the current more complex NHS cohort, and also from the current case-mix internationally, and therefore it is difficult to extrapolate from older literature to this current group (para. 5.10).

The Cass Review interim report highlights the difficulties faced by clinicians responsible for making diagnoses and recommending treatment. Teachers are neither qualified nor capable of critically evaluating existing evidence. They must carry out their duties within statutory and non-statutory frameworks. This included ensuring that any necessary referrals are made as specified by their schools' safeguarding protocols.

Diagnostic overshadowing

Another significant issue raised with us is one of diagnostic overshadowing –

many of the children and young people presenting have complex needs, but once they are identified as having gender-related distress, other important healthcare issues that would normally be managed by local services can sometimes be subsumed by the label of gender dysphoria (para. 4.10).

School staff must be clear that they are not qualified to offer students advice in this area. Moreover, the promotion of specific beliefs about the source(s) of gender-related distress could influence children's attitudes toward the diagnostic process before meeting with a clinically trained professional. Guidance from the Department for Education states that teachers "are in a position of authority and will typically be respected and trusted by the pupils they teach, giving their personal opinions greater weight and credibility. As a general principle, they should avoid expressing their own personal political views to pupils unless they are confident this will not amount to promoting that view to pupils [4]."

Affirmative vs developmental models

Broadly speaking, there are two approaches to treating children with gender-related distress: the gender-affirmative approach and the developmentally-informed approach. The gender-affirmative approach is based on the theory that a child's gender identity is innate. The developmentally-informed approach is based on the theory that a complex interaction of multiple factors underlie gender-related distress. The Cass Review interim report acknowledges that some clinicians report being under pressure to adopt a gender-affirmative approach.

Following directly from this is a spectrum of opinion about the correct clinical approach, ranging broadly between those who take a more gender-affirmative approach to those who take a more cautious, developmentally-informed approach (para. 4.15).

Some secondary care providers told us that their training and professional standards dictate that when working with a child or young person they should be taking a mental health approach to formulating a differential diagnosis of the child or young person's problems. However, they are afraid of the consequences of doing so in relation to gender distress because of the pressure to take a purely affirmative approach (para 4.20).

There is a spectrum of academic, clinical and societal opinion on this. At one end are those who believe that gender identity can fluctuate over time and be

highly mutable and that, because gender incongruence or gender-related distress may be a response to many psychosocial factors, identity may sometimes change or the distress may resolve in later adolescence or early adulthood, even in those whose early incongruence or distress was quite marked. At the other end are those who believe that gender incongruence or dysphoria in childhood or adolescence is generally a clear indicator of that child or young person being transgender and question the methodology of some of the desistance studies (para. 5.8).

School staff are unqualified to evaluate the merits of these approaches. Moreover, they have an obligation to remain politically impartial. This means not supporting one approach over another.

Social transition

Social transitions (the act of treating children as if belonging to the opposite sex) are performed by some schools in England. A social transition is a powerful psychological treatment that affects a child's psychological development. Not only are school staff unqualified to judge the appropriateness of such interventions, the outcomes are poorly understood.

Social transition – this may not be thought of as an intervention or treatment, because it is not something that happens within health services. However, it is important to view it as an active intervention because it may have significant effects on the child or young person in terms of their psychological functioning. There are different views on the benefits versus the harms of early social transition. Whatever position one takes, it is important to acknowledge that it is not a neutral act, and better information is needed about outcomes (para. 5.19).

Pressure

The Cass Review interim report acknowledges the pressures clinicians are under to adopt an unquestioning affirmative approach. Similarly, there is an acknowledgement that children are under pressure to identify with societal stereotyping. Schools cannot erase the pressures that children are under from, for example, social media and peers. However, teachers should promote acceptance for children's non-stereotypical behaviour (boys and girls exhibiting stereotypically 'feminine' and 'masculine' behaviour, respectively) and avoid reinforcing harmful stereotypes.

Primary and secondary care staff have told us that they feel under pressure to

adopt an unquestioning affirmative approach and that this is at odds with the standard process of clinical assessment and diagnosis that they have been trained to undertake in all other clinical encounters (para. 1.14).

From the point of entry to GIDS there appears to be predominantly an affirmative, non-exploratory approach, often driven by child and parent expectations and the extent of social transition that has developed due to the delay in service provision (para. 1.18).

It is not the role of this Review to take any position on the cultural and societal debates relating to transgender adults. However, in achieving its objectives there is a need to consider the information and support that children and young people access from whatever source, as well as any pressures that they are subject to, before they access clinical services (para. 2.5).

We have heard that distress may be exacerbated by pressure to identify with societal stereotyping and concerns over the influence of social media, which can be seen to perpetuate unrealistic images of gender and set unhealthy expectations, especially given how long children and young people are waiting to access services (para 4.13).

These will be considered further during the lifetime of the Review and include: . . . The complex interaction between sexuality and gender identity, and societal responses to both; for example, we have heard from young lesbians who felt pressured to identify as transgender male, and conversely transgender males who felt pressured to come out as gay rather than transgender. We have also heard from adults who identified as transgender through childhood, and then reverted to their birth-registered gender in teen years (para. 4.14).

Safeguarding

Children with gender-related distress may pose specific safeguarding concerns. They have a higher incidence of comorbid psychiatric and/or developmental difficulties. They are also more likely to be looked after children. Teachers need to be aware of possible harms such as breast binding or tucking (of male genitals). Children may also be subjected to grooming and/or coaching, and encouraged to deceive parents, clinicians and teachers in order to secure particular outcomes such as clinical diagnoses of gender dysphoria. They may also be receiving cross-sex hormones from unregulated sources.

In addition, approximately one third of children and young people referred to

GIDS have autism or other types of neurodiversity. There is also an over-representation percentage wise (compared to the national percentage) of looked after children (para. 3.11).

We have also heard about the distress experienced by birth-registered females as they reach puberty, including the use of painful, and potentially harmful, binding processes to conceal their breasts (para. 4.3).

Most children and young people seeking help do not see themselves as having a medical condition; yet to achieve their desired intervention they need to engage with clinical services and receive a medical diagnosis of gender dysphoria (para. 4.4).

We have heard that some young people learn through peers and social media what they should and should not say to therapy staff in order to access hormone treatment; for example, that they are advised not to admit to previous abuse or trauma, or uncertainty about their sexual orientation (para. 4.5).

We have heard about families trying to balance the risks of obtaining unregulated and potentially dangerous hormone supplies over the internet or from private providers versus the ongoing trauma of prolonged waits for assessment (para. 4.7).

Summary

There has been a huge increase in the number of children (predominantly female teenagers) seeking help for distress in relation to their biological sex. Research into this new phenomenon is limited. The lack of high-quality data from longitudinal studies together with the changing epidemiology means that no consensus exists about the possible causes for this recent surge in children wanting to change sex. Clinically trained professionals face difficulties in making diagnoses and recommending treatment. School staff who now affirm my daughter are neither qualified to evaluate existing research nor clinically trained. Therefore, they cannot judge the appropriateness of, for example, socially transitioning children. It is an intervention with poorly understood outcomes that affects children's psychological development. The Cass Review interim report outlines some of the specific safeguarding issues that surround gender-questioning children.

Thank you most sincerely for your time and consideration.

Yours sincerely,

Maurice Lawson

In view of the many testimonies of individuals and families and including medical data regarding "transgener" thinking, it is ostensibly obvious that thoughts/feelings about gender and transitioning from one's biological gender to another, changes over time. Over 90% embrace their own birth gender. This is especially true for children through young adulthood. Parents, as legal guardians and responsible for the health and welfare of their children must be included in any care or decisions regarding medical intervention. Funding for transgender procedures must not be provided by insurance or government subsidy as this type of treatment is not necessary for the physical health of the person and it can actually cause permanent harm.

Any treatments should be limited to adult age individuals who initiate the procedures after having received full-spectrum information for informed consent.

Anyone imposing influence to encourage a child toward transitioning must be held accountable for psychological and emotional abuse.

For the Florida hearings, here is a short summary of what happened to my son when he found a trans identity online.

Please contact me if you have any questions.

Thank you,
Martha

Jake's story

My son was a typical, very happy boy for most of his childhood. His interests started with construction at age 2, Superheroes at 3, then Ninjas and martial arts, tanks and ancient weapons, and hockey in Middle School. When he was 16 his personality changed after a series of sinus infections that we later learned had affected his brain, and he experienced trauma upon the sudden death of his close friend.

That same year my son experienced racial dysphoria – he is Caucasian but truly believed he was black. After the death of his friend, my son did not want to discuss it and immersed himself in research on the computer, where he apparently found a transgender Reddit group. A few months later, he announced that he was “trans.” On the advice of our pediatrician, who believed this was mental illness, we took him to Dallas Children’s Hospital for evaluation by their gender clinic. Our pediatrician was as shocked as we were that despite my son's history of trauma, brain illness and racial confusion all beginning the year before his transgender announcement, the gender clinic in Dallas diagnosed our son with gender dysphoria, and advised us to start our 16-year-old on cross-sex hormones and blockers. This was outrageous to us, considering that our son had no history whatsoever of gender dysphoria or hatred of his boy body. My husband and I would not consent to the treatment and luckily in Texas parental consent is still required, but the surprising diagnosis and “affirmation” of his trans-identity set the stage for our son to start hormones as soon as he went off to college. Since no one affirmed my son's racial confusion, he recovered from that as soon as his brain got a break from the infection, but since many doctors and therapists, as well as my son's girlfriend, have AFFIRMED his gender confusion, he has not recovered from the dysphoria.

We are terrified for our son after having read accounts from numerous detransitioners about the hideous and permanent side effects from the treatments prescribed to “trans” young adults, even without the gruesome surgeries that often follow. We pray every day that we’ll find a cure for our son’s mental illness before he allows greedy doctors to completely destroy his chances of ever having a normal sex life (or a normal life at all).

Subject: gender affirming care
Date: Monday, September 19, 2022 4:28:32 PM

Some people who received this message don't often get email from alamotime@gmail.com. [Learn why this is important](#)

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

I am grateful for the opportunity to provide comments regarding the Florida board of medicine evaluation of gender affirming care. My name is Tim McNicoll MD, I am board certified in family practice since 1984 with an additional year of residency training in Pediatrics, a certificate of added qualifications in geriatrics from the AAFP and ABIM and a masters degree in bioethics. I also practiced OB early in my career and have cared for patients from conception to death.

I have watched with some dismay over the last few years the rapid progression from gender insecurity to permanent gender transition in many youths. I have cared for children for the last 40 years and have witnessed how quickly they can progress through developmental stages acquiring and vacillating between new physical, psychological, emotional, and sexual identities. They are constantly and rapidly acquiring new skills but have mastered none of them. Their search for themselves often involves different clothing, different hair styles or color, different speech, and different peer groups. Some more potentially permanent or damaging changes include tattoos, anorexia, overeating, alcohol, smoking, drugs, self-harming behaviors, suicidal ideation and even suicide. These are often aggravated by anxiety, depression, and family dysfunction.

Gender insecurity seems to be another manifestation of the almost cataclysmic changes that result from general adolescent identity insecurity. One could conceive of this almost as a living suicide as you destroy a major part of who you have been throughout your life – and unlike the other developmental experiments listed above, you may never be able to return from this gender experiment. There are always exceptions to rules, and likely there are some who may always desire transition, but the tremendous recent increase in gender dysphoria seems to be more of a social trend rather than an inherent human characteristic. Hopefully, like anorexia, it will regress to a much smaller fraction of the adolescent population in 20 years. In the meantime, one has to wonder how many regrettable and irreversible changes will be made.

Other body altering surgeries such as bariatric surgery are rarely offered to adolescents and usually only after prolonged counseling and non-surgical medical treatments. Even adults must go through rigorous counseling and non-surgical weight loss treatments before undergoing such surgery. Breast augmentation again is rarely offered to adolescents and we now know after 50 years of the risks of autoimmune disease, potential cancer risks, difficulty with cancer detection, infection and prosthetic rupture associated with various breast implants.

It is likely a universal human characteristic that at times we all imagine being somebody or somewhere different. A place where all our troubles in life vanish. This is likely a more common and more powerful feeling in adolescence as we try to determine who we are and where we fit in. However, because of the rapid developmental changes that adolescents are constantly experiencing, we should take a long pause before embarking on gender transition treatments. As with driving, smoking, alcohol consumption, leaving high school campus without authorization, and even adults having sex with a minor, there are some activities that we should strictly limit or proscribe until adolescents have successfully navigated through a good part of their development. This is the least we can do for our children before they permanently alter the rest of their long life.

Grateful for your public service,

Tim McNicoll M.D., M.S. Bioethics

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

To the Board of Directors:

I am writing to express my deep concern about the consideration of the Florida Board of Medicines gender affirming care. This push to accept such care is clearly ideologically driven and not based in either reason or sound medical evidence.

There is excellent evidence coming from our European colleagues that such treatment fails to show improvement in youth experiencing gender dysphoria. In the UK an Independent systematic review of the data concluded that evidence was very low regarding hormonal interventions in gender dysphoric youth disorder. Finland, as a country, adopted a position of early transitioning of pediatric patients and they too showed a lack of improvement in mental health and have now moved to psychotherapy as first line therapy.

As a recent Medscape article pointed out by Dr William Malone Endocrinologist

- “Most cases of early childhood-onset gender dysphoria self-resolve. [Eleven out of 11 studies](#) that followed the trajectory of gender-variant youth show that the most common outcome is natural resolution of gender dysphoria [around or after puberty](#). Among those diagnosed as having gender identity disorder, 67% no longer met the diagnostic criteria as adults; among those subthreshold for diagnosis, [93% were not gender dysphoric](#) as adults. Gender dysphoria in childhood is a far better predictor of future homosexuality than of future trans identity.
- The future trajectory of people whose transgender identity emerged during or after puberty is entirely unknown. No one has studied future trajectories of patients whose transgender identity emerged for the first time after the onset of puberty — a previously rare but now increasingly common presentation. Growing numbers of young detransitioners and

desisters are precisely from this demographic, suggesting that a transgender identity that emerges in adolescence may not be durable.

- Social transition does not improve mental health outcomes. Recent studies show that while socially transitioned children can thrive in the short term, they [do not fare any better](#) than their non-socially transitioned dysphoric peers. It appears that [peer relations](#), not the social transition status, predict mental health in gender-dysphoric children. We don't yet know the long-term trajectories of socially transitioned minors, but [emerging evidence](#) suggests that they may [be more likely to persist](#) with gender-related distress rather than outgrow it, as previously observed. This in turn necessitates decades of invasive and risky medical interventions. In fact, the Dutch researchers who pioneered the protocol used to medically transition minors (see Box) [explicitly and strongly discouraged](#) social transition of children and early adolescents.
- Nearly 100% of children who begin puberty blockers will proceed to cross-sex hormones and surgeries. The two main studies that have [evaluated the effects of puberty blockers](#) on mental health found [no improvements](#) or [improvements of marginal clinical significance](#). Both studies are also at critical risk of bias due to the absence of control groups. [Four additional studies looking](#) at the mental health effects of puberty blockers were plagued by [design limitations](#) and also [failed](#) to show any convincing positive effects on psychological health. However, one effect of puberty blockers has been consistently replicated: [At least four studies show](#) that [virtually all of the children who start puberty blockers proceed to cross-sex hormones](#). This suggests that rather than being a pause button, puberty blockers may serve as the "gas pedal" for gender transition.
- Most of the long-term health risks are largely unknown. No long-term studies exist of patients who underwent medical transition as teens or young adults. Therefore, our ability to assess risks vs benefits is limited. Puberty blockers have been demonstrated to [significantly impair bone health](#), and it is not clear whether this will result in future [osteoporosis](#). Cross-sex hormones are associated with [roughly 3-5 times the risk](#) for [heart attacks and strokes](#), though long-term studies are of insufficient quality for accurate risk assessments. Other risks associated

with these endocrine interventions will come to light as the practice continues to scale and as young people spend years and decades on these interventions. The risks to fertility are largely unknown, but it is almost certain that if puberty blockers are given at the early stages of puberty and followed by cross-sex hormones, sterility will result.

- The medical pathway of "affirmative care" rests on a single Dutch study that is not applicable to the current populations of gender-dysphoric youth. Most of the youth presenting for care today would have been explicitly disqualified by the original Dutch protocol, as most have significant mental health comorbidities and post-puberty onset of trans identities. This fact has been recognized by the principal investigators of the Dutch protocol itself, who have [recently begun to sound the alarm](#) about the [potential misapplication of their protocol](#) and who suggest that psychotherapy — rather than gender reassignment — is more appropriate for many of the currently presenting cases.”

The fundamental principle in good medical practice is “do no harm”. The evidence clearly shows that harm is being done by these hormonal transitions and should not be encouraged or promoted. An individual is born either male or female and this accords with both reason and common sense. We as physicians should be working for the wholeness and well being of your patients and not contributing to further distress.

I appreciate your consideration of my comments in your deliberations.

Sincerely,

Margaret J. Hart, DO, FAAFP

Chandler, Arizona

Dear Paul A. Vazquez, J.D.

Executive Director Florida Board of Medicine

I am a parent of a 17 year old girl, who identifies as transgender.

Our daughter is not transgender: she has struggled all her life with mental health challenges and with her social anxiety.

We are constitutionally opposed to the affirmation model and with hormonal and surgical interventions. These are not based on science or ethics for this new population of teenage girls. A very vulnerable population.

Great Britain recently commissioned a highly distinguished public health and pediatric expert to

reconsider the affirmative model in the United Kingdom.

Please consider with care the findings of the Cass Review interim report.

What is the Cass Review interim report?

The Cass Review is an Independent Review of Gender Identity Services for Children and Young People. It was 'commissioned by NHS England and NHS Improvement in Autumn 2020 to make recommendations about the services provided by the NHS to children and young people who are questioning their gender identity or experiencing gender incongruence [1].' In March 2022, the Cass Review submitted an interim report to NHS England. This interim report '[set] out [the] work to date, what [had] been learnt so far and the approach going forward [2].'

Who is Dr. Hilary Cass

Dr Hilary Cass was appointed by NHS England and NHS Improvement to chair the Independent Review of Gender Identity Services for children and young people in late 2020.

A former President of the Royal College of Paediatrics and Child Health from 2012-2015, Dr Cass recently finished a term as Chair of the British Academy of Childhood Disability (2017-2020).

Although retired from clinical practice, she remains an honorary Consultant Paediatrician at Evelina London Children's Hospital, Guy's & St Thomas's NHS Foundation Trust, where she was also previously Director of Education

and Workforce.

Dr Cass is currently Chair of Together for Short Lives, and a Trustee for Noah's Ark Children's Hospice. She is also leading work on how to address the challenges for both families and professionals in supporting the rising numbers of children with complex medical conditions and disability.

Other recent roles include acting as the Senior Clinical Advisor for Child Health for Health Education England.

Prior to this Dr Cass held a range of senior education and management roles in NHS hospital trusts and was previously Head of School of Paediatrics in London. Her consultant clinical practice was as a tertiary neurodisability consultant from 1992 to 2018 in three very different specialist centres and she has published widely in this area.

In addition to her neurodisability practice, Dr Cass was closely involved in the development of paediatric palliative care services at Evelina London Children's Hospital.

Dr Cass was awarded the OBE for services to child health in 2015. She was also awarded an honorary fellowship by the Royal College of Nursing in 2015, and by RCGP in 2016.

Background

The United Kingdom has seen a significant increase in the number of children seeking help for distress in relation to their biological sex. Many school staff first started noticing the phenomenon of children – predominantly teenaged girls – wanting to change sex during the last decade.

In recent years, there has been a significant increase in the number of referrals to the Gender Identity Development Service (GIDS) at the Tavistock and Portman NHS Foundation Trust (para. 1.1).

From a baseline of approximately 50 referrals per annum in 2009, there was a steep increase from 2014-15, and at the time of the CQC inspection of the Tavistock and Portman NHS Foundation Trust in October 2020 there were 2,500 children and young people being referred per annum, 4,600 children and young people on the waiting list, and a waiting time of over two years to first appointment (para 3.10).

This surge in children seeking help for distress in relation to their sex is occurring in the context of an ongoing public debate around issues relating to sex, gender and gender identity.

Over the last few years, broader discussions about transgender issues have been played out in public, with discussions becoming increasingly polarised and adversarial. This polarisation is such that it undermines safe debate and creates difficulties in building consensus (para. 2.4).

No consensus

This being a new phenomenon, research is limited and no consensus exists (within the scientific community) about possible causes and most appropriate treatment options.

At primary, secondary and specialist level, there is a lack of agreement, and in many instances a lack of open discussion, about the extent to which gender incongruence in childhood and adolescence can be an inherent and immutable phenomenon for which transition is the best option for the individual (para. 1.7).

We must secure a balanced treatment of political issues, they must take a child-centred, evidence-based approach, and take care not to express personal beliefs in ways which could exploit pupils' vulnerabilities. We should not for example, present, as fact, childhood gender incongruence as an inherent and immutable phenomenon as this is a contested idea rather than an established evidence-based fact.

Low quality evidence

The Cass Review interim report acknowledges that '[over] the last few years, broader discussions about transgender issues have been played out in public, with discussions becoming increasingly polarised and adversarial' (para. 2.4). Many of us feel confused or conflicted about approaching the issues of sex and gender identity with adolescents. The above-mentioned rise in referrals to GIDS has been accompanied by an increasing number of news reports claiming that some teachers and/or schools are promoting the idea that gender identity supersedes sex. However, there is insufficient high quality, longitudinal data (relating to gender-questioning children) from which to draw robust conclusions. There is a notable gap in the evidence base pertaining to the surge in female teenagers seeking support from gender identity services.

Aspects of the literature are open to interpretation in multiple ways, and there is a risk that some authors interpret their data from a particular ideological and/or theoretical standpoint (para. 1.29).

Decisions need to be informed by long-term data on the range of outcomes, from satisfaction with transition, through a range of positive and negative mental health outcomes, through to regret and/or a decision to detransition. The NICE evidence review demonstrates the poor quality of these data, both nationally and internationally (para. 3.21).

It is also important to note that any data that are available do not relate to the current predominant cohort of later-presenting birth-registered female teenagers. This is because the rapid increase in this subgroup only began from around 2014-15. Since young people **may** not reach a settled gender expression

until their mid-20s, it is too early to assess the longer-term outcomes of this group (para. 3.23).

Since the rapid increase in this group began around 2015, they will not reach late 20s for another 5+ years, which would be the best time to assess longer-term wellbeing (para. 5.10).

This is an area of research where no scientific consensus exists. Schools must be aware that any claims made about the reasons behind the increase in gender-questioning children are speculative and cannot be treated as established evidence-based facts.

Changing epidemiology

Early childhood gender dysphoria is not a new phenomenon. However, **the existing literature on treatment and outcomes is largely based on early childhood gender dysphoria in male children. It may not apply to the current cohort of gender-questioning children who are older, predominantly female and often presenting with a range of neurodevelopmental and mental health co-morbidities.**

In the last few years, there has been a significant change in the numbers and case-mix of children and young people being referred to GIDS (para 3.10). This increase in referrals has been accompanied by a change in the case-mix from predominantly birth-registered males presenting with gender incongruence from an early age, to predominantly birth-registered females presenting with later onset of reported gender incongruence in early teen years (para. 3.11).

The mix of young people presenting to the service is more complex than seen previously, with many being neurodiverse and/or having a wide range of psychosocial and mental health needs. The largest group currently comprises birth-registered females first presenting in adolescence with gender-related distress (para. 1.10).

Much of the existing literature about natural history and treatment outcomes for gender dysphoria in childhood is based on a case-mix of predominantly birth-registered males presenting in early childhood. There is much less data on the more recent case-mix of predominantly birth-registered females presenting in early teens, particularly in relation to treatment and outcomes (para. 1.28).

Secondly, the cohort that the original Dutch Approach was based on is different from the current more complex NHS cohort, and also from the current case-mix internationally, and therefore it is difficult to extrapolate from older literature to this current group (para. 5.10).

The Cass Review interim report highlights the difficulties faced by clinicians responsible for making diagnoses and recommending treatment. Teachers are

neither qualified nor capable of critically evaluating existing evidence. They must carry out their duties within statutory and non-statutory frameworks. This included ensuring that any necessary referrals are made as specified by their schools' safeguarding protocols.

Diagnostic overshadowing

Another significant issue raised with us is one of diagnostic overshadowing – many of the children and young people presenting have complex needs, but once they are identified as having gender-related distress, other important healthcare issues that would normally be managed by local services can sometimes be subsumed by the label of gender dysphoria (para. 4.10).

School staff must be clear that they are not qualified to offer students advice in this area. Moreover, the promotion of specific beliefs about the source(s) of gender-related distress could influence children's attitudes toward the diagnostic process before meeting with a clinically trained professional.

Guidance from the Department for Education states that teachers “are in a position of authority and will typically be respected and trusted by the pupils they teach, giving their personal opinions greater weight and credibility. As a general principle, they should avoid expressing their own personal political views to pupils unless they are confident this will not amount to promoting that view to pupils [4].”

Affirmative vs developmental models

Broadly speaking, there are two approaches to treating children with gender-related distress: the gender-affirmative approach and the developmentally-informed approach. The gender-affirmative approach is based on the theory that a child's gender identity is innate. The developmentally-informed approach is based on the theory that a complex interaction of multiple factors underlie gender-related distress. The Cass Review interim report acknowledges that some clinicians report being under pressure to adopt a gender-affirmative approach.

Following directly from this is a spectrum of opinion about the correct clinical approach, ranging broadly between those who take a more gender-affirmative approach to those who take a more cautious, developmentally-informed approach (para. 4.15).

Some secondary care providers told us that their training and professional standards dictate that when working with a child or young person they should be taking a mental health approach to formulating a differential diagnosis of the child or young person's problems. However, they are afraid of the consequences of doing so in relation to gender distress because of the pressure to take a purely affirmative approach (para 4.20).

There is a spectrum of academic, clinical and societal opinion on this. At one end are those who believe that gender identity can fluctuate over time and be highly mutable and that, because gender incongruence or gender-related distress may be a response to many psychosocial factors, identity may sometimes change or the distress may resolve in later adolescence or early adulthood, even in those whose early incongruence or distress was quite marked. At the other end are those who believe that gender incongruence or dysphoria in childhood or adolescence is generally a clear indicator of that child or young person being transgender and question the methodology of some of the desistance studies (para. 5.8).

School staff are unqualified to evaluate the merits of these approaches. Moreover, they have an obligation to remain politically impartial. This means not supporting one approach over another.

Social transition

Social transitions (the act of treating children as if belonging to the opposite sex) are performed by some schools in England. A social transition is a powerful psychological treatment that affects a child's psychological development. Not only are school staff unqualified to judge the appropriateness of such interventions, the outcomes are poorly understood.

Social transition – this may not be thought of as an intervention or treatment, because it is not something that happens within health services. However, it is important to view it as an active intervention because it may have significant effects on the child or young person in terms of their psychological functioning. There are different views on the benefits versus the harms of early social transition. Whatever position one takes, it is important to acknowledge that it is not a neutral act, and better information is needed about outcomes (para. 5.19).

Pressure

The Cass Review interim report acknowledges the pressures clinicians are under to adopt an unquestioning affirmative approach. Similarly, there is an acknowledgement that children are under pressure to identify with societal stereotyping. Schools cannot erase the pressures that children are under from, for example, social media and peers. However, teachers should promote acceptance for children's non-stereotypical behaviour (boys and girls exhibiting stereotypically 'feminine' and 'masculine' behaviour, respectively) and avoid reinforcing harmful stereotypes.

Primary and secondary care staff have told us that they feel under pressure to adopt an unquestioning affirmative approach and that this is at odds with the standard process of clinical assessment and diagnosis that they have been trained to undertake in all other clinical encounters (para. 1.14).

From the point of entry to GIDS there appears to be predominantly an affirmative, non-exploratory approach, often driven by child and parent expectations and the extent of social transition that has developed due to the delay in service provision (para. 1.18).

It is not the role of this Review to take any position on the cultural and societal debates relating to transgender adults. However, in achieving its objectives there is a need to consider the information and support that children and young people access from whatever source, as well as any pressures that they are subject to, before they access clinical services (para. 2.5).

We have heard that distress may be exacerbated by pressure to identify with societal stereotyping and concerns over the influence of social media, which can be seen to perpetuate unrealistic images of gender and set unhealthy expectations, especially given how long children and young people are waiting to access services (para 4.13).

These will be considered further during the lifetime of the Review and include: . . . The complex interaction between sexuality and gender identity, and societal responses to both; for example, we have heard from young lesbians who felt pressured to identify as transgender male, and conversely transgender males who felt pressured to come out as gay rather than transgender. We have also heard from adults who identified as transgender through childhood, and then reverted to their birth-registered gender in teen years (para. 4.14).

Safeguarding

Children with gender-related distress may pose specific safeguarding concerns. They have a higher incidence of comorbid psychiatric and/or developmental difficulties. They are also more likely to be looked after children. Teachers need to be aware of possible harms such as breast binding or tucking (of male genitals). Children may also be subjected to grooming and/or coaching, and encouraged to deceive parents, clinicians and teachers in order to secure particular outcomes such as clinical diagnoses of gender dysphoria. They may also be receiving cross-sex hormones from unregulated sources.

In addition, approximately one third of children and young people referred to GIDS have autism or other types of neurodiversity. There is also an over-representation percentage wise (compared to the national percentage) of looked after children (para. 3.11).

We have also heard about the distress experienced by birth-registered females as they reach puberty, including the use of painful, and potentially harmful, binding processes to conceal their breasts (para. 4.3).

Most children and young people seeking help do not see themselves as having a medical condition; yet to achieve their desired intervention they need to engage

with clinical services and receive a medical diagnosis of gender dysphoria (para. 4.4).

We have heard that some young people learn through peers and social media what they should and should not say to therapy staff in order to access hormone treatment; for example, that they are advised not to admit to previous abuse or trauma, or uncertainty about their sexual orientation (para. 4.5).

We have heard about families trying to balance the risks of obtaining unregulated and potentially dangerous hormone supplies over the internet or from private providers versus the ongoing trauma of prolonged waits for assessment (para. 4.7).

Summary

There has been a huge increase in the number of children (predominantly female teenagers) seeking help for distress in relation to their biological sex. Research into this new phenomenon is limited. The lack of high-quality data from longitudinal studies together with the changing epidemiology means that no consensus exists about the possible causes for this recent surge in children wanting to change sex. Clinically trained professionals face difficulties in making diagnoses and recommending treatment. School staff who now affirm my daughter are neither qualified to evaluate existing research nor clinically trained. Therefore, they cannot judge the appropriateness of, for example, socially transitioning children. It is an intervention with poorly understood outcomes that affects children's psychological development. The Cass Review interim report outlines some of the specific safeguarding issues that surround gender-questioning children.

Thank you most sincerely for your time and consideration.

Yours sincerely,

Neroli Lacey

Paul A. Vazquez, J.D.
Executive Director
Florida Board of Medicine

This is a comment on regulations for gender medicine.

Discussions of this topic focus on "gender" and on "gender identity". My request is that these concepts be given precise definition in any regulations.

The word "gender" can mean "sex". Or it can mean "gender role". Or it can mean "gender identity". For this reason, the word "gender" by itself is best avoided.

The expression "gender identity" is also ambiguous. Any discussion should make sure to specify whether or not gender identity is implicitly assumed to be permanent, or whether it can be temporary. It should also give a list of possible gender identities. Are these possible gender identities "sex" (male or female) or are they "gender role" (masculine, feminine, neutral, etc.)? Finally, there should be a precise specification of how "gender identity" for an individual at a particular point in time is to be determined.

Most important of all, there should be a distinction between "declared gender identity" and "innate gender identity". These expressions should be used instead of the uninformative "gender identity". The phrase "declared gender identity" could in some cases refer to a "gender identity" that is a belief or preference, declared by the individual. The term "innate gender identity" is more specific; it is a declared gender identity that purports to be an intrinsic property of the individual, possibly even present throughout the entire course of life. This could include a male with a female gender identity, or a female with a male gender identity. It could also possibly include a male or female with a neutral gender identity. An "innate gender identity" is presumably permanent, or at least immune to external efforts to change it.

The notion of "innate gender identity" is central to discussions of medicalization; it needs to be made explicit and explored in detail. In particular, "innate gender identity" is more likely to be associated with "affirmative therapy", while the broader category of "declared gender identity" might lend itself to "exploratory therapy".

Thank you for your attention. I hope this contribution can make it into the record of your proceedings. The results will be important and have national impact.

Sincerely yours,

William Faris

Dear Members of the Florida Board of Medicine,

As a surgeon and physician, I am writing to ask you to oppose any efforts to implement medical practices and surgery that seek to offer so-called “gender-affirming care”, including rapid gender transition for children and adolescents. As we all know, the medical and evidence-based studies of these methods do not support such medical practice. Rather, the short and long-term harm of these interventions is clear, and this distinction needs to be emphasized and upheld by the Florida Board of Medicine.

To whom it may concern,

My name is Andrew Mullally and I am a family physician. I am concerned about your upcoming meeting regarding sex based medicine practices in Florida.

Gender affirming care is not evidence based. If anything, there is growing evidence of the short term and long term harms that this treatment strategy confers on patients. As you are likely aware there is a significant increase in suicide and depression in patients even after gender affirming care and a large majority of those with this treatment regret their transition as they age. Gender dysphoria is showing itself to largely be a self limited condition for most patients. Additionally, it is well documented that this diagnosis is very regional and not consistent in a population. For these reasons and others, many of the European countries that pioneered this treatment strategy are moving away from gender affirming models -- it is bad medicine.

Please do not move to advance the gender affirming care model in Florida.

Thank you,

Andrew Mullally, MD

To whom it may concern, and colleagues,

As a licensee of the State of Florida, and a conscientious physician and surgeon, I am writing to express my concerns over enacting laws in FL that would facilitate rapid care for gender affirming care and surgery, especially amongst our young. Medical literature does not support this type of care for children and adolescents, and the push to do this is strictly based on emotion and politics. I would ask that you protect our developing and vulnerable young people and allow this type of care for adults who have affirmed these decisions after extensive counselling. Many patients change their minds on these unalterable treatments, and are done irreparable harm by it, even after care consideration, much less facilitated and rapid care.

My best,

Brian Burkey MD

Dear Florida Board of Medicine,

Although I do not practice medicine in Florida, I have been made aware of the Board's upcoming discussions on transgender issues especially regarding transitioning of youth away from their biological sex identified at birth. You are at the forefront of what every state medical association will be facing in the near future. You may well set a precedent. For this reason, I am writing you this short email.

I am not in favor of the chemical and physical mutilation of children. It makes no sense to allow youths to make life-altering decisions with mental complications (19-fold increase in suicides) and reproductive complications (permanent infertility), to name a few. And this at a point when the decision-making capacity of the brain is woefully underdeveloped and will remain so for several more years.

The medical literature is clear about the harmful effects and that over 90% of children and adolescents adopt their biological sex as they mature. Additionally, the experiences in European countries have caused, in recent times, more reticence in offering transition therapies. I pray the guiding principle of 'do no harm,' be the basis of your decisions.

Thank you. Sincerely,

Peter Rosario MD

As a Developmental and Behavioral Pediatrician, I have been trained to understand both the physiology and the psychology of children. That is why I implore you to please RESTRICT rapid gender transition for children and adolescents. Most children who have gender dysphoria resolve their struggles and uncertainty by the end of adolescence, and thus it is essential that we allow them to work through this struggle in the proper timeline before making a permanent decision that involves hormone disruption and/or surgical intervention.

In fact, many European nations are CLOSING their gender transition clinics because their long-term, real life experience is that many who transition at a young age return with immense regret and a desire to transition back to their biological sex.

I am happy to be of assistance if you would like further explanation of how the process of gender dysphoria proceeds.

Sincerely,
Karen Landmeier, MD

To: Paul.Vazquez@flhealth.gov
Subject: Youth transition and the informed consent process

TO: Paul Vazquez

There have been very rapid developments in Florida that are worrisome to me as a pediatrician . As you are aware, your Florida Board of Medicine will be meeting very soon to consider implementing regulations related to sex based medicine practices in Florida. The Board is specifically concerned about “youth transition” and the “informed consent process”.

It is my understanding, I those who support so-called “gender-affirming care,” including rapid gender transition for children and adolescents, have inundated the Board of Medicine with their comments. As medical professionals (CMA), we feel compelled to make sure you are aware the medical and evidence-based studies of these methods do not support such claims. Rather, the short and long term harm of these interventions is clear.

I am a Cuban American. My father was a pediatrician in Camaguey. I went to schools in Miami for over 3 yrs before moving to West Virginia. I even swam in the Florida Jr Olympics qualifying meet. I practiced general pediatrics for 37 yrs prior to retirement.

I strongly believe children are incapable of making life long decisions till mid twenties. Much medical evidence proves this. Please allow children to be children. Don't allow the approval of politically driven, unethical, child experimentation procedures or drug treatments with lifetime consequences.

Sadly, if allowed, we'll live to regret it, and many children will have to live with the horrible consequences, physical and emotional.

To whom it may concern:

The field of transgenderism is very new and so there is much that is unknown regarding its foundational ideology. Especially unknown are the psychological and corporal effects of the so called "therapies" because there is little data. Therefore great care must be taken when applying these therapies to minors and young adults because they are the most likely to not fully understand the consequences of the chemical and surgical interventions involved in "transitioning". It is almost certain they do not realize that the effects of many of these interventions are permanent and will irrevocably alter their lives. I believe that is why we are now seeing young individuals who have gone through all or part of this "transitioning" now regret what they did and are desperately trying to reverse the effects. I earnestly ask you to be very slow and deliberate in your study of this issue and not to rush any decisions. I ask you to make a thorough study of the results of those youth who have participated both in the U.S. and abroad to see how they have fared especially those who are speaking out in regret. Please do not affirm any "rapid transition" plans until you have completed your study. The very lives of our children are at stake.

Sincerely,

David P. Martinez M.D.

Our article in PITT substack details it well. Based on extensive research by Dr Guillamon it is clear that exogenous Estrogen leaches water from Astrocytes damaging synaptic formation and causing downstream effects like Schizophrenia, Dementia and other harmful effects

<https://pitt.substack.com/p/transgender-medical-interventions>

Recently Dr Guillamon was interviewed about his brain research and he clarified that wrong sex hormones are harmful to natal male brains. The hormones do the exact opposite of what the intended outcome is. He responds to the safety of these treatments here based on his extensive cause effect research. No other group has done such extensive cause effect work. Most research presented are low quality statistical chicanery without randomization and cannot reach conclusions they claim to reach.

Are gender-affirming treatments safe?

A. After puberty, hormonal treatment with testosterone (transgender boys) or estradiol (transgender girls) is not harmless; like any treatment, it can have adverse effects. In the brain, for example, we see enlarged ventricles. The first study on the effects of hormonal treatments on the brain dates from 2006. We did a second, broader study in 2014, which we published in the Journal of Sexual Medicine, and we offered an explanatory hypothesis. In the case of androgenization for a trans man, what happens is the same thing that occurs with the muscles when one takes an anabolic, the same anabolic and anti-catabolizing effects of the androgens in the rest of the body happen in the brain. In feminization, what we observe is that, as the thickness of the cerebral cortex and subcortical nuclei decrease, the ventricles expand. We recently showed that this happens because estradiol affects water metabolism in the cerebral cortex, not because the neurons shrink. We study the effects of the treatment in order to improve care for transgender people. We have proposed that a brain scan be included in the protocols every two years.

But absolutely nothing is known about the treatment of children with blockers on the brain. We have just been granted a ministry project to study them.

if we look at recent large cohort statistically significant studies they all point to much worse mental health (as expected since astrocytes are damaged) in natal males post Estrogen treatment.

Here is an analysis by Biggs et al.

Estrogen is associated with greater suicidality among transgender males, and puberty suppression is not associated with better mental health outcomes for either sex | PLOS ONE

Please define succinctly what is meant by "gender" and how is it differentiated from a human's reproductive state/sex. Sex has two meanings, the reproductive state humans are born into, either male or female, and, sex means, fornicating. Gender only means the reproductive state/sex humans are born into. That is why polite society uses the word, gender, to denote one's sex. The use of the word, gender, differentiates our sexed state from the sex act. That is why we have gender reveal parties for babies and not sex reveal parties. Sex and gender can have different connotation.

BIG PHARMA "trans" activists are deliberately obfuscating the meaning of words to push an incoherent - and highly profitable - agenda. "Gender" is not a medical condition. Puberty is not a medical condition. Teen angst is not a medical condition. No human being can change another human's sex. No drugs or surgeries can "trans" a little boy's body into a girl-body, or vice versa. Our sex is embedded in our DNA, apparent in blood and saliva samples, and easily observed at birth.

No human has the right to deceive the public about their sex in situation where it matters, such as, who showers in the women's locker room, how plays in female-only sports, who gets a pap smear, who needs a prostate exam, who gets pregnant, who show up when I request a woman care-giver to bathe my elderly mother, or when I request a female-only chaperone. Women and girls, FEMALES, needs the privacy, dignity and safe-guarding of single-sex spaces AND the accurate language to describe and protect our sexed rights and realities. We don't need "Trans" activists corrupting the medical community to deliberately erase women and harm children.

There are only 2 sexes as humans need only 2 gametes to reproduce. Females produce the gamete, ova. Males produce the gamete, sperm. Intersex is a birth defect not a 3rd sex. No person with the intersex condition produces a 3rd kind of gamete. "Trans" is not a sex at all. "Trans" is a deliberately pushed trend, a sexual fetish, or a body dissociative disorder. We don't perform anorexic affirming care on starving young girls, why deliberately deceive, destabilize and victimize CHILDREN with predatory "Trans" ideology? How is this not a CRIME?

Thank you for respecting biology and protecting children from "trans" predators.
T. Keefe
Woman, adult human of the female sex.

Dear Board Members,

I am writing to you as a parent of a daughter who was approved by a gender clinic in a Canadian Children's Hospital, for testosterone injections and a double mastectomy to treat gender dysphoria when she was 17 years old. As she was approved after only two appointments with a psychologist and a brief physical examination by an endocrinologist my husband and I did not feel she had been assessed thoroughly enough for such severe interventions and did not return to the clinic.

Despite what they had told us (that gender dysphoria never goes away) our daughter's distress around her gender gradually resolved on its own over a two year period without any chemical or surgical interventions. Today as an adult she is grateful she did not receive those treatments. While gender affirming interventions may be beneficial to some, my daughter is an example that a one size fits all approach can potentially result in overtreatment.

The dangers of false positive results, diagnostic overshadowing and overtreatment appear to occur anywhere where the affirmation model is used with adolescents, regardless of the type of healthcare system in which it is being used.

Recently in the BCMJ (British Columbia Medical Journal) three guest editors wrote a letter defending gender affirming care with youth, based on their belief that interventions were only administered after comprehensive psychosocial assessments were completed. This is the link to their letter:

<https://bcmj.org/letters/guest-editors-reply-drs-sinai-regenstreif-and-leising#a7>

After reading their letter, I had several questions which I passed on to the BCMJ. They forwarded my questions to one of the guest editors who declined to answer them. I have included my questions below and ask that your board review them and consider whether those who are promoting the affirmation model in Florida would be able to answer them.

1. Under what circumstances would gender affirming hormones and surgeries not be administered to an adolescent diagnosed with gender dysphoria?
2. If the only criteria is a diagnosis of gender dysphoria, what are the sensitivity and specificity of the assessment tools used in the comprehensive psychosocial assessment?
3. Can the psychosocial assessment determine cases of gender dysphoria that may ease or resolve over time without medical interventions?

4. Are there types of gender dysphoria? If so, does the psychosocial assessment determine which type?
5. Can the psychosocial assessment determine severity levels of gender dysphoria?
6. Are non pharmacological interventions the first line of treatment in cases of mild to moderate gender dysphoria?
7. Are hormones and surgeries only offered to patients after non pharmacological interventions have failed to ease the distress of gender dysphoria?
8. Are the waiting lists for gender affirming surgeries based on the patient's level or type of gender dysphoria?
9. Are outcomes of medical interventions better with certain types of gender dysphoria?
10. How is competency to provide informed consent determined in youth?
11. Is a health literacy precautions approach taken with adolescents when reviewing the risks of interventions?
12. Is it not also compassionate to consider the risks of overtreatment, the long term health outcomes of young patients and the lifelong medical burden these interventions create?

I hope that your board will also consider the fact that North American gender clinics have not appeared to be following up on adolescent patients to determine long term outcomes and these experimental treatments have been administered outside of regulated experimental trials. The gender clinic where my daughter was seen only found out that her gender dysphoria had resolved on its own after I filed a formal complaint. I have attached that complaint (with names redacted) to this email to provide you with an example of the gaps of care that occur with the use of the affirmation model with adolescents.

I hope your board will take the time to review what I have written and recognize that it is not political in nature, but has been sent to you in the interest of safeguarding adolescents.

Sincerely,

Victoria G.

Formal Complaint C

Introduction:

My complaint concerns the hormone readiness assessment that the team at _____ Children's Endocrinology and Gender clinic accepted and used to determine that my child, _____, had undergone a sufficient amount of evaluation to begin cross sex hormone treatments. A consent form for those treatments was given to my child at the clinic on _____.

Description of complaint:

1. Inadequate assessment process resulted in the approval of unnecessary testosterone injections and the delayed diagnosis and treatment of co occurring conditions.
2. The clinic did not evaluate or have checks and balances in place to ensure that the clinician, Dr. _____, who the clinic had recommended, had conducted a comprehensive assessment.
3. Concern that the _____ checklist for hormone readiness was not followed. Two items in particular do not appear to have been addressed.

The first checklist item is # 6 "Baseline blood work". To my knowledge my child never had any blood work done in relation to the hormone readiness assessment. Nor did the endocrinologist advise my child to get blood work done before the start of treatment. When my child eventually did get blood work done after withdrawing from the care of the Endocrinology clinic, the results showed very low levels of iron, increased levels of TSH and the presence of PCOS which are all conditions linked with depressive symptoms.

The second checklist item is #10 "Exclude rare differential diagnoses". I do not know if the psychologist made an attempt to screen or assess for co occurring conditions. It appears not, because three years later my child was diagnosed with autism by a psychiatrist. Neither the psychologist nor _____ Children's Gender Clinic recommended or made the referral for that assessment to take place. That is a concern given that an adolescent with ASD would possibly require additional support and a different communication style when discussing the effects of hormone therapy and issues surrounding informed consent. The information that there is an overlap between gender dysphoria and autism was withheld from me even after I mentioned my concerns that my child may be dealing with another condition that was contributing to the gender dysphoria and I gave examples of black and white thinking that I had observed my child exhibiting. In addition, sexual orientation was not adequately explored despite the association that gender dysphoria in youth is strongly associated with a lesbian, gay or bisexual outcome in adulthood. This vital information was withheld from me by both Dr. _____ and the Clinic and I did not learn of it till some time after our visit at the clinic. This information should be included prior to patients and parents making decisions about irreversible chemical interventions. My child is an example of this as her gender dysphoria diminished and eventually resolved without testosterone injections as she began to accept her same sex attraction, bisexuality and gender non conforming behaviour.

4. The assessment did not appear to include an evaluation process to help determine the level of my child's distress and if the most extreme treatment option which involves chemical and surgical interventions was the best option. My child was experiencing a significant amount of distress at the time of the assessment and while she was not functioning optimally, she was still functioning with family support. She was going to school, volunteering and preparing for post secondary. She did appear depressed but had not expressed suicidal ideations nor had she harmed herself physically. Nor were my husband or I ever told that she had. Yet she was approved for testosterone injections and a double mastectomy based on her self diagnosis. An option that was once only reserved for adults.
5. The lack of transparency and acknowledgment by both Dr. _____ and the clinic that there is no evidence base for clinicians to use to be able to predict which patients will truly benefit and which patients may regret irreversible changes to their bodies. Not enough research has been done on the new demographic seeking gender affirming medical interventions, adolescent biological females. Despite this, as a parent I was told my child's self diagnosis was accurate and should not be explored by Dr. _____. This was corroborated by the clinic as they were prepared to administer testosterone injections based on Dr. _____ report.
6. The statement that the clinic provided to the National Post recently, "Treatment with hormones and surgery only occurs after considerable assessment that involves families." was not what my daughter and I experienced. My daughter would have received testosterone injections based on two appointments with Dr. _____ who did not follow the recommended checklist by _____ with the exception of affirming my child's self diagnosis. The examples that I gave to the psychologist about my concerns that my child's gender dysphoria may be complicated by another condition were dismissed. As a parent I expected my child would receive a thorough evaluation and that the clinic would check that one had been done since they had recommended the psychologist involved. In addition, I was expecting further assessment at the clinic given the fact that psychologists do not prescribe medications and therefore was anticipating that the evaluation process would continue at the clinic.
7. My child never received a considerable assessment nor was family input encouraged. It was not explained to me that the "considerable assessment" would only include affirmation of my child's self diagnosis for medical interventions. Nor was I told why there would not be an exploration, evaluation or attempts at differential diagnosis. It is not fair to patients and families for the clinic to use the phrase "considerable assessment" if that is not what all of their patients receive. It misleads parents and the public into thinking that an evaluation process took place that examined less invasive options for dealing with the distress of gender dysphoria prior to settling on chemical interventions. My child was not provided with other options nor does it appear that any exploration or evaluation took place.
8. My daughter and I were not given a precise definition of what the evaluation process includes. Which items on the checklist are mandatory? Who is responsible for checking that baseline bloodwork is done? The GP, psychologist or endocrinologist?

9. The team did not attempt to assess my child's understanding of the possible side effects of testosterone injections that were read out loud to her during the clinic appointment (_____). No attempt was made to determine if my child had reasonable expectations concerning what the injections could or could not do.
9. The assessment process did not attempt to determine whether my child's gender dysphoria was secondary to another condition and therefore would require an extended diagnostic timeframe. As mentioned earlier my child was eventually diagnosed with ASD. Children with ASD experience gender identity development differently than neurotypical children and therefore require clinicians to take more time before clinical decisions concerning gender affirming procedures are made.
10. The clinic did not make an attempt to record the eventual outcome of my daughter's gender dysphoria. Therefore, it appears that despite the experimental nature of gender affirming chemical interventions for children and adolescents there is no attempt being made to keep track of short- and long-term outcomes. My daughter's gender dysphoria resolved without the implementation of testosterone injections. If cases like my daughter's are not recorded the data will be skewed and opportunities for clinicians and researchers to better understand which type of patient can benefit from an affirmation only approach versus an extended clinical assessment is lost. My child narrowly escaped receiving unnecessary treatment that would have resulted in irreversible changes and possible regret. Perhaps if the outcomes of previous patients had been followed, studied and recorded it would have helped clinicians recognize how my child's presentation differed from those individuals who have benefitted from gender affirming medical interventions. Instead, my child was offered a one size fits all solution despite the potential consequences of irreversible treatments. Understanding adolescents like my daughter whose gender dysphoria was secondary to another condition will not only help patients who may not need medical interventions but also those for whom medical intervention is beneficial.

Recommended Outcome:

Patients and parents are provided with a clear definition of what will or will not be done during a cross sex hormone readiness assessment. Parents are informed of the recommended guidelines and checklists for hormone readiness assessments. Parents are informed which guidelines are mandatory and which are optional for a clinician to address.

Patients and parents are provided with the information that in some cases gender dysphoria resolves without medical interventions.

_____ Children's Endocrinology and Gender Clinic reviews the practice of outsourcing the assessment process for cross sex hormone therapy and considers the challenges of such a practice which can result in inconsistent, substandard and varying levels of care, leaving patients such as my child who had co occurring conditions, unprotected.

Patients and parents are provided with the option of a psychosocial assessment that includes ASD screening. Given the overlap between gender dysphoria and ASD and the fact that neurodiverse patients may not have a diagnosis, autism screening has become part of the regular assessment process at Seattle Children's Hospital to ensure that communication is enhanced with this demographic that presents with both conditions. My daughter did not receive this added protection from _____ Children's Hospital Gender clinic.

Patients with previously diagnosed ASD are provided with additional support to help address the communication needs and executive function complexities of this demographic. Patients without a diagnosis but who exhibit signs of neurodiversity are also provided with this support.

The short- and long-term outcomes of patients who sought chemical interventions are recorded and analyzed even when the patient stopped pursuing hormonal interventions.

The cross-sex hormone readiness assessment for adolescents should allow the parent to provide the clinician with an extensive childhood history if the adolescent has given permission.

Parental questions and concerns regarding medical interventions should be considered with an open mind. These are experimental and irreversible treatments that were once only done on adults. This is a developing field where more research is sorely needed so it should not be surprising that parents instinctively will want to ask questions about procedures that can potentially negatively impact cardiovascular health, sexual function and fertility.

Clinicians at the gender clinic should be open to examining what is happening in other countries that treat minors with gender dysphoria and offer options to patients. Finland changed its approach in 2020 and now prioritizes psychotherapeutic non-invasive options and recognizes adolescence as a time of identity exploration. The experiences of desisters and detransitioners should also be taken into consideration and academic articles on this topic should be reviewed. The following article is an example of the need to address this issue. Pablo Expósito-Campos (2021) A Typology of Gender Detransition and Its Implications for Healthcare Providers, Journal of Sex & Marital Therapy, DOI: [10.1080/0092623X.2020.1869126](https://doi.org/10.1080/0092623X.2020.1869126)

Summary:

The assessment process for cross sex hormone readiness that my child received was inadequate. The purpose of this complaint is to communicate to the clinic the gaps of care that my child experienced in order to improve the system for future patients who may be experiencing gender dysphoria secondary to other conditions.

Sincerely,

Dear Florida Board of Medicine,

Thank you for taking up the vital question of regulating the so-called “gender-affirming” hormones and surgeries for young people.

As a parent of three teenagers, I have seen some very well-meaning but misinformed doctors recommend these radical life-changing interventions sometimes on the first or second visit. The myth that our children are getting “assessments” is propagated widely, but no requirements have ever been clearly articulated about which child or young person distressed with their gender role will benefit vs will be harmed. This intervention sterilizes 100% of children if administered according to the Endocrine Society’s recommendations.

Older adolescents can get hormones with no assessments at all, and have their healthy body parts amputated by eager surgeons on little more than self-declaration of “trans identity.” Many of our children are gay, autistic and many have experienced abuse or other trauma. They have come to believe their very real distress is explained by the fact that they are “transgender” and that hormones and surgeries will help. They do not. We have seen our children’s mental and physical health plummet following “gender-affirmation.”

We also encourage you to require exploratory psychotherapy and to issue a clear statement that psychotherapy for gender dysphoria is not conversion. Our children and families need safe non-invasive alternatives to radical experimentation known as “gender affirmation.”

Thank you for doing what you can to regulate this experiment on our vulnerable children.

Sincerely,
Melody Dunn

Paul A. Vazquez, J.D.

Executive Director Florida Board of Medicine

BOM.MeetingMaterials@flhealth.gov

Dear Mr. Vasquez,

I am writing in regards to the proposed regulations on “gender-affirming” care currently under review in Florida. I am a California attorney who is watching gender issues closely across the US.

I believe I have the best interest of children in mind, not only because my 17-year-old daughter is obsessed with transition but also because I know 36 kids - organically from family relationships- who also self-identify as “trans.”

One of these children is my best friend’s son. Another is my sister-in-law’s daughter. The numbers defy logic. Sadly, most of the children I know are on the spectrum, including mine.

My child suffers greatly from depression and anxiety. I took her to a psychiatrist who immediately told my daughter and I that she would kill herself if she doesn’t get immediate gender medical care. Can you imagine someone saying that to your child?

I could write chapters on gender medicine and mental health but I’ll stick to my short letter. Please be rational when dealing with our kids’ health. They’re so precious and shouldn’t be experiments.

Best regards,

Avery Kennedy

I am very upset over what is happening with gender ideologies. PLEASE do not teach my child she can change her sex...but that's what our school did and my daughter is now permanently altered and cut off from her family. BECAUSE the schools went along with her name change and pronouns...so they became the heroes and she hated on her parents for not going along with it.

We know our children best. She told me she was glad God made her a girl...loved dolls, dresses, babysitting, etc. but Im guessing did not feel feminine enough for her friends. Met someone at school who was on hormones and it made her curious. She becomes so obsessed over things. Decided she felt more comfortable when people THOUGHT she was a dude.

We love her. We can use a nickname but she will never be my son...always daddys little girl. She does not like that so she has lost contact. Its what the activists tell them to do...LOSE CONTACT. We miss her more than words can say. We beg her to come home...but she listens to all of the voices out there telling her we are her enemy. It's sick. Her dad is dying from a lung disease. She said she would care for him but wanted him to use her pronouns...He won't...she will not care for him.

I believe these kids will live with huge regrets later in life.

Hi paul.

18 years Hashis patient here - acquired via childbirth ptsd (previously full health)

I'm a uni educated (psych/ comm), reasonably progressive woman with 2 (young) adult children, female eldest having had thyroid cancer treatment at 20 immed post uni grad. It has changed/ restricted our lives beyond measure. I refer to this new reality as 'locked in syndrome' - my brain says DO THiS (fun, high energy activity as normal before) then body goes NOPE, nap time. We will never enjoy the energy, health or independence as prior, we are now dependent on worst the medical field can throw at us. And it's pretty overwhelming how substandard the field of endocrinology is if you are a patient with a brain.

During period living in Munich I underwent careful, detailed EXPENSIVE health testing for private insurance - doc stated I would not have any issue as retention from earlier athletics (rowing/ tennis) meant despite hashis I was still well above average health wise. Imagine surprise when every German insurer rejected me on basis endocrinology is such a mess patients are untouchables, subject to early, rapid decline. This is future of these children, travel restrictions, activity restrictions, employment limitations & health issues that will escalate rapidly & for which there is no solution.

In bluntest terms possible, endocrinology is a field full of charlatans. Their "science" is ephemera based on individual opinion - I have no idea how they get away with it. The idea you can artificially hormonally medicalise children is ludicrous. Any decent medic knows you cant, unfortunately at this point being a decent medic appears to intersect with cowardice. This is a fad. funding for ongoing medications will inevitably be withdrawn & I have no idea how

these new endo+ patients will get through. I have lived in multiple “top” countries with “excellent” healthcare - no system is set up for basics never mind this crap.

The people pushing it are reprehensible. Do not fall for their hubris - or that of delusional parents who deserve to be criminalised. Spare impressionable children the toxicity of these failed human adults, hold fast & regulate this industry into annals of horrible histories where it belongs. Have fun, these health terrorists are intent on making every Halloween slasher/zombie film come to life, you're going to need serious backbone.

Best -

Leslie Renfrew

Here is my story and I now know I am not alone. I live in California but grew up in Florida. My teen daughter suddenly came out as trans 1 ½ years ago. There is a life pattern and a path to transness that is almost comical to hear. This is NOT normal. Many of these trans identifying teens are girls. This is new. They fit into a pattern identified as ROGD. Read Dr. Lisa Littman's [studies](#) because they are spot on. These teens are the average age of 16 when they come out. They have struggled with mental illness their entire lives. They have been bullied as children. They have struggled socially to fit in their entire lives. They never mentioned gender or sex as ever being an issue their entire lives. They hung out on Youtube or other social media that lean heavily on algorithms to suggest the next thing to watch. They often came out as lesbian a year prior. And as we now know, they are often on the Spectrum. And then they dropped a bomb on our house that we're still trying to dig out from.

Here's what else is going on in our lives: We seek help and we're only told of the 'affirming' therapists. We're put on waiting lists because there aren't enough therapists. After months of waiting, we take whatever therapist we can find. They tell us to 'trust the process.' We see things moving too fast but realize too late that we're caught in an agenda that we want no part of. Some of us still don't realize this. We're told our teen will kill themselves at any moment if we don't give them medical treatment right away. The endocrinologist creates a disease to list in our teen's medical chart to treat them with testosterone so the insurance will cover treatment. Our child has no such disease and yet, it's on her chart: "Unspecified Endocrine Disorder". Meanwhile, they fail to point out to us that our child is suffering from severe to extreme anorexia (we were told our child just needed to 'gain some weight') when in a rational medical world, they would have been immediately hospitalized. The severe anxiety that the therapist didn't treat at all before referring us to the gender clinic gets worse. We want what is best for our child but medically torturing our child while not first acknowledging and addressing these severe mental health issues first is medical malpractice. And we go on. Eventually, we wake up and seek care at several eating clinics to help treat our daughter. All of them affirm. None of them know how to treat eating disorders caused by Autism. So we stay at home, suddenly becoming medical experts ourselves because we can no longer safely seek care for our daughter within the medical

establishment. We are now seeking life outside of the US. It is not safe to take your child to the doctor anymore. It's that simple. How on earth did we come to this?!

Please stop the medicalization of trans children. Many of these children are often girls who have many co-morbidities such as eating disorders, depression and anxiety that often have simply manifested due to undiagnosed or diagnosed Autism. It is often the autism that is speaking, not because they were 'born in the wrong body.' We all know it is physically impossible to be 'born in the wrong body.' Everyone is born simply biologically male or female with a tiny contingent of people who are intersex. Children reach true maturity at age 25 and we know that children on the Spectrum often lag behind with maturation, which is closer to 30. Parents are being turned away as not trustworthy when they are the ones who know their own children. The 4000% increase in girls identifying as trans should not be normalized, especially when 48% of the patients at Tavistock were considered on the Spectrum. Medicalizing these children with cross sex hormones and puberty blockers will likely lead to surgery and it will lead to infertility. It will also make their co-morbidities amplified. This we can see early signs of and yet, trans centers are not fully explaining this to the families who enter these clinics. The 'affirmation only' model is pushing these vulnerable children and families into a future life being tied to the medical industry. They will make a fortune off of these children. As a parent, I'm appalled that I can no longer take my child to a doctor and trust that they won't push them towards this ideology. We are looking into leaving the US now because the entire industry has been co-opted and I now trust no doctor. None!. I've been burned four times already in the past year by 'affirmation only' care. Please, please heed parents warnings and stop this insanity. There will be reckoning one day on all of this but in the meantime, so many families are suffering as are these children.

To whom it may concern,

We already know the facts. Children do not understand what they are consenting to. My friend has a child who is gender questioning...When her mother told her being put on puberty blockers can leave a person unable to have an orgasm the 16 yr old said "who cares about having orgasms?!?" In other words, she hadn't had one so how can she EVEN understand what she is leaving behind!

The idea of consent REQUIRES understanding the consequences of actions. These children have under developed frontal cortex's (the thoughtful decision making part of the brain) and are being put in the driver seat on making radical life long changes to their bodies. They haven't had their first kiss, but they are being led to sterilization and removal of healthy flesh! How is this NOT a major medical scandal waiting to explode.

We already know the facts. Parents all over the world are being told that transition will save their kids lives which we now know from UK's Cass review is not actually true. Suicide rates go UP after transition!

We already know that the children have no idea what they are ACTUALLY doing to their bodies, or how to assess the consequences, or how to consent. How can you consent to something you do not understand?

Transition, obviously, can sometimes aid a person in feeling more comfortable in their bodies. But shouldn't that decision, since it has such extraordinary repercussions, be made once the person can actually consent? The brain is completely developed around age 26/27....Can we see a way towards compassionately providing mental health support, therapy that explores why someone might feel uncomfortable with their birth sex? Autism, OCD, trauma, being gay, having internalized homophobia, internalized misogyny....these can all explain why a child may suffer from these feelings...but currently they are not allowed exploring. That's absurd!

Please. Let's create a space where children can become comfortable in their bodies over time and not rush to mutilation. Then, at age 26/27 when they're fully cognizant of what their sexuality is, what the actual transition will actually mean, THEN they can pursue it! Children require safeguarding. It's our duty as parents and adults.

Thank you,
Linda Hayden

To whom it may concern,

I would like to put my voice towards this very serious issue of young vulnerable adults with underlying comorbidities being able to transition without thorough medical investigations.

I am very hopeful, thankful and encouraged that The State of Florida Medical Board is considering implementing regulations regarding the practice of gender medicine. We live in Queensland, Australia. Last year (2021) my adult son who suffers from Functional Neurological Disorder (FND), Depression and Anxiety was given Spironolactone and Estradiol. The prescription was given after just over an hour appointment with a General Practitioner. My son has been and continues to be under the care of a Psychiatrist since 2015. He suffers from dissociative episodes, full body and limb tremors, confusion and fatigue. After only 6 months on the medications he developed breasts, his testicles shrunk and he is left unable to ever father children. He regularly attends hospital because he is now suicidal, mostly bed ridden and unable to work. In fact, I clean his unit, wash his dishes and launder his clothes, shop for groceries and subsidise his rent. I made an appointment with the General Practitioner that prescribed the medication to explain how unwell my son is as this had been his first appointment with this Doctor. The doctor had not even read the years of clinical notes taken by his treating Psychiatrist. My whole family cannot understand the injustice that has occurred as there were no signs of gender dysphoria throughout his life. We are in shock and left reeling with dismay and devastation.

I truly do not feel this is "Affirmative Care" or "Informed Consent" as it is called in Australia, but instead butchery and mutilation of our beautiful young people. My son's body is irreversibly damaged. Vulnerable people need protecting. Doctor's take an oath to "first do no harm", my son is truly harmed.

Thank you for taking the time to read my email. I eagerly await your findings. Best of luck.

Kind regards Naomi Green

Dear Paul,

I am pleased to see you are considering implementing regulations regarding the practice of gender medicine.

I have a son who believes he is a woman. If he is pressed into gender reassignment surgery without any and all medical professionals making sure he knows the full ramifications and risks around this experimental procedure, then the medical profession will open itself up to serious consequences for their actions. Equally if he is given powerful drugs to facilitate his transition process without fully informed consent of the full range of side effects that have the potential to cause him harm, again the medical professionals who neglect to do this open themselves up for litigation.

My son is under 18 years of age and he is aware of proper procedure as far as informed consent is concerned and he is also aware of the process of gathering evidence to support him if he is harmed by not being given full disclosure and fully informed consent. I am sure more and more youth are realising they need to take precautionary measures as they see their peers in the transgender community suffering when they were not fully informed and as a result had no idea what they were really allowing doctors to inflict on them, a life long condition that has robbed them of many healthy aspects of their lives without any way to hold these medical professionals to account. So youth are now learning how to gather information they are given in preparation for any possible harm that occurs so that they can take this information to court to not only get recompense but to ensure case law is created to protect others. However this can all be avoided if competent and thorough regulations are put in place around this issue.

The medical profession that is capable of giving prescriptions and performing operations, need to be the last step after serious in depth counselling that includes informing the patient of any potential harm of allowing doctors and other professionals to prescribe powerful drugs and/or to carry out experimental operating procedures.

Regulations need to cover this aspect thoroughly so that anyone involved in the care of youth with transphobia or any other gender related condition are made fully aware of their responsibilities and the ramifications for them if these responsibilities around patient care are neglected. If this is done then doctors and clients dealing with gender issues of any kind will be in a much safer and more caring environment with professionals taking the care that is seriously lacking in some medical practises.

The regulations put in place need to state the step by step procedures health professionals need to follow to ensure client and medical professional alike are protected.

Eg

1. Ensure the client has had in depth counselling with a counsellor who will help them question if this is the right path for them.
2. Ensure the client has written examples of what potential side effects can occur with any prescription for hormone treatment (puberty blockers, testosterone, progesterone etc) before they give their consent so there is no doubt that they have been fully informed
2. Ensure the client has written examples of what potential side effects can occur with any operational procedure before they give their consent so there is no doubt that they have been fully informed

Kind Regards

Dear Florida adults

I am from the UK and we have been struggling with our children being caught up in this social contagion.

It's a terrible choice to push young children down a medicalised path without trying talking therapies or watchful waiting.

86% of children desist. Puberty blockers and hormones for children are so dangerous and cause long term damage.

Don't let it ruin your Floridian children who are beautiful and confused. No one is born in the wrong body. I strongly feel children should not be pushed down the affirmation path.

Love your children as they are

I recommend you read this

[76% of referees to The Tavistock & Portman Gender Identity Service \(GIDS\) are adolescent girls, and we also know from The Tavistock's statistics that 48% either have a diagnosis of, or show traits of Autism. 1](#)

Mr. Vazquez,

I have a daughter with mental health problems who has been pulled into dangerous beliefs that gender dysphoria equates always to being "transgender" (when in fact it has always been common in the gay community), that sex is not binary (the biology of sex is binary. If it were not, then we would not have a fight over transition from one sex to the other sex), and that sex is "assigned". This narrative has as much scientific basis as the belief that COVID vaccines will turn recipients into zombies. Children who are vulnerable and in distress hear false narratives constantly on social media, teaching that their self-image pain, or sexual orientation confusion, will be cured by joining the trans community. But the most terrifying fact is that they hear it from physicians, and therapists, the very people we as parents have trusted to guide us when our children are in distress. After my daughter announced to me that she had gender dysphoria (which she equates to be transgender), I learned that a therapist had brought this up to her when she was only 13, without ever discussing it with me. I have spent two hellish years researching and trying to understand this phenomenon, and it's impact on my daughter. **One of her psychologists, and her psychiatrist, told me in confidence that they don't believe my daughter is really transgender, but that they HAD to use the affirmative care model (meaning that they immediately used her "chosen" pronouns and name) with her. Their recommended path forward was to affirm, but try to slow her attempts to medicalize. HOW IS THIS RESPONSIBLE MEDICAL PRACTICE?** We know that the use of a new name and identity can alter a person's sense of self; that the longer they are in that identity, the more it solidifies. We know this from cult research, for one. So these professionals helped to lead my daughter down a path they did not believe to be right, hoping that by slowing her down, she would find for herself that the path was not right. Isn't it their job to explain that to her?? But these professionals have been bullied into this therapy, which appears in the standards of care. And the kids are the victims of it. They are instantly affirmed in their "choice" of gender, then hear that surgery and off-label use of drugs to "change" sex is a safe and necessary therapy, when in fact we have very little historical data of the outcomes and side effects of medical transition. Unlike any other condition treated by the medical community, they are allowed to self-diagnosis as having gender dysphoria and being transgender, and receive instant affirmation and treatment. And the rampant advocacy of affirmation and transition by the medical community is destroying families. I am not speaking as someone who reads this on the internet, but as a mother with first-hand knowledge of the tragedy taking place.

If you have any power to alter the course of this train, please use it. Not every child is susceptible to this ideology, but a great many are. And the medical community is doing a huge disservice to the most vulnerable.

Summary of responses

The Cass Review

Introduction

Context

About the Cass Review

The Independent Review of Gender Identity Services for Children and Young People (the Cass Review) was [commissioned by NHS England](#) to make recommendations about how to develop and improve the services provided by the NHS to children and young people who are questioning their gender identity or experiencing gender incongruence.

The scope of the review is broad and will look at different aspects of gender identity services from primary care through to specialist services with a focus on how care can be improved.

Background

In May this year, the Review Chair, Dr Hilary Cass [wrote to NHS England](#) setting out some of the immediate issues with current provision of services and suggesting how the Cass Review team might help with the challenging problem of establishing infrastructure outside of the specialist Gender Identity Development Service (GIDS).

In Autumn 2021, the Review worked with an independent research and engagement organisation to create an online multi-professional panel of primary and secondary care clinicians and social care staff to explore their views on how to build and sustain the capacity, capability and confidence of the wider workforce.

You can read the report of this activity on the Cass Review website: <https://cass.independent-review.uk/>

About the gender specialists survey

Having concluded the professional panel exercise, the Review wanted to triangulate what it had heard with the thoughts and views of professionals working predominantly or exclusively with gender questioning children and young people.

To do this in a systematic way we conducted an online survey which contained some service specific questions, but also reflected and sought to test some of what we had heard from specialists through our listening sessions and from primary and secondary care professionals engaged in the professional panel activities. Some of the questions posed were therefore deliberately provocative to stimulate discussion of some of the key issues. The survey included a mixture of quantitative and qualitative questions.

The survey was conducted between 14 December 2021 and 16 January 2022. The survey link was sent by email to current staff working in the Gender Identity Development Service (GIDS). It was also circulated to a number of former GIDS clinicians who had previously been in touch with the Review. The purpose of the exercise was explained to the participants, and they were informed about how the material collected would be used (including the use of quotes).

A total of 33 responses were received from current and former gender specialists. While this is a relatively small sample, the quality and fullness of the responses received was very high and the exercise yielded valuable insight and feedback. We are immensely grateful to all those who took the time to respond to the survey with such thoughtful and full answers.

About this report

This report presents summary thematic findings from the online research survey seeking the views and thoughts of clinicians and associated professionals working predominantly with children and young people needing support around their gender identity. All quotes have been anonymised.

The information gathered represents the views and insights of the survey respondents at a moment in time and findings should be read in the context of a developing narrative on the subject, where perspectives may evolve. This relates to both the experiences of professionals, but also the extent to which this subject matter is discussed in the public sphere.

Where comments have been made that relate to the quantitative questions these have been used to illustrate the insight from those questions. On a couple of occasions within the report, longer quotes have been shortened to allow as many different perspectives to be represented as possible. Where this is the case three dots (...) have been used. Every effort has been made not to change the meaning of the comment made. If a word has been added for ease of reading, this is represented in square brackets [].

The report represents a sample of the specialist workforce and cannot be considered to represent the position of all specialists who are currently working or have previously worked in this field.

This is one part of the work that the Cass Review is undertaking to understand the experiences and views of those involved and/or engaging with health services for gender questioning children and young people.

Overview of responses

Summary of findings

There are a number of consistent themes arising from the survey:

- The specialty is a rewarding but challenging field to work in, particularly given the waiting list pressures and level of external scrutiny of the service.
- The detrimental impact of the long wait to be seen by the specialist service can be seen both in terms of the mental health and wellbeing of the child/young person and their openness and ability to engage with assessment when they are seen at GIDS.
- There needs to be better links between specialist services and local services such as CAMHs to ensure the Child/young person receives a timely and holistic assessment and support.
- For the service offer to improve there needs to be more workforce capacity not just within specialist services but within the wider system, different pathway options and clear clinical guidelines.

However, there are also a number of areas where there is less consensus:

- There is not a clear agreed view about the primary purpose of puberty blockers, which may be different depending on the young person's age and stage of puberty.
- There is not a clear view amongst the specialists who responded to the survey as to the purpose of the assessment. Some respondents felt that assessment should be focused on whether medical interventions are an appropriate course of action for the individual. Other respondents believe that assessment should seek to make a differential diagnosis, ruling out other potential causes of the child or young person's distress.
- There are different perspectives on what the role of the specialist service should be within the wider care pathway.
- While there was general consensus that diagnostic or psychological formulation needs to form part of the assessment process, there were differing views as to whether a mental state assessment is needed, and should it be, where in the pathway and by whom this should be done

Detailed Responses

About the service user cohort

Respondents were asked what they consider to be the differences or commonalities when providing a service for a child or young person who needs support around their gender identity compared to another child or young person experiencing non-gender-related distress.

Commonalities: Some respondents felt that there were many commonalities between this patient cohort and other children and young people experiencing non-gender related distress.

"In many ways [there are] more commonalities than differences - dealing with developmental issues, relationships and systemic issues."

Among the commonalities cited were:

- **The nature of young people themselves.**

"Young people questioning their gender identity and those who are not are similar in having a great many personal resources and resilience, as well as often having had very difficult early experiences in their lives (such as trauma)."

"Young people and families in distress are young people and families in distress. I feel that what often gets lost on the wider political debates is how to actually support the individual young people and their families who are in high states of distress who are locating that distress in gender."

- **The professional skills needed.**

"All of the usual skills for providing a service for young people and families are the same - e.g. engagement, compassion, curiosity, being responsive, and conducting appropriate assessments, formulations and intervention plans."

"There are lots of commonalities, in that you would be looking at all parts of a young person's life to understand their distress and how to support them best. You would be listening to the child or young person and really trying to understand their feelings and ideas about the world, and their understanding of themselves. You would be encouraging them to explore and question. You would be helping them to improve their confidence and self-esteem. Cultural competence and an open mind would hopefully be a commonality."

"Some of the commonalities are having an open and honest approach, empathy and caring. Multi disciplinary working, clinical skills."

- **The need to provide a safe space to discuss concerns.**

"Supporting young people and family to discuss difficult/complex/multi layered topics is a transferable from gender to non gender related distress. This involves creating spaces that feel safe, creating new ways of talking or thinking about things, helping families to navigate topics they are stuck with or find hard to talk about without support."

"The importance of building a therapeutic relationship to enable engagement and communication. A safe space and time to discuss concerns/distress is a desire for young people whether they are experiencing gender related distress or not."

- **The need for a (non-directive) thoughtful approach and assessment.**

"I think all young people experiencing gender related distress could benefit from the same kind of therapeutic approaches as their cis counterparts managing distress, such as ACT, CFT, mindfulness and DBT techniques for managing distress, and trauma-focussed and systemic interventions."

"If it weren't for the availability of the medical pathway then I would argue that there is little difference in working with a child who is distressed about their gender as compared to any other child. For any distressed child you would need to do a full assessment, develop a formulation to help explain their particular distress, and then use interventions to try and alleviate that distress."

"All children experiencing psychological and physical distress should access thorough assessment and formulation to ensure that we can be clear about what intervention should be offered"

- **The need to work with the young person's family and the wider network.**

"Commonalities are that we work with the young person within their family and systems - school, CAMHS etc, we are interested in their experience of their gender identity as well as what other people around that have observed and heard."

"Involvement of families/parent/carers to support the young person."

About the service user cohort

Respondents were asked what they consider to be the differences or commonalities when providing a service for a child or young person who needs support around their gender identity compared to another child or young person experiencing non-gender-related distress. Continued.

Differences: Other respondents felt that there are more differences than commonalities between this patient cohort and other young people experiencing non-gender related distress.

"As well as there being commonalities, I would say the differences outweigh them."

Among the differences cited were:

- **The need for clinicians to have specialist knowledge about gender identity.**

"A thorough understanding of gender diversity is needed by the clinicians, alongside knowledge of the difference between gender identity and expression, the available pathways and what these involve (especially that there is more than one pathway - there is a need to invite uncertainty and curiosity into the conversation - just because someone is trans does not mean that medical transition at this time is the right thing for them)."

"I think it is important to be as knowledgeable as possible about trans and queer identities, and conversations about gender which young people have...I think coming to the work with a general understanding of terminologies, 'debates', multiple perspectives on gender is important when having therapeutic conversations with young people, in order to clearly position yourself as not aiming to change their gender identity but hoping to help them to better manage gender based distress."

- **Societal contexts including systemic and societal transphobia.**

"Social contexts can be very challenging for someone presenting with gender related distress. Young people presenting with gender related distress can seem to provoke strong reactions - both for and against - in others close by. I do not seem to have witnessed this to the same extent for other young people presenting with non-gender related distress."

"Experiences of transphobia - such as bullying at school, or systemic transphobia in terms of lack of funding for services or systemic barriers to care."

"Young people with gender-related distress often experience societal discrimination/bullying, needs to be taken into account within the work and addressed on a wider level."

- **The need to be non-directive.**

"There needs to be a nuanced, education and thoughtful approach to support young people accessing gender services with no preconceived ideas as to what the young person may want. This differs to other areas of healthcare where there may be somewhat of an expectation that the medical professional will direct the appropriate clinical pathway."

"You aim to reduce distress that some young trans and non-binary people experience by supporting them with their mental health and wellbeing; promoting self-acceptance, esteem, confidence etc. all of which can suffer due to minority stress and dysphoria. It's hard work and there isn't much evidence to let us know the most effective psychotherapeutic ways of alleviating distress in this group."

- **Availability of local services / support for co-occurring conditions.**

"The GIDS model does not allow treatment for Mental Health problems to be provided at GIDS so we rely heavily on the local Network... It is becoming increasingly difficult to obtain support from CAMHS unless the young person is self-harming or suicidal, and even then the support offered is short-term and increasingly not fit for purpose...GIDS staff are left 'holding' these young people who do not have local support, which is inappropriate and unsafe/risky."

"At present when there [are] associated Mental Health difficulties, I would not carry out the therapeutic work around this but rely on local services, however local CAMHS services are under resourced and the required work does not take place."

- **The competence and confidence of clinicians outside GIDS to work with these young people.**

"I suppose one of the main differences is that mental health services think they know how to support young people experiencing things like low mood, anxiety, self-harm - and there are plenty of evidence-based therapies they can offer...I think with gender, people can feel very out of their depth. They worry about saying or doing the wrong thing, and there is a distinct lack of training on professional courses about helping people with gendered distress. This means that generally these young people will end up at specialist services, even if they have co-occurring needs that should have been met locally."

"There is a lack of knowledge, understanding and expertise to support young people with gender related distress within mainstream services."

"It is different in that other services have positioned gender as being so expert that only GIDS can manage it - with other difficulties often having gone untreated and worsening during the long waiting time."

- **The medical model and medical interventions.**

"To work with gender related distress at the moment, you are constantly aware of the pressure of the medical model. A child/family can fixate on this being the only solution to the suffering and that makes them less likely to engage in the regular psychotherapeutic techniques described above."

"Physical interventions for gender feel like a more long-term medical intervention than most other medical interventions offered to distressed young people."

"The medical interventions we provide are not well-researched or evidence based, and they also have potentially life-long and life-altering impacts, which means the work we do is inherently more difficult, complex and thoughtful"

- **The focus on Gender alone and risk of diagnostic overshadowing.**

"Gender tends to be seen as the unique factor responsible of the young person's difficulties and distress, and it is much more difficult to hold in mind the possibility of addressing other needs, both for young people and their families, but also for other professional support services like CAMHS or GP."

Gender tends to be seen as the unique factor responsible of the young person's difficulties and distress, and it is much more difficult to hold in mind the possibility of addressing other needs, both for young people and their families, but also for other professional support services like CAMHS or GP."

About the service user cohort

Respondents were asked the extent to which they agreed or disagreed with a series of statements:

In your professional experience, children and young people who need support around their gender identity have already obtained information about potential interventions and care pathways available to them

In your professional experience, children and young people who need support around their gender identity are well informed about their options

About the service user cohort

Respondents were asked the extent to which they agreed or disagreed with a series of statements:

In your professional experience, children and young people who need support around their gender identity arrive with a pre-determined preferred intervention/pathway in mind

In your professional experience, parents/carers of children and young people who need support around their gender identity arrive with a pre-determined preferred intervention/pathway in mind

About the service user cohort

Overview of findings:

- While a majority (87.5%) of respondents felt that children and young people often (48.5%) or sometimes (39%) arrived with some level of information about potential interventions and pathways there was less confidence that they were well-informed about their options on arrival with 24% of respondents stating that this was rarely the case and 61% suggesting this was sometimes the case.
- A majority (70%) of respondents felt that children and young people and to a lesser extent their parents/carers (45%) often arrived at clinic with a pre-determined preferred intervention in mind.

Comments made to other questions in the survey add more context to this and how it can affect the work GIDS does:

"In general, I regularly see children and parents who would have done extensive research on what is available to them in relation to gender related and therefore sometimes it can be a barrier to the exploration and assessment work if they have a fixed idea on what they want/feel they should receive. I would add that this is not the case for every family and even some who have perhaps set ideas when they arrive at GIDS do engage well with exploration."

"Young people and families often came with very definite views of the 'solution', which largely lies in physical interventions. Unlike in other services, GIDS were often seen as withholding something that private services were selling as the cure. This meant a higher proportion of people coming in with quite antagonistic attitudes towards the clinicians and armed with a very challenging approach."

"Often young people and parents have a fixed idea in their mind about the cause of the young person's distress, and the intervention needed to manage this (medical intervention)."

"I have found that initially young people present with very similar narratives to one another and events in [the] family tend to have unfolded in very similar ways however over time it becomes clear that the reasons why a particular adolescent has become immersed in online transgender spaces and has become drawn to the belief that they are trans do tend to be rather idiosyncratic."

"Families and clinicians often constitute polar opposites of [an] unhelpful dynamic. Parents and young people very often demand physical interventions, and do not see the need to engage in talking therapy; clinicians attempt to do their jobs, but often there is very little scope, the whole assessment being structured around deciding whether a young person will be referred to access endocrinology services by the end of it."

Assessment

Respondents were asked the extent to which they agreed or disagreed with a number of statements regarding the purpose of assessment of children and young people experiencing gender dysphoria.

Children with gender dysphoria know their mind, and the purpose of assessment is to determine whether they wish to have medical intervention and their readiness for this.

Gender Dysphoria in children and young people is a symptom, and it is important to make a differential diagnosis as to whether transition is the right option or whether there is another way to address their gender-related distress.

Gender dysphoria is always an indicator of another underlying problem and assessment should focus on understanding the causes of their distress.

Assessment

Respondents were asked the extent to which they agreed or disagreed with a number of statements regarding the purpose of assessment of children and young people experiencing gender dysphoria

There was no clear consensus for any of the given statements regarding the purpose of assessment.

For all three of the given statements, more respondents disagreed than agreed.

It should be noted that several respondents commented that these statements were overly simplistic, which may be reflected in the numbers selecting “neither agree or disagree”.

The strongest consensus was disagreement with the statement *“Gender dysphoria is always an indicator of another underlying problem and assessment should focus on understanding the causes of their distress.”* (39.4% strongly disagreed and 33.3% disagreed with this statement).

The statement receiving highest level of agreement was *“Gender Dysphoria in children and young people is a symptom, and it is important to make a differential diagnosis as to whether transition is the right option or whether there is another way to address their gender related distress.”* (6% strongly agreed and 21.2% agreed with this statement).

However, even in this case, more respondents disagreed (27.7%) or strongly disagreed (12%) with the statement than agreed.

Assessment

Respondents were asked the extent to which they agree or disagree that it can be helpful to undertake a mental state assessment on children and young people presenting at their clinic.

They were also asked what role they think a mental state assessment has in the care of children and young people needing support around their gender identity.

- **A majority (55%) of respondents agreed or strongly agreed that a mental state assessment would be helpful in assessing the children they were seeing at their clinic. However, a notable minority (27%) did not agree with this.**

- **Respondents who agreed that a mental state assessment would be helpful reasoned that it would provide a fuller picture of the young person and was helpful in managing risk.**

"It is helpful to understand risks and enable a multi-professional response within the YP [young person's] network. It is also helpful to understand the YP functioning so that assessment and intervention is tailored to the YP needs and level of understanding."

"I think it is imperative that young people receive a mental state as well as risk assessment in order to ensure all of their mental health needs are met and to reduce/manage risk. Living with gender dysphoria for a number of years (whilst on the waiting list) without the intervention of a specialist service can impact someone's mental health and increase their risk greatly."

- **Some respondents suggested that it can be helpful but only part of a broader assessment process.**

"I think mental state assessments are important, but only a (small) part of a broader assessment around gender development. It doesn't cover gender identity development over time and context, developing an understanding, family perspectives, hopes for future, developmental assessment, etc.."

- **A smaller number of respondents felt that a mental state assessment had no role in the care of children and young people needing support around their gender identity and doing so risked pathologizing the young person unnecessarily.**

"None. It is a snapshot of someone's presentation on that particular day at a particular time. It is a psychiatry tool that risks undermining the validity of patient experience and the ongoing, dynamic, and relational nature of the therapeutic relationship between client and clinician."

"None. This would be irrelevant for the young people I see. The tool lacks depth and complexity, and I would be unsure of the purpose of using it. The tool is part of psychiatry and has no place in GIDS."

- **Some clinicians said that a mental state assessment should be undertaken only when clinically indicated but that it should be done by local CAMHS and was not the role of GIDS.**

"The same as in any service, that if someone is presenting in acute distress/mentally acutely unwell then a mental state assessment would be appropriate but would be done by their local network and not in GIDS."

"As gender dysphoria isn't considered a mental health condition, it is unclear what role a mental state assessment would play. If there were concerns regarding mental health needs, my view is that it would be the responsibility of the local CAMHS team to undertake a mental health assessment."

Assessment

Respondents were asked the extent to which they agree or disagree that it can be helpful to use psychological formulation* with children and young people presenting at their clinic.

They were also asked what role they think psychological formulation has in the care of children and young people needing support around their gender identity.

- The majority (79%) of respondents agreed or strongly agreed that psychological formulation can be helpful in assessing children and young people needing support around their gender identity. 18% neither agreed or disagreed and 3% (1 respondent) strongly disagreed.
- Those respondents that agreed that psychological formulation is helpful reasoned that it can provide a structured process for understanding the child or young person's distress and provides a more holistic picture of the young person which can be helpful in developing an appropriate care plan.

"The process can build an understanding around the factors underlying any distress. This may identify those related to gender or those not and can enable exploration with the young person and build an understanding and picture. This can also enable signposting to other services if required, i.e. CAMHS, GP etc."

"Bringing together all relevant aspects of someone's life and context to make sense of their current experiences and indicate possible helpful ways forward. When co-created this can be one of the most powerful interventions when working with children, young people, and families. With gender-related distress, the aim is to explore and understand, rather than explain away, someone's experiences"

"It's key - how can you know how to help someone if you haven't got an individualised hypothesis as to why they are suffering? If you just use diagnostic assessments then you lose the individual details and so the differences between children's experiences - which are vast - and you are at risk of both confirmation bias and a one size fits all treatment approach, which we know inevitably won't work for everyone."

- Other respondents, while recognising psychological formulation can be helpful in some circumstances, were concerned that it could serve to further stigmatise the young person.

"I don't think it's fair to use gender dysphoria as a psychological formulation as a way to further stigmatise young people as it's not a mental health condition. Some young people and family may internalise having gender dysphoria as having something wrong with them."

"It depends what you're formulating. If you're formulating distress, then yes absolutely. If you're formulating someone's trans or non-binary identity, then no as that feels discriminatory. We don't formulate why a person is cisgender or straight... We need to be constantly self-reflective to detect and interrogate these underlying assumptions that might underpin our desire to formulate a person's gender identity."

"A psychological formulation may be useful in understanding the emotional and relational aspects of existing as a trans person in society. However, it is not appropriate to understanding the aetiology of why someone may turn out to be trans or gay for that matter."

- A couple of respondents felt that it was not possible to have formulation and diagnosis.

"...you can't really have a formulation and a diagnosis, so if a diagnosis is essential for progress through the system the diagnosis trumps the formulation. Some clinicians and the young people do not want a formulation they want diagnosis to go onto treatment, that's what they come for."

* Diagnostic Formulation: A structured approach to understanding the factors underlying distressing states in a way that informs the changes needed and the therapeutic intervention for these changes to occur.

Assessment

Respondents were asked if there was anything else they wanted to say about assessment of children and young people needing support around their gender identity.

- **The assessment process needs to be tailored to the individual.**

"The assessment of children and young people has to be tailored to the individual child and families circumstances, this includes when certain topics are asked and the pace of the assessment. It is also dependent on their communication needs and readiness to speak about gender. Speaking about gender and the pertinent issues (relationship to the body, gender identity development over time, puberty, sexuality) is emotive and has to be done with respect and sensitivity."

"I believe it is crucial to be able to respond to an individual young person and their circumstances, which means as a clinician I need to retain flexibility and manoeuvrability in response to the young person."

- **Many respondents said that there needs to be adequate time and space given to holistically explore with the child and their family based on their individual needs.**

"What is needed is a space whereby people's understandings of themselves are valued, whilst also providing an open space for exploration of what this means to the individual, and what support they need in order to live a happy and fulfilled life."

"It needs to be done carefully and take as much time as required. It must be conducted in an ethical, purposeful way, that respects the needs of the young person and their families. It should be accountable and open to challenge."

"As a development service, we should be just that. A service that enables a young person space and time to explore, rather than feeling the pressure (clinicians feeling the pressure) to diagnose a young person and place them on a medical pathway."

- **The extensive waiting list has hampered GIDS staff's ability to take this approach.**

"[The] wait has changed the work that we do with families considerably. When we can see young people soon after they seek a referral, we are able to do some exploratory work with them, some of them come to us wanting to explore gender or think about possibly socially transitioning. We are also then able to provide timely and appropriate interventions to [them]. However, now, young people have waited several years, have sought support elsewhere and now mainly come to us wanting to access physical interventions, however for many of them it is too late and we just do an onward referral to an adult GIC [Gender Identity Clinic]."

- **While some respondents feel the current GIDS assessment is robust and thorough they have suggestions on how it could be improved.**

"I think GIDS assessment process is robust, holistic and thorough, which I fully believe is the best way to be conducting these assessments at the current time. I would hope that going forwards, there would be more treatment options available for young people experiencing gender-based distress as well as physical interventions, such as third wave CBT, family therapy or psychotherapy at GIDS"

"I really value the assessment process in GIDS and see this as a cornerstone of the work. It is an intervention unto itself. It is generally a very helpful collaborative process which can support gender diverse young people and their families/carers in a range of ways. I do think the format could be somewhat different perhaps allowing for more flexibility in terms of times between sessions and longer sessions utilizing more creative methods in terms of assessment."

- **Better links between specialist services and CAMHS is needed to ensure the CYP receive a timely and holistic assessment and support.**

"Having worked at both GIDS and CAMHS, I strongly feel that there is a need to change the way in which young people are assessed to ensure they receive a timely and holistic assessment and support. I believe GIDS clinicians should be linked to all CAMHS services in order to support more localised holistic assessments."

"I cannot stress enough the importance of the local support for co-occurring mental health problems, and how it's almost non-existent in many parts of the country... I would very much like to be able to offer therapy to young people at GIDS as I think we might be able to make a difference. A group of us at GIDS are interested in using 3rd wave CBT therapies such as CFT and ACT to alleviate distress and build self-compassion in our trans and NB young people."

- **There is variation of practice in how assessments are carried out.**

"I think the service has tried to be open to different perspectives on the role of adverse life experiences but this results in variations in practice in how assessments are carried out. I think these variations in practice mean that different clinicians end up having different ideas about how common complexity is amongst the population we are seeing (to what extent the developmental history is explored depends on the belief of the clinician about the importance of the developmental history)."

- **The assessment should not be rooted in pathology.**

"The assessment should not be rooted in pathologising young people and/or their experiences. Assessment and outcomes should be holistic- extending to family members, members of network such as GPs and schools."

"We need to be creating gender services that listen to and respect the experiences of young trans people. And that help to normalise those experiences rather than pathologise them."

Respondents were asked what they think the role of the specialist service should be.

- To be specialist in their specific area of expertise**

"Offer specialist intervention, support and knowledge to those it works with. To add to and develop the research base for the specific area of specialism. To advocate for this area of expertise and for the people who use services in this area. Be a beacon for knowledge, skills and training. To have a national presence to add to the discussion in this area."

"To be the lead in assessing and care planning around gender identity."

"The service should have specialist knowledge and training."

- To provide a fuller assessment, including addressing other cooccurring conditions.**

"Detailed assessment of all areas of health before 17-year-olds go to adult services."

"To provide a fuller specialist assessment and advise [the] young person/family on options for the future - including addressing co-existing mental health issues and watchful waiting."

- To upskill local services, provide expert consultation and manage more complex cases**

"Ideally local services should be available to young people where they can discuss and explore their gender, be supported to try out social transition etc. If this was the case a specialist service would only be needed if they wanted assessment for physical interventions or there were multiple factors at play that local services felt unable to support with."

"GIDS should move to a consultation only model with all work around gender carried out locally. I think young people are not well served by having gender-based distress separated out from broader thinking about their mental wellbeing. Often, I have felt young people could benefit from more intensive therapeutic support that it is not possible for our service to manage due to current waiting times and the distance that families would have to travel for more regular appointments."

"Primarily consulting with and skilling up local services, to enable them to feel much more confident and capable to manage gender distress within their daily work. Alongside this there would need to be more funding for local services though... I feel that GIDS could then only see the more complex cases rather than any case where gender or sexuality is just mentioned."

"To liaise with a wider network and to educate local services who can support that person in a more robust way"

- To review and support a young person and family to explore gender and have a safe space to do so.**

"A service that enables children/young people and/or their parents/carers [to have] a safe space to explore around gender. For them to feel supported and listened to, and [have] time to build the therapeutic relationship. For the clinician(s) to adapt their approach to enable accessibility to the service and provide [the] child/young person and/or their parents/carers with appropriate information around this area to enable them to make informed choices."

"To support young people who are experiencing gender related distress, both through therapeutic discussions and [to] support them in thinking about medical interventions and if this is the right path for them."

- To explore whether physical interventions are appropriate for the individual**

"To hold a curious, open, safe, reflective, informed and knowledgeable space to think broadly around gender identity [and] gender development with young people and their families. If a young person would like to access a medical pathway, to support a young person with this process via an assessment and as part of this [give] further consideration to the medical pathway to fully support the young person to make an informed decision without having an opinion either way whilst bearing in mind we are working with a community that experience systemic oppression and there is a need to ensure that the work we do is collaborative and gentle and without judgment."

"Providing gender related advice and support to young people and explore whether physical intervention (hormone blockers and cross sex hormones) is an option for the young person, and [if] it's not support and exploration of other pathways should be given. Support around managing gender dysphoria, and young people feeling validated and supported. Managing uncertainty around the future and providing support on how to manage this. Offering a space for reflection for the young person and family. Also liaising with school, CAMHS, GP and other organisations to ensure the young person's holistic needs are met."

- It should contribute to research and thinking**

"To research and publish treatment findings, as well as reflective and sociological pieces."

"To develop a coherent and evidence-based understanding of the massive increase in adolescents identifying as transgender and develop a therapeutic psychological model for helping children and young people to feel comfortable with themselves and with their bodies that can then eventually be disseminated across local services."

Care Pathways

Respondents were asked about their minimum expectation of the support other agencies should have offered to young people and their families before they are referred to GIDS

- **The top responses were:**

- Safeguarding risks.
- Risk of suicide and other urgent mental health issues.
- History of trauma or abuse.
- Diagnosis of other possible mental health conditions.
- Diagnosis or assessment of suspected neurodiversity.
- The child's understanding of gender identity.
- Degree of distress / preoccupation regarding gender identity.

- **Respondents added a couple of "other" types of support or information they would expect other agencies to have offered prior to referral to GIDS:**

- Physical health and whether they are on any medical treatments.
- Who is involved in the [young person's] network.
- Broader mental health support to manage a range of associated difficulties.

- **In addition, general comments made were:**

"None of these are support, they are assessments."

"I have ticked the above in terms of what I would like to see provided to us, but we struggle to get GPs to do risk assessments of young people let alone more detailed assessments"

"Professionals completing referrals and children/parents need an awareness, understanding and knowledge that each person's gender journey is individual (even a heteronormative one) and there is no right way to transition, if indeed one does choose to transition. Not all people experiencing gender and/or sexual diverse identities need or want to access a specialist service or treatments."

"This all really depends on what model of understanding – [as to] why a child identifies as transgender - is underpinning the professional's approach."

"The above depends on the role the service should take. I have answered based on the way GIDS works at the moment."

Care Pathways

Respondents were asked what factors might indicate that a child or young person would not be appropriate for GIDS referral.

- **If the child is not experiencing significant levels of distress a GIDS referral would not be appropriate.**

"No significant distress or impairment in relation to gender."

"If they are not experiencing gender related distress. If there is no impact on their daily functioning because of gender."

"In terms of how services stand at present I would say the only factor would be that gender is not a concern for the young person, sometimes referers don't understand the difference between gender and sexuality."

- **However, any distress relating to gender made a referral to GIDS necessary.**

"If there is distress in relation to gender then all referrals for GIDS are appropriate"

"I think that anyone who is experiencing distress related to their gender should be eligible for a GIDS referral. I don't think a referral should be delayed by input for any other needs as the waiting list is 3+ years, however if other needs are identified at the point of the referral they should be addressed and updates sent to GIDS while the young person is on the waiting list."

- **If the child or young person's gender identity is newly formed or still evolving.**

"If the young person had recently started exploring their gender and there was low levels of distress (i.e. if there was trained/competent staff in CAMHS they could be supported by CAMHS in consultation with GIDS if needed)."

"Very recent onset of gender questioning/gender-based distress/self-reporting thoughts about gender."

"A young person who has only been presenting with gender incongruence for a very short period of time and little exploration has been done locally."

- **If there are safeguarding concerns that would affect ability to engage.**

"Safeguarding issues that mean it may be unsafe to engage [the] child in work relating to gender before these issues have been resolved"

"Experiencing a level of distress that poses an immediate risk to their safety or prevents them from being able to meaningfully weigh-up decisions (e.g. eating disorder, psychosis, significant self-harm or suicidality)."

"Where the young person does not have sufficient stability (housing, risk, mental health, addiction, etc.) to engage in intensive psychosocial exploration."

- **Lack of a full formulation/general support from local services.**

"If there are other underlying issues that have not been addressed, a referral to GIDS in its current form would not be appropriate. Either GIDS clinicians need adequate training to work with co-morbid or underlying mental health issues, or these issues need addressing elsewhere first."

"Significant additional mental health difficulties that have not been managed locally"

"Unclear formulation from mental health service in relation to complexity, risk, unmet mental health needs, or safeguarding; evidence that the need can be met by local support services"

"A high level of risk that is not being managed. A young person being in the midst of complex trauma work and perhaps not being able to engage with two processes at one time."

- **If the referral is more about supporting the parents than the young person.**

"[If the] young person [is] not expressing any distress about gender (we receive referrals which are more about a parent's worry than a young person's)."

"[Where] parents [are] not aware of the referral."

"Their age - sometimes we get referrals for 3, 4, 5 year olds. Young children that have no true comprehension of gender identity at all. Here it is more the parent that needs support on holding options open for their child, but I'm not sure this should come from a national specialist service."

"Concerned parents more focused on gender issues than [the] young person."

- **If the child / young person is already accessing treatment privately.**

"That they [the child or young person] are already seeking medical intervention from a private provider for gender related distress."

"[If the] young person [is] already accessing treatment privately and [has] been assessed in the private sector - the young person will have to go through another assessment at GIDS which may cause distress."

"If they accessed private [treatment] which meant there was no way for them to come back into NHS protocol (e.g. cross-sex hormones under 16)."

Referral for medical intervention

Respondents were asked what factors they take into consideration when deciding suitability for puberty blocking treatment.

- A full exploration of gender identity, level of distress around puberty and understanding of general development is needed.**

"Full exploration of gender identity including discussion about puberty/relationship to body and fertility - consideration around distress and the benefit of the blocker to reduce this."

"Gender Development History: strong narrative/ weak narrative/Binary/Non Binary/Consistent"

"Exploration of sexuality and how this is or not linked to gender identity development."

"Young person's gender development history, current gender identification. Consistency of gender identification, understanding of gender identity as separate from gender roles etc."

- The young person and parent/carer's understanding of the medical treatment.**

"That it is what a young person wants and has expressed independently that this is what they would like to access, having been informed in detail of what Puberty Blockers do and don't do, expectations and side effects etc."

"Parental consent, as well as parents having a robust understanding of [the] risks/benefits of hormone blockers."

"Psychological and physical wellbeing. Ability to make an informed decision. i.e. to understand information relevant to the decision, retain this over time, weigh up and communicate their decision."

"Young person's and family understanding of [the] treatment pathway, and a ability to manage with uncertainty around the future, and also their expectations."

"[Whether the child or young person has] realistic expectations around treatment [and] realistic ideas about the outcome of accessing a medical treatment."

- Understanding of external factors/influences.**

"[Getting a] sense of life in school, friends and broad wellbeing."

"[The need to] understand the relationship to online communities and any risk issues."

"[The need to] understand family context and history, key attachments [and] parent/carers stance towards issues."

"[The need to] understand spiritual, religious and cultural beliefs."

"[The need to understand any] coercion – ensuring [the] young person isn't coercing [the] parent and visa versa - individual sessions [held] with both parties."

- The extent to which alternative approaches have been explored.**

"How much they have explored alternatives and are aware of risks and benefits and whether they have thought about what they want in the future, areas such as fertility or their body."

"Exploration of alternative approaches (non-medical). Exploring how they [the child/young person] would see their life if they did not go down the medical route."

"Distress around the body (needs to be significant distress, and other attempts to alleviate distress have not been successful before we can consider blocker)."

"Clear indication that gender is a pressing issue and has been present as such for some time. That the child/young person and their family have been provided with access to and considered alternative options to puberty blockers. that shared decision making is based on informed choice, and a demonstrated ability to weigh up options."

- Mental health and general stability.**

"Relative stability in mental health and all other domains of life - or a ability of accessing treatment being a factor in achieving stability."

"If there are mental health problems, how well the person is supported by local services. [The] level of functioning across the different areas in the young person's life."

"Get a thorough grasp of the nature of any additional difficulties and the impact of these on life and functioning."

"If there are mental health problems, how well the person is supported by local services."

"Stability around decision-making - is there sufficient stability and has the young person communicated a desire for this intervention for a prolonged period of time."

- A small number of respondents expressed the view that blocking puberty should not be practiced due to unknown long-term effects and young people's ability to give fully informed consent.**

"Blocking puberty isn't safe because we don't know what the long-term impact is on brain development and it also means that male adolescents will require more invasive genital surgery if they continue with gender transition as adults and if they don't continue, they will be stuck with immature genitals."

"It is my experience that the vast majority of children and young people under 18 do not have the emotional maturity to discuss issues around fertility preservation, the possibility of wanting to have children in the future... etc. Hence, as I do not think under 18 young people should be in a position to actually decide about these treatments."

Referral for medical intervention

Respondents were asked what factors they take into consideration when deciding suitability for feminising/masculinising (cross-sex) hormones.

- **Young person's ability to consent.**

"Their chronological age (need to be 16+), do they have capacity/can give consent."

"Consideration if the young person requires any adaptation to understand and retaining information and if there is any conflict with parents/ carers [regarding] access to medical pathway."

"Current age/stage of development - level of maturity."

- **Young person/parent/carer's understanding of the treatment and side effects.**

"Young person/parents or carer's ability to understand, weigh and retain information about the treatment."

"Awareness of irreversible effects and exploring this with the young person and their parent/carer."

"Opportunity to consider fertility and fertility preservation options."

"When considering gender affirming hormones consideration [should be] given to [whether] it is what a young person independently wants and has been informed in detail of what GAH [gender affirming hormones] do, side effects, expectations etc."

"The potential benefit of starting [hormones] in the slow graded way at UCLH – University College London Hospital - (slowly increasing to an adult dose) versus starting on a full adult dose in adult services."

- **Exploration of different pathway options and understanding of potential outcomes.**

"[That the young person has the] opportunity to consider multiple gender pathways, potential for gender development and change."

"The degree of therapeutic engagement that has been possible. How much do I feel I have been able to think with this young person in a meaningful way?"

"[That the young person has the] opportunity to consider a range of influences on experiences of gender and distress if they wish (e.g. trauma, family relationships, gendered experiences growing up, heteronormativity and patriarchy, sexuality)"

"The young person's thoughts on how they would manage if they came to a different idea about their gender in the future - whether the young person understands possibility of regret."

- **The young person has a holistic view of what it means to transition and the impact of taking hormones.**

"How well a young person is doing in their life in a broader way. Is there evidence that a young person has been able to meaningfully engage in life whilst presenting in another gender."

"A young person's experience of relationships - friendships as well as romantic/sexual relationships, their sexuality and how they currently identify."

"Plans for the future in relation to gender."

"Able to think to the future about impact on life, relationships, medical care, openness vs secrecy."

"How the young person has responded to hormone blocking treatment."

"That they hope to move toward something rather than/alongside escape from something, e.g. not just trying to escape societal expectations regarding women."

- **Mental health and general stability.**

"Their mental health and if they need/are getting any support."

"[That the child/young person has had] stable and consistent mental health for at least six months."

"Consideration around mood/mental health and if there is any further support needed alongside support from GIDS."

- **A small number of respondents expressed that cross-sex hormones are not safe for adolescents.**

"It's not possible to predict in adolescents who will continue to identify as transgender into adulthood and the risks of harm are profound."

"Adult issues are being 'thought about' with children who simply do not have the emotional development to be able to really think about it all."

Referral for medical intervention

Respondents were asked how they would describe the main purpose of puberty blockers when discussing treatment options with a child/young person.

- **The top responses for the given statements were:**

- To pause puberty to allow further time to explore options (30.3%)
- To alleviate or reduce distress associated with pubertal changes (21.2%)
- The formal start of a transition pathway (9%)

- **Several respondents indicated that there are multiple purposes.**

"I think the puberty blockers main use is more than just one answer. I think it is to firstly pause puberty to allow a young person space to explore whilst hopefully reducing distress associated with the pubertal changes."

"To both pause puberty in younger children and create space for further exploration, and/ or alleviate distress associated with pubertal changes."

- **Several respondents said that it depends on the individual's age and stage of development.**

"This is hard because the answer depends on age and stage of puberty, it would allow further time to explore in perhaps older young people who have mostly been through puberty."

"There isn't one main purpose, it really depends on where a young person is at and what they want. For younger children [it] is to reduce any anxiety about further pubertal changes which can in itself give more time to think - these points go together, they are not separate. For older teenagers many of them want the blocker because it enables them to access hormones, this is a fault with our service pathway as the blocker has very little use to them when they are post puberty."

- **Others said that it is important to understand the young person's expectation of what the blocker will achieve.**

"I think it's much more helpful to explore what the young person and family hope for hormone blockers to achieve so that this can be explored."

"This will be individual to the young person. Providing the young person with an understanding around why other young people may access these pathways could help build understanding. But also acknowledging not all young people access medical pathways, and exploring what they would like and what this would mean to them."

- **Some respondents mentioned the uncertainty around the purpose and impacts of puberty blockers.**

"I speak about the purpose as being the first [statement] but talk about how there is a possibility that going on the blocker may close down thinking for some young people. Note that people who do not take the blocker are less likely to take further physical interventions in the future. I explain how we don't know whether this is because we are only letting the "right" people go on the blocker or whether this is because there is something about the blocker that prevents young people from considering different pathways."

"I'm not actually sure what the purpose of the blocker is for us as a service right now. I would state the potential benefits to young people as being about pausing puberty, preventing further development of sex characteristics (which may prevent further intervention later on), and an experience of being on medical intervention and a medical pathway can also be useful"

Referral for medical intervention

Respondents were asked to describe the most challenging aspect of supporting children and young people in relation to informed consent to puberty blockers.

- **Concerns about the ability of young people to consent to treatments when they may not fully understand the consequences.**

"Assessing competence to make a decision now about something which may have life long future consequences, which are hard for young person to understand or imagine."

"Ensuring that enough information has been provided given that we are drawing from a limited amount of research, especially of long-term effects. And balancing that with how much of a positive difference they can make to some young people."

"Aware of the side effects - like hot flushes, and that the young person may need to be able to leave a class at times to manage hot flushes."

"[There is a] worry that young people can not meaningfully think about what it means to risk their potential for future satisfying sexual relationships and fertility"

- **Difficulties if the child is non-communicative due to distress or other factors.**

"[It] can be challenging if young people have learning difficulties/ASD/high levels of anxiety so say very little in their sessions."

"It can be difficult if young people have additional significant needs that make conversations and assessment of understanding difficult, especially if parents or guardians are unable to support with this."

"[There are] lots of difficulties/challenges when children/young people present as very distressed but are unable to engage in assessment process because of this."

- **A focus on accessing hormone treatment can limit exploration of other options.**

"The expectation from young people and families that this is the one and only answer to the difficulties being experienced. This forces clinicians into a gatekeeping role which obscures the options for exploration and psycho-social support."

"Another challenge is that young people/their parents are usually very focused on accessing the hormone blocker. While we can get informed consent, there is still often little alternative."

"The bind young people find themselves in where they have to both show that they could consider different options and could think about other ways of managing puberty at the same time as demonstrating that they are adequately distressed by puberty."

- **The friction between needing to do a full and complete assessment and a desire to resolve the child/young person's distress quickly.**

"Increased parental anxiety hoping for the assessment to speed up when more space/time is required to explore."

"Often due to distress, young people and [their] parent/carer request the process to be 'quick', however, thorough assessment is required to enable the informed consent to be obtained. Complexity of this can increase when a young person and/or parent/carer is unable to verbally consent/engage in the assessment either due to other complexities or distress - and alternative methods are used/extended time is required = to ensure the young person and/or parent/carer voice is heard and deemed informed."

"The tension between the child's puberty development and processes/waiting lists/assessments which means it is a tightrope of timings."

- **The additional scrutiny decisions around decision to refer for puberty blockers.**

"The process following on from the judicial review has significantly lengthened the process for young people accessing a medical pathway and caused in many cases extreme amounts of distress and for many young people traumatic experiences of going through pubertal changes that has negatively impacted their experience of themselves, their body and overall wellbeing."

"The bureaucracy, scrutiny and challenges of carefully considered and formulated clinical decision making [that] the service and professionals working in it experience, which disadvantages service users of GIDS and people waiting to become service users of GIDS."

- **The impact of external influences/factors.**

"The fact of their life stage - that they are at an adolescent stage of development and therefore forming their identity, of which gender is a major part. Societal pressures to conform to the gender binary, particularly when many are at secondary school. Bullying in the form of name calling."

"There is so much peer pressure. The teens are all comparing themselves and their transitions to that of their peers. It makes it hard for them to think clearly about their individual needs and long-term health I think."

"The most challenging aspect at the moment are the layers of systemic transphobic barriers to care that the young people experience."

"When everyone around you (media, other staff in GIDS, people in the Tavistock etc.) are so anxious and fixated on possible regret. We do not see the level of focus on regret in other areas of medicine, even when the regret rates are known to be much higher. The current media frenzy sometimes makes it hard to think clearly."

About your role

Respondents were asked what would make their role supporting children and young people around their gender identity easier. They were given a number of options and asked to rank the options from most helpful to least helpful. The list of options was constructed from feedback from the primary and secondary professionals' panel (see introduction).

- The top responses were:**

- An increase in wider system capacity.
- Improved service pathway.
- An increase in specialist workforce capacity.
- An increase in clinician's own time/capacity.
- Clear clinical guidelines.

- Respondents indicated a number of other aspects that would make their role easier:**

- A reduction in time spent doing administrative tasks.
- An upskilling of the wider workforce.
- Research into epidemiological changes.
- Consensus on how GIDS works as a service.
- A transformed societal understanding of what gender means.
- Safeguarding in relation to gender.
- Exploratory therapeutic support to be seen as primary intervention.
- To have GIDS clinical work properly valued, respected and supported.
- Removal of the endocrine pathway.

- Additional comments made included:**

"To have GIDS clinical work properly valued, respected and supported."

"I don't think we need more staff, I think we need consensus as a service on how we work, what we offer and why, and clearer guidelines. As well as reduced case/workloads so we have time for the thought and reflection this work requires"

"We need to increase capacity. Fiddling about with the waiting list or making referral criteria is not the way to approach this. We are massively under resourced. Either invest properly in specialist services. Or open up the protocols to ensure treatment pathways, including endocrinology, can be accessed via primary and secondary care."

About your role

Respondents were asked, in their professional interaction supporting children and young people around their gender identity, on which of the following areas would it be helpful to have more information to guide their thinking on appropriate care/management – respondents could tick multiple answers. The list of options was constructed from feedback from the primary and secondary professionals' panel (see introduction).

- **The top responses were:**

- Evidence base around the use of medication.
- Evidence base around other interventions.
- Information/training on development of identity.
- The consent framework.

- **Respondents indicated a number of other aspects where more information would be useful:**

- How people develop an understanding about their relationship to their body.
- Training in the induction about gender affirming hormones/puberty blockers and their mode of action.
- Safeguarding in relation to gender.
- Ethics.
- Sexuality, detransitioners/long term outcomes.
- Long term studies with follow-ups of psychological/psychotherapeutic work with young people who presented with gender dysphoria.
- Working effectively with neurodiverse and Autistic people who are also gender diverse.

- **Additional comments included:**

"I believe all of the above are in place already. Improvement and ease of access, including clinicians' capacity to review and continued professional development inclusive of the above would be beneficial for all disciplines."

"It is not really a question of more information. It is more a question of creating a climate in which different therapeutic approaches can be discussed and developed without fear of vilification, legal action or complaints being brought. I believe the Cass review has a role to play here."

"I think we do have a lot of the above already. I am not clear about what 'other interventions' refers to, do you mean how safe binding is, or how useful psychosocial support is?"

General comments

Respondents were invited to add any further comments about services for children and young people needing support around their gender identity.

• Thoughts on the current service.

"It's been a tough few years in our service and young trans people are the ones who have suffered in terms of treatment being halted and huge waiting lists."

"The [GIDS] team offer a very unique service and that it is impossible to compare it to another service within this country, therefore it is very hard to review its success or its failures. That staff shortages should be looked at as a priority and recruitment and retention drives [should] be at the centre of change and also ensuring training is available. The image of GIDS to the wider arena may need to change for this to happen."

"I really enjoy working at GIDS- I like working with the client group and their families, I like working with my colleagues."

"We are drowning in paperwork at GIDS and overwhelmed with high caseloads of increasingly complex young people... It is no wonder people have left GIDS in droves. If many more people leave there won't be enough expertise to manage the current patient numbers and certainly no capacity to train newly hired staff- so the waiting list will remain in the dire state it's currently in."

"I feel disheartened and disappointed by the long waiting lists and the fact that these young people are not receiving the support they so desperately need in a timely manner."

"There continues to be a climate of fear and intimidation when discussing the issues connected to children and adolescents who identify as transgender. Our profession needs support or some kind of intervention that enables Clinical Psychologists to think and speak freely about our professional experiences, theories and concerns."

• Thoughts on a future service model.

"With the current numbers, the model of a single national service that treats this matter as a 'specialist service' is no longer sustainable. After more than 5 years working at GIDS, I have come to the conclusion that the matters needs to be addressed locally through CAMHS and other TIER 2-3 services, in the context of the other difficulties that these young people inevitably experience. We have to face this is no longer a specialist issue, but a wide-spread experience amongst young people, and local services should be equipped to address this as such."

"I think that services should be completely overhauled and the focus should be on reduction of waiting times."

"In my previous role at CAMHS I was attempting to set up a specific pathway at a local level as I felt it was very much needed. I still do."

"We need to maintain our clinical excellence and develop it further on all fronts. We also need to be able to offer more psycho-social interventions alongside the known medical interventions."

• Thoughts on pathway options.

"Differentiation of pathways within GIDS for [different] age groups, different associated difficulties (LD/ASC/MH) and a differentiation for those AMAB [assigned male at birth] and AFAB [assigned female at birth] would be beneficial - especially in the case of AMAB where stigma, safety and risk in wider society are most problematic."

"I believe there should be a range of therapeutic and medical options for young people, including psychological therapy for gender diverse young people, and non-blocker pathways for those who have completed puberty."

"To be able to offer a non-blocker pathway to the older adolescents. Lots of older trans boys want the blocker so they can have [testosterone], it has very little physical benefit to them but can result in side effects. It is more ethical to offer them a non-blocker pathway."

"I think the main thing that is needed over and above everything is a clear pathway for young people to be offered meaningful psychological therapy in order to explore what is going on. Currently we offer people physical interventions or very sporadic sessions... I feel that we are failing these young people by not at least offering this as an option."

"I believe there should be more specific provision for 17-20 year olds who are often lost in the gap between children and adult services."

The Review is grateful to all the participants for sharing their time and expertise and for their thoughtful consideration in responding to the survey.

The Review will build on the work undertaken and, alongside our academic research, will continue with a programme of engagement with professionals, service users and their families, which will help to further develop the evidence base.

JOURNAL

Entry 7 – Research

July 28, 2022

Hilary Cass (<https://cass.independent-review.uk/author/hilary-cass/>).

“

Without data, you're just another person with an opinion.”

W. Edwards Deming

Last week I sent a **[letter to NHS England](https://cass.independent-review.uk/publications/)** (<https://cass.independent-review.uk/publications/>), expanding on the advice in my interim report, and giving more detail about the proposed new regionalised model of care for children and young people questioning their gender identity or experiencing gender related distress. I recognise that it will take time before the staff and structures of the proposed regional services are in place. More immediately, I know that NHS England is setting in place interim arrangements to ensure the continuity and safety of current services.

NHS England also asked for advice on how to address the gaps in the evidence base that were flagged in my interim report, and I want to say a little more about that here.

I have explained previously the three components of the research commissioned by the Review: a comprehensive literature review focused on the questions that were set out in our terms of reference from NHS England; a qualitative study to understand more about the experiences of service users, parents and carers, and professionals, including young adults up to age 30; and a quantitative study to try and fill some of the gaps in follow-up data for the approximately 9,000 young people who have been through the Gender Identity Development Service (GIDS), many of whom are now adults.

Over the last few weeks, I have been concerned about the distress generated by the laying of the statutory instrument (SI) which was required before the proposed quantitative study commissioned by the Review could be considered by the Research Ethics Committee (REC) and the Confidentiality Advisory Group (CAG). Unfortunately, there was a lot of misinformation about both the purpose of the SI and of the research itself. Concern was also expressed that the research might not be subject to the proper ethical scrutiny and approval processes. During the last month we have had discussions with members of the community and advocacy groups to address the questions that have been raised about this. The most important points to share are that:

- The purpose of the research study is to understand the range of service use and outcomes of young people who have been through the GIDS, and there will be involvement of service users in interpreting any data that is generated.
- We were unfortunately not able to discuss the SI in advance because it was Department of Health and Social Care policy in development; however, our webpages now give detailed information about the reasons for the SI, the protection of data, and the very tight limitations on access and use.
- The research will go through all normal ethical and research approvals, and no records will be accessed until and unless those approvals are received.

- Subject to approval from REC and CAG the full protocol will be published on our website along with details about how you can opt out of the study should you wish to do so.

Fuller details can be found on our [research pages](#)

(<https://cass.independent-review.uk/cass-review-quantitative-research/>).

Obviously looking at pre-existing data (retrospective research) is never as good as planning research going forward (prospective research); in prospective studies it is much easier to agree the research questions, involve service users in designing the studies, obtain consent and collect the necessary data. In my letter to NHS England I have highlighted some of the questions that we need to address prospectively and have emphasised the collaborative work that will need to be undertaken to incorporate these into a comprehensive research programme.

As Edward Deming said, “*scientific data are not taken for museum purposes; they are taken as a basis for doing something.*” Improving the level and quality of evidence will enable young people seeking NHS support, their families and carers, and clinicians to have better information to help them determine the best support and interventions for them as individuals.

Hilary Cass (<https://cass.independent-review.uk/author/hilary-cass/>).

“

Medicine is the science of uncertainty and the art of probability”

William Osler

There has been wide-spread reporting of NHS England’s decision to establish two early adopter services and as a result bring the contract for the Gender Identity Development Service (GIDS) at the Tavistock and Portman clinic to a managed close next Spring. Within this coverage I feel that some of the detail about the key components of the future regionalised service delivery model, that I set out in my [latest advice to NHS England](https://cass.independent-review.uk/publications/) (<https://cass.independent-review.uk/publications/>), has sometimes been overlooked.

Medicine is a science of uncertainty in a world where we all want clarity and black and white answers. In medicine, when there is controversy or doubt about treatment decisions, the immediate reaction is to blame individuals, and sometimes organisations. However, the most important

way to reduce risk, improve decision-making and manage uncertainty is through safe systems. The purpose of my Review is to be forward-looking and define what a safe system of care should look like, and how to support that care with the best evidence.

In my interim report I said that a single specialist provider model is not a safe or viable long-term option in view of concerns about lack of peer review and the ability to respond to the increasing demand. The purpose of the regionalised model is to improve access, networked care, research capacity and workforce development.

I have previously said that the care of gender-questioning children and young people needs to be everyone's business, with responsibility taken throughout the health system rather than resting solely with a small expert workforce. The staff working at GIDS have demonstrated compassion and a strong professional commitment towards their patient population. Their experience and continued engagement will be essential in ensuring a smooth progression to the new service model. At the same time, we need to encourage, grow and develop the future workforce that will be key to the delivery of regionalised services.

This challenge is not unique to the NHS; speaking to colleagues in Finland, they describe a similar picture. When they opened their tertiary level gender identity service, others were reluctant or did not feel they had the capability to work with individuals with gender identity issues. Across schools, social services and local children's mental health services, staff did not feel that they had sufficient knowledge or expertise to explore gender identity or even address other issues that these young people might be struggling with. I am told that this has now changed completely; other professionals recognise that it is not helpful to exceptionalise gender identity issues, and that they have the transferrable skills to work in this area. There are useful lessons that we can take from their experiences.

The regionalised services that I have described will be direct service providers, assessing and treating children and young people who may

need specialist care, as part of a wider pathway. Alongside this, the regional centres will support networks of designated local services, in what is known in the NHS as an Operational Delivery Network (ODN). I have set out the functions of an ODN in my letter. This model will give the opportunity to provide targeted training, upskilling and additional staffing to a more manageable number of centres within a geography. For children and young people, this will mean improved access to services with flexible pathways that better respond to their individual needs.

Advancement in medicine is all about reducing uncertainty and risk through research, clinical experience, peer review and clinical networks. I have advised that the regional centres should also come together to form a national provider collaborative to ensure consistency of standards and data collection across all providers, as well as providing opportunities for peer review and a forum for discussion of complex cases and/or decisions about medical care. This will mean that whichever centre a young person attends they can expect the same standard of care and better information upon which to base their decisions.

There is still a lot of work to do in addition to the ongoing research programme, which I spoke about in my [previous journal entry](https://cass.independent-review.uk/entry-7-research/) (<https://cass.independent-review.uk/entry-7-research/>). I have always been clear that the Review will be an iterative process and that we will release information and advice when it becomes available so that improvement work can begin as soon as there is a clear direction of travel. I am pleased that NHS England has taken on board the Review's advice to date and has set out the [interim arrangements](https://www.england.nhs.uk/commissioning/spec-services/npc-crg/gender-dysphoria-clinical-programme/implementing-advice-from-the-cass-review/) (<https://www.england.nhs.uk/commissioning/spec-services/npc-crg/gender-dysphoria-clinical-programme/implementing-advice-from-the-cass-review/>) being put in place to move towards the new delivery model. We will continue to work with them and all our stakeholders as the longer-term service model is established.

LETTER TO THE EDITOR

Puberty blockers for gender dysphoric youth: A lack of sound science

Dear Editor,

The medical transition of children and adolescents with gender dysphoria remains highly debated and there is significant divergence in policy internationally.¹⁻⁷ Mills and colleagues' review the interventions that comprise the "gender-affirmative" care pathway, an approach currently promoted by many medical organizations in North America.⁶⁻⁸ We strongly agree with the authors that pharmacists have a responsibility to "understand the evidence," and "place the well-being of the patient over any personal cultural beliefs."⁸ However, we think the use of evidence to support the authors' claim that gonadotropin releasing hormone (GnRH)-analogs are fully reversible and have been shown to improve mental health, requires critical appraisal.

GnRH-analogs have been used for decades to successfully delay the *early* onset of puberty in children with precocious puberty.⁹ While generally considered safe for this indication, recent concern about impacts on polycystic ovarian disease, metabolic syndrome, and future bone density, have been raised.¹⁰ Even less is known about the use of GnRH-analogs to halt *normally* timed puberty in youth with gender dysphoria; no long-term, longitudinal studies of GnRH-analogs for this indication exist.

Puberty-related hormones have wide ranging effects on brain structure, function, and connectivity.¹¹ Concerns have been raised that hormonal suppression of puberty may permanently alter neurodevelopment.^{2,11-13} The possible impact of puberty blockade on a young person's cognition has important implications for the decision to initiate exogenous cross-sex hormones and the capacity to give informed consent.¹⁴ Moreover, it has been suggested that pubertal suppression may alter the course of gender identity development, essentially "locking in" a gender identity that may have reconciled with biological sex during the natural course of puberty.¹³ Over 95% of youth treated with GnRH-analogs go on to receive cross-sex hormones.¹⁵ By contrast, 61-98% of those managed with psychological support alone reconcile their gender identity with their biological sex during puberty.¹⁶⁻¹⁸ This lack of evidence to support the durability of a transgender identification is conceptually consistent with significant psychosocial determinants of cross-sex identity, while the belief in immutable biological influences can best be described as a "current hypothesis."¹⁹

There are also concerns that GnRH-analogs may have irreversible effects on sexual function and bone development. In some youth

pubertal blockade at Tanner stage 2 followed by exogenous cross-sex hormones has resulted in a complete absence of adult sexual function.²⁰ Profound effects on future sexual function may even occur when puberty is paused and later allowed to proceed, since the precise timing of hormone exposure during the peripubertal window is a determinative factor in adult sexual function.²¹ Finally, several studies have found that the expected pattern of bone mass accrual during adolescence does not occur when puberty is halted.²²⁻²⁵ The long-term clinical consequences of failure to accrue normal bone mass are unknown.

Uncertainties about long-term risks of medical transition are often overshadowed by the most potent argument provided by advocates of the affirmative model: failure to affirm a young person's transgender identity may result in suicide. Suicidal ideation and self-harming behaviors have been found to be higher than age-matched peers, but comparable to nongender dysphoric youth referred for management of other mental health diagnoses.²⁶ However, the relevant question is whether affirmative care reduces suicide risk. Mills and colleagues assertion that GnRH-analogs have been shown to decrease lifetime suicidal ideation stems from a nonrepresentative, low-quality survey of transgender adults that has been thoroughly critiqued by others.^{27,28} Moreover, their claim that these drugs are effective for other mental health outcomes is at odds with recent systematic reviews that concluded there is little change from baseline to follow-up in depression, anxiety, body image, gender dysphoria, or psychosocial functioning.^{2,12,29} A seminal Dutch case-series of children with early-onset gender dysphoria is cited to support the assertion that GnRH-analogs improve psychological functioning.¹⁵ The magnitude of posttreatment improvement in mental health outcomes in this study was small and of questionable clinical significance. Furthermore, the applicability of results to the most common demographic presenting today, that is, adolescent females with pre-existing mental health problems or neurodevelopmental conditions and no prior history of gender dysphoria, is questionable.^{4,30} A recent attempt to replicate the results of the Dutch study in the United Kingdom found no psychological benefit with GnRH-analogs, but treatment was associated with adverse effects on bone development.³¹

Multiple European countries that were pioneers in youth medical transition are now adopting a more cautious approach to the use of

GnRH-analogs and cross-sex hormones after their own evidence reviews failed to show mental health benefits and highlighted a profound lack of knowledge about harms. The UK's Cass review emphasized the paucity of data in their interim report stating, "it is important that it is not assumed that outcomes for, and side effects in, children treated for precocious puberty will necessarily be the same in children or young people with gender dysphoria."¹³ The NHS updated guidance on treatment of gender dysphoria removed statements about the reversibility of GnRH-analogs and now states, "little is known about the long-term side effects of hormone or puberty blockers in children with gender dysphoria."⁴ The Swedish Health Authority no longer offers GnRH-analogs to minors except in exceptional cases stating, "the risks of puberty suppressing treatment with GnRH-analogues and gender affirming hormonal treatment currently outweigh the possible benefits."³ Finland has severely restricted their use and now recommend psychotherapy as first-line treatment for gender-dysphoric youth.² Lastly, the French Académie Nationale de Médecine recently issued a press release stating, "great medical caution must be taken in children and adolescents, given the vulnerability, particularly psychological, of this population and the many undesirable effects, and even serious complications, that some of the available therapies can cause."⁵ Although puberty-blockers and cross-sex hormones will still be available, the Académie emphasized, "the greatest reserve is required in their use, given side effects such as impact on growth, bone fragility, risk of sterility, emotional and intellectual consequences and, for girls, symptoms reminiscent of menopause."⁵

In summary, we believe the authors' review does not present a balanced assessment of the evidence and betrays a bias toward uncritically promoting medical transition. The widespread methodological weaknesses in the research coupled with the lack of certainty that benefits outweigh harms, should raise questions about affirmation being positioned as the "standard of care" in the United States and Canada.²⁹ Patients and their families rely on pharmacists to resist ideological influence and communicate transparently. To this end, we call on Mills and colleagues to revisit their important review and provide a more nuanced discussion of the evidentiary basis for gender-affirming care.

Scott Newgent

On 2/9/21 at 7:30 AM EST

I am a 48-year-old transgender man. I was thrilled when the medical community told me six years ago that I could change from a woman to a man. I was informed about all the wonderful things that would happen due to medical transition, but all the negatives were glossed over. Since then, I have suffered tremendously, including seven surgeries, a pulmonary embolism, an induced stress heart attack, sepsis, a 17-month recurring infection, 16 rounds of antibiotics, three weeks of daily IV antibiotics, arm reconstructive surgery, lung, heart and bladder damage, insomnia, hallucinations, PTSD, [\\$1 million](#) in medical expenses, and loss of home, car, career and marriage. All this, and yet I cannot sue the surgeon responsible—in part because there is no structured, tested or widely accepted baseline for transgender health care.

Read that again: *There is no structured, tested, or widely accepted baseline for transgender health care.* Not for 42-year-olds, and not for the many minors embarking on medical transition in record numbers. It is not transphobic or discriminatory to discuss this—we as a society need to fully understand what we are encouraging our children to do to their bodies.

Throughout transition, I second-guessed my decisions, but each counseling session and doctor's appointment amounted to one more push convincing me I could be cured of being born in the wrong body. The truth was that I didn't fit in as a dominant, aggressive, assertive lesbian. The dream of finally fitting in dangled like a carrot: The idea that I could fit in catapulted me to a time much like adolescence, with its drive for acceptance, inclusive peers and the fantasy of being normal.

During my post-operation 17 months of sheer survival, I discovered that transgender health care is experimental and that large swaths of the medical industry encourage minors to transition due, at least in part, to [fat profit margins](#). I was gobsmacked. Each day I researched more and became increasingly appalled. As I jumped from ER to ER desperately seeking help, I realized that nobody knew what to do. Each physician told me to return to the original surgeon. I was trapped like a child with an abusive parent.

My recurring bladder infection not only demolished my body; it started to ravage my mind, too. I stopped being able to problem-solve, and then lost my health insurance when I couldn't work. I spent many nights in the bathroom in too much pain to even make it to the toilet, forced to

urinate on the floor, screaming as what felt like razor blades left my body. Rest came only in 45-minute increments that I induced with four shots of vodka, six Benadryl pills and a handful of melatonin—with only sleep-deprived hallucinations for my trouble.

One night I simply couldn't take it. I wanted to die. I crawled to bed and had another hallucination. My children's lives flashed before my eyes, and I saw the devastation my death would cause them. Right then, I made a deal with God, the universe, whatever you call it, that if my life were spared, if I were allowed to be here for my kids, I would help other kids by ensuring people knew what the experimentation of transgender health care really entails. I remember my whimpers: "God, an eye for an eye—in reverse. I will fight with a mother's passion for others if I can be here for my kids."

So here I am, a trans man, sifting through my good and bad decisions, and for the first time embracing who I am—what I have created, and the life I now lead. It took me 48 years to realize I transitioned because I never wholeheartedly accepted being a lesbian. Our children don't have a prayer to embrace the reality of something it takes a lifetime to understand. That's *our job*, as parents: to protect them from foolish, lifelong mistakes.

Here's what I could not comprehend before transitioning and what I honestly believe no child is capable of consenting to:

- [Decreased life expectancy](#)
- [Increased risk of premature death from heart attacks and pulmonary embolisms](#)
- [Bone damage](#)
- [Possible liver damage](#)
- [Increased mental health complications](#)
- [Increased chances of mood-syndrome symptoms](#)
- [Higher suicide rates than non-trans population](#)
- [12 percent higher chance than non-trans population to develop symptoms of psychosis](#)
- [Chance of stunted brain development](#)
- [Much reduced chance for lifelong sexual pleasure](#)
- [Higher chance of sterility and infertility](#)
- [No improved mental health outcomes](#)
- [Not completely reversible](#)

Trans activists tout studies that say medically transitioning gender-questioning children improves mental health. But those studies have often been [retracted](#) (and those retractions underreported by the media).

Transgender rights activists in New York City in 2018 Drew Angerer/Getty Images

Moreover, no *long-term* studies have been conducted on children who grow up without the benefit of natural puberty. No studies at all have been done on de-transitioners (people who return to identifying as their natal sex). What are the psychological effects? No one has a clue, and researchers are too often [shut down by cancel culture](#) for even raising the questions.

Peer-reviewed studies show a shocking correlation between gender dysphoria and [autism](#), depression, anxiety, eating disorders and [other co-morbidities](#). Additionally, it seems that many of these children are simply [gay](#). Could pushing people on a one-way path to medical transition be a different form of "conversion therapy?" We need to ask and study these hard questions—for the good of all children. But we're not—not in the mainstream media, and certainly not in President [Joe Biden](#)'s new administration.

America is proceeding down its path of total affirmation just as other countries are restoring greater balance. This past December, [the U.K. High Court of Justice](#) ruled that puberty blockers for minors are both experimental and a one-way ticket to permanent transition. [Finland](#) in 2020 completely overhauled its approach to treating minors with gender dysphoria, prioritizing psychotherapeutic non-invasive interventions and recognizing adolescence as a time of major identity exploration. [Sweden](#) is conducting a systematic literature review of the scientific basis of the long-term effects on physical and mental health of puberty blockers and hormones. The researcher who championed the "[Dutch protocol](#)" recently called [for a rethink](#), while other research is beginning to show that [the current one-size-fits-all status quo](#) is too limited.

So if we are now waking up to the fact that gender dysphoria is over-simplistically [conflated](#) with transgenderism, medical treatments have understudied long-term consequences, some are getting rich off transgender medicine and [de-transitioners](#) are speaking up in skyrocketing numbers, why are we only making it *easier* for children to unquestioningly transition?

We now have the obligation to work together to slow trans medicalization of minors until they are adults and have the capacity to truly understand the lifelong consequences of transitioning. As a former lesbian and current trans man, I maintain this is *not* transphobic. It is actually sensitive and caring to recognize that not just one treatment or pathway is right for all kids.

Therefore, I am currently building a bipartisan army to protect our children, hold the medical industry accountable and educate our president and the rest of society about the dangers of transgender extremism. We must throw our differences aside for a moment; I promise you, once children are safe, we can resume fighting. But until children are safe, nothing else matters.

So, endocrinologists and pediatricians, moderate [Democrats](#) and moderate [Republicans](#), radical feminists and evangelicals, lawyers and psychologists, parents and teachers: My hand is out. I will grab yours and turn down no one. Together, we can build a circle around our most precious resource: our children. Help me fulfill the promise I made on the night I almost gave up, to be here for my children—and now yours. Who's with me?

What I wish I'd known when I was 19 and had sex reassignment surgery

Corinna Cohn, Washington Post

<https://www.washingtonpost.com/opinions/2022/04/11/i-was-too-young-to-decide-about-transgender-surgery-at-nineteen/>

By Corinna Cohn

April 11, 2022 at 1:05 p.m. EDT

Corinna Cohn, a software developer in Indianapolis, is an officer in the Gender Care Consumer Advocacy Network.

When I was 19, I had surgery for sex reassignment, or what is now called gender affirmation surgery. The callow young man who was obsessed with transitioning to womanhood could not have imagined reaching middle age. But now I'm closer to 50, keeping a watchful eye on my 401(k), and dieting and exercising in the hope that I'll have a healthy retirement.

In terms of my priorities and interests today, that younger incarnation of myself might as well have been a different person — yet that was the person who committed me to a lifetime set apart from my peers.

There is much debate today about transgender treatment, especially for young people. Others might feel differently about their choices, but I know now that I wasn't old enough to make that decision. Given the strong cultural forces today casting a benign light on these matters, I thought it might be helpful for young people, and their parents, to hear what I wish I had known.

I once believed that I would be more successful finding love as a woman than as a man, but in truth, few straight men are interested in having a physical relationship with a person who was born the same sex as them. In high school, when I experienced crushes on my male classmates, I believed that the only way those feelings could be requited was if I altered my body.

It turned out that several of those crushes were also gay. If I had confessed my interest, what might have developed? Alas, the rampant homophobia in my school during the AIDS crisis smothered any such notions. Today, I have resigned myself to never finding a partner. That's tough to admit, but it's the healthiest thing I can do.

As a teenager, I was repelled by the thought of having biological children, but in my vision of the adult future, I imagined marrying a man and adopting a child. It was easy to sacrifice my ability to reproduce in pursuit of fulfilling my dream. Years later, I was surprised by the pangs I felt as my friends and younger sister started families of their own.

The sacrifices I made seemed irrelevant to the teenager I was: someone with gender dysphoria, yes, but also anxiety and depression. The most severe cause of dread came from my own body. I was not prepared for puberty, nor for the strong sexual drive typical for my age and sex.

Surgery unshackled me from my body's urges, but the destruction of my gonads introduced a different type of bondage. From the day of my surgery, I became a medical patient and will remain one for the rest of my life. I must choose between the risks of taking exogenous estrogen, which [include](#) venous thromboembolism and stroke, or the risks of taking nothing, which includes [degeneration](#) of bone health. In either case, my [risk of dementia](#) is higher, a side effect of eschewing testosterone.

What was I seeking for my sacrifice? A feeling of wholeness and perfection. I was still a virgin when I went in for surgery. I mistakenly believed that this made my choice more serious and authentic. I chose an irreversible change before I'd even begun to understand my sexuality. The surgeon deemed my operation a good outcome, but intercourse never became pleasurable. When I tell friends, they're saddened by the loss, but it's abstract to me — I cannot grieve the absence of a thing I've never had.

The Equality Act is a positive step forward for the LGBTQ community. But it came with swift backlash from conservative lawmakers. (Video: Monica Rodman, Sarah Hashemi/The Washington Post)

Where were my parents in all this? They were aware of what I was doing, but by that point, I had pushed them out of my life. I didn't need parents questioning me or establishing realistic expectations — especially when I found all I needed online. In the early 1990s, something called Internet Relay Chat, a rudimentary online forum, allowed me to meet like-minded strangers who offered an inexhaustible source of validation and acceptance.

I shudder to think of how distorting today's social media is for confused teenagers. I'm also alarmed by how readily authority figures facilitate transition. I had to persuade two therapists, an endocrinologist and a surgeon to give me what I wanted. None of them were under crushing professional pressure, as they now would be, to "affirm" my choice.

I may well have transitioned even after waiting a few years. If I hadn't transitioned, I likely would have suffered from the world in other ways. In other words, I'm still working out how much regret to feel, but I'm comfortable with the ambiguity.

What advice would I pass on to young people seeking transition? Learning to fit in your body is a common struggle. Fad diets, body-shaping clothing and cosmetic surgery are all signs that countless millions of people at some point have a hard time accepting their own reflection. The prospect of sex can be intimidating. But sex is essential in healthy relationships. Give it a chance before permanently altering your body.

Most of all, slow down. You may yet decide to make the change. But if you explore the world by inhabiting your body as it is, perhaps you'll find that you love it more than you thought possible.

Keira Bell: My Story

Keira Bell, Persuasion

<https://www.persuasion.community/p/keira-bell-my-story>

As a teen, she transitioned to male but came to regret it. Here's how it felt to enter history in the trans debate.

[Keira Bell](#)

Apr 7, 2021

After a landmark court ruling in December, the name “Keira Bell” was cited worldwide, admiringly by some, with hostility by others. (Photo: Paul Cooper/Shutterstock)

By Keira Bell

From the earliest days, my home life was unhappy. My parents—a white Englishwoman and a black American who got together while he was in Britain with the U.S. Air Force—divorced when I was about 5. My mother, who was on welfare, descended into alcoholism and mental illness. Although my father remained in England, he was emotionally distant to me and my younger sister.

I was a classic tomboy, which was one of the healthier parts of my early life in Letchworth, a town of about 30,000 people, an hour outside London. Early in childhood, I was accepted by the boys—I dressed in typically boy clothing and was athletic. I never had an issue with my gender; it wasn't on my mind.

(Courtesy: Keira Bell)

Then puberty hit, and everything changed for the worse. A lot of teenagers, especially girls, have a hard time with puberty, but I didn't know this. I thought I was the only one who hated how my hips and breasts were growing. Then my periods started, and they were disabling. I was often in pain and drained of energy.

Also, I could no longer pass as “one of the boys,” so lost my community of male friends. But I didn’t feel I really belonged with the girls either. My mother’s alcoholism had gotten so bad that I didn’t want to bring friends home. Eventually, I had no friends to invite. I became more alienated and solitary. I had been moving a lot too, and I had to start over at different schools, which compounded my problems.

By the time I was 14, I was severely depressed and had given up: I stopped going to school; I stopped going outside. I just stayed in my room, avoiding my mother, playing video games, getting lost in my favorite music, and surfing the internet.

Something else was happening: I became attracted to girls. I had never had a positive association with the term “lesbian” or the idea that two girls could be in a relationship. This made me wonder if there was something inherently wrong with me. Around this time, out of the blue, my mother asked if I wanted to be a boy, something that hadn’t even crossed my mind. I then found some websites about females transitioning to male. Shortly after, I moved in with my father and his then-partner. She asked me the same question my mother had. I told her that I thought I was a boy and that I wanted to become one.

As I look back, I see how everything led me to conclude it would be best if I stopped becoming a woman. My thinking was that, if I took hormones, I’d grow taller and wouldn’t look much different from biological men.

I began seeing a psychologist through the National Health Service, or NHS. When I was 15—because I kept insisting that I wanted to be a boy—I was referred to the Gender Identity Development Service, at the Tavistock and Portman clinic in London. There, I was diagnosed with gender dysphoria, which is psychological distress because of a mismatch between your biological sex and your perceived gender identity.

By the time I got to the Tavistock, I was adamant that I needed to transition. It was the kind of brash assertion that’s typical of teenagers. What was really going on was that I was a girl insecure in my body who had experienced parental abandonment, felt alienated from my peers, suffered from anxiety and depression, and struggled with my sexual orientation.

After a series of superficial conversations with social workers, I was put on puberty blockers at age 16. A year later, I was receiving testosterone shots. When 20, I had a double mastectomy. By then, I appeared to have a more masculine build, as well as a man’s voice, a man’s beard, and a man’s name: Quincy, after Quincy Jones.

(Courtesy: Keira Bell)

But the further my transition went, the more I realized that I wasn't a man, and never would be. We are told these days that when someone presents with gender dysphoria, this reflects a person's "real" or "true" self, that the desire to change genders is set. But this was not the case for me. As I matured, I recognized that gender dysphoria was a symptom of my overall misery, not its cause.

Five years after beginning my medical transition to becoming male, I began the process of detransitioning. A lot of trans men talk about how you can't cry with a high dose of testosterone in your body, and this affected me too: I couldn't release my emotions. One of the first signs that

I was becoming Keira again was that—thankfully, at last—I was able to cry. And I had a lot to cry about.

The consequences of what happened to me have been profound: possible infertility, loss of my breasts and inability to breastfeed, atrophied genitals, a permanently changed voice, facial hair. When I was seen at the Tavistock clinic, I had so many issues that it was comforting to think I really had only one that needed solving: I was a male in a female body. But it was the job of the professionals to consider all my co-morbidities, not just to affirm my naïve hope that everything could be solved with hormones and surgery.

Last year, I became a claimant against the Tavistock and Portman NHS Foundation Trust in a judicial-review case, which allows petitioners in Britain to bring action against a public body they deem to have violated its legal duties. Few judicial reviews get [anywhere](#); only a fraction obtain a full hearing. But ours did, with a panel of three High Court judges considering whether youths under treatment at the clinic could meaningfully consent to such medical interventions.

Bell in January 2020, after she brought legal action against the clinic. (Photo: Sam Tobin/PA Wire)

My team argued that the Tavistock had failed to protect young patients who sought its services, and that—instead of careful, individualized treatment—the clinic had conducted what amounted to uncontrolled experiments on us. Last December, we won [a unanimous verdict](#). The judges expressed serious doubts that the clinic's youngest patients could understand the implications of what amounted to experimental treatment with life-altering outcomes.

In their ruling, the judges repeatedly expressed surprise at what had been going on at the Tavistock, particularly its failure to gather basic data on its patients. They noted the lack of evidence for putting children as young as 10 years old on drugs to block puberty, a treatment that is [almost universally followed](#) by cross-sex hormones, which must be taken for life to maintain the transition. They also had concerns about the lack of follow-up data, given “the experimental nature of the treatment and the profound impact that it has.”

Notably, a growing wave of girls has been seeking treatment for gender dysphoria. In 2009-10, [77 children](#) were referred to the Gender Identity Development Service, 52% of whom were boys. That ratio started to reverse a few years later as the overall number of referrals soared. In England in [2018-19](#), 624 boys were referred and 1,740 girls, or 74% of the total. Over half of referrals were for those aged 14 or under; some were as young as 3 years old. The court noted the practitioners at the Tavistock did not put forward “any clinical explanation” for the dramatic rise in girls, and expressed surprise at its failure to collate data on the age of patients when they began puberty blockers.

The ruling does not completely prevent a minor from beginning a medical transition. But the judges recommended that doctors consider getting court permission before starting such treatment for those 16 to 17; they concluded it was “very doubtful” that patients aged 14 and 15 could have sufficient understanding of the consequences of the treatment to give consent; and that it was “highly unlikely” for those aged 13 and under.

In response, [the NHS said](#) that the Tavistock had “immediately suspended new referrals for puberty blockers and cross-sex hormones for the under-16s, which in future will only be permitted where a court specifically authorizes it.” The Tavistock appealed the ruling, and the court will hear its appeal in June.

The puberty blockers that I received at 16 were designed to stop my sexual maturation: The idea was that this would give me a “pause” to think about whether I wanted to continue to a further gender transition. This so-called “pause” put me into what felt like menopause, with hot flushes, night sweats, and brain fog. All this made it more difficult to think clearly about what I should do.

By the end of a year of this treatment, when I was presented with the option of moving on to testosterone, I jumped at it—I wanted to feel like a young man, not an old woman. I was eager for the shots to start, and the changes this would bring. At first, the testosterone gave me a big boost in confidence. One of the earliest effects was that my voice dropped, which made me feel more commanding.

Over the next couple of years, my voice deepened further, my beard came in, and my fat redistributed. I continued to wear my breast binder every day, especially now that I was completely passing as male, but it was painful and obstructed my breathing. By the time I was 20, I was being treated at the adult clinic. The testosterone and the binder affected the

appearance of my breasts, and I hated them even more. I also wanted to align my face and my body, so got a referral for a double mastectomy.

My relationship with my parents continued to be difficult. I was no longer speaking to my mother. My father had kicked me out of his apartment shortly after I turned 17, and I went to live in a youth hostel. He and I were still in touch, though he was adamantly opposed to my transition. Reluctantly, he took me for the surgery. I was a legal adult when it took place, and I don't relieve myself of responsibility. But I had been put on a pathway—puberty blockers to testosterone to surgery—when I was a troubled teen. As a result of the surgery, there's nerve damage to my chest, and I don't have sensation the way I used to. If I am able to have children, I will never breastfeed them.

Around the end of that first year post-surgery, something started happening: My brain was maturing. I thought about how I'd gotten where I was, and gave myself questions to contemplate. A big one was: "What makes me a man?"

I started realizing how many flaws there had been in my thought process, and how they had interacted with claims about gender that are increasingly found in the larger culture and that have been adopted at the Tavistock. I remembered my idea as a 14-year-old, that hormones and surgery would turn me into someone who appeared to be a man. Now, I was that person. But I recognized that I was very physically different from men. Living as a trans man helped me acknowledge that I was still a woman.

I also started to see what I was living out was based on stereotypes, that I was trying to assume the narrow identity of "masculine guy." It was all making less and less sense. I was also concerned about the effect my transition would have on my ability to find a sexual partner.

Then there was the fact that no one really knew the long-term effects of the treatment. For instance, the puberty blockers and testosterone caused me to have to deal with [vaginal atrophy](#), a thinning and fragility of the vaginal walls that normally occurs after menopause. I started feeling really bad about myself again.

I decided to stop, cold turkey. When I was due for my next testosterone shot, I canceled the appointment.

After I came to this decision, I found a subreddit for detransitioners. The number of people on it started rising, as if all these young women had come to a collective realization of the medical scandal we had been a part of. It was a place we could talk about our experiences and support each other. I felt liberated.

What happened to me is happening across the Western world. Little of my case was a surprise to those paying attention to the Tavistock whistle-blowers who in recent years have [spoken out](#) in alarm to the media, sometimes anonymously. Some have [left the service](#) because

of these concerns. But the transgender issue is now highly political and wrapped up in questions of identity politics. It can be perilous to raise questions or doubts about young people's medical gender transitions. Some who have done so have been vilified and had their careers threatened.

At the Tavistock, practitioners provide "gender affirmative care"—in practice, this means that when children and teens declare a desire to transition, their assertions are typically accepted as conclusive. Affirmative care is being adopted as a model in many places. In 2018, the American Academy of Pediatrics released [a policy statement](#) on the treatment of young people who identify as transgender and gender diverse that advocated for "gender-affirmative care."

But former Tavistock practitioners have [cited varied problems](#) suffered by the kids who sought help, such as sexual abuse, trauma, parental abandonment, homophobia in the family or at school, depression, anxiety, being on the autism spectrum, having ADHD. These profound issues, and how they might be tied up with feelings of dysphoria, have often been ignored in favor of making transition the all-purpose solution.

As the High Court found, much of the clinic's treatment is not even based on solid evidence. At the time our case was accepted, the NHS was asserting that the effects of puberty blockers are "fully reversible." But recently, the NHS [reversed itself](#), acknowledging "that 'little is known about the long-term side-effects' on a teenager's body or brain." That didn't stop them from prescribing these drugs to people like me.

Dr. Christopher Gillberg, a professor of child and adolescent psychiatry at Gothenburg University in Sweden and a specialist in autism, was an expert witness for our case. Gillberg said in his court statement that over his 45 years of treating children with autism, it was rare to have patients with gender dysphoria—but their numbers started exploding in 2013, and most were biological girls. Gillberg told the court that what was happening at the Tavistock was a ["live experiment"](#) on children and adolescents.

Parents who are reluctant or even alarmed about starting their children on a medical transition may be [warned](#), "Would you rather have a dead daughter or a live son?" (Or vice versa.) I had suicidal thoughts as a teen. Suicidal thoughts indicate serious mental health problems that need assessment and proper care. When I told them at the Tavistock about these thoughts, that became another reason to put me on hormones quickly to improve my well-being. But after the court ruling, the Tavistock released an internal study of a group of 44 patients who had started taking puberty blockers at ages 12 to 15. It [said](#) that this treatment had failed to improve the mental state of patients, having "no significant effect on their psychological function, thoughts of self-harm, or body image." Additionally, of those 44 patients, [43 went on to cross-sex hormones](#). This suggests blocking puberty isn't providing a pause. It is giving a push.

Before beginning on testosterone, I was asked if I wanted children, or if I wanted to consider freezing my eggs because of the possibility that transition would make me infertile. As a teenager, I couldn't imagine having kids, and the procedure wouldn't have been covered by the NHS. I said I was fine if I couldn't, and I didn't need to freeze my eggs. But now as a young

adult, I see that I didn't truly understand back then the implications of infertility. Having children is a basic right, and I don't know if that has been taken from me.

As part of its defense, the Tavistock put forth statements from a few young trans people who are happy with their care. One is S, a 13-year-old trans boy who got puberty blockers from a private provider because the waiting list at the Gender Identity Development Service was so long. S told the court that he had "no idea what me in the future is going to think" about being able to have children and that since he has never been in "a romantic relationship," the idea of one is not "on my radar at the moment."

Lots of teenagers, when contemplating future sexual relationships, feel baffled and even disturbed at the thought. Those same people, when adults, often feel very differently. I know, because this happened to me. I'd never been in a sexual relationship at the time of my transition, so I didn't truly understand what the transition would mean sexually.

S's statement demonstrates how difficult it is for minors to give consent for procedures they can't yet understand. As the judges [wrote](#), "There is no age-appropriate way to explain to many of these children what losing their fertility or full sexual function may mean to them in later years."

Bell speaking to the media after the court ruling last December. (Photo: Sam Tobin/PA Wire)

Today, at 24, I'm in my first serious relationship. My partner is very supportive of everything I do, and I am the same for her. She has a large group of female friends who accept me; it's been very healing. For now, I don't speak to either of my parents or have a relationship with them.

I still get taken for male sometimes. I expect that, and I'm not angry about it. I know that I will live with that for the rest of my life. What I am angry about is how my body was changed at such a young age. People want to know if I'm going to have reconstructive surgery of my breasts or do other things to make me look more female. But I haven't fully processed the surgery I had to remove my breasts. For now, I want to avoid more such surgical procedures.

When I joined the case, I didn't realize how big it would become. What has happened since the ruling has been a rollercoaster. Many people have thanked me. I have also been [attacked online](#). If you're someone who regrets transitioning and decides to speak out about your experiences, you're considered a bigot. You may be told that you're trying to take away trans rights, that children know what's best for themselves and their bodies, and that you're ruining kids' lives.

But I am focused on what is best for distressed young people. A lot of girls are transitioning because they're in pain, whether it's from mental-health disorders, or life trauma, or other reasons. I know what it's like to get caught up in dreaming that transitioning will fix all of this.

Although sharing my story has been cathartic, I still struggle, and have yet to receive appropriate therapy. As I go on with my life, I plan to continue to be an activist on behalf of this cause. I want the message of cases like mine to help protect other kids from taking a mistaken path. This year, I helped create the first [Detrans Awareness Day](#), on March 12. I hope that, in years to come, this day can be a beacon to empower others.

I do not believe in rigid gender expression. People should be comfortable and feel accepted if they explore different ways of presenting themselves. As I said in my statement after the ruling, this means stopping the homophobia, the misogyny, and the bullying of those who are different.

I also call on professionals and clinicians to create better mental health services and models to help those dealing with gender dysphoria. I do not want any other young person who is distressed, confused, and lonely as I was to be driven to conclude transition is the only possible answer.

I was an unhappy girl who needed help. Instead, I was treated like an experiment.

Keira Bell is a British activist.

Top Surgery Regret

Grace Lidinsky-Smith, <https://hormonehangover.substack.com/p/top-surgery-regret-part-1>

Part One: The Post-Surgery Bad Feelings, Expectations Vs. Reality, and Grief

[Hormone Hangover](#)

Feb 15, 2021

This is a three part essay series about detransition/regret after top surgery, or double mastectomy.

[This essay was influenced and inspired by Carey Callahan's great essay about detransition.](#) If you're a detransitioner or know someone who is, give that a read. It's a great balm. I wrote this in collaboration with [Carol](#) and [Jamie](#), who contributed their post-op detransition experiences and wisdom. You'll be hearing quotes from them in the next two essays. Thank you so much to Carol and Jamie!

This, the first section, is about being my experience of being surprised with grief and pain after top surgery.

What it's like to regret your mastectomy

"You arrive at the place

It is not what you want

But it is what you chased"

-[The Spine Song](#), by Cake Bake Betty

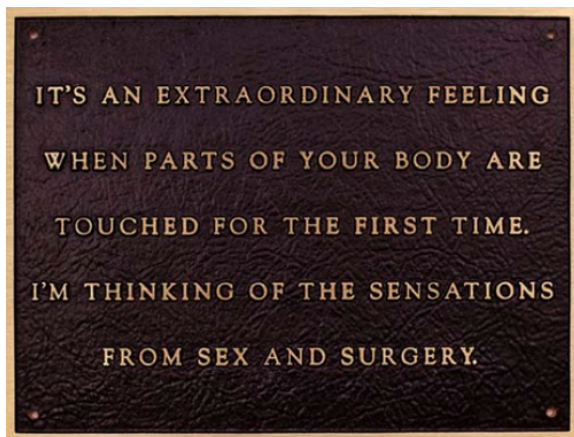

I've made a lot of mistakes in my life. But none have impacted me so indelibly, or caused as profound regret, as my 2017 decision to transition FTM: female-to-male. As I write this, the mastectomy scars are twinging on my chest. 4 years later, I've grown older, wiser, and way more cautious. But the scars remain.

When I realized that being a trans man wasn't what I wanted anymore, I fell into despair. My body was permanently changed. The surgery was the hardest thing to deal with. The scars hurt. I missed the feeling of having an intact, unscarred body. I was convinced my life had been ruined.

As a detransitioner, regret can be crushing. But somehow, eventually, even after the most catastrophic of mistakes, life goes on. It's still your only life, and you still have to figure out how to survive. It took me a while, and I learned I could survive.

Above all, I just want to say: you can come back from this. People have lived through a lot more. I am not a guide, I have no special wisdom, but I come to you humbled, scarred, and holding out my hand. You can get through this, and build a life.

Top Surgery, Expectations Vs. Reality

by Jenny Holzer

If you've never had a body part removed, or at least a major surgery, it's hard to understand what it feels like to have "top surgery." I used to romanticize it. The removal of the breasts leaves a smooth, flat chest with two sexy, mysterious slashes. The scars themselves were like a testament to suffering and transformation. I wanted it really bad. And more than the physical

results, I wanted what it represented. It was freedom from binding, it was the first step to truly, powerfully reshaping my body with my own will. It was freedom from the physical sensations of having breasts. I fixated on it as the quasi-religious ceremony of my becoming.

It was what I thought I wanted. As the date got closer, ragged jolts of fear started to come through me. But I persisted, and bolstered my belief by reading happy stories of post-op trans people.

During our brief pre-op consultation, [my surgeon](#) said that this was an easy surgery. Quick recovery, back to normal in no time, really. She glanced over my body and told me that I would look great. I was imagining a transformative and spiritual experience when I went in for surgery. I'd hyped myself up to believe that this was going to be a beautiful turning point to becoming the real me. Of course I knew in an intellectual way, it was going to be tough to have surgery. Nonetheless, I expected powerful relief from my dysphoria.

I had no idea how bad it was going to be. But once I got the surgery, I found out for myself.

After my mastectomy, I felt sewn up, aching, ghastly. My sutures oozed blood, my abdomen was swollen and grotesque. My chest didn't feel at all natural. A disturbing, never-abating sensation of numbness and occasional pain had replaced what I now realized was the natural feeling of my intact body. And almost immediately after the surgery, the dread of regret started to sink in. Whatever I thought I was getting into, I had failed to contend with the fleshy reality.

Lesson learned, younger me. Don't let the pushy, glitzy Instagram "before and after" photos fool you- a mastectomy is ALWAYS a big deal.

I felt like I might be crazy having this kind of reaction to the surgery. I had binged on smiling, triumphant pictures of post-op trans men. The gore and the pain and sadness were not what I had expected. I posted on the ftm reddit about feeling a strange sense of grief at the surgery, and asked if anyone felt the same. Many other members of the forum came out of the woodwork to agree. Even if they were happy with the end results, they still felt loss and pain.

Not only that, but my feelings of gender dysphoria increased. My obsession migrated to my hips, my voice, and my very mannerisms. The top half of my body looked okay, but what was I going to do about my hips? The way I moved? I was more obsessed than ever before with monitoring myself. I told myself I was being liberated, but really it felt like I was stacking the bricks to my own prison walls.

I had this nagging feeling - that nothing would ever be enough, that I could just keep cutting and cutting my body but I'd still be the same increasingly-wounded me underneath it all. That feeling grew and grew. When it got loud enough, I began to realize I would have to detransition. I stopped T, and then my hormone-dampened sadness came flooding back.

Loss and Grief

ouch (Ryder-Waite tarot deck)

I was taken aback by the deep, serious loss I felt. I tried to connect to other people who were struggling with the same feelings, and searched for more information about mastectomies. In *The Cancer Journals*, Audre Lorde said that losing a breast (from a mastectomy for cancer) was as viscerally painful as losing her own mother. Another friend described the post-op feeling as being like she had been placed on a strange planet and she could never go home. I think if you haven't experienced it, it's hard to convey the feeling.

There was also the psychological fallout of having body parts missing. I felt a harrowing feeling that something was wrong with my body, something was missing. Alarm-signals went off in my brain constantly. In a bleak way, it was fascinating - I had discovered a whole new range of bad feelings I had never felt before. I fantasized feverishly about turning back the clock. Life as I knew it seemed to be over.

It was also really upsetting to cope with the difference between what I hoped the surgery would do for me, and what it actually was. It's easy to think top surgery will fix your life in some magical way. It's supposed to help you pass as a man or be androgynous. It's a huge step on your transition journey. To have those expectations fall through for whatever reason and end up regretting is really hard.

When I realized my mastectomy had been a mistake, I felt betrayed, disoriented, and confused. My fantasies of what transition would do for me, the road map I had structured my future on, dissolved into meaninglessness. How did I get in this situation? Why did I think this awful, awful surgery would help me? Why didn't I run screaming away from the surgeon's table?

And on top of all of that, if you end up reverting to a female gender identity, there's the entire collapse of your understanding of yourself to deal with. While detransitioning is different from transitioning, they share the feature of reckoning with the nature of your life and identity. What's

your new name? Who are you after all this? What does it mean to be yourself, now? To a large extent, you have to find your own way out of the wilderness.

So: this was hard. Especially the first year, especially the first six months. It got worse after I realized I needed to detransition and make peace with my body, because that also involved accepting that my natural body would never be restored.

If you had top surgery and you're taking the loss of your breasts really hard, I'm sorry. You're not alone. You are entitled to healing and relief. You can find it. I'll talk about that more in the next essay.

The next essay will be about physical and emotional healing, forgiveness, and reconstruction surgery.

Edit: I deleted a line joking that I would be playing Tennis 2 weeks after top surgery. It was a joke, but I'm worried it didn't come across correctly and don't want to misrepresent my surgeon. My surgeon did say about 2 weeks would be recovery time for most activity post-surgery.

My Letter to the Surgeon Who Performed My Double Mastectomy

Laura, <https://pitt.substack.com/p/my-letter-to-the-surgeon-who-performed>
Aug 10

This is a copy of the letter I mailed to the surgeon who performed my double mastectomy or “top surgery” when I was 20 years old. This letter, addressed as a “Notification of Detransition” was mailed to the cosmetic surgeon. I wrote this letter to inform the doctor and his staff that a former patient of his 100% regrets the operation performed on her, and has detransitioned and is now living as a biological female with no functioning breasts.

I kept the letter short and emotionally detached and, despite my traumatic feelings around this loss of self and body parts in my private life, knew it was crucial to maintain a rational composure in stating the facts of my situation. I described how my gender dysphoria was not cured by surgery or medical transition, but instead was fully resolved within 2 years through cognitive behavioral therapy, because the “gender dysphoria” was in reality, complex post-traumatic stress disorder. I described how I realized, only 2 years later at age 22, that the surgery had been a mistake, and that I didn’t receive proper mental health treatment when I was obtaining the surgery, the supposedly necessary gatekeeping he required to perform the operation.

This was important to include because, although I doubt as a cosmetic surgeon who has made his career entirely dedicated to performing double mastectomies on young women and girls as young as 16, that he cares about the mental wellbeing of his cliental, he advertises his practice as being a legitimate medical service by insisting that he follows the “WPATH Standards of Care”, the leading organization of trans medicine which requires at least 2 letters of referral from mental health providers for a patient to receive medical transition. The Standards of Care

advocate for thorough screening for mental wellness, and selecting only appropriate patients who would truly benefit from transition.

It was crucial to inform the doctor that, in my case, the Standards were not met, as the mental health care I was receiving, and the subsequent referral letters, were negligent in providing assessment of my mental health situation, and therefore, his practice was not actually following the WPATH Standards of Care. Furthermore, what I did not include in the letter due to a desire to preserve my anonymity, was the fact that I openly discussed being suicidal with the doctor during our consultation, and feeling suicidal on the day of the actual surgery. Regardless of the recommendation letters, I presented to my doctor as not of sound mind to make a major elective surgical decision, but he performed the operation anyway.

After relaying my personal beliefs that this treatment was unethical in my case, I made it known to my doctor that I am far from the only former FTM patient who regrets medical transition, and cited Dr. Lisa Littman's study of detransitioners showing how high the comorbidity rates are of various mental disorders in the FTM population, and how this issue is not just a personal error, but a growingly widespread phenomenon. I closed the letter with a call to action for the doctor to reconsider what his practice views as 'medical treatment' to treat mental disorders. I plainly asked him to confront the reality that he removes young women's and even minor children's breasts to treat problems inside their minds, and if he truly believes that is following the medical oath to "Do No Harm."

My story is similar to many detransitioners who share why they felt they needed to transition. I grew up on the autism spectrum, experienced verbal, emotional, and psychosocial abuse from family resulting in PTSD, depression, and anxiety, had severe depression from attachment issues and hormonal dysregulation from PCOS, felt chronically othered and different as a girl, young woman, and person, suffered with relationship difficulties with romance, sex, and friendship due to undiagnosed trauma, and latched onto "gender dysphoria" as the cause of most of my difficulties.

I sought treatment for my gender related distress and learned online that the only solution was to accept being transgender and transition to live as a gay man. I followed the usual coaching of the process to "healing", first, to socially transition and come out as nonbinary and transgender, second, to receive hormones from an informed-consent clinic, with no mental health evaluation or gatekeeping, and finally to have top surgery, the greatest rite of passage for the FTM cult. Throughout this process I saw multiple doctors, a psychiatrist, and therapists, none of whom questioned my identity, traumas, or provided help for my complex mental health issues. I had just turned 20 and was fresh out of an inpatient psychiatric ward for suicidal ideation when I desperately made my appointment to try and heal my depression through altering my body with surgery.

There is no need for further explanation. I was 20, developmentally immature, mentally ill, suicidal, had PTSD, and not in a rational state of consciousness, yet the mental health system failed to provide its due service, and my doctor and other cosmetic surgeons hungrily leapt at

the opportunity for fresh meat to profit from operating on, in this unchecked, wild west market for “gender medicine.”

I share this letter with you to showcase real-life consequences of trans medical propaganda, and the repercussions our young people and children are facing. The last I checked; my doctor operates on girls as young as 16. I’ve done my soul-searching, grieving, extensive therapy, and self-punishment for the mistakes of my childhood self, but am healed enough to have progressed into self-forgiveness, acceptance, and upholding unrelenting boundaries around my peace, sanity, and healing process. I did not provide a return address on the letter I mailed, as I did not want to endure excuses or shaming correspondences.

The letter remains a rallying cry from the young women of the detrans movement to advocate for better medical treatment, no placation or bullshit apologies desired. I don’t claim to speak on behalf of anyone else, but unfortunately appreciate that my story is identical to countless other girls, and I hope that sharing this will somehow help them heal, or better yet, prevent the need for their healing in the first place.

Dear Dr. XXXX and Top Surgery Clinicians,

I am a former patient who you performed a double incision mastectomy on in 2017 while I was 20 years old. I am writing to inform you and your office that I have detransitioned and no longer identify as male/transgender and have returned to living fully as my biological female sex. I want to inform you that I fully regret having the surgery to have my breasts removed. My symptoms of gender dysphoria were the result of CPTSD from childhood abuse and my transgender identity was a maladaptive coping mechanism to deal with the reality of the trauma.

I have fully resolved my feelings of gender dysphoria through cognitive behavioral therapy and view the surgery and transition as a placebo that gave me only false hope of feeling better about myself. I 100% regret the surgical outcome of my body and miss having my healthy breasts. I was 20 when I had my identity crisis and detransitioned 2 years later at 22. I believe I did not receive proper mental health screening by my psychiatrists who wrote my surgery recommendation letters because they said I was mentally stable while I was actually suicidal and exhibiting symptoms of undiagnosed PTSD.

I have found healing and community within the online population of other detransitioned women with similar experiences of trauma, and I want to inform you that I do not believe removing the breasts of young women, especially minors, is medically ethical given the severe rates of comorbid mental health issues in the FTM population. I do not believe I was stable or mature at 20 to transition and I don’t think a minor child under 18 in any circumstance is stable or mature to consent to having her breasts removed.

There is a rising number of detransition cases just like mine as evidenced by the rapid increase of detrans stories on Youtube, and the Subreddit r/detrans. There has also been a recent study

by Lisa Littman at littmanresearch.com on detransition which shows that 60% of the detrans study participants transitioned due to underlying mental health and trauma reasons, and 25% due to being lesbian or gay.

I ask you to consider my story and the stories of others as your ethical duty as a clinician to first do no harm, and rethink if removing healthy breasts of women and children so they can pretend to be men is physically or mentally doing no harm.

Your patient, Laura

Trans to Detrans

Ritchie Herron/TullipR, <https://tullipr.substack.com/p/trans-to-detrans>

From a detransitioning males perspective

[@TullipR Detrans Male](#)

Mar 21

If "trans" means "to cross" then "detrans" means "to come back" - to come home.

There's a reason why people sometimes refer to their trans identities in the third person, because it is such a disconnect within yourself that you start to create a character.

You give that character a name, and you try and take the image of what you envisage that character to look like into reality through a skewed, deeply controlled and filtered perspective.

You take 100 photos, delete 97 and then post it as if you didn't spend hours getting it right. *"Wow you look amazing, oh my god" "you look cis" "100% pass!" "imagine what HRT would do to you"*

The affirmation becomes intoxicating.

You then start to really change the way your character sends messages, becoming aware of not using enough emotive speech in my character's instance. Saying phrases like "awwwwww" or anything I felt would resemble a woman talking rather than a man.

Your 'unique' character becomes a clichéd stereotype, following the grain of what is considered right or wrong at the time by your fellow trans peers.

You then seek out other characters, who reinforce and refine your own character.

Then you tell your entire family that you are this character now and that's the way its always been.

You tell your bank, driving insurance, energy supplier, mobile phone provider of your characters name. You now have proof your character exists.

You tell your doctors that it is their duty to make this character come to life and you demand a referral to the gender clinic.

You get bored of waiting and go your own way. You know what you need, you need HRT! You book a private assessment and you get two separate opinions for £500.

Congratulations! You have a diagnosis, don't worry that its full of errors and they clearly wrote it quickly knowing you just wanted HRT and you probably wouldn't correct them anyway.

You're still waiting for the gender clinic, but because you now meet the criteria, you can start HRT on bridging hormones! Heyyyy!! Success!

All the other characters gather round and tell you how happy they are that you have finally be given the *'right'* HRT.

This is the best day of your character's life.

Your family tell you its just a character.

They worry endlessly that you will do something stupid, they tell you; come on, this isn't you, this is a character!!

“NO! I AM THE CHARACTER! IT WAS ME ALL LONG. BIGOT!”

Some family don't know what to do. They cut you out. They can't bear to sit and watch. They know what's going to happen. Some family stick by – they'd rather be there then lose you.

You are not well. You go back online and tell people "hey, maybe I'm not this character after all?"

“...THEY are the problem...” “this is internalised transphobia from your transphobic family, I'm sorry”

You are getting so much attention for your suffering, you finally are being heard, you tell them about all the awful homophobic things that happened. All the other characters sit and hug, validate and affirm.

They say all the things that a salesman will tell you about a broken car, obscuring the truth and focusing on the fact 'hey it's got wheels don't it?'

You work hard with a therapist, and you begin to see the character you've created.

You are so desperate not to lose it, you know what you could do to keep in the service, even though you really don't want to.

You ask to be referred for SRS.

They tell you to go for hair removal. You drag it out as long as you can, you defer appointments and make up excuses.

What should have taken 12 months took 2.5 years.

It's the day before surgery, there's something ticking in your mind trying to break through a formidable defence of cognitive dissonance.

You neatly lay your character on the bed, ready for the surgery you're convinced will make you better and save your life.

You wake up in a hospital bed. Your character was just that all along, it was you. This is the big reveal, the curtain call – the gravity of what you've just done hits you so hard.

It's not what you thought it would be and it's full of hidden terms and conditions; incontinence, discharge, areas of no sensation, some sensation, pain, UTIs, infections, low energy, varicose veins...

You become demoralised and realise this wasn't worth it all.

You can climax, that's great, but actually you've started to realise your dysphoria down below wasn't even that bad to begin with, and in fact the idea of being with another male is quite a nice idea in your head.

Then you realise actually you wrote your character all wrong to begin with, and no one really helped with that.

You're gay, and you're traumatised from a life of severe homophobia.

You realise there is no undoing any of this.

But you do realise you can come home.

You can detransition, which means throw away the character. Scrap it, it never was you to begin with, it was an idealised fiction that never met the test of reality.

You were always a feminine soul, but that doesn't mean you're a woman, it just means you're a feminine man. And that's okay! In fact it's freeing.

I feel like the shackles have come off, and I am myself again, I am back in the room.

I realise it was always just a character to begin with.

-TR

By Any Other Name

Helena, <https://lacroicsz.substack.com/p/by-any-other-name>

The story of my transition and detransition.

[Helena](#)

Feb 19

My name is Helena, and as of this writing I'm a 23-year-old woman who, as a teenager, believed I was transgender. In the years since detransitioning (stopping testosterone treatment and no longer seeing myself as transgender), I've become interested in exploring why, in the last decade, nearly every English-speaking country has seen a meteoric rise in adolescents believing they are transgender and pursuing cosmetic medical and surgical interventions. Here, I'd like to go over how and why I came to see myself as transgender, the process of transitioning, and the events leading up to and following my detransition.

The short version of my detransition story for those who want the bare details is that when I was fifteen, I was introduced to gender ideology on Tumblr and began to call myself nonbinary. Over the next few years, I would continue to go deeper and deeper down the trans identity rabbit hole, and by the time I was eighteen, I saw myself as a "trans man", otherwise known as "FtM". Shortly after my eighteenth birthday, I made an appointment at a Planned Parenthood to begin a testosterone regimen. At my first appointment, I was prescribed testosterone, and I would remain on this regimen for a year and a half. It had an extremely negative effect on my mental health, and I finally admitted what a disaster it had been when I was 19, sometime around February or March 2018. When the disillusionment fully set in, I stopped the testosterone treatment and began the process of getting my life back on track. It has not been easy, and the whole experience seriously derailed my life in ways I could never have foreseen when I was that fifteen-year-old kid playing with pronouns on Tumblr.

But what leads a girl with no history of discomfort with stereotypical "girl" toys and clothes, or even the slightest desire to be a boy in childhood, to want to be a "man" through hormonal injections as she approached adulthood? In a vacuum, such a profound confusion leading to such drastic measures sounds like it should be rare and a sign of some sort of severe mental disturbance. Was I a fluke? Was I some kind of idiot who mistakenly believed I was trans because I'm crazy or just downright irresponsible?

The truth is that there has been an extreme rise in adolescents, especially girls, believing they are transgender. UK NHS referral data shows a [4000% increase](#) in pediatric gender service referrals (not a typo). So-called "gender dysphoria", which was once a very rare diagnosis that

described mostly prepubescent boys and adult men, is now most commonly diagnosed in teenage girls. Activists will argue that these explosive numbers are a result of increased societal acceptance, and that at long last trans people are coming out of hiding and living as their authentic selves. If this were true, one might expect to see comparable rates of transgender identity across all age groups and between both sexes, but its disproportionately adolescent females feeling that warm and fuzzy inclusive acceptance. Considering “acceptance” now implies supraphysiological doses of cross sex hormones and having healthy body organs surgically rearranged, it’s worth a deeper look into what kinds of factors are driving this population clamoring to go under the knife.

How did it happen?

As a child, nobody would have pegged me as a future transitioner; I was never particularly masculine or even tomboyish. I hated sports, roughhousing, and getting dirty. I liked Barbies, playing dress up, and getting toy makeup sets for Christmas. Of course, nobody is a walking sex stereotype so there were certainly “boy” things I enjoyed, but my point is that neither female-typical activities nor being seen as a girl caused any distress for me before I was introduced to gender ideology. On the other hand, even at a young age I was beginning to experience some deep emotional difficulties unrelated to gender that would get more urgent over time. I suffered a serious loss when I was seven, and the rest of my family took the “don’t talk about it” approach, so my grief festered like an infected wound. My family was also very preoccupied with image, especially dieting and weight, and this began to have a pronounced effect on how I saw myself (and on my brother, too). By the time I was thirteen, I was isolating myself, self-harming, and had developed an eating disorder. In eighth grade, I lost touch with most of my school friends, and was too self-conscious and preoccupied with my eating disorder to put myself out there again. I started skipping school, spending lunch in the bathroom, and in general just keeping my head down, trying to get through the day unnoticed.

During this time, I developed an obsession with classic rock, and while searching the internet for photos of young Elvis Presley I found a website called Tumblr. I immediately noticed that on Tumblr, there were many accounts posting about 50s, 60s, and 70s artists and that best of all, they were other teenage girls. I made an account and began posting scans of some vintage pop magazines I had bought off eBay, and soon enough, these accounts were following me back. Between sharing photos, drawings, and fanfiction, these girls were posting about their lives and going into deep detail about their struggles. Many were social outcasts like me, also struggling with things like self-harm and eating disorders. Finding a community of such like minded people felt amazing, and I quickly began spending nearly every waking moment on Tumblr or messaging some friend I had met on there. If I had any remaining motivation to integrate myself into real life, I lost that here. At school, I would sit in the back of the class, scrolling Tumblr and talking to Tumblr friends without engaging in class. When I returned home, I would open Tumblr on my laptop or hop on Skype to voice call with girls halfway across the planet, ignoring homework and studying all the while. As you can imagine, my high school GPA was abysmal. Tumblr would stick with me as I moved through various interests, from classic rock to Harry Potter, to One Direction and Justin Bieber, each iteration subsumed in a community of countless other intense, obsessive girls like me. I was in love with my new world, and even now I look back on some of these times spent on Tumblr, and the girls I met, with incredible fondness.

Me at 15; not identifying as trans yet but well into Tumblr, eating disorder, and being sad all the time.

Tumblr, though, wasn't only a place to post art and make friends. Being such a secluded platform with a fairly homogenous user base not only

demographically (mostly teenage girls, many of whom white and middle to upper middle class), but especially in terms of personality type, it developed its own culture, distinct from the youth culture of the general population. Because many of its users were like me, using Tumblr as an all-day alternate reality escape from the real world, this “culture” should be understood in the most literal sense of the word. One should think of Tumblr, especially from 2009-2016, as a secluded island nation whose people rarely interact with the outside world, and thus have language, customs, hierarchy, and history that is entirely unique and at first incomprehensible to people from other nations visiting the island. There’s something about it that almost selects for a particular type of person, and I’ve heard so many times from normal people (for lack of a better word) that they “tried Tumblr, but couldn’t figure it out.”

We’ve all read *Lord of the Flies*, right? A bunch of tween boys get stranded on an island and all of their deepest, most repressed urges surface as they desperately attempt to organize and manage the tiny preteen society they’ve found themselves in. The novel ends in bloodshed, as the author theorizes that the immaturity, communication breakdown, and decision making difficulties one would find in a group of adolescent boys would create a chamber of destruction. How would it have ended differently, some have asked, if the story was one of a stranded group of girls? What would happen if every troubled, isolated, self-loathing, depressed, and emotionally overwrought teenage girl in the world wound up alone on an island?

Tumblr. Tumblr would happen.

~A quote from [this series](#) I began long ago, and unfortunately have yet to finish.

A major aspect of Tumblr culture has always been social justice ideology. Things that are now being played out and witnessed by the general public on platforms like Twitter and TikTok, like dissociative identity disorder LARPers, demisexuals, neopronouns, otherkin, and everything you see on @LibsOfTikTok, have long existed in an uncannily identical form on tumblr.com. The oppression hierarchy of racial and gender identities now being written into law in many of our once serious nations was the state religion of the People’s Republic of Tumblr long before your political junkie uncle knew the term “CRT”. As cultish religions tend to operate, open devotion to the religion is mandatory. Perhaps the outsiders most likely to understand the way social dynamics worked on that website would be survivors of Scientology or the Jehovah’s Witnesses. On Tumblr, the situation was such that any claim to being “oppressed” would accumulate social credibility, while any unfortunate “privileged” status was justification for verbal abuse. As a “privileged” person, you were expected to constantly grovel and apologize, you had no right to speak on any issue involving the group you were “oppressing”, and you could not object in any way to any mistreatment hurled against you because of your race, gender, or sexuality.

I found myself in a bit of a double bind. On one hand, I had found what felt like the perfect group of friends who understood me on an intuitive level, who I was able to talk to openly about the things I liked and made me “weird” in real life, but on the other hand I was a “cishet white girl” in an environment where that was one of the worst things to be. Since Tumblr users are mostly

biological females, the “cishet white girl” holds the position of most privileged and therefore most inherently bad group. In this climate, you are made to feel guilty and responsible for all the horrors and atrocities in the world. No hardship you could possibly go through could ever be as bad as the prejudice and genocide POC and LGBT people face every. Single. Day. Insert clap emoji. LGBT people and POC can’t even walk out of their houses without being murdered by cishet white people just like you!

Its understandable that any young person exposed to this kind of belief system would grow to deeply resent being white, “cis”, straight, or (biologically) male. The beauty of gender ideology is it provides a way to game this system, so that you can get some of those targets off your back and enjoy the camaraderie of like-minded youths. You can’t change your race, pretending to have a different sexuality would be very uncomfortable in practice, but you can absolutely change your gender, and it’s as easy as putting a “she/they” in your bio. Instantly you are transformed from an oppressing, entitled, evil, bigoted, selfish, disgusting cishet white scum into a valid trans person who deserves celebration and special coddling to make up for the marginalization and oppression you supposedly now face. Now not expected to do *as much* groveling and reaffirming to everyone how much you love checking your privilege, you can relax a little and talk about your life without wondering if you are distracting from the struggles of or speaking over marginalized groups, because you are marginalized too. With the new pronouns often comes a wave of positive affirmation from friends and followers, and the subconscious picks up quickly that there’s a way to make the deal of being on Tumblr even sweeter.

This is the incentive I felt to comb through my thoughts and memories for things that might be further evidence that deep down, I wasn’t really a girl. I hated my body; it must be because I don’t like that its female. Boys have never been interested in me like they are with other girls; well, maybe I would be attractive as a boy, and then I could be like all these cute “gay trans boys” I saw dating each other online. I didn’t have many friends, it must be because being a girl isn’t my “authentic self”, and that was getting in the way of my social life. Plus, people were nicer to me since I said I was trans so that must be an indication that being trans is the right thing to do to make friends. Female sexuality is hypersexualized and pornified, yet it’s supposed to be “empowering” for women to do porn, be prostitutes, or have dangerous, kinky, scary sounding sex with many different men. I heard that my discomfort with this made me “vanilla”, and a girl who is vanilla has no chance of really pleasing a man when competing with “empowered” women. I must not have really been meant to be a girl, because if I was, this wouldn’t all be so scary and confusing. I felt like my family didn’t care about me or pay attention to me, it must be because they subconsciously have always known I’m trans and they’re transphobic. I mean, they did make fun of Caitlyn Jenner that one time. They hate me! Just wait until I tell them I’m going to start testosterone; they’ll *have* to pay attention to me then.

I was also certified boy-crazy, but in the weird nerdy stalker way, not the actually dating boys way. I always had a crush on some boy I would never talk to, whether he was a celebrity, fictional character, or someone I just saw around at school. When I had a crush, it would utterly dominate my mind. I would become infatuated with every little detail of how they looked, spoke, laughed, and moved. I had elaborate fantasy worlds in my head down to the minutia of what we

would talk to each other about on the drive back from delivering our third baby at the hospital. I had a one-track mind and I craved an intense fantasy element. This led me to the world of fanfiction, mostly male/male pairings. What could be better than boys? Double boys! But they're written by girls so they make sense and feel familiar instead of different and intimidating. I loved the unlimited amount of creative and exciting content other girls were writing about my favorite characters. I wasn't super into erotic fanfiction, and if I did read it, it was always within the context of a longer, more relationship-oriented story, but pure erotica was popular too (often carrying heavy kinky themes...). I began to identify with these representations of boys written by other young females, and the themes within male/male fanfiction were so much more titillating than anything in mainstream, professionally produced media, or even heterosexual fanfiction for that matter. The pairing being same sex seemed to give writers and readers the freedom to explore these characters and their relationships without being constricted by the norms that come with heterosexual dynamics. It became this liminal space where I could explore what interested me about boys and fantasies about relationships, connecting it to whatever my media obsession was at the time, without the pressure of interacting with real boys, as real boys made me painfully bashful.

I wasn't alone in these mental and emotional traits that led me to shipping and fanfiction, and I *certainly* wasn't alone in wanting to be a boy after immersing myself in this kind of content. "Shipping" is the word for being interested in a pairing between two characters or people, and each "ship" has a community comprised of devoted shippers as well as people with a casual interest in the pairing. Being involved in these communities, comprised of mostly other trans-identified teenage girls, created a feedback loop in which we would obsess over these male characters or celebrities, share fantasies, art, and writing, and affirm and engage each other over these interests. One last aspect that bears discussion is the concept of "head canons". In a story, the "canon" is the timeline and facts of the story as the official author or historical evidence relays. A "head canon" is anywhere where one's personal perception of or preferences for the story deviates from the official canon. For example, if in the canonical Harry Potter story Harry is an English teenage boy attending wizard school, one might have a head canon that Harry is actually black, nonbinary, and drops out of Hogwarts to become a professional chef. The concept of head canons opens a whole world of possibilities for projecting onto a character and muddling the fantasy of one's personal identity or desired reality with the fantasy of the identity and life of an entirely fictional character in a fictional universe. In my head canon, Harry Potter, who I related to and was a meaningful character to me, was born female and was either nonbinary or a trans man depending on what point in my life you would have asked me. When I watched the Harry Potter movies, where Harry is obviously played by a male actor, or read the books, where nowhere in the text does J.K. Rowling state Harry is transgender, I would still kind of interpret the story through my own lens in which he was, and thus further see myself in him.

The adolescent brain is in a developmental stage primed to incorporate experiences into the process of identity formation, and spending so much time in fantasy without building much of an identity through real social and life experiences can lead to the identity and fantasy elements becoming indistinguishable.

My perception of myself as trans formed in the intersection between overwhelming emotional struggles, heavy fantasy, emotional and intellectual infatuation with males (real people, fictional characters, and the idea of males generally), fanfiction, social and ideological incentives to be trans, and insulation from experiences and perspectives that might have challenged the views I was developing about myself and the world. Each individual girl's story will vary, give or take a few factors, but in the broadest sense these are the basic factors that comprise the trans "social contagion" described by people like researcher Lisa Littman and Abigail Shrier in her book, *Irreversible Damage*, particularly when we are talking about male-attracted girls. What I've said here barely scratches the surface.

From fantasy to reality

Over the three years that I identified as trans prior to reaching legal adulthood, I kept this huge aspect of my self-perception to the confines of Tumblr and the few school friends I met after switching high schools, also avid Tumblr users, and all but one also identified as trans. I cut my hair, wore baggy clothes to hide my body, and was gifted a breast binder by a friend from Tumblr that I would wear out and about, but I didn't talk to my parents about any of this until late into my senior year of high school. By this time, I fully identified as a "trans boy", wished I had a male body, and wanted to medically transition.

Some examples of how I looked in high school after beginning to identify as trans. I would alternate between wearing a lot of makeup, long fake nails, and other very "feminine" things and making awkward attempts at looking more boyish.

When I told my mother about all this it was on an impulse. I had a whole spiel planned out where I would tell her all about how I was always trans, I just didn't know it, and hand her a big packet of printed out articles from pro-trans organizations about what different words meant and why I needed to transition. For some reason I still don't quite understand, on one gloomy day we were driving back from the grocery store and I just blurted it out mid conversation, telling her that I was going by a male name, male pronouns, and was going to transition. I immediately wanted to stuff my foot into my mouth, but it was too late, and the dead awkward silence was setting in. For what seemed like eternity, she drove in silence. I stared at the headboard, eyes wide and heart thumping. Finally, she responded with a word: "No."

"No, I am not going to call you that. You are Helena and you are a girl," she said, maintaining her glare at the road before us.

Deflated and conflict avoidant, I remember saying something meek and passive aggressive like "if you feel that way, I guess..." and we finished our drive in silence.

The next day, I went to the school library and printed out all those articles I had saved for my planned "coming out". When I got home, I scrawled a long-winded letter on loose leaf paper with what was originally going to be my "coming out" spiel, stapled it all together, waited for her to get home late and head to bed, then I slipped it under her bedroom door at night as she slept. The following day, I anxiously awaited speaking to her, wondering what she thought of all the articles. Had they convinced her? They had to, right? I was showing her that experts clearly agreed that trans people like me are valid.

When I returned from school that day, the packet was face down in the kitchen trash.

Distraught, I agonized over what would happen when she got home. Would she yell at me? What did she think of the packet? I wondered if she had already read "transphobic" material that countered the articles I sent her. Hopefully she read my letter and could see past any transphobia and realize that this was the real me. She didn't yell at me though. Instead, we mostly avoided each other for a few days and then both acted like nothing ever happened.

This would continue for months until another fateful confrontation, ironically at the same grocery store we were driving home from the first time. I don't remember how the argument started, but somehow, we got into it over my conviction that I was transgender.

"I don't understand why you can't just be a masculine woman," she said.

I responded, "Because I'm not a masculine woman! I'm a trans boy!"

She didn't understand that the issue wasn't of repressed masculinity itching to be let loose, it was a conviction that I was a part of the transgender identity group, and any masculinity I engaged in was a conscious supplement to that end.

Yelling and crying between us ensued, very classy for the middle of the dairy aisle at Kroger. She told me I had lost my mind and needed to see a psychiatrist. I told her she was a hateful person who wanted trans people to die. We went back to not talking much after that.

I was heartbroken. Now that I'm older and on the other side of this, I understand why my mom was struggling so much with her reactions to what I was demanding of her. We never had a relationship where we confided in each other often, and she can be somewhat emotionally distant. I don't demonize her for it anymore, but at the time I interpreted her unwillingness to entertain my identity as a disregard for what I was feeling and a rejection of who I was. To me at the time, being trans and wanting to transition was a desperate attempt to do something about my misery, and when she rejected my trans identity, it felt to me like she was telling me I didn't

deserve to feel better, and she wanted me to continue feeling the way I was, which was suicidal, lonely, and self-loathing. I do wish she had responded with more compassion and curiosity, but she was doing the best with the skills she had. It's an unreasonable expectation for most parents to respond perfectly to something as outlandish as an unexpected transgender identity and the possibility of irreversible medical interventions, especially when teenagers like I once was are under the influence of a noxious ideology that makes authentic communication nearly impossible.

To add fuel to the fire, I went to my school guidance counselor and told her I was very depressed (true) because my parents wouldn't accept me as trans (not so true). She completely affirmed my perception and told me how sorry she was that my parents weren't more supportive. She looked online with me at the local children's hospital gender clinic and said she would call to see how long their waiting list was. We also came up with a budget plan for how I would pay for testosterone using an informed consent clinic if I waited until I turned eighteen. In the meantime, she said I should talk to the school psychologist to help me deal with my family being so transphobic. I asked my mom if I could stop seeing the therapist I had been seeing occasionally and switch to the school psychologist. My mom, having no idea that the school was affirming me and helping me put together plans to transition behind her back, agreed.

The psychologist was also very affirming, and again told me how sad it was that my parents weren't supportive and that I was a real and valid boy. After years of self-harm, depression, and struggling with an eating disorder in silence, it felt nice to have all these adults suddenly take such an interest in my "mental health". It was just further proof to me that being trans was my ticket to happiness, anybody who urged caution only wanted to hurt me and hold me back. The psychologist brought up the idea of a family session to work things out between me and my mom, and once I felt assured that she would take my side in the matter, I agreed. I hoped coming face to face with a psychologist would finally convince my mom to take the fact that I was transgender seriously. In our session, the therapist and I all but ganged up on my mom, telling her that I needed to transition to be happy, and that trans youth are at a high risk of suicide if they are not given "access" to hormones and surgeries. Predictably, my mom did not respond well and we both left the session feeling bitter.

Some time over the summer, my mom told my dad about my "trans thing" and he told me calmly that he didn't think I was a boy, but he wasn't going to fight me on it either because he could see it wasn't going so well for my mom. He even took me out to drive his stick shift car thinking I might like to do something "manly". I couldn't figure out how to do it and got really upset that I wasn't able to easily do something he considered "manly". I think he was trying to show me that I didn't need to be trans to enjoy "guy things", but that was sadly missing the point. It was this weird belief system I found on the internet that made me want to be trans, not a repressed yearning to do "guy things". I had never been all that interested in "guy things". My dad and I didn't talk about it much other than that.

Soon after, I turned eighteen. I have a July birthday, and over that summer after graduation I began to put more intention into "passing" as male in preparation for testosterone and my plan to "live as male" in college. I went out and bought what I thought were "boy" clothes that would

fit my curvy, slightly overweight female body. Joggers, basketball shorts, and hoodies. Ugh, I cringe just thinking about it. So not my style, but I wanted people to think I was a boy. I believed once the testosterone transformed my body, I could be more creative with my outfits.

I want to take some time to explore what my expectations were for how testosterone would change my body. I am a female, 5'3 and a half, and at the time probably weighed about 150lbs. I don't have the curviest body, but I certainly carry a lot of my weight in my legs and arms and almost none in my waist. Even with the fat redistribution caused by testosterone, there's no way that a testosterone regimen could give me what I wanted: a tall, lanky, bony male physique. During puberty in natal males, testosterone is able to sculpt the male body while bones are still growing, which is part of the reason why this kind of physique was unrealistic. Testosterone also cannot change a female's height, or elongate leg bones, so no matter what I did I would never be tall or have long, spindly extremities. I also have long struggled with my weight, so my expectation to look bony was unrealistic in that regard too. I would look at male "thinspo" (pro-anorexia term for imagery of very thin people that is used as inspiration to restrict food) and "transition goals" (a similar concept in trans circles where people look at photos of the opposite sex that they want to emulate through style, hormones, and surgeries), which caused a massive disconnect between how my body really looked and what I thought could by some magic happen in the future. This kind of unrealistic fantasy obsession over body changes is one of the many ways in which trans identity resembles anorexia, which also involves an unhealthy obsession with unrealistic body goals and shifting goal posts. I spent much of my time before being trans looking at pro-anorexia content and chasing the ideal of an ultra-thin, androgynous [female] body. My restrictive dieting led to binge eating, and I convinced myself testosterone would do what I never could myself through starvation.

These are examples of the kinds of images I was perusing daily which formed my "transition goals". Notice the cropped faces in each picture; the images are objectifying in a similar way to anorexia "thinspo" images. This allows the viewer to enmesh their self-perception with the bodies in the images. Anime and Tumblr art were also hugely influential. Search terms like "tumblr boy aesthetic outfits" or "tumblr soft boy art" will show countless additional examples of this aesthetic which is popular among young trans identified girls. Incidentally, these

androgynous, pretty boy types are also the kinds of young men that adolescent girls tend to be attracted to.

Now a legal adult, I could pursue testosterone without my parents or laws holding me back. I searched around in my area, but back in 2016 there weren't any informed consent model gender clinics around. Informed consent is the model of treatment whereby someone of the legal age according to their state (in the US) who desires an intervention must only sign their name on a legal disclaimer informing them of certain risks in order to acquire those interventions. There is no therapy, psychological screening, or in my case even physical health screening involved in the informed consent model. At most, a provider could decline a candidate for some reason at their personal discretion. Whereas in the past, people who wanted to transition often had to be in treatment with specialists for years before being prescribed hormones or operated on, informed consent is now the most popular methods of distributing cross sex hormones and surgeries to people old enough to give medical consent in their state of the US today. There are even online telehealth services that will ship you hormones so you don't even have to leave your house to get them. Don't you love innovation?

Since there were no informed consent clinics in my area that I could find in a quick Google search, I decided to see which Planned Parenthoods offered it, as I had heard raving things about Planned Parenthood from people on Tumblr. The closest location to me offering informed consent HRT (hormone replacement therapy) was all the way in Chicago, a six-hour drive from my home town. I figured I could tell my parents I was out with friends and would make the drives to and from Chicago in one day. I had only gotten my drivers license a few months before, and had never attempted such a long drive. On the drive back, I got caught in a terrifying thunderstorm so bad that I couldn't see 10 feet in front of me and the winds were shaking my car. Now that I'm older and have done many long drives, I recognize this was a stupid thing to do. But I was doing a lot of stupid things.

My appointment, and first injection of testosterone, was on August 15th, 2016. I had just turned eighteen.

Me at 18; putting more effort into “passing” as male. I wore that hat all the time because I had no idea how to do or cut my hair in a way that resembled a typical man. I was too scared to go to a barber or men’s hairstylist. Also, because people have made this comment before, the thing on my shirt isn’t a confederate flag, its the logo of a local pirate themed laser tag place my brother used to go to and I stole the shirt from him.

I woke up early on the morning of the appointment, which I believe was for some time around noon, got together my couple hundred dollars in cash, put on my uniform of basketball shorts

and hoodie, and got in my car. I was banking on my parents waking up and leaving for work without coming to my room and would text them I was heading over to a friend's house at some point during the day. My mom called me during my drive, at which point I remembered I had actually been supposed to attend a dentist appointment that day, and I made up a story to her about how I was on my way to the dentist appointment and would head to a friend's house after. She wished me luck at the dentist, and we said goodbye. I still have always been too scared to admit to her what I was really doing that day, and that I didn't get that cavity taken care of for an embarrassingly long time.

This was my second time in Chicago (the first was for my high school senior trip), and as I merged onto Lake Shore Drive, the urban landscape excited me. I felt affection towards the city, believing that this place with its ultramodern lifestyle and progressive values was going to deliver me into a whole new life. As I exited onto LaSalle, I was met with several posters and signs related to LGBT, and felt my affections confirmed. This place was welcoming me. Validating me. I couldn't wait to get to my appointment.

I was probably late because I didn't factor in the whole issue of finding parking, and if you've ever been to Chicago its always a disaster. Directly through the door was a woman behind plexiglass next to a locked door. She asked for my identification, and I remember thinking how great it was that Planned Parenthood was keeping women and trans people safe from violent haters who might try to get into the clinic. Upon confirming my identity and appointment, she buzzed me in and I proceeded to the reception area. As I completed my intake forms, I looked around me at the people in the room with me, mostly women and a few couples, mostly black and Hispanic. I remember thinking how cool it was to see so much diversity in such a great and helpful place like Planned Parenthood. Being a Tumblr SJW from a mostly white area, I was euphoric at the thought of a place that affirms trans people and caters to a poor black and brown people. I think I was feeling that this connection confirmed my status as "marginalized", as this was still very important to me.

Before long, my (trans) name was called and I looked up to see a tall, heavy woman with shoulder length brown hair and a clipboard. As we walked back through the halls of the clinic, she introduced herself as a social worker and told me we would do a brief intake to understand what I was looking to get out of the services at Planned Parenthood. I told her that I had drove six hours all the way from my hometown, and I think she responded with some comment about how I must be so determined. When we arrived at our room, she motioned for me to sit and she began the intake process. This process consisted of a handful of basic questions, which you can see below, along with her notes on my answers.

Social Work Intake Form

TODAY'S DATE: 8/15/16	PATIENT #: 4 [REDACTED]	DATE OF BIRTH: 07/24/1998
PREFERRED NAME: [REDACTED]	LEGAL NAME: Helena [REDACTED]	PRONOUN(S): Male
GENDER: Male	SEX ASSIGNED AT BIRTH: Female	SEX LISTED W/ INSURANCE: N/A

<p>What do you know about Hormone Therapy? What are you hoping Hormone Therapy will do for you?</p> <p>Patient was well versed and knowledgeable about hormone therapy. Patient reports that he has thought about using hormones for some time, especially over the last 2 years. Patient states that turning 18 is why he was able to start the process.</p>	<p>Who knows about your plans to start hormones?</p> <p>Patient states that he is "out to everyone" and identifies trans. Patient states that he has told one friend about starting hormones and is also connected to online communities for support.</p>
	<p>Do you live alone or with other people? If with others, does it feel like a safe place to transition? (consider coping methods if they do not know or may have negative reactions)</p> <p>Patient does live with his family; however he is going to college in Columbus in 2 days. Patient states that his family is not supportive of his transition; however he does indicate that his mother and father have started to come around more. They refuse to identify him by his preferred name or pronoun in the home and with family, but have made a commitment to do so at college. Patient feels that once his family sees how truly happy he is once he transitions; he feels they will come around and be more supportive.</p>
<p>Why hormones now (vs. past/future)?</p> <p>Patient states that he is now 18 and can initiate the process himself.</p>	<p>Do you work and/or go to school? If so, are you out at work/school or considering talking to your employer/school?</p> <p>Patient does not work currently. Patient going to college in a couple days and would like to study biochemistry.</p>
<p>Aside from hormones, are there other changes you are considering or thinking about making?</p> <p>Patient states that he is 100% confident that he will get top surgery in the future. Patient states that he has considered some facial masculinization work as well, but states that he wants to see what the hormones will do first. Patient states that he would consider bottom surgery if the options that he would like for a penis became available, but he is not interested with the current options.</p>	<p>Do you date or have a partner? Thoughts about how you might talk to partner/dates about your identity?</p> <p>Patient is not in a relationship currently. Patient states that he has no fears about this as he believes that he will only connect with other trans people or an individual who is supportive of his process.</p>
<p>How are you thinking about coping with stressors from the changes you will experience?</p> <p>Patient states that he feels like he will be much happier. Patient states that he has struggled with depression currently and in the past. Patient states that this summer was tough for him with depression and suicidal thoughts. Patient states that since he has been able to make this appointment, his depression has already started to improve. Patient expects that his whole life will be quite different and he will be very happy when he starts to change.</p>	<p>General Screen:</p> <p>Oriented to person/place/time/situation: YES / NO</p> <p>Mood and affect appropriate to situation: YES / NO</p> <p>Suicidal ideation or thoughts of self-harm: YES / NO</p> <p>Patient endorses a hx of depression and SI. Patient denies any current SI, plan or intent. Patient states that his most recent thought was about 2 weeks ago. Patient states that he was very suicidal over the summer and it was tough for him. Patient states that now that he has started his transition, his depression is significantly improving.</p> <p>Client can make informed consent: YES / NO</p>

Feminizing: How do you handle depression when you get sad?

Masculinizing: How do you handle anger when it happens?

Patient states that he feels that he will be able to manage his emotions. As stated, patient feels that his mood will significantly improve.

In most of the records I share here, certain information is redacted, because at the time I took these photos I was speaking to a lawyer who advised me against naming Planned Parenthood publicly, or releasing other information. Nothing came of those pursuits, and I am now more

open about these things. My real name, Helena, is also used on the Planned Parenthood records because their policy was to use my legal name on official records, but my clinicians called me by my preferred name, and on some of the records my preferred name was also listed.

I remember the intake process taking about 20 minutes, at which point the social worker told me she would talk over my intake with the nurse practitioner, and they would decide if I was a good candidate for testosterone. I waited anxiously by myself for a couple of minutes, and then the social worker came back. She told me that I was a perfect candidate for testosterone, and since I had traveled so far, and seemed “so sure”, that they would even work around their typical policy of taking blood samples and waiting for test results to prescribe the hormones, and give me my prescription that very day.

Ecstatic, I burst into tears of joy and called my friend who was also trans (at the time, she isn't anymore) that they were going to give me my first injection that day. My friend and I squealed to each other over the phone and when we calmed down, we hung up and the social worker motioned me into a new room. There, I met the nurse practitioner who handed me the informed consent document and asked me to read it over. I gave it a glance, knowing that I had already made my decision and some silly formality wouldn't stop me. I and the professionals already knew what was best for me. I signed the document.

The image shows two copies of a document titled "Client Information for Informed Consent: Masculinizing Hormone (Female to Male) Therapy". The document is dated "Revised June 2016". The left copy is a scan of the original document, and the right copy is a scan of the signed version. The signed version has "Helena" written in the signature line and "8-15-16" written in the date line. The document includes sections on "What is masculinizing hormone therapy?", "What is testosterone?", "What are the benefits?", "What are the risks?", "What are the side effects?", "How long does it take to work?", "How long do I need to take testosterone?", "Can I get pregnant?", and "Proprietary property".

My full informed consent document. My main criticism is that testosterone as a hormone and testosterone as a treatment are presented as primarily cosmetic, when in fact testosterone is involved in many physiological processes, and healthy in different amounts for men and women. I took a closer look at the contents of this document in [this thread](#).

Now that all that legal liability nonsense was taken care of, it was time to get to the exciting part: dosage. Typically, females beginning a masculinizing testosterone regimen are started on a relatively low dose and monitored for a few weeks or months, at which point the dose may be

increased. Considering I hadn't even had blood work, in hindsight this would have been the more responsible way to do it. That is not what happened in my case, though. When the nurse practitioner suggested a lower dose to start, I objected, saying I believed I had "higher estrogen than most AFABs" (people "assigned female at birth"), citing the size of my thighs and breasts as evidence. This was acceptable to the nurse practitioner, and she asked me what dose I would like to start at. Nervously, I said something along the lines of, "well what's the highest we can go?"

Most female transitioners I've known have told me they started at 25mg, or even less. Some of my FtM friends who are still on testosterone and look remarkably like natal males, are only on 50mg. I was prescribed 100mg of testosterone, to be self-injected into my thigh muscle weekly, starting that very day.

There were no words that could have prepared me for what was about to come.

PATIENT: Helena [REDACTED]
 BIRTH SEX: Unknown
 GENDER IDENTITY: TransMale/TransMan
 DATE OF BIRTH / AGE: 07/24/1998 / 18 Years
 MEDICAL RECORD: 417847

Androgen	Initial - low dose ^b	Initial - typical	Maximum - typical ^c	Comment
Testosterone Cypionate ^a	20 mg/week IM/SQ	50mg/week IM/SQ	100mg/week IM/SQ	For q 2 wk dosing, double each dose

My medical record showing that I was prescribed testosterone cypionate on my first appointment, without blood work (results take at least a few days), and that my dosage was the maximum recommended dosage per the [UCSF dosing guidelines](#).

Shit, meet fan

Two days after I started testosterone was my first day of college. The weekend prior, I told my mom that I had requested for the university to list me under the male name I had chosen, and that to avoid confusion she should use this name if only when interacting with the school. She agreed to use the name and male pronouns when she and my dad dropped me off at my dorm so that at least I could start my first day of college on one page, even if she wasn't on that page herself. I was content with this, and felt like I was finally getting her to understand.

On August 17th, 2016, my parents and brother dropped me off at college and helped me carry all my new college stuff into my dorm, unaware of my testosterone expedition. I hid my vials and needles deep in the recesses of a bag of clothes, which I insisted my parents let me unpack later. My bed sheets were standard red and navy-blue plaid from Walmart, my school supplies were all some mix of grey and navy blue, and my only dorm decoration was a Star Wars poster. My wardrobe was a handful of sweatpants, hoodies, and t-shirts, all mostly from Walmart or the men's section of TJ Maxx. Gone were the days of glitter gel pens, notebooks covered in cat stickers, my cozy bedroom with a plush, floral comforter, fluffy rug, and One Direction poster. It was now time to "act like a boy", because if I acted like myself, nobody would believe I was trans.

My roommate was another trans guy (whom I will call "he", because that is how I remember him), who I later learned was one of the youngest people in my state to have gone on puberty blockers and testosterone. My school had a "self-ID" policy, and I was originally supposed to be placed with an actual male, but when I looked him up on Facebook, he was some massive ripped sports guy and the idea of sleeping next to him scared the living hell out of me. I'm sure he wouldn't have appreciated coming to school and finding out he was rooming with a girl, either. I chickened out of rooming with him and asked an administrator if they could find me another trans person to live with. That first day, I was simultaneously intimidated to meet another trans guy and feeling incredibly awkward introducing my parents into this whole new trans world when just a few months ago they'd had no idea I wanted to be trans at all. We all went through the motions of pretending everything was normal until my mom accidentally called me "she" to my roommate and he locked eyes with me apologetically, signaling to me he witnessed the incredible violence that had just occurred. My mood soured for the rest of my parent's visit, and I gave them both attitude until they left for the drive back home. That night, my roommate and I got to talking, and he said he was sorry that my parents were so transphobic and unaccepting. He told me that his mom was very supportive of him being trans, and fought tooth and nail to get him "access" to transition at a record setting age. I was seething with jealousy.

That week was eventful, and I made a bunch of new trans friends. My roommate introduced me to his ex that he was still friends with, who at the time was also trans and eventually became my

closest relationship for nearly four years (I will call her “Jamie”, and “she”, because that is how I know her now). She and I clicked immediately and would be inseparable for years, even long after any resemblance of a romantic relationship fizzled away. I consider myself heterosexual and would not date a trans man now, but at the time as a “gay trans man” under the influence of gender ideology, which tells you biological sex isn’t real, and experiencing surges of testosterone, I convinced myself I was attracted to this girl who looked like a boy at the time and had rapidly become my closest friend. Since in the back of my mind I knew she was a biological female, she didn’t intimidate me as much as actual men did.

In a classic *me* maneuver, I had forgotten one of most important items: my laptop. The first week was just orientation week, so I didn’t need it, but I would need to drive back down to my home town to retrieve my laptop before Monday. On Friday or Saturday, I said goodbye to my friends and drove the two hours back to my parent’s house. As I pulled up to the house, I saw my mom had just arrived home from work. Stiffly, we greeted each other and entered the house through the garage. I nervously wondered if either of my parents would be able to guess that I had started testosterone, even though a week is hardly long enough for there to be visible effects.

As I walked from the kitchen to the stairs, my mom called me “Helena” and I whipped around, snapping back at her that she needed to respect me now and use my “real name” (my trans name). She yelled after me as I stomped upstairs to my room, and as I was collecting my laptop and charger cable, she stormed in behind me. Six months of pent-up frustration and rage spilled out of her, and she tore into me in a tirade that felt eternal as it was in progress. I don’t say these details to demonize her, I understand why things happened the way they did, but it’s an important part of the story. The tirade reached some dark places, and she said things I won’t repeat here but hurt me deeply. As she yelled, I sat on my bed staring at the floor and whispering “okay, okay” over and over. One of the last things she said was that I shouldn’t come back until I realized I was a girl. Whether she meant this literally or not, I already had a narrative in my head that transphobic parents disown their trans kids, so that’s how I took it. Plus, I thought I would never stop being trans.

She left the room, and I began panicking. Hyperventilating, I grabbed my laptop, a few extra things I meant to retrieve, and headed for the door. As I went to walk out, my sweet old cat, Puff, was standing in the doorway like he always would when he came upstairs around the time I went to bed. He was my little buddy, and always slept next to me. The night before I left for college I cried and told him that I would be back to sleep next to him all the time, but I never got to again.

Tears welling, I patted Puff on the head, and gave him a little kiss goodbye.

I was properly shaking by the time I started my car and drove it to a near by gas station. There, I allowed myself to break down and called a [trans] Tumblr friend of mine. I cried to her and told her that my mom had just disowned me, and I didn’t know what to do. She helped me remember that I had left money in a box in my room, and told me to call a family friend to retrieve it for me, which I did. Once I had the money, I began the drive back to my university, getting in at one in the morning, throwing my belongings on the floor and crashing to sleep in my top bunk bed.

The Dark Days

Everything that followed this altercation with my mother was dark, and things were dark for a long time. I won't bore you with every story, but let's just say there was a succession of demotivating, stressful, and painful events in quick succession. There was a lot of drama, I lost nearly all my new friends, and I started to feel really, really down again. Within a month, I moved into the campus LGBT house due to issues with the room mate and the three other people who lived there with me were my entire social circle. We mostly sat around smoking weed and drinking, and my academic performance plummeted. I was also advised to financially emancipate myself by one of the campus gender studies professors who was "helping" me navigate being "disowned" by my parents, which just created financial issues for me down the line that added to the stress. I remember feeling numb for months, and when I wasn't numb and checked out, I was angry. I'm still not sure how much of that was due to the testosterone or the general state of my life.

The anger started as a smoldering anger at first. I found myself feeling more irritable, less able to put up with the little things that bothered me about other people. I was uncomfortable with my newfound tendency to get bent out of shape at everybody so I started isolating myself, trying to hide this awful person I thought I was turning out to be. I didn't make the connection between this and the testosterone, I just thought I was a bad person. I didn't feel like being around people, and when I was, I felt so unlike myself that I didn't know how to relate to them. Even five years after the fact, I still feel like this experienced has damaged my self esteem and social capabilities in a major way. It definitely changed me as a person.

These next few years of my life are still incredibly hard for me to think about, much less write about for everyone else to see. The one redeeming quality of this dreadful time period is that I adopted my cat, Corndog (yes that's his name) early in 2017, and he has been by my side through all of it. I remember myself as a shell of a person, a monster, someone who didn't recognize the feelings in her own body anymore. To make things worse, the testosterone injections themselves were causing significant distress for both me and Jamie; it would take us hours of crying and hyperventilating to drive the needles into our flesh once a week. I had always had emotional problems, but this was different. In high school, I had always banked on the future where I would be in college, transitioning, and part of me genuinely thought testosterone would somehow make me into this outgoing male jock archetype and I would be handsome, have lots of friends, and love life. That wasn't really panning out. I was lonely, enmeshed in toxic and stressful relationships, on academic probation, in legal trouble due to substance use, and feeling possessed by some sort of demon I now recognize was at least partially the testosterone's worsening grip on my mind. With the reality of my old future fantasy having rapidly deteriorated, but not yet realizing the fundamental issues with my life, I set my sights on another route of escape.

Jamie, who was in a similar position of plummeting mental state, still maladaptively coping with the trauma of growing up in a severely dysfunctional family, one night suggested that we run away; just take what little stuff we can fit in the car and move to a whole new city, one that will

embrace our transness and will allow us to realize our true potential. I told her I knew just the place...

Chicago.

And so not long before the end of that school year, we told the few acquaintances we had that we were moving and they wished us luck, excited to hear we were getting out of suburbia and moving on to better things. I remember feeling awkward telling them, like there was some cognitive dissonance between the fact that chasing trans had only made my life worse, and the fact that I was making another drastic life decision to chase trans once more.

I quit my crappy fast food job, unenrolled from the university, which was going to kick me out anyway, paid a visit to my mother to let her know of my plans (we were on strained speaking terms at this point), and soon enough I was en route to Chicago. We had managed to rent a small studio apartment, and both applied to schools in the city. I didn't end up attending school, though, because not long after getting settled in to the new apartment my mental health would get even worse.

What I thought would be a fresh start turned out to be more of the same. I isolated, too uncomfortable with myself to even make eye contact with other people. I didn't get a job, didn't go to school, didn't meet any people, and for the most part, didn't even get out of bed. It was around this time that something really weird started happening to me, and this part I largely do contribute to the testosterone.

When they tell you about testosterone, they mostly frame it as a cosmetic thing. Sure, you might feel more irritable, you'll probably have a higher sex drive, and there is that whole thing about increased risk for heart disease and cancer, but for the most part its all about fat redistribution and getting a deep, commanding voice. My informed consent document even generously warned me about "mood changes". But I don't know if anything would have prepared me for what it actually felt like.

During the initial months following my first shot, I recall a general feeling of suffocating numbness and inability to identify my emotions, with bouts of anger that were easy to trigger dispersed throughout. Something that before would have made me mostly sad, or even frustrated, made every cell in my body overflow with rage. The anger was also of a different quality than the kind of anger I experienced before. Previously, I might have gotten so angry that I cried, or yelled, or very occasionally slammed a door, but I rarely if ever felt much more of an urge to externalize it physically beyond that. While I was on testosterone, the anger demanded to be externalized. I felt like my body would explode if I couldn't hit or throw something, and this scared me. Crying was no longer an option, at least at first, as crying was nearly impossible to achieve. When I was emotionally overwhelmed, instead of easily crying like before I would start to feel extremely angry, and instead of hitting others or anything in my surroundings, I resorted to hitting myself. I would struggle against the anger by punching myself and eventually, after there was enough pain, I could cry and when I cried I'd cry for hours, often falling asleep and not

remembering much when I'd wake up. I had these kinds of meltdowns about once a week or so, and regularly had bruises on my head and body from where I would hit myself.

One day, I had a meltdown like this and instead of hitting myself I hurt myself quite seriously with a kitchen knife, and when I calmed down enough to be spoken to I was coaxed into going to the emergency room by Jamie. I can only imagine how traumatic it was for her to be around me during this time. I still, at this point, made no connection to the testosterone. We both just thought I was a severely mentally ill person; even though I had never experienced anything remotely like this before testosterone (and never again since!).

I was checked into the hospital psychiatric ward that night and remained for seven days. There, no inquiry was made into my high testosterone dosage or whether it might have been having an impact on my behavior. Instead, I was diagnosed with borderline personality disorder, depression, and acute psychosis, for which I was prescribed four separate psychiatric medications. Upon my discharge, I dutifully took my prescribed medications and even felt validated by my being prescribed an "anti-psychotic". I was thankful that I had finally been diagnosed as severely mentally ill and given strong medications that would fix my faulty brain chemistry and allow me to live a better life. For the next few weeks, I was to attend a thrice weekly outpatient group therapy program that was three hours a day. In this intensive group therapy, we talked about mindfulness and how to manage the demands of work while living with "mental illness", but deeper psychological work was absent, and once again the fact that I was a young biological female on a supraphysiological dosage of synthetic testosterone remained completely unaddressed. Throughout every experience in any mental health treatment during my trans identification, my testosterone treatment was never identified as a potential source of mental health symptoms, and my desire to be a "boy" was never questioned as possibly a result of pre-existing emotional issues. My "preferred name and pronouns" were always used without hesitation or question, and I was "affirmed" by every professional I saw during this time. I had still not developed the skepticism of the mental health and medical industries that I have now, so I saw this as even more reason to not question my identity as trans.

While I was enrolled in the outpatient program, I was not improving. I was still unemployed, using substances (including some of my prescribed medications), unable to get out of bed most days, talking about suicide in group, and having "episodes". Eventually, the psychiatrists and therapists at the outpatient program sat me down and told me I needed to go back into inpatient. I did, and this time stayed for about half a week. When I got out, I decided these programs were not helping me and that once I unenrolled from them, I was going to get a different therapist (at the local LGBT center), get a job, and try making some friends, the latter of which didn't happen until after I detransitioned.

For the next six months or so, I worked in a small cookie shop where I often worked ridiculous hours, including relatively frequent 10 hour solitary night shifts, not returning home until nearly 5 am. Needless to say, this wasn't fantastic for my mental wellbeing either, but its where some changes started to take place. I started interacting with people regularly, and though I didn't make any long-term friends, it was helpful just to know some names and faces and be a fly on the wall listening to the drama in the lives of my coworkers. A trans coworker of mine clued me

in to an organization that issued grants that paid for trans surgeries, as my insurance at the time didn't cover them. My coworker showed me the website to apply, but I always procrastinated it. Strange, considering I would publicly talk about how badly I wanted the surgery. So I never got any surgeries, something for which I am extremely grateful.

During some of the late night, solitary shifts, I had a lot of time to reflect. In some ways, it was a bit maddening, but dispersed within the general neuroticism were moments of clarity. I remember deciding to take my chest binder off at work for the first time, because it was just me and one other worker who always sat in the back, and that fucking thing hurt. It felt so much more natural not to have anything constricting my chest underneath my work shirt. I started skipping testosterone injections because they made me so anxious, so I was only injecting once or twice a month. With this, my "episodes" dramatically decreased. I remember browsing trans subreddits in hopes I would get some answers for what to do if transitioning wasn't improving my mental health. There were many posts asking this question, and by far the most common answer was to "just keep going" and that one day, when you passed well enough, it would all be worth it. There were times when I sat back and questioned nearly every choice in my life, like the relationship I was in and moving to Chicago. I thought about how all these things I desperately jumped into thinking they would save me had not don't anything of the sort. The only thing I didn't outright question was my choice to be transgender. That would require a more up-front reality check.

The call is coming from inside the house

Not everyone has an "a-ha!" moment when they realize they want to detransition, but I did. Mine was after a few weeks of occasionally thinking back to before I had transitioned, the comfortable clothes I used to wear and how I didn't worry about whether or not the "feminine" stuff I liked would make people "doubt I was trans". I thought about how much I loathed the way men's clothes fit me and the way masculine styles looked on me in general, and I remember wishing society was more accepting of "gender non-conforming men like me". I also wished I "wasn't trans", and even recall making a reddit post to this effect, lamenting how even though "being trans" was making me miserable, I knew it was who I really was and after I got surgeries it would be right for me.

This kind of thinking, I now realize after talking to so many detransitioners, is common in the weeks or months leading up to detransition. My "a-ha!" moment happened in February of 2018, when Jamie made a video montage consisting of photos of us chronologically from the day we met (2 days after I started testosterone) until recently, set to music. As I watched the video, I saw the way my face changed from so young, hopeful, and most of all, recognizable, to weary, deadpan, and foreign.

Top row: Photos of me from the first month of my transition. Bottom row: Photos of me from the final months before detransitioning.

I began to sob uncontrollably. At first, Jamie thought I was crying because I loved the video so much, but I quickly informed her it was something else, but I wouldn't say what. I cried, and cried, and cried. Every memory those photos evoked was flashing before my eyes, all the pain I knew was behind my eyes was emerging vividly. I saw innocence turn to anguish and I knew I had been on the wrong path for a long, long time. I didn't know. I didn't know it would be this way. I was just a kid.

How could I have been so stupid?

I couldn't bring myself to tell Jamie what I was truly thinking. I knew that she would probably freak out and try to make me rationalize away these feelings, but it was too late for that now. The dam had broken. Instead, I silently berated myself and catastrophized internally until I mustered the courage to tell my very pro-LGBT therapist: being trans had been a massive mistake.

I remember her response clear as day: "But you always tell me about your terrible dysphoria!"

"I know, but I... I don't think that's what it is" I replied, and started to tell her my still developing thoughts on how I had developed the "dysphoria" after finding out about gender identities online as a teenager, when I had been struggling with so many other emotional issues for a long time, and that in retrospect I must have gotten carried away, thinking that being trans was the explanation and solution for all of my problems. She wasn't really hearing me, and questioned the things I said from the angle of "you're trying to talk yourself out of being trans because transphobia is making you hate yourself." Ironical that nobody ever questioned my desire to be trans that way.

This was the first moment I started realizing something was off about the trans movement, and institutions in general. I had experienced this massive realization, and it was agonizing but at least it was finally something real, and here I was being met with all these rationalizations for why this of all things was a psychological symptom. Not the effects of the testosterone, not my belief that all of my problems would be solved by transitioning, not my aversion to being female, but the fact that I now knew transitioning had been a mistake.

I left this session feeling frustrated, and I don't think I ever went back. Sitting in the car outside the building, I told Jamie that I was regretting my transition and questioning my trans identity in general, and predictably she was extremely upset. She reacted in anger, saying I must be confused and, like my therapist, accusing me of having these thoughts due to some underlying psychological issue, like only an insane person would ever regret being trans.

She was not being uniquely harsh here, this is a common occurrence in the trans community. In one direction, there's a desire to encourage gender questioning in others who have not questioned their gender yet (some people call this "cracking an egg"). In the other direction, there is an intense fear of others changing their minds about being trans or wanting to transition. Once someone is questioning their gender, there's a push to encourage them to take steps towards social and medical transition, which, once initiated, makes changing one's mind more complicated and going back to living as they did before more difficult. I personally have gotten very angry and desperate when friends in the past would voice doubts about identifying as transgender, and I have also encouraged gender questioning and trans identity in friends of mine who did not yet identify as trans. I regret this very much now, as some of these friends have gone on to medically transition, and I no longer believe this was remotely in their best interest. But in the trans community, people cope with the inherent doubts and cognitive dissonance of pretending to be someone they are not by encouraging others to do the same. This is also why so many adult trans people advocate for child transition. If an innocent, pure child can "be trans", that validates their identity and belief system too. An enormous amount of

mental energy is devoted to the crowdsourcing of validation and firefighting of anything that triggers internal conflict, which is always nagging in the back of the mind.

When a person is at peace with themselves and expressing themselves naturally, they don't desperately micromanage everything and everyone around them.

Around this time, Jamie and I were preparing for a trip my mom had invited us on with herself and my brother. Now finally on cordial terms, we agreed to go, and our dramatic conversation in the car occurred in the week before. We both felt pressure to act like everything was fine because I had worked so hard to get my mom to tolerate my transition, and I was feeling guilty and humiliated. Being somewhere else kind of felt like a neutral ground where we could have conversations more freely with less judgement. We took many long walks to talk about our transitions, trans identities, and reflect on our lives up to this point. During these walks, Jamie also admitted to herself and to me that she didn't want to be trans anymore. We felt crushed, scared, confused, and regretful, but so much more free.

Back in Chicago, we now had to figure out what to do next. Neither of our families knew what we were thinking, and we were both scared to tell them. There's an enormous amount of shame in realizing how much hurt and chaos has been inflicted on others in your pursuit of ideas you now think were ridiculous and destructive. You think of all the decisions you made that weren't directly related to your transition, but were made in the effort of chasing the fantasy more broadly, and you feel like you've just woken up in a pit of your own digging, too deep to climb out of. You feel trapped, cornered, panicked, and deeply ashamed. Regret comes with a lot of self flagellation, and at the time, there wasn't the big detransition community there is today to let us know that we weren't alone. I remember looking up transition regret online, and I found one essay by an older lesbian. While we did have detransition in common, everything else about her experiences were different and I couldn't see myself in that story. I felt an incredible emotional whiplash, like I had just woken up from a five-year spell and was suffering amnesia about how I'd gotten to where I was. I was hungry for clues that would help me make sense of my position.

I began to search online with key words like "regret", looking for anything that might resonate with what I was experiencing. I knew the standard trans narrative was wrong, at least in my case, but looking at other perspectives still scared me. In fact, I called myself nonbinary, and picked a "gender-neutral" name to go by, because I was still reflexively averse to being myself, a filthy "cis girl". It felt incredibly uncomfortable -- more uncomfortable even than being FtM -- and I dropped that pretty quickly. Once the dam broke, the same old tricks of self-deception were no longer tolerable to me. I remember finding the reddit r/detrans forum, which at the time had only around 100 subscribers, if memory serves me (it now has tens of thousands). This clued me in to the fact that at least a handful of people out there were feeling regret too.

When I had my detransition realization, I immediately wanted to go back to looking like a girl. The men's clothes, short hair, and my wispy little testosterone moustache made me sick to look at. I bought some basic clothes, like leggings and long sleeved, women's cut shirts, simple things I used to like wearing before I transitioned. I also bought some cheap make-up and a wig. Though these made my reflection in the mirror less jarring, I felt kind of like a man in drag. It was

a really gross, uncomfortable feeling. I didn't know if I would ever feel normal. The realization that my escapist fantasy I had hoped would save me from my teenage misery was a fraud sucked me right back into that old misery. The consequences of my decisions compounded it further. I felt utterly, hopelessly trapped.

Somehow, I kept picking jobs where I'd end up doing entire shifts alone, which once again made things more difficult in some ways, but also allowed me to do lots of internet searching, and it was during these lonely shifts that I found a subreddit called r/GenderCritical. At first, the "transphobic" language (such as calling trans women "men") horrified me. I felt so incredibly guilty for even reading the words in front of me, but I couldn't look away. It was my first exposure to a perspective towards trans issues that wasn't the mainstream narrative, which I now knew was at least not true for me. I searched the subreddit for topics of detransition and regret, and I saw other young women posting similar stories to mine. I made a post, and was met with a surge of positive, encouraging comments. Somebody recommended me the book *Female Erasure* by Ruth Barrett, which presented me with both illuminating facts that contradicted the trans narrative and an alternative, positive image of womanhood. I still remember the exact moment, standing crouched over the work iPad alone in my smoothie store, when I had the mind-bending realization that not only was I not the only one going through this, but it was a full fledged phenomenon. I had been manipulated, taken advantage of, and involved in a cult-like community.

For a short time, I became enthused by radical feminism, and the gender critical feminist perspective greatly appealed to me. I was still very confused and used to receiving external validation, so I tried to fit myself into the "lesbian who transitions due to internalized homophobia and misogyny" narrative that I found was common in gender critical circles. With time, I would grow to form my own beliefs and understandings of myself and I gradually distanced myself from radical feminism, but it was a stepping stone away from gender ideology.

From r/GenderCritical, I found out about parent groups and advocates like 4thWaveNow and Lily Maynard (who I wrote [this essay](#) for early on in my detransition). Here, I could read a lot of thoroughly researched information on trans activism, corruption, regulatory and institutional capture, and more non-ideological critiques of the trans movement that weren't from a strong feminist angle. I found out about "Rapid Onset Gender Dysphoria" (ROGD), which is a term coined by researcher Lisa Littman. It describes certain patterns parents have reported that preceded the sudden declaration by their adolescent children that they are transgender, most notably in adolescents who showed no pronounced gender incongruence in childhood. I read her study, and I just about ticked every box.

Pre-existing mental health issues, check. A friend group where multiple people began identifying as trans around the same time, check. Decline in mental health and parent-child relationship since identifying as trans, check. Expressing distrust/dislike of non-transgender people and spending less time around non-transgender friends, check. Isolating self from family, check. Only trusting information about gender from pro-transgender sources, check. Increased social media use directly preceding the identification as trans, check.

I was in shock. This was... me! Perhaps more importantly, this was... EVERYONE! All of those young biological females I had been friends with online and offline who identified as trans also fit this *exact* description.

While researching this phenomenon, I also learned that in the years that I began identifying as trans, the demographics of people seeking to transition had changed dramatically. I learned that gender dysphoria was once seen primarily in pre-pubescent boys and adult men. I learned that there had already been research into these men, and that they had completely different histories and motivations to myself and the other girls who fit the description of ROGD.

Finally... I saw that Dr. Littman had been targeted for her research. Targeted by activists infuriated by her evidence that contradicted the trans narrative they were so emotionally dependent on, her institution turned its back on her, unwilling to stand up to the activists.

I was pissed.

I was angry about having this kind of information kept from me by the community, which I now understood exhibits information control dynamics similar to that of cults or extreme religious sects. I was angry that clinicians either didn't understand or didn't make the effort to read this information about demographics and gender dysphoria. I was angry that I had been affirmed every step of the way, and only questioned when I was starting to express regret. I was angry that people who seemed to be making a genuine attempt to understand this new phenomenon were being targeted, and I was angry that I would have targeted them too if I had known about this not long ago.

This inspired me to boot up that old 25 follower twitter account I had made in college and subsequently abandoned. Furiously, I began typing away a thread defending the idea of ROGD, and offering details of my own life trajectory to back it up. I didn't know if anybody would see my post, but I wanted to get these thoughts out. People did see it though, and I began to interact with other detransitioners, parents, and gender critical people. Hearing how deeply so many people were being affected by this phenomenon that had been so damaging to me too was invigorating, and I became passionate about understanding it (and my experiences) as thoroughly as I could and exchanging ideas with others who were lost in the confusion with me.

As I began to feel strengthened by the knowledge that this was a phenomenon and not a personal failing, I decided I would tell my parents when I saw them next. Sometime in the spring of 2018, they invited me to visit them back in my hometown. I felt myself growing more and more nervous as the day of my flight approached, and on that day, I was a wreck. The airport in my hometown has a long hallway that requires maybe 10 minutes to traverse from the terminal to baggage claim. I distinctly remember my walk down this corridor and seeing my parents as two little dots at the very end. The dots grew and their image came into focus, and with every step I felt more afraid, my heart pounding in my chest, stomach churning, and a dizziness overcoming my body. At about 50 meters away, my vision blacked out for a few seconds! That's how terrified I was to admit to my parents what I had realized!

When I told them, it was that night at dinner when they asked me “what’s new?” It was an awkward conversation, but at least they didn’t say “I told you so”. They didn’t say much; maybe they didn’t know what to say. They did say they were glad to hear it though and that they thought detransitioning was the right decision. My brother was fairly silent throughout, and later that night I heard him say to his gaming friends on Discord, “Sooo, my sister isn’t trans anymore.”

The hardest thing about detransitioning in my case has thankfully not been living with permanent damage to my body, something many other young people with similar histories to mine cannot say. It has been coming to terms with the bad decisions I made that made my emotional struggles much more painful, my ability to socially adjust and have healthy relationships much more difficult, and generally took my life in an unexpected direction that has been very hard to climb out of. In many ways I am still climbing out of it. The years following my initial decision to detransition have been fraught with challenges that, with each overcoming, have required me to mature beyond my age. I am very thankful for that, and am growing to truly enjoy and respect myself, but it has also made finding my place in the world difficult. I have continued to struggle with many of the original problems that lead me to identify as trans in the first place, like social weaknesses, anxieties about not fitting in, poor body image, unresolved childhood grief, shame, and conflicts in my family.

Living life by delusion and going to such extreme lengths to chase a falsehood steer one away from true resolution of such natural human issues. Even if the testosterone itself hadn’t had such a damaging effect on my mind and my life, the very act of trans identity and transition was, for me, an act of immense self-harm. Emotions are a way for the unconscious, all sensing body to communicate to the part of us that experiences conscious thought information about how our environment and the people around us affect us. In order to move through and overcome painful emotions, we must first acknowledge the core emotion that is occurring and have compassion towards ourselves for feeling the emotion in the context within which it is occurring. Trans identity took me far away from this into blaming and punishing my body for the emotions I was feeling. It resulted in an even wider disconnect from understanding the conditions that led me to feel such sadness, fear, and grief. Transitioning made my mental health much, much worse. Not better. It was a “fuck you” to the hurting child inside of me. It was telling her that she didn’t matter. It was telling her that I hated her and wanted to annihilate her. It was an act of war against myself.

War against yourself comes with a cost. In the aftermath, there are fires to put out, ashes and debris to clean up, towns to rebuild and ground to fertilize so that life may exist once again. Having just been at war, these necessities of the aftermath feel insurmountable; the body and mind is too exhausted. I had to begin not with action but with turning inward and finally respecting the emotions I had tried to cast away and smother. With each level of depth into compassion with myself, I could then turn to one step of action that would move me forward in the outside world. That has been my back and forth process of healing and recovery from years that not only were wasted, but pulled me down so deep I nearly drowned.

I often felt that upon waking up from “the spell”, I was transported backwards in time into the consciousness of my fifteen-year-old self. Like all the years of being trans were not really me,

and the real me lied dormant under it all, finally able to come forward once the false persona disintegrated. Being the “real me” again, years out from detransitioning at this point, I still can’t fully wrap my head around having been consumed by that false persona. It doesn’t really feel like that was me. And it makes me sad that I did feel the need to reject myself to such a degree as to completely dissociate from who I was, because I quite like myself now, actually. I recognize that many of my qualities that have made certain aspects of life more difficult also make me unique in a very powerful way.

Photo 1: about 6 months after I quit testosterone. Photo 2: About a year post detransition. Photo 3: About 2 years post detransition. Photo 4: About 2.5 years post detransition, I still was really not doing well up until the time of the next photo. Photo 5: About 3 years post detransition. 2021 was a big year for me because I made some major strides in my emotional wellbeing and

started practicing far better nutrition. Photo 6: About 3.5 years post detransition. My mental and physical health are better than they have ever been, but there is still much work to be done!

I firmly believe now that overcoming adversity is the only way a human being can truly come to enjoy and feel proud of themselves, but there is such a thing as unnecessary harm. I am undecided on whether my experiences constitute this, and I guess I just hope the reward is sweet when I more fully overcome the challenges I have been dealt.

My story is not a fluke, and I am not uniquely troubled or irresponsible. What I am though, is fortunate, because there are others for whom the harm has been exponentially worse. Though there is much strength to be found in overcoming, the fact is that today, any young person who remotely struggles with self-esteem, making friends, fitting in to common gender roles, or body image is now vulnerable to being subjected to what amount to medical experiments that may permanently destroy the prior functioning of their bodies before they have had the chance to build identity and strength through the normal means of overcoming life's challenges. I have seen firsthand that for some people, the medical and psychological damage is far beyond what could be considered a healthy amount of adversity.

Transition was easy...Detransition was not

Abel, <https://pitt.substack.com/p/detransitioner-perspective-transition-1f1>

Aug 17

My name is Abel Garcia, I was born in 1997 to a Mexican family who came to the US illegally. Due to my parents' illegal status, I was raised by my grandparents because my parents were working non-stop so they could support me. Growing up I was a very shy, quiet, and timid boy, I was and still am an over-thinker. With my father working non-stop, I did not have a male role model in my life growing up. As a kid, I did not feel comfortable as a boy because of my overthinking and also because I was not the most masculine boy growing up. My feeling that I was not a typical boy led to my belief that I must be a girl.

Even though I had issues with what it meant to be a boy or a man while confusing my different nature as a girl/woman, I did not know what the word "transgender" was until I was much older and found the word through YouTube. Not knowing much and assuming that was what I was, especially with my childhood, I believed I was transgender. But because I was a minor I did not move forward on those thoughts, and I just put them in the back of my mind. It was not until after I left high school that I decided to transition from male to female.

I came out as transgender to my friends who were all supportive of my decision, I then came out to my mother a few months later in December of 2015. My mother broke down crying when I came out to her as transgender, she then asked me many questions mostly regarding what if I made a mistake or what if I realized I wasn't transgender, I informed my mother then that I knew this is what I wanted and that I could not be wrong regarding this. A few months later I went to see a therapist regarding my identity as a transgender woman at my local LGBT center, I received a female therapist. This therapist did not know how to handle transgender patients so, after three sessions with her, she then transferred me to her supervisor who had more experience with transgender patients.

The next therapist that I spoke with, immediately affirmed me as a transgender woman and informed me that she had my letter to transition during my first session with her. When I asked her why she felt comfortable recommending this during my first session with her, I was informed that she did not want to gatekeep me from my transition. Even though I wanted to transition then I waited a couple of months before I accepted the letter to transition— a part of me knew that this could be irreversible and due to that possibility, I took a bit longer to start my transition and gave myself a plan regarding surgeries. My original plan was to wait five years before I received top surgery (aka breast implants) and ten years before I got bottom surgery aka penile inversion/neo-vagina.

Before accepting my letter to start hormones, my father had learned about my plans to transition from male to female. My father being Mexican did not approve of my choice and decided to fix me because, at this point in my life, I had not been in a relationship with a woman. My father's idea to fix me was for me to have a relationship with a woman. In 2016, my father took me to Mexicali under the pretense that he needed a backup driver to return from Mexico to the United States. Later in the day after completing his business in Mexico, we parked in a parking lot, and my father then brought me into a "restaurant" for a bite to eat.

The building was painted black both inside and outside, and had tinted windows. I had a horrible gut feeling but I went along with my father because I was in a country where I did not know nor knew how to stand up for myself. After a few minutes of sitting down, I heard my father's voice telling me to stand up and pick a woman. At that moment I realized that I was not at a restaurant but instead at a brothel.

I looked up and noticed a row of women who looked to be in their 20s. My father told me to pick one of the ladies and, not knowing what to do, I picked a random lady from the group. Before she had a chance to lead me inside, my father told the woman that I had picked that he wanted to speak with her alone. I was told to go on ahead without her, but instead I hid around the corner, and I overheard my father informing the young lady "take care of him, it's his first time". After my father and the woman who I was supposed to have intercourse with finished their conversation, the woman walked toward me, and together we walked into a room.

I do not recall most of what happened next, not because I was drugged or anything, but because I have chosen to repress those traumatic memories. From what I do recall, after entering the room, I was told to undress and that she was going to give me a massage. Eventually, we went from the massage table to the bed. While I do not recall exactly what happened next, I could not perform with her, and eventually, our time ended. But before we left the room and went back to my father, I asked her to lie to my father that we had a great time and that it went very well, which she did. I was utterly disgusted by the event but, for my father's sake I acted like I enjoyed the experience. My father seemed proud of me—he believed he had fixed me with this encounter.

Actually though, this experience had the opposite effect. It was the pivotal moment that led to my decision to continue with transition, and to go down a path of self-destruction. I eventually spoke with my therapist informing her of the incident in Mexico but, because she was a

gender-affirming therapist who worked with transgender patients, she did not see my recent trauma as a causal event and continued to affirm me as a transgender woman.

I continued to see my therapist for five more months before I finally moved out of my parents' house and, a month later, I started hormones, after obtaining medical clearance from a doctor who lied to me in saying that I could become a woman, I just needed hormones and surgeries. The doctor even brought in a transgender activist to inform me that I was not just a feminine man, but I was a transgender woman—and he could tell this by the proportions of my body. I sadly believed the lies that I was told.

Once I started hormones, I was happy that I was finally able to be my true authentic self. I was affirmed by everyone who knew that I was transgender. A few months later I got my name and sex marker changed on all my documents and was recognized as a woman legally. A year after I started hormones, I got my letter to get both top and bottom surgery approved. During that session I only requested top surgery, but I did not want to get bottom surgery yet. I did not know it at the time, but I was given both letters of approval at that appointment. I only found out when I got a letter from my insurance company saying that I was cleared to meet up with my surgeons for both top and bottom surgery. I ignored the letter for the bottom surgery at that time.

In May 2018, I had breast implants. Initially, I was very happy with the results of my surgery. Three months after I got surgery, however, I realized that I made a mistake and that this was not for me. I had to then accept that I had damaged my body, but that I would always be a man even if I continued to go down this path of self-destruction. I was just a man—a man who was in the process of being mutilated to appear as a woman—and I was now a decoy or caricature of what I believed a woman looked like.

When I reached out for help to detransition from the therapist who signed off on my transition, I was met with pushback. My therapist informed me that my desire to detransition was caused by childhood trauma. I realized that this therapist would only affirm my transgender delusion, and would never give me the proper help I needed. I looked for a new therapist through my medical clinic—but this new therapist was as worse as the last one maybe even worse.

This was late 2018. In early 2019 I decided that joining the military was the only or best way to get a therapist to sign off on my detransition, because at the time you could not enlist in the military if you were trans unless you detransitioned or finished your transition. My new therapist did not like that I was willing to throw away my progress regarding my transition because of the military and instead told me to look at other avenues that did not require me to detransition. He informed me that I should not be too cavalier regarding my detransition as it could have irreversible damage to my body and be dangerous. I again tried to find another therapist but instead, I found a detransitioner by the name of [Walt Heyer](#).

Mr. Heyer is a detransitioner in his 80s but when I reached out to him, I told him that I had nowhere to look for help and I felt hopeless. After telling Heyer my story and where I lived, he informed me that he had a friend and therapist in my area who could help me fix my life. A few months later I was finally able to see Walt's friend, my final therapist and the one who was able

to help me detransition. During the first session I had with this therapist, he informed me that because we were in California, everything we were talking about and doing, was of my own free choice and not of his doing, because if the state were to find out they would accuse him of conversion therapy and strip him of his license.

A few months later I started my transition back to being a man. As you will see, this process was infinitely more involved, time consuming and difficult than the cavalier sign off of my original transition—the exact opposite of the way it should be. The process required me to find two medical professionals to sign off on my detransition, submit it to my health insurance and then find a surgeon who would remove my implants. Months passed and I was eventually able to find a second medical professional to sign off on my detransition, but this was after pinpointing who was covered by my insurance and explaining my story to the medical professional and his staff until I was given an appointment. It was an ordeal. Once we secured both letters for my detransition, next we had to submit them to my insurance company which was easier said than done.

Once we submitted the documents to my insurance company, we waited—and then, finally, I was denied! Fortunately, I was able to appeal the decision, which I did and after thirty days I was approved. My implants were removed (by the original surgeon!) in December of 2020. I had to then fight the state of California to allow me to change all my documents back to male, which took a total of 6 months. I then spent the next year and two months wearing a chest binder—the same product that young women wear to transition from female to male to make their chest appear flat. For me the binder was necessary because I had developed gynecomastia from the cross sex hormones I took, from the trauma to my body of having implants added and removed, and because I was overweight. Fast forward to February of 2022 I had one final surgery to finalize my detransition, I had my chest reconstructed to be flat and removed all the excess skin that I had developed. Unfortunately, I could not reverse everything done to my chest, I now have a chest with scars that will forever serve as a reminder of the choices I made.

Looking back to these last seven years, I am a young man in his mid-twenties who has damaged his body for a lie. Amongst the many negative side effects of my “trans journey”, many of which may only be revealed later in my life, my genitals have atrophied and shrunk. I have difficulties relieving myself in the bathroom, and pain when I urinate. I do not know my fertility status, but I do not suspect to be fertile after being on estrogen for two and a half years while compressing my genitals with tight clothes and because of the atrophy I now suffer from. I have also developed a shake on the left side of my body, mostly affecting my shoulder and face. I’ve been told it is more than likely Multiple Sclerosis—which estrogen put me at a much higher risk for. I also have numbness in my chest due to the multiple surgeries I underwent.

I am now speaking out—I think it’s long past time that others learn about the costs of transition, which I am now, sadly, paying. It’s not as advertised, to say the least.

An open letter

Watson and Others, plus Angus Fox, <https://genspect.org/an-open-letter/>

By [Angus Fox](#) / 22 September 2021

This letter was recently tweeted out by Genspect advisor Sinéad Watson. We continue to be inspired by Sinéad's commitment, and the depth of her understanding of the trans phenomenon. Sinéad's kindness and thoughtfulness shine through, as ever, and we are proud to count her among our team.

Dear Professor Shashank V. Joshi,

I am writing to you on behalf of a group of detransitioned women regarding your fellow Dr Jack Turban. We are deeply concerned with Dr Turban's disparagement of psychiatric intervention

and exploratory psychotherapy, his singular endorsement of affirmative therapies for people with gender dysphoria, and his dismissive and derogatory treatment of those of us who detransitioned due to transition regret.

We are but a few of many that have been the victims of this type of cavalier attitude. We all suffered from gender dysphoria at one point (and some still do), and were led to believe that our best chance of treating our dysphoria was to medically transition. As it turned out, this was not the case. As a result, we now have to live with bodies and voices that have been irreversibly changed (and in some cases damaged) by hormones and surgeries, when what we needed was a compassionate and thoughtful exploration of our gender distress through talk therapy. Some of us will now never be able to have children and many of us live with great distress and regret every day.

Not only did physicians like Dr Turban fail us by sending us down a singular path of transition, they are now letting us down once again by disparaging our experiences and even our existence, when they should be providing us with support to help us heal from our unnecessary medical transitions. The fact that Dr Turban is a psychiatrist at Stanford and uses his credentials to promote his reckless approach is especially troubling, as he has been granted a large and influential media platform. As we see more and more distressed young people following in our footsteps of a rushed medical gender transition, in a few years, we fear the consequences of Dr Turban's activism will be catastrophic and visible to all.

Dr Turban does not hide his disregard for the role of psychotherapy in treating gender distress, and his singular belief in medical and surgical approaches to treating gender dysphoria, whatever its cause may be. Appearing on the GenderGP Podcast episode 'Exploring Detransition with Dr Jack Turban' (2021), hosted by Dr Helen Webberley, a UK physician criminally-convicted for running an illegal clinic, Dr Turban says:

"There's no psychiatric intervention for gender dysphoria. There are medical interventions for gender dysphoria, if you will. And it's not the rule like right, how the psychiatrist's going to treat gender dysphoria, they're not like they're not going to make that go away. The only way that it's ever been proposed that psychiatry can do that was through conversion therapy, which obviously doesn't work."

As you will read later in this letter, many detransitioners report that they strongly wish they had received exploratory psychotherapy rather than affirmation, thus Dr Turban's insinuation that this would be tantamount to conversion therapy is highly disturbing.

Dr Turban describes detransition, in the GenderGP podcast, as having "*become this really awful word... I feel like 90% of the time when you read it, it's really being weaponized.*" The claim that discussing detransition is problematic due to the topic being "weaponized" has been used to shame and silence detransitioners who try to tell our stories. This bullying of a very vulnerable group is unacceptable, and we find it incredibly worrying that Dr Turban would participate in the accusation that detransition is "being weaponized," furthering the bullying of detransitioned individuals. This is not only a matter of rhetoric. Many of us are unable to receive any

meaningful support from the mental health community. Instead of helping us heal, many mental health professionals informed by the likes of Dr. Turban continue to steer us toward medical transition, unable to accept our lived experience. There are more and more people like us sharing their stories of transition regret openly online, and we implore you to look these up.

Dr Turban goes on to say:

“when you say detransition people usually think that means like transition regret. It brings up this idea that somebody transitioned, then realize like, oh my god, that was a huge mistake. I’m actually cisgender, I regret every domain of gender affirmation I’ve ever had. And as I’m sure you know, that’s not the reality of the situation.”

Dr Turban is, again, completely dismissing those of us who have experienced transition regret. As detransitioned woman, we are deeply hurt that Dr Turban would find it appropriate to suggest that our pain and distress is not a reality. We do, in fact, regret every domain of gender affirmation we ever had and the irreversible changes that medical transition did to us that we must now live with for the rest of our lives. It is, therefore, highly unprofessional and deeply offensive to see comments like this from a fellow at Stanford.

At the same time as Dr Turban dismisses our existence, he also claims to represent us in research, but his bias is clear: the goal is to minimize detransition because it contradicts Dr. Turban’s professional aspirations to promote transgender medical and surgical interventions. In the GenderGP podcast he also says:

“We have a paper that hopefully is coming out soon, where we took the data from the 2015 US Transgender Survey. So this was a survey of over 27,000 transgender adults in the United States. And we found that of those who had transitioned in some way, don’t quote me on that exact number, but it’s something like 13% of them said that at some point in their life, they had detransitioned. And when we looked at why they did that, the vast majority of them, like close to 90%, I think, had detransitioned due to some external factor.”

We bring to your attention that the 2015 USTS survey that Dr Turban repeatedly uses for his research is an online convenience survey that was promoted by transition advocacy sites. We believe in and support transgender rights and trans people, but respectfully submit that this survey, subtitled “Injustice at Every Turn,” which is full of biased questions that promote a political agenda, serves as a poor base for respectable research. Dr Turban previously attempted to use this survey to claim that psychotherapy leads to suicide; his problematic analysis and conclusions were thoroughly outlined in a rebuttal by Roberto D’Angelo et al. in ‘One Size Does Not Fit All: In Support of Psychotherapy for Gender Dysphoria’ (2020), to which Dr. Turban never replied, even though he had the chance to do so. Instead, he attacked the researchers on Twitter. Dr Turban also used the same survey to attempt to show that puberty blockers saved lives. Another rebuttal showed just how flawed that piece of research was (‘Puberty Blockers and Suicidality in Adolescents Suffering from Gender Dysphoria’ (2020) by

Michael Biggs). Dr Turban failed to respond to that critique in the scientific area, but did go on media circuit to promote his deeply flawed conclusions.

Most recently, Dr Turban misused this problematic sample to discredit detransition experiences in his research, 'Factors Leading to "Detransition" Among Transgender and Gender Diverse People in the United States: A Mixed-Methods Analysis' (2021). Dr. Turban did not seem troubled by the fact that 100% of the respondents were transgender-identified and did not identify as detransitioners. This is an expert from his study:

These [detransition due to internal factors] experiences did not necessarily reflect regret regarding past gender affirmation, and were presumably temporary, as all of these respondents subsequently identified as TGD, an eligibility requirement for study participation.

Dr. Turban's conclusions were that detransition is largely a temporary phenomenon, happens in response to external pressures, and does not really represent a problem for those who detransitioned. These conclusions are highly flawed and ignore those of us who have detransitioned due to transition regret, and who were excluded from the survey for no longer being transgender-identified.

In comparison, recent detransition research conducted within the actual detransition community ('Detransition-Related Needs and Support: A Cross-Sectional Online Survey' (2021) by Elie Vandebussche) found very different results: that most of us detransition due to the internal realization that transition was not what we needed, that transition did not help and can actually make things worse for us, and that we found other non-invasive ways to alleviate our dysphoria. Further, the research showed that detransitioners expressed the need to find alternative treatments to deal with their gender dysphoria, but reported that it was nearly impossible to talk about it within LGBT+ spaces and in the medical sphere.

Vandebussche found that most detransitioners currently are in dire need of psychological support on matters such as gender dysphoria, co-morbid conditions, feelings of regret, social/physical changes and internalized homophobic or sexist prejudices. The research confirmed that detransitioners experience prejudice when working with medical and mental health systems, which Dr. Turban's vocal activism directly emboldens and reinforces.

We feel it important to add that in May 2021, the Karolinska Hospital in Sweden issued a new policy statement regarding the treatment of gender-dysphoric minors. This policy has ended the practice of prescribing puberty blockers and cross-sex hormones to gender-dysphoric patients under the age of 18. Finland also revised its treatment guidelines in June 2020, prioritizing psychological interventions and support over medical interventions. Major changes are also underway in the UK, as the NHS has convened a "Cass Review" to examine the practice of transition for young people and the evidence that underlies it.

Thus, it seems evident that there is a growing concern over the proliferation of medical interventions that have a low certainty of benefits, while carrying a significant potential for

medical harm. It is worrying that Dr Turban does not seem to demonstrate the professional curiosity to rethink his endorsement of medical transition for minors and his dismay at psychotherapy and its role in the care of gender dysphoric individuals of all ages.

We are also deeply concerned by Dr Turban's activism to suppress the debate on the proper care for gender dysphoria in the public arena. On May 25, 2021, Dr Turban tweeted the following:

"When I spoke with @60Minutes about their "detransition" story and asked where they found the people to profile – they refused to tell me and became defensive. We still don't know if they searched for people on TERF forums, and transparency would be appreciated."

We bring to your attention that "TERF" (an acronym for "trans-exclusionary radical feminist") is a pejorative term, and that Dr Turban's use of it to smear and dismiss the experiences of the detransitioners who appeared on 60 Minutes is incredibly hurtful. That a fellow at Stanford would criticise 60 Minutes for having a brief segment featuring detransitioners has many of us very concerned that, should one of his patients experience transition regret and subsequently decide to detransition, Dr Turban would be unfit to help them due to his hostility towards the subject.

Therefore, we are deeply concerned with how Dr Turban may practice as a clinician, specifically how he may treat a transgender person struggling with transition regret or a detransitioner seeking to discuss their regret or reverse their transition. His comments on the GenderGP podcast, his flawed use of the USTS, and his hostility towards any discussion of transition regret are all highly problematic and in need of addressing. We ask Stanford to speak out for more thoughtful approaches because, as it stands now, Stanford appears to be silently endorsing Dr Turban's harmful claims that exploratory psychotherapy is tantamount to conversion therapy and that hormones and surgeries are the only appropriate treatment for people with gender dysphoria.

I received affirmative care at my gender clinic. I received no exploratory talk therapy. I injected myself with cross-sex hormones and underwent a double mastectomy. I now suffer from transition regret, and have detransitioned as a result. The distress and harm that I have endured because of the knee-jerk affirmative approach that people like Dr Turban advocates for has been immense. I implore you, on behalf of the detransitioned women who co-signed this letter and myself, to please consider its contents carefully – we wish only to help the many others like us.

Sincerely,

Sinéad Watson

Aug 24

My sudden desire to transition in young adulthood felt like an epiphany. I came across this concept—transgenderism—which, as I heard it explained over and over, increasingly sounded like something that might apply to me. The visualization I had of the moment I made the decision (because there is a moment in time I can pinpoint) was completely cinematic in my head and has an epic soundtrack.

The part of me that likes to see the positive in everything commends my younger self's flair for the dramatic. I want everything in my life to go like a movie. I want everyone in it to automatically know what I'm thinking and how I'm feeling, I want everything in it to go exactly how I've visualized it a hundred times before, and I want my story to *mean* something because what's the point of suffering this life if it doesn't *mean* anything. (Sorry. Apparently my present self also has a flair for the dramatic.)

Otherwise, though, having the benefit of what I know today, remembering this moment is kind of sobering. I now understand all the moving parts that make up the so-called epiphany. I now understand how they all went together in a way that gave me the wrong answer. And I've also now learned a word for what I was experiencing: apophenia.

"Apophenia is the tendency to perceive meaningful connections between unrelated things."¹ It's over-interpreting patterns from what is essentially just random noise. It's the same concept that leads people to believe in conspiracy theories. At an extreme, it's a type of delusional thinking... you know, like believing you're not a woman when all of the credible evidence points to the contrary?

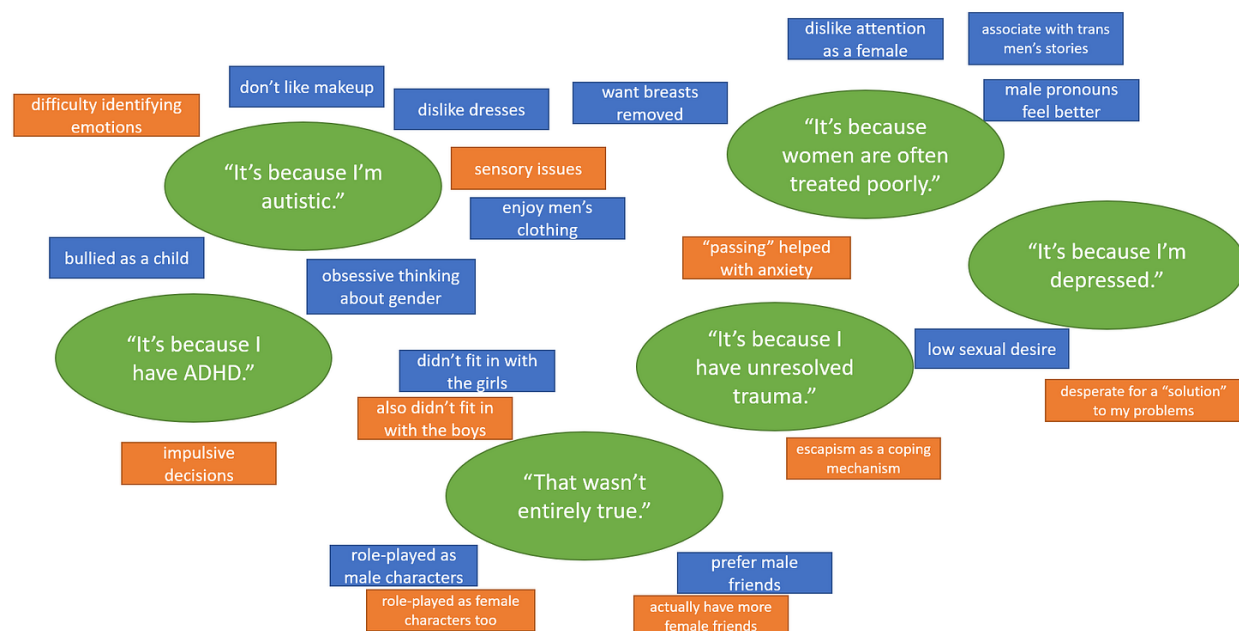

I didn't have an epiphany. I had an apopheny.

When I was making the decision to transition, I came up with a list of evidence that I felt explained why I was not a woman (and was somehow a man instead). I now have better explanations for everything on that list.

I went from something that looked like this:

...to something that looks like this:

I hear frequently that I am meant to take “personal responsibility” for my decision to transition, particularly because I was an adult. This is my take on the situation: I became completely convinced about something that was ultimately untrue. It was a delusional belief. I brought that belief to health professionals who had been taught that it was kinder to affirm the belief than to question it. As a result, I was prescribed cross-sex hormones which caused irreversible changes to my body, and with my belief affirmed, I continued further, having surgeries that disconnected me even further from the reality of my femaleness.

I believe it was medical negligence for them to have failed to properly investigate my delusional belief. My argument is three-fold: “gender identity” is a faith-based belief, not an empirically-recognized condition, and when it comes to medicalization, it is unethical for health professionals to simply accept such a belief at face value; the evidence base for medical transition does not present a straightforward narrative where the benefits always outweigh the risks; and my consent could never have been informed without a proper and thorough exploration of what was affecting my mental health—particularly egregious was the failure to screen for developmental disabilities.

I’ve also written about how [social influence](#) and [developmental disability](#) played parts.

I don’t place blame in one single place. I don’t understand the purpose of yelling “personal responsibility” at me when it is clear that the health professionals who facilitated my transition had their own responsibility towards me. Particularly, I believe they had a responsibility to offer me the type of therapy that would have led to an understanding as in the second diagram above before proceeding to an invasive treatment with permanent effects.

I do have to take responsibility for *something*, though. Of course I do. I may have been delusional, but coming to the wrong conclusion was still my mistake. I have the responsibility of figuring out how I was able to make such a massive mistake. I have to learn from the process. I have to teach myself what critical thinking looks like. I have to recognize logical fallacies. I have to be able to identify abusive behaviour. I have to see red flags for what they are and not what I want them to be. I have to acknowledge that my voice of reason sometimes says things I don’t want to hear but which are true.

I think nearly everyone who transitions experiences that voice of reason. At least, when I experienced doubts about transition, people were certainly happy to remind me that everyone who transitions does. It’s just internalized transphobia. Maybe young transitioners don’t hear it as often, especially if they have a regular routine of people affirming them. As a transitioning adult, though, it’s a lot harder to live in the real world. It’s a lot harder to establish yourself in society. It’s a lot harder to find satisfying relationships. Over time, it gets harder and harder to ignore the fact that it feels like everything you’ve invested into this identity has been for absolutely nothing. All transition does is create virilized women and feminized men, and we have so few long-term studies about what lifelong synthetic cross-sex hormones does to a person. The whole thing is just one giant experiment.

Doubt is why so many true believers, when confronted with biology or the existence of detransition, feel like they have been traumatized by the interaction instead of being able to laugh it off. People who transition are invariably prone to rumination, and doubt can cause a spiral. Imagine the devastation if you are wrong. What's been done to you. What's been done to thousands of others. What we're happily doing to naive little children. The thought would send anyone into a tailspin. Of course it's easier to believe everything's fine.

Imagine feeling your whole life like you're "crazy" until you find a community who assures you that you aren't and enables you on a journey of self-discovery, only to find at the end that... hey, you actually were crazy the whole time. It's a bummer.

I don't know if I'm succeeding at critical thinking. I have a difficult time taking hard positions on anything nowadays. Some days I'll be really firm on one thing, and other days I'll start to loosen up a bit. I'm worried about overcommitting... what if I make a mistake again? I second guess whether I'm doing the right thing. Sometimes when assessing people, I wonder if I'm giving them the benefit of the doubt or just ignoring red flags.

This whole ordeal has left me feeling like I can't trust anyone, including myself. I had a hard time asking for help *before* I transitioned. Health care professionals felt a little safer. Now I don't know if I'll ever be able to forget the kind of recklessness they had with my life. People who loved me cheered me on as I nullified every body function that identified me as a woman, then berated me and claimed I had been radicalized when I shared that I felt like I'd been brainwashed.

How am I supposed to know who has my best intentions in mind? How do I know which authorities to believe? How do I know if the people I think are my friends actually care about my well-being? Which of these people just want me for my story? Who is safe to be vulnerable in front of?

Transition was a form of escapism for me, and escapism is still my coping method of preference. I'm still chronically online. I feel like most of my existence is just a concept on the Internet. Otherwise I'm just electricity auto-piloting a meatsack that barely feels a thing. Most days, it is so difficult to just be present.

I value material reality because it keeps me grounded. It's good to have things that you feel you can safely put your faith in. I trust empiricism. I don't trust me. I've let myself down too many times. But I'll get there.

The Boy Who Shifted Shapes: A Detransitioner's Story

Shape Shifter, <https://reduxx.info/opinion-the-boy-who-shifted-shapes/>

By

Shape Shifter

June 22, 2022

I call myself Shape Shifter.

While the name is not my own, I feel it describes me well. I have traversed the darkest reaches of the so-called “gender spectrum” in search for what – who – I was, and transformed myself in the process multiple times.

I can say now that I am a 31-year-old gay male who lived life as a transgender woman for a decade.

I grew up in predominantly Muslim country in Eastern Europe. From the youngest years of my life, I was ‘gender non-conforming,’ and even before I hit puberty I knew I wasn’t like the other boys. But as I got older, I realized that my sexuality and desire to present myself the way I felt most comfortable was not accepted by the society I had been born into. I was rejected both at school and in the home. Bullied by peers, and treated as a burden by my family for my femininity.

My father would tell me I “wasn’t a real man.”

My mother expressed shame over my height and physical attributes.

It doesn’t take long to drown when you’re thrown into a sea of resentment with no lifejacket.

Slowly but surely, I began to hate everything about myself. My “feminine” body and mannerisms were a burden, as was my sexuality. Still, all I could focus on was improving my English with the dream I could leave my country and move to the West.

When I was 20-years-old, that dream became a reality. I moved to the United States to begin graduate school, and for a moment breathed the fresh air of a liberation I’d never before known. I was finally able to grow out my hair and dress in the manner I preferred, and I could be openly gay without fear of persecution.

But that moment was tragically brief.

A question from a well-meaning classmate would put the breaks to the freedom I was enjoying.

“What are your pronouns?”

I was confused, uninitiated. I'd never been exposed to the concepts present in contemporary gender ideology before, and began to research into it like any curious person would. Little did I know at the time, every page I scrolled through and concept I learned was tugging me farther and farther away from the liberation I had just barely begun to enjoy.

Faced with an avalanche of testaments to affirmation and validation, I began to convince myself I was a “straight woman” trapped in a man's body. After the life I had lived, wrought with such repression and condemnation, it almost made sense.

It explained everything, in fact. The reasons why I never fit in or felt comfortable with my body suddenly became crystal clear. The logic behind it also promised an escape, something I had been desperately searching for my whole life.

I could be free from the homosexuality that I had been shamed for since my earliest years. I could be free from being a “feminine” man. I could be a heterosexual woman. Then I could be accepted, find love, and live a normal life.

In my excitement, I almost immediately began presenting myself as a transgender woman. I distanced myself from my gayness and my maleness. I changed my pronouns and quickly changed my name and legal documents.

But despite my initial feelings I had done the right thing, the escape – the freedom – I sought continued to elude me.

While I had been told while I was growing up that I was too “feminine,” male sexual partners were now telling me I was too “masculine,” and not womanly enough. I decided it must have been because my “wrong body” still needed medical correction.

I was able to get feminizing hormones rather quickly through Fenway Health in Boston, Massachusetts, which only required me to tell them I was living as a woman and “felt” like a girl on the inside. Soon after, I got facial feminization surgery and breast implants.

While my dating pool initially increased, I was told by members of my transgender community that men who were comfortable with my penis were “tranny chasers” who didn't see me as a real woman. This, coupled with the fact these men often didn't want anything to do with me out of the bedroom, made me feel like I would never find true love until I had completed all of the surgeries associated with transitioning. My mental health began to deteriorate, and I decided that I needed bottom surgery in order to feel happy.

I ended up getting two letters from mental health professionals at Fenway Health stating that I had gender identity disorder and that I was a good candidate for sex reassignment surgery. At no point was I asked about my childhood trauma, the repression of my sexuality in my home

country, or even whether I had any co-morbid mental health concerns. They assumed that my depression and anxiety issues were due to gender identity disorder, and that radical medical intervention would be the solution.

I had my surgery in 2015, and my life has been a living hell since then.

The “neo-vagina” the surgeon had constructed was too tight for comfortable penetrative sex, and I started rapidly losing depth despite rigorous and painful dilations because my body was treating the tunnel as a wound and was constantly trying to heal itself.

Within a few months, I was back on the operating table to widen the constructed passage. The surgeon blamed me for not dilating enough, though I had followed the instructions he’d given. Even after I left the hospital, I lost one inch of the canal’s depth in the drive from Pennsylvania to Massachusetts as my body continued to treat the surgical creation as a wound that needed to be closed.

Despite all of my efforts, most of which resulted in extreme discomfort during urination, the canal was narrowing once again.

My second revision was done with a different surgeon, one who harvested tissue from my colon in order to add it to the constructed canal. Within one month, the passage had tightened once again and dilation was painful.

Shape Shifter in a 2017 YouTube video documenting the aftermath of one of his neo-vagina revisions.

By my third revision surgery, I had done so much research that I was begging the surgical team to order certain supplies to keep my passage from closing again. During this surgery, my pelvic bone was shaved down to make the entrance to my hole wider. But after I removed the inflatable stent I had inserted during surgery, I discovered I had developed a colorectal fistula — an abscess-like infection. I had to be scheduled for fistula repair surgery.

The fourth revision to my neo-vagina resulted in the fistula tearing back open.

It was then that I realized no one had known what they were doing. Everything was experimental. All of it was being made up as they went along — and I was nothing more than a guinea pig.

I later discovered the surgeon, Dr. Salgado, who had done my last three revisions was let go from the University of Miami for taking pictures of his patients while they were under anesthesia and posting them to Instagram.

Currently, my neo-vagina is only 1 inch deep. I have spent thousands of dollars flying across the United States trying to find a surgeon with a solution, but I have been told that due to the

amount of revisions I have had, any attempts would likely result in me having to wear a colostomy bag.

I realize now that in my search for freedom... I have mutilated myself.

I lost my perfectly healthy genitals. I lost my 20s. I lost family and friends. I lost my chance at a comfortable, fulfilling sex life.

My insurance, however, has paid out over \$250,000 to surgeons and hospitals for the various hack-jobs that had been performed on my body. Everyone made out like a bandit, yet I had nothing to show for it. Not one of the surgeons who lined their pockets off of my trauma has ever called to check up on me, ask about my quality of life, or see if I was still alive.

In 2018, I made my first YouTube video discussing my complications. At the time, I was still living as a "woman," and I had thought I would document my thoughts and experiences as I believed they were rare.

But after I uploaded my first videos, I had many trans-identified individuals write me and explain they were in similar positions. I realized there were a lot of people with complications, but they weren't included in any official statistics or data.

Just as my journey had started, it would end with research.

I realized hormone treatments were not even FDA approved for treatment of gender dysphoria. That there were no studies proving that hormone replacement therapy was safe in the long run. And, just as I had thought, all of the surgeries were experimental.

But more than anything else, I realized I was not a "woman." I was a gay man who had been sold a lie.

After everything I have been through. I realize medical transition destroyed my mental and physical health, and lowered my quality of life substantially.

At 31-years-old, I have osteoporosis and scoliosis from the impact of hormone replacement therapy. In fact, my testosterone was so low that in January I began taking it to improve my bone density. My T-levels increasing resulted in a slew of extreme emotions towards my transition. It was as though a part of my brain that had been dormant was activated, and I was suddenly wrought with the full depth of the realization that I had made a mistake I could never take back.

I was at my breaking point, and experienced suicidal ideations. Entering therapy helped me realize I had heavy childhood trauma that should have been addressed prior to ever allowing me to proceed with an irreversible medical intervention. I discovered I had borderline personality

disorder as well as body dysmorphia, and no matter how far I took my surgical modifications, I would have never felt “at home” in my body.

Since I have come out as a detransitioner, I have spoken to so many people like me whose stories are important and deserve to be heard. In fact, I believe the detransitioner community will be growing exponentially in the coming years. It is tragic to think about the parents who will one day realize they ruined their child’s body by jumping to “affirm” how they perceived themselves at one moment in time — kids who may have just been gay or gender-nonconforming like myself.

I have also met criticism from those who still subscribe to gender ideology who claim that me speaking on my experiences will take away “life saving” care from trans people.

But I got that care. And where is my life?

Sometimes I feel like I am in a nightmare I will wake up from. My eyes will open and I will have my original body and have my whole life ahead of me to make decisions. Since beginning testosterone, I also sometimes get ‘phantom penis’ symptoms which are extremely traumatic.

Medical detransitioning is even more experimental than medical transitioning, but I am not rushing into anything anymore. One thing is for sure, I will never again identify as transgender woman — a label that not only endorses questionable medical experimentation, but also has a negative impact on the rights and dignity of females.

My idea of freedom is different now than it was those years ago, but the challenges are, ironically, the same.

In addition to the criticism from those who champion gender ideology, I also get flak for having long hair and nails but identifying as a man. Yet again I am being criticized for not fitting certain rigid definitions of masculinity — the very thing that set me down this path in the first place.

But I am done trying to ‘correct’ myself to please others.

I am done shifting shapes.

 @TullipR

I want to tell everyone what they took from us, what irreversible really means, and what that reality looks like for us.

No one told me any of what I'm going to tell you now.

I have no sensation in my crotch region at all.

You could stab me with a knife and I wouldn't know. The entire area is numb, like it's shell shocked and unable to comprehend what happened, even 4 years on.

No one told me that the base area of your penis is left, it can't be removed - meaning you're left with a literal stump inside that twitches.

When you take Testosterone and your libido returns, you wake up with morning wood, without the tree.

I wish this was a joke

TullipR 🌈🏳️‍🌈🏳️‍🌈 @TullipR · 4h ...

And if you do take testosterone after being post op, you run the risk of internal hair in the neo-vagina. Imagine dealing with internal hair growth after everything?

What a choice... be healthy on Testosterone and a freak, or remain a sexless eunuch.

Chloe's story: puberty blockers at 13, a double mastectomy at 15

Chloe Cole & Michael Cook, MercatorNet,

<https://mercatornet.com/chloe-cole-gender-transition/80073/>

Note: most of Chloe's remarks were originally from a speech in the public forum of the California State Assembly.

Laying bare the iniquity of doctors and psychologists who exploit the confusion of children and adolescents.

by

Jul 27, 2022 / 3 mins

[Michael Cook](#)

/ 12

Chloe Cole / Facebook screenshot

The California State Assembly has been studying a bill, [SB 107](#), to declare the state a sanctuary for minors who have been denied transgender -affirming medicine and surgery elsewhere.

SB 107 would permit insurance companies, physicians, and contractors to disregard subpoenas about child custody if the child is being medically treated for gender dysphoria. It would also ban health care providers from providing medical information requested from another state if that state has a policy allowing civil action to be taken against individuals who perform “gender-affirming health care” on children.

A young California woman, Chloe Cole, has testified before legislators in her own state, in Louisiana, and in Florida about her experience at the hands of gender-affirming doctors. She began to transition to a male at 13; she had a double mastectomy at 15; and she detransitioned at 17. Her brief speech lays bare the iniquity of doctors and psychologists who exploit the confusion of children and adolescents.

This is [the text of her address in Louisiana](#). It is heart-breaking.

My name is Chloe Cole, and I am from the Central Valley of California and a former transgender child patient. I am currently 17 years old and was medically transitioning from ages 13-16.

After I came out to my parents as a transgender boy at 12, I consulted a pediatric therapist in July of 2017 and was diagnosed with dysphoria by a ‘gender specialist’ the following month. The healthcare workers are trained to strictly follow the affirmative care system, even for child patients, in part because of California’s ‘conversion therapy’ ban. There was very little gatekeeping or other treatments suggested for my dysphoria.

When my parents asked about the efficacy of hormonal, surgical, and otherwise ‘affirming’ treatments in dysphoric children, their concerns were very quickly brushed aside by medical professionals. I didn’t even know [detransitioners](#) existed until I was one.

The only person who didn’t affirm me was the first endocrinologist I met. He refused to put me on blockers and expressed concerns for my cognitive development. However, it was easy to see another endocrinologist to get a prescription for blockers and testosterone, just like getting a second opinion for any other medical concern. After only two or three appointments with the second endocrinologist, I was given paperwork and consent forms for puberty blockers (Lupron) and androgens (Depo-Testosterone), respectively. I began blockers in February of 2018, and one month later, I received my first testosterone shot. I received Lupron shots for about a year.

After two years on testosterone, I expressed to my therapist that I was seeking top surgery, or the removal of my breasts. I was recommended to another gender specialist, who then sent me to a gender-affirming surgeon. After my first consultation with the surgeon, my parents and I were encouraged to attend a ‘top surgery’ class, which had about 12 Female-to-Male (FTM) kids. I was immediately struck by how early some of them seemed in their transition and how

some were much younger than I was; I was 15 at the time and had been transitioning for 3 years.

In retrospect, the class inadvertently helped to affirm my decision because of the sense of community provided by seeing girls like me going through the same thing. Despite all these consultations and classes, I don't feel like I understood all the ramifications that came with any of the medical decisions I was making. I didn't realize how traumatic the recovery would be, and it wasn't until I was almost a year post-op, that I realized I may want to breastfeed my future children; I will never be able to do that as a mother.

The worst part about my transition would be the long-term health effects that I didn't knowingly consent to at the time. I developed urinary tract issues during my transition that seem to have gotten worse since stopping testosterone. I have been getting blood clots in my urine and have an inability to fully empty my bladder. Because my reproductive system was still developing while I was on testosterone, the overall function of it is completely unknown. I have irreversible changes, and I may face complications for the rest of my life.

I was failed by modern medicine."

Did Chloe give informed consent to these life-changing procedures? Is her experience really different from the atrocities committed by German doctors at Auschwitz or American doctors in the Tuskegee syphilis studies?

Michael Cook

Purification Rites

Cut Down Tree, <https://cutdowntree.substack.com/p/purification-rites>

An autobiographical essay

[Steven A Richards](#)

Apr 26

There's a concept which I was exposed to a lot while I was transitioning: "testosterone poisoning". It's talked about online and in trans spaces, and is pretty common; I've seen multiple trans women wearing "I survived testosterone poisoning" t-shirts.

The idea is that, for male-to-female trans people, the testosterone naturally produced by their bodies is toxic. It makes them grow hair, causes their bodies to develop in a masculine direction during puberty, deepens their voices, changes how they smell, increases their libido, and often makes them more aggressive and prone to anger. Later in life, it can cause male-pattern baldness. These changes are upsetting and confusing to many young boys as they enter puberty, but most of them learn to cope with, and even appreciate, the changes that come to their body as they grow into adults.

I didn't get that chance, and never will.

I was terrified of what testosterone was doing to me. I didn't want to be a man. I didn't want to be big and hairy. Men scared me. I'd seen my mom assaulted when I was young, and I didn't want to be like the man who'd done that to her. The idea of testosterone poisoning made sense to me because maleness itself terrified me. I'd been bullied a lot in school by other boys, and a lot of that bullying involved sexual abuse—groping, inappropriate touching, striking my butt and genitals, and verbal harassment (wolf-whistling and yelling sexual comments at me). These, I felt, weren't the sorts of things that happened to men. My suffering was only legible if I was a woman.

This background made me vulnerable to the ideology of transgenderism. I had no friends in high school and spent a lot of time online, and I was exposed to the burgeoning social justice/woke movement before it entered the mainstream. When I connected to the internet, I was inundated with messages about the violence of maleness. This wasn't just "toxic masculinity"—I saw feminists saying *all* masculinity was toxic, that all men were rapists, all men were oppressors, all men should be killed. As a white man, I was directly responsible for all of the oppression experienced by women and people of color. I was fourteen years old and had never been in a fight in my life or said a racist or misogynistic word to anyone, but I believed that the circumstances of my birth made me a monster. I wasn't mentally mature enough to think critically about these ideas, or to take them as anything but literal fact. (Literal thinking is common among autistic people, and I would be diagnosed with autism a few years later.) I believed, all the way down to my core, that all men were evil and all women were unimpeachably virtuous. This was black-and-white thinking; it's one of the reasons why so many autistic people are transitioning. I believed that my very existence was sinful.

I picked up these messages from the internet because I was a chronically online loner. Now this stuff is everywhere, online and off. Is it any surprise that teenagers (frequently autistic teenagers who take everything literally) want to transition when they're exposed to societal messages telling them "men are bad, men are dangerous to women, only men have power" and "you can change your gender if you want to"? Young boys will want to transition to escape the masculinity they're being told is harmful and toxic; and while I can't speak with authority on the subject, I imagine young girls will want to transition to escape the violence they're being told is around every corner, in the eyes of every man who looks at them, and to access the power they're being told they're denied. These hyperbolic, oversimplified distortions of a complicated reality are neither healthy nor empowering, and hurt more than they help. Add that onto the fact that puberty is often a miserable experience, and you have an epidemic of child transition. The same pressures that made me want to transition are everywhere now.

I wanted to transition because my body was my enemy, and my body was the enemy of the world. I hated myself and wanted to punish myself. It was the same feeling that motivates cutting, binge-eating, anorexia, and lashing oneself. My very nature meant I deserved pain. I couldn't remove my whiteness from myself, but maybe I could remove my maleness. The first step was to get rid of the poison coursing through my body: testosterone, the hormone turning me into an animal and a brute. I needed to purify myself.

When you're being poisoned by a chemical which makes your mind and body monstrous—when your very soul is at risk—you'll do anything to make it stop. For me, that meant transitioning. I didn't have any particular reason to want to be female except that women were better than men—in my mind women were smarter, kinder, more empathetic, more beautiful, more moral. I was attracted to women, and felt guilty about that attraction—straight male sexuality, I was told, was repulsive and rapey and objectifying. If I were a woman, I could be attracted to other women in a virtuous way. Maybe I was fetishizing lesbians, but there was nothing leering about it—I simply believed the things that women online were saying about themselves.

Women also, in my perspective as a confused and traumatized fourteen-year-old, were valuable and worthy of consideration in a way that men were not. When women were sexually victimized by men, they seemed to receive sympathy and caring. People moved mountains to protect them. When I told my dad about the sexual harassment I faced at school, he told me I should punch the next person who did something like that to me. My whole life I'd been told that violence was never the answer, and I believed that. I was a gentle soul. Now, because of my sex, I was expected to use violence to protect myself in a way I had no idea how to do. I didn't, and if I had I suspect I would've been suspended for defending myself and the bullying would've gotten exponentially worse when I returned. I didn't receive any protection. If I couldn't handle it myself, I deserved what I got.

I perceived that society viewed women as having inherent value (“women and children first!”) and I envied that, because in my life I felt that no one valued me. My transition wasn't driven by fetishism or misogyny. I was just a lonely, wounded child. All I really wanted was to be loved.

Still, teenagers try on a lot of different identities and beliefs. I'd already had a militant atheist phase. This trans phase might have also passed on its own—if it weren't for the Queer Youth Center. An organization in my area offered resources for “queer youth”, including community groups and sex ed. Opting into a trans identity didn't just mean aligning myself with some vague concept of female goodness, it also gave me a community of friends when I had none. I met my first girlfriend (she called herself a lesbian) at the Queer Youth Center. I went from being utterly alone to being surrounded with love. Adults at the Queer Youth Center affirmed my identity, introduced me to trans activists, and encouraged me to engage in activism myself. (The activism is a central part of the trans movement—these people don't want you to *just* transition, they also want you to spread the ideology. This moral drive to proselytize is part of how the movement has spread so quickly.) While I can't remember if I was ever urged to medically transition, there was definitely a sense that medical transition was the “next step” after adopting a trans identity. I didn't even need that much motivation. People cared about me. I had friends. I was sold.

So I had to transition, which meant I had to convince my parents and doctors to let me transition. Remember, I had been convinced by online hyper-left rhetoric that my soul was on the line here, so nothing was off the table. Adult trans people online gave scripts for how to talk to parents and doctors when you wanted to access trans medical care. I dug through my memories, searching for evidence of a good, gentle female soul buried deep inside my awful, twisted male body. When I was a kid I tried on my mom's sandals. I wore nail polish with my mom and sister. When my mom was nursing my sister, I tried to mimic what she was doing by

holding a doll to my chest. I didn't like haircuts that made me look too masculine. I used these isolated incidents to construct a narrative, and I even convinced myself it was true. I also convinced myself—following the guidance of online transsexuals—that I'd kill myself if I didn't transition. I made suicide threats. I claimed that I'd buy hormones off the black market (again, adult trans women on the internet told me how I could do this if I needed to). I begged, pleaded, and threw fits. Health care providers told my parents that I was trans, that transitioning was the best thing for me, that it would be good for my health. I got my mom on my side, and together we talked my dad into letting me start puberty blockers at 15, after I'd banked sperm (thank God they made me preserve my fertility, because I wouldn't have done it myself) and estrogen at 16. Even this was too slow for me. Every day, my body was masculinizing. Every day, that slow drip of poison was mutating me into a bestial horror.

I wasn't old enough to understand what I was doing to myself. I didn't realize what I was giving up, how permanent these changes I was making were. But I hadn't yet made the worst decision of my life. That would come a few years later, when I decided to have myself castrated.

I was about 20. (I remember being 21 when I got the surgery, while my mom remembers me being 19, and I really don't want to dig up medical records to check—even writing about it conjures traumatic memories.) I no longer cared about being female, but the fundamental self-hatred was still there. I'd chosen a new name—I'd chosen a lot of new names, and none of them stuck—and was telling people to use "they/them" pronouns for me. I wanted to have my testicles removed. They were the source of testosterone, the source of the poison I had to take medication to block. They were symbolic of everything I hated about myself.

No responsible doctor should have performed this surgery. I was frequently changing my name and identity. I had no clear conception of who I was or what I wanted. The delusional thinking which began with me believing I was a woman deep down had morphed into something stranger and darker, encouraged by a trans woman who'd struck up a friendship with me when I was fifteen and they were in their mid-twenties. I saw myself as a being of water and light, an angel imprisoned in a filthy human body. I resented having to eat, sleep, piss, and shit. I particularly hated having sexual desires and wanted to be rid of them. I'd been diagnosed with autism, and would later be diagnosed with OCD. That OCD manifested as a constant fear that my testicles would get tangled up and somehow kill me in my sleep (I told the doctors about this and it didn't raise any red flags). Shortly before the surgery, I'd briefly tried to detransition in a moment of lucidity, but I didn't have a supportive community waiting on the other side to welcome me. After a few months of loneliness, scary changes to my body, and a significantly increased libido that didn't know how to handle, I fled back to the neutering medication and the open arms of my local trans community. All of this should have screamed to any sane person that I wasn't in a mental state where I could understand what this surgery meant or fully consent to it. I needed serious psychiatric help and deprogramming, not to have my balls cut off so I could more closely resemble the sexless angel I wanted to be.

I saw the surgery as a rite of purification. I felt that by removing a part of myself I would become whole. Years of online grooming and ideological brainwashing had made me delusional, but no one pushed back on it. I heard, through my mom, that my dad was worried about me, but we

never spoke about it. I can't remember if he tried; if he did, I'm sure I wasn't receptive. What did he know? The doctors were happy to go through with it, and they had medical degrees. So I took two weeks off work, went into the hospital, and had my balls cut off.

They called the surgery an "orchiectomy", but these days I think of it as a castration. I sometimes have nightmares about waking up afterwards. In my dreams I scream and scream, I run through the hallways howling and begging for them to undo it, to fix me, to make me right again. In reality, I stuffed all my feelings of grief, regret, and horror as far down as they would go. My testicles were gone. My healthy endocrine system, which would have begun to function again if I'd ever gone off medication, had been destroyed. For several years I lived with severe cognitive dissonance, constantly pushing away any negative feelings about the surgery, but eventually I had to admit to myself what had happened.

I hadn't cleansed myself, I'd ruined myself, and I'll never get back what I lost. I've made myself permanently reliant on the pharmaceutical industry for artificial testosterone which will never be as good as the real thing and which can be taken away in a heartbeat if I ever lose my insurance or there are problems with the supply chain. I still have phantom pains, and probably always will, as well as intense cramping in my groin when I do certain exercises. I wasn't warned about any of this by the doctor who performed my surgery.

For many people, transition is an obsessive quest to compulsively eradicate one's own sexed characteristics. It's born from ideology, self-hatred, trauma, and grooming by online strangers. Gay, autistic, mentally disabled, and gender non-conforming teenagers, as well as victims of sexual violence, are the most affected. Pharmaceuticals and plastic surgery investors are getting rich off of the butchery, mutilation, and mass sterilization of these vulnerable and traumatized populations. Doctors and therapists who assist people in transition aren't providing care, they're enabling self-harm and practicing eugenics.

A transition is never done. There's always more surgeries, new treatments, more work to do. You can never carve away enough pieces of yourself to be satisfied. You can never rid yourself of the fundamental facts of your own biology. You can never be cleansed of sin.

The end goal of transition isn't self-actualization. It's self-annihilation.

We are LGB Alliance USA, an organization that represents the interests of lesbian, gay, and bisexual individuals across the United States. We are writing in anticipation of the September 30th meeting of the Florida Board of Medicine regarding proposed rule changes for the medical treatment of gender dysphoric minors. This is an important issue for us, as some of our members are detransitioners and desisters who have been harmed by so-called "gender affirming care."

Here are some reasons we oppose the current trend of affirming and medicalizing trans identities in youth:

- [Most trans-identifying children](#) desist by adulthood and grow up to be lesbian, gay, or bisexual, making "transition" a new self-appointed form of conversion therapy.
- [Over half](#) of detransitioners cited internalized homophobia as a reason for transition.
- People with suicidal ideation need psychological treatment, not medicalization and affirmation.

The fact that many trans-identifying youth may be suicidal does not make medicalized transition "lifesaving care." The lifesaving care they need is counseling, not bodily modification. When did it become "hatred" and "bigotry" to learn bodily acceptance? As gender dysphoria is a psychological issue, it should be treated with psychological care. Doctors do not give diet pills to young people with anorexia. Psychological distress over one's physical body deserves psychological care. Physical intervention may provide a superficial or temporary solution but will not and cannot resolve the underlying issue because the underlying issue is psychological. People with eating disorders do not suddenly love their bodies when they lose weight because, like dysphoria, the underlying issue is body image perception.

To examine this issue at the root, we must examine the reality of raising children in a sexist and homophobic society. Children are being raised in a culture full of hyper-sexualized influencers and celebrities, where the exploitation of women in pornography is normalized, where gender constructs are inherent in nearly everything children consume: books, movies, TV, advertising, their peers, their households, their families, even their school textbooks. Virtually all imagery, narratives, and words they are exposed to are heteronormative and reinforce gender roles (masculinity/femininity as inherent to the sexes). From the misogyny in religions in which children are indoctrinated, to the hyper-

masculinity of sports culture, to self-proclaimed “feminists” declaring makeup and high heels are “empowering choices,” regressive gender roles are everywhere, all the time—and now many of them are being rebranded “progressive.” In the digital age, we are bombarded by it every waking hour. Combined with the cult contagion of social media, this is where gender dysphoria is born.

Thank you for considering our input

Paul A. Vazquez, J. D., Executive Director
Florida Board of Medicine
BOM.meetingmaterials@flhealth.gov
Paul.Vazquez@flhealth.gov

Sir,

Please accept this message in testimony from 2 pediatricians from Miami FL.

Gender dysphoria (GD) in children is diagnosed when children show gender confusion. When GD occurs in the pre-pubertal child, it resolves spontaneously in 80-90% after the children naturally develop through puberty. A high proportion of children with GD have other neuropsychiatric disorders such as autism and anorexia. GD is considered a body integrity disorder and ought to be treated by a mental health specialist.

The treatment recommended for this disorder is affirmation of the confusion exhibited by the child, suppression of puberty with hormones, high dose cross hormones (testosterone for the girls estrogen for the boys) and mutilating surgeries.

Puberty is an essential milestone in the development of the child. Puberty blocking medications like Lupron (most used) cause a disease state. Harms include impaired brain maturation, decreased bone density with risk of later fractures, sexual dysfunction, and infertility. Are puberty blocking effects reversible? No. Time lost from developing together with peers and reaching important milestones can never be regained.

High dose cross hormones can result in heart disease, hypertension, diabetes, and cancer.

Once a child is given a puberty blocker, the majority go on to mutilating surgeries. Girls as young as 14 have had completely healthy breasts removed. Surgeries for males include dissecting the penis and inverting into a pelvic wound. For girls, removal of skin of the forearm and attachment to the pelvis to simulate a penis.

There are no long-term studies that show that gender changing therapies done to children have any beneficial effects. Suicide risk among trans-identified youth is the same as for other at-risk groups, such as depression, autism, and anorexia.

Prevention of suicide ought to be the same as for other youth: talk therapy and FDA approved psychiatric medications. Psychiatrists in the US and Europe agree that there is no evidence that gender transition reduces gender dysphoric children likelihood of killing themselves.

Studies of transgender adults show a high incidence of depression and suicide. In Sweden, a 30 year follow up of sex-reassigned adults showed rates of suicide 20 times greater than the general population.

Acts which are performed by doctors which mutilate, sterilize or otherwise harm children such as blocking puberty, high dose cross sex hormones, and sex organ removal are not healthcare, but are atrocities. *Especially when the children diagnosed with GD resolve their confusion as they grow naturally through puberty and align their perceived gender with their biological sex by late adolescence.* Our children are the victims of this terrible experiment, as confused adults impose their disordered ideology onto the most innocent and vulnerable.

What we focus on the longest, grows the strongest.

Emotional literacy in all schools. Transformative coaching.

Office: [305.646.0112](#)

Greetings to all,

We are writing to The Board of Medicine because the mental health of our children is our most significant concern.

My husband and I have a combined mental health experience of almost 70 years. I am a psychotherapist who has had a mental health center for the past 21 years, serving our community with a team of over 20 professionals. My husband is a psychiatrist who holds medical licenses in 34 states and presently practices in 120 emergency rooms around the nation.

In the past 30 years in the field, I've had one adult male patient who had partially transitioned to be a female. My husband remembers having no more than 4-5 transgender cases in his career (none children) until about three years ago. Now, he sees 5-10 children with gender dysphoria per month in emergency rooms. In my clinic, not long ago, we received a phone call from a mother, and in that call, we identified ten preteen girls experiencing gender dysphoria—her daughter and four girls in her class, as well as five friends from another school. None of the clients who have come to us with gender dysphoria have presented with a history of childhood gender dysphoria. Instead, parents describe a sudden onset of their symptoms. This rapid onset is a clear picture of peer contagion. Historically, there has always been a small number of children who present with gender dysphoria, and 80% of them outgrow it.

Many say that the rise in gender dysphoria visits to mental health professionals like us has to do with increased acceptance which helps the clients not feel marginalized. However, we have not seen an increase in adults exploring transitioning. It is solely children seeking it. There is an increase of 4,400% in kids identifying with gender dysphoria, and we need the help of The Florida Board of Medicine not to harm these children permanently. Many psychotherapists explore other factors affecting the child's mental wellbeing, not affirm, and have found great success.

We can learn a lot from looking at the history of John Money, the psychologist who originally introduced terms such as gender identity, sexual orientation, and gender roles that are now adding to our current mental health crisis.

Money stated that pedophilia is not always pathological. He argued that there are affectional pedophilia and sadistic pedophilia. According to Money, affectional pedophilia was about having too much love for a child. Money had considerable research on sexual identity and the biology of gender based on the case of the Reimer twin brothers. One of the twins had a condition that was attempted to be corrected by circumcision. The procedure went wrong, and the boy lost his penis. Money suggested raising the boy as a girl, and the parents did. He often brought the two kids to his office to do therapy and show them how they needed to perform sex acts. Both twins killed themselves when they were in their 30s. In the 1960s, John Hopkins pioneered sex reassignment procedures, and in 1979 the clinic was closed because they realized that reassignment procedures did not bring happiness or any of the benefits they were looking to find.

Transitioning does not bring wholeness and happiness. We have already traveled those waters. Many young women who transitioned in adolescence later regretted it and de-transitioned. We can read about many of them. "What we focus on the longest grows the strongest" is a phrase I often use with my clients and students. Social media and academia are creating a climate that propagates gender confusion at unprecedented rates. They do it by putting pressure on young children to identify with a gender, introducing books about gender identity at an early age, and more.

Our children need the help of the Florida Board of Medicine to protect them and do no harm. Please do not allow the medical transition of minors with hormones, puberty blockers, or gender surgeries. Our current mental health crisis merits it. Our children deserve it.

Respectfully yours,

Beatriz Martinez-Penalver, LMHC Florida Lic. MH4158

Dear Florida Board of Medicine,

I write to you as a concerned Mother of a 15 year old girl who is biologically female but identifies as Transgender, A trans boy, and everyday there are safeguarding issues. E,g she either doesn't use the toilet at all, or if need be uses the Men's Toilet. You Tube and online influencers have guided her throughout this journey, and it is the same for so many other young people, many who have spent more time online due to lockdown.

Parents need better guidelines to help their Children, and I believe Teachers and Medical professionals also need better guidance on this new and pressing issue.

Additionally to being a Mum of a Trans identifying teen I am a registered Art therapist working with Children and Young people, and am concerned at the amount of young people who are self diagnosing, and self-identifying. Often they are heavily influenced by social media.

Since identifying as Trans I have seen my child's mental health deteriorate drastically. The one thing that has helped is limiting social media time.

My Child is waiting on an autism assessment. In the meantime she is very focused on things that I don't believe a 15 year old should even be contemplating.

She plans to 'Go on T' – (Testosterone), and have 'Top Surgery'- (A double masectomy)

As a Mum and a practising Art Therapist, I wholeheartedly believe that the best approach for Children and Adolescents questioning their gender is a watchful waiting one.

I would not recommend the affirmative approach as I have seen first hand how it can narrow their options. Once a child has socially transitioned and 'come out' to friends, family, and their School, it is very difficult for them to backtrack if they are having doubts. This means that many Children are going on hormones, drugs, and having life changing procedures which they often go on to regret, This is morally and ethically wrong.

I advocate for a compassionate approach for gender questioning young people.

A slowing down, of this often fast track to sex change, which is completely inappropriate for young people who are still growing and developing.

It is time to stand up to the Trans Activists and Influencers, and those in the positions of power, money and greed, and do the right thing for this generation.

For my teenage daughter, and for the many, many young people caught up in gender ideology, please be part of a movement that allows them the space to grow up, healthy in their own bodies and minds.

Should they wish to transition as an experienced well informed Adult then that is another matter.

I recommend a holistic approach for gender questioning young people, and would be happy to correspond with you on this matter.

With Best Wishes,

Ruth Muir

Dear Health Board of Florida

As the mother of a trans identifying teenage girl I am writing to encourage you to protect children in Florida by stopping the affirmative care model for trans health.

My daughter was an outgoing, funny, loving girly girl growing up. She loved all things that were stereotypically girl. This was not something her father or I pushed. As she got to middle school we started to notice changes that concerned us. She was sad all the time, spent too much time online, hardly talked to people and mumbled when she did, had very complicated friend issues, and started hiding herself behind dark, very baggy clothing. She attended a small middle school. Her friends were a group of six socially awkward but highly intelligent young ladies. My daughter and one other girl went on to identify as nonbinary and transgender respectively in eighth grade.

Being highly gifted in art, we allowed my daughter to apply to a gifted high school with a focus on art and technology. We knew that there would be many other trans identifying students there, but also believed it would be a chance for her to be with other kids who were intelligent, awkward and gifted in art. In short, we thought she would find a place to belong. In this ultra affirming school my daughter quickly went from identifying as nonbinary to trans.

Since high school my daughter has pushed hard for testosterone and a double mastectomy. Teachers, society, social media and our government have encouraged her to pursue these medical interventions. It has been impossible to find a therapist that would do the deep work of exploratory therapy. Her first psychologist in eighth grade thought she only needed support in learning how to live as nonbinary, after only one test that she skipped multiple questions on, and one other meeting. Two therapists since have dropped her. When I talk to a doctor or therapist about gender, puberty, menstruations etc. I have try to find a way to secretly contact them and make sure they won't encourage her to make permanent changes she may later regret. Many of these conversations are tense and hushed because doctors and therapists are worried about losing licenses due to conversion therapy laws.

Last year she was diagnosed as autistic. The psychologists she worked with and a teacher we contract to help develop social skills and transition to college, have both told us that they are seeing an epidemic of patients/students who identify as trans. The teacher told me I was the fourth parent in two weeks to tell her their child identified as trans.

We have told our daughter all along that we will love and support her no matter what. We have made her wait until adulthood to pursue any medical interventions. She will be 18 in a little under a year. She has been on this path for four years. Some may ask, since this has been persistent, why we don't allow testosterone. But for a child that was never gender non-

conforming until the most difficult time of her life and has had no one but us try to figure out why, to suddenly take on this persona, while being bullied, an undiagnosed autistic, and having every other authority in her life encourage her to transition, it is absolutely crazy to think testosterone is a good choice. And with years of affirmation without real exploration of her issues, it doesn't make sense that she will be prepared to transition next year either!

There are thousands of kids like mine out there. The Tavistock in the UK recorded a 4000% increase in adolescent females identifying as trans over a ten year period in the late 2000s to the late 2010s. This issue can't be described as anything but a social contagion. We have seen it before as suicide attempts, anorexia, cutting, goth, but at no other point in history have we taken an adolescent girl who is stressed, depressed and confused and encouraged her to follow her heart and hurt herself.

You must stand up for the children of Florida and stop all medical transitioning of children and young adults. Give them time for their brains to mature. Make sure that true exploratory therapy is done before medical interventions are pursued. Protect thousands from a lifetime of regret.

Respectfully,
Stacy Riddle

Dear Florida Board of Medicine,

Thank you for taking up the vital question of regulating the so-called "gender-affirming" hormones and surgeries for young people.

As a parent of one of these children, I have seen some very well-meaning but misinformed doctors recommend these radical life-changing interventions on the first or second visit. The myth that our children are getting "assessments" is propagated widely, but no requirements have ever been clearly articulated about which child or young person distressed with their gender role will benefit vs will be harmed. This intervention sterilizes 100% of children if administered according to the Endocrine Society's recommendations.

My son is high functioning ASD (what used to be called Aspergers). He never had a lot of friends. In his last year of high school, he made friends with a classmate who went through various stages of gender / sexual confusion, ultimately deciding that she wanted to be a male. Soon after, my son expressed feelings of gender dysphoria. His pediatrician recommended that we talk to an endocrinologist and indicated that there would be at least two years of therapy required before any interventions were prescribed. However, the endocrinologist discussed gender affecting hormones on the first visit, recommending to my son that he consider freezing his sperm because he would be sterilized (he was 16 at the time). I took him to a therapist who wrote him a letter after only a few weeks' time. The therapist told me not to worry because the cost of the drugs would be prohibitive and that would delay his implementation of gender therapy. My son was prescribed these hormones a few months later, on his second visit to the endocrinologist, and was easily able to afford the monthly cost of them, as all three drugs he was prescribed cost under \$12 total per month.

Along the way, we relied on professionals who were well intentioned, but woefully misinformed. The pediatrician was shocked when we followed up with him and told him what had actually occurred. His therapist wrote the letter in order to 1) keep a patient and 2) build a patient's trust in her, all the while thinking that she had many months to continue therapy with him before any permanent biological changes would happen. At no point did the therapist try to work with my child on the cause of his dysphoria - her entire focus was on helping him "adjust" to living as a female.

Many young people have gender questions around the time of puberty. Some simply need a few years to get used to the changes in their bodies. The swift medicalization of "addressing" issues that are often a normal part of progressing to adulthood is robbing these children of the opportunity to work through their questions in a non-harmful way.

Older adolescents can get hormones with no assessments at all, and have their healthy body

parts amputated by eager surgeons on little more than self-declaration of "trans identity." Many of our children are gay and autistic and have come to believe their very real distress is explained by the fact that they are "transgender" and that hormones and surgeries will help. They do not. We have seen our children's mental and physical health plummet following "gender-affirmation."

We also encourage you to require in depth psychotherapy to address the feelings of dysphoria, and to issue a clear statement that psychotherapy for gender dysphoria is not "conversion". Our children and families need safe non-invasive alternatives to radical experimentation known as "gender affirmation."

Thank you for doing what you can to regulate this experiment on our vulnerable children.

Please do not cave to this erroneous effort to change our America The Beautiful - One Nation Under God, Indivisible, with liberty and justice for all into an unruly garbage pit. The proposal for Gender affirmation has no scientific basis and No Religious basis whatsoever. Our forefathers have sweated blood and tears to gift our nation with the values and dignity we have been enjoying until most recent years of Marxist influence. It is heartbreaking to see our government and country compromised by the corrupt leadership that proposes those sort of evil and calls it "rights" and Gender affirming. It sure does not affirm Gender of male and female as God created us.

Say no to Gender affirmation and say yes to true American values.

Good afternoon. I am aware that the state of Florida is considering limiting affirmative care in terms of youth transition and informed consent process. I urge you to consider banning or stricting limiting surgical youth transition and encouraging parental consent for any medical procedures. Children under 18 are not aware of their family's medical history and may be consenting to medical procedures that could be complicated by hereditary conditions that they may not be aware of, which can change response to procedures, recovery and risk their lives. Minors may also have other undiagnosed mental health issues that can affect their decision-making as well and may very well be the cause of their desire to change themselves. All other federal and state laws for making decisions regarding the human body and property in general involve decisions to be made by adults over 18, like getting a tattoo or piercing, voting, buying or renting property and more. Besides this regarding minors, it's also against the fundamental nature of the medical profession to "first do no harm," which cutting off perfectly functioning organs and body parts would be doing.

With such an intense, life-changing process of multiple surgeries--one surgery may not be enough to complete gender transition--also creates a medical customer/client for life who lives dependent on hormones, doctors for continuing body changes and adjustments and mental health professionals to help them deal with all of the social, physical, emotional and mental changes they experiences. Young children and teens, all under 18, do not have the brain development necessary to make such lasting decisions, which is why in every other area of our country and government they are limited from doing so. It is common knowledge and medical consensus that the adolescent brain doesn't finish developing until the early 20's. Parents have historically been the protection for these children and trusted with their medical well-being, which they have done with vaccinations for school, managing allergies, getting emergency care as well as wellness care, among normally daily care. Limiting parents involvement and help with decision-making would put children in the face of very real danger to themselves. It is abhorrent that the medical community would consider risking the live, health and function of children and their bodies in the face of political pressure. It undermines their very sole purpose in helping our children grow in health.

Please consider this as you all make your decision. Although I didn't include links and pages of research, I am stating facts that we have sealed in law right now and have depended on as foundational scientific facts for centuries and decades. Thank you.

Melanie

Dear Mr. Vazquez:

I am writing to say I agree with Stephanie Winn's recent comments on "gender affirming care". I want to be very clear that I am a lifelong progressive and defender of human rights, and I am appalled by the ways the political right has responded to this issue. At the same time, Ms. Winn makes an extremely strong and compelling case against "gender affirming care". It is a myth that all liberals and progressives support this perspective; actually, many, many of us find it poorly thought out, frightening, and dangerous to children.

Ms Winn presents many strong points in her letter. I will only add that health services and organizations in Europe that originally promoted "gender affirming care" are now advising extreme caution in this area. Britain recently closed the Tavistock clinic, which focused on "gender affirming care."

Thank you, and please look at this issue thoughtfully and carefully.

Dear Paul A. Vazquez, J.D.
Executive Director Florida Board of Medicine

I am a parent and a concerned citizen and educator. I am vehemently opposed to the affirmation model and with hormonal and surgical interventions without thoughtful, informed and cautious decision making by an adult and a team of up-to-date experts, including in the field of mental health. Currently in the US, we are seeing a social contagion with the numbers of teenagers and young adults identifying as trans and non-binary having risen (and continuing to rise) at alarming rates in the past year. At the same time, the number of desisters and detransitioners are increasing at incredible rates in a short period of time. The World's largest Gender Clinic, Tavistock, recently closed down and there are over 1,000 lawsuits of malpractice. Great Britain recently commissioned a highly distinguished public health and pediatric expert to reconsider the affirmative model in the United Kingdom. Other nations are following suit, such as France, Sweden and Finland. Additionally if you review the original intent from the Dutch model and sole study, which is what the US is based off of, it was and still is, supportive of a slow, intense intervention at the mental health level to ensure that the adolescent is receiving the best possible care and informed of the risks involved. This is NOT happening in the US as it has become a political and economic issue. Many people are profiting off our youth and duped parents, who are the newest form of guinea pigs for social justice advocates. I am a life-long liberal and now find myself completely and utterly perplexed and disgusted as to why we, in the US, would ever allow this to happen. But if you look at our history, this has happened before. It is time to change things immediately and stop the harm that is being done to children. We can stop this now, instead of having to look back and say, well, we didn't know. We DO know the harms and this is the biggest scam that has ever entered western society. Vulnerable kids of being rushed to hormones and surgeries with life-long adverse effects to their health, including 100% sterilization. I also encourage you to require exploratory psychotherapy and to issue a clear statement that psychotherapy for gender dysphoria is not conversion. Our children and families need safe non-invasive alternatives to radical experimentation known as "gender affirmation."

Please consider with care the findings of the Cass Review interim report.

What is the Cass Review interim report?

The Cass Review is an Independent Review of Gender Identity Services for Children and Young

People. It was 'commissioned by NHS England and NHS Improvement in Autumn 2020 to make

recommendations about the services provided by the NHS to children and young people who are

questioning their gender identity or experiencing gender incongruence [1].' In March 2022, the

Cass Review submitted an interim report to NHS England. This interim report '[set] out [the] work to date, what [had] been learnt so far and the approach going forward [2].'

Who is Dr. Hilary Cass

Dr Hilary Cass was appointed by NHS England and NHS Improvement to chair the Independent

Review of Gender Identity Services for children and young people in late 2020.

A former President of the Royal College of Paediatrics and Child Health from 2012-2015, Dr

Cass recently finished a term as Chair of the British Academy of Childhood Disability (2017-2020).

Although retired from clinical practice, she remains an honorary Consultant Paediatrician at Evelina London Children's Hospital, Guy's & St Thomas's NHS Foundation Trust, where she was also previously Director of Education and Workforce.

Dr Cass is currently Chair of Together for Short Lives, and a Trustee for Noah's Ark Children's

Hospice. She is also leading work on how to address the challenges for both families and professionals in supporting the rising numbers of children with complex medical conditions and disability.

Other recent roles include acting as the Senior Clinical Advisor for Child Health for Health Education England. Prior to this Dr Cass held a range of senior education and management roles in NHS hospital trusts and was previously Head of School of Paediatrics in London.

Her

consultant clinical practice was as a tertiary neurodisability consultant from 1992 to 2018 in three very different specialist centres and she has published widely in this area.

In addition to her neurodisability practice, Dr Cass was closely involved in the development of

paediatric palliative care services at Evelina London Children's Hospital.

Dr Cass was awarded the OBE for services to child health in 2015. She was also awarded an honorary fellowship by the Royal College of Nursing in 2015, and by RCGP in 2016.

Background

The United Kingdom has seen a significant increase in the number of children seeking help for distress in relation to their biological sex. Many school staff first started noticing the phenomenon of children – predominantly teenaged girls – wanting to change sex during the last decade.

In recent years, there has been a significant increase in the number of referrals to the Gender Identity Development Service (GIDS) at the Tavistock and Portman NHS Foundation Trust (para. 1.1).

From a baseline of approximately 50 referrals per annum in 2009, there was a steep increase from 2014-15, and at the time of the CQC inspection of the Tavistock and Portman NHS Foundation Trust in October 2020 there were 2,500 children and young people being referred per annum, 4,600 children and young people on the waiting list, and a waiting time of over two years to first appointment (para 3.10).

This surge in children seeking help for distress in relation to their sex is occurring in the context of an ongoing public debate around issues relating to sex, gender and gender identity. Over the last few years, broader discussions about transgender issues have been played out in public, with discussions becoming increasingly polarised and adversarial. This polarisation is such that it undermines safe debate and creates difficulties in building consensus (para. 2.4).

No consensus

This being a new phenomenon, research is limited and no consensus exists (within the scientific community) about possible causes and most appropriate treatment options. At primary, secondary and specialist level, there is a lack of agreement, and in many instances a lack of open discussion, about the extent to which gender incongruence in

childhood and

adolescence can be an inherent and immutable phenomenon for which transition is the best

option for the individual (para. 1.7).

We must secure a balanced treatment of political issues, they must take a child-centred, evidence-based approach, and take care not to express personal beliefs in ways which could

exploit pupils' vulnerabilities. We should not for example, present, as fact, childhood gender incongruence as an inherent and immutable phenomenon as this is a contested idea rather than an established evidence-based fact.

Low quality evidence

The Cass Review interim report acknowledges that '[over] the last few years, broader discussions about transgender issues have been played out in public, with discussions becoming increasingly polarised and adversarial' (para. 2.4). Many of us feel confused or conflicted about approaching the issues of sex and gender identity with adolescents. The above-mentioned rise in referrals to GIDS has been accompanied by an increasing number of news reports claiming that some teachers and/or schools are promoting the idea that gender identity supersedes sex. However, there is insufficient high quality, longitudinal data (relating to gender-questioning children) from which to draw robust conclusions. There is a notable gap in the evidence base pertaining to the surge in female teenagers seeking support from gender identity services.

Aspects of the literature are open to interpretation in multiple ways, and there is a risk that some

authors interpret their data from a particular ideological and/or theoretical standpoint (para. 1.29).

Decisions need to be informed by long-term data on the range of outcomes, from satisfaction

with transition, through a range of positive and negative mental health outcomes, through to regret and/or a decision to detransition. The NICE evidence review demonstrates the poor quality of these data, both nationally and internationally (para. 3.21).

It is also important to note that any data that are available do not relate to the current predominant cohort of laterpresenting birth-registered female teenagers. This is because the rapid increase in this subgroup only began from around 2014-15. Since young people may not reach a settled gender expression until their mid-20s, it is too early to assess the longer-term outcomes of this group (para. 3.23).

Since the rapid increase in this group began around 2015, they will not reach late 20s for another

5+ years, which would be the best time to assess longer-term wellbeing (para. 5.10).

This is an area of research where no scientific consensus exists. Schools must be aware

that any claims made about the reasons behind the increase in gender-questioning children are speculative and cannot be treated as established evidence-based facts.

Changing epidemiology

Early childhood gender dysphoria is not a new phenomenon. However, the existing literature on

treatment and outcomes is largely based on early childhood gender dysphoria in male children. It may not apply to the current cohort of gender-questioning children who are older, predominantly female and often presenting with a range of neurodevelopmental and mental health co-morbidities.

In the last few years, there has been a significant change in the numbers and case-mix of children and young people being referred to GIDS (para 3.10).

This increase in referrals has been accompanied by a change in the case-mix from predominantly birth registered males presenting with gender incongruence from an early age, to predominantly birth registered females presenting with later onset of reported gender incongruence in early teen years (para. 3.11).

The mix of young people presenting to the service is more complex than seen previously, with

many being neurodiverse and/or having a wide range of psychosocial and mental health needs.

The largest group currently comprises birth-registered females first presenting in adolescence

with gender related distress (para. 1.10).

Much of the existing literature about natural history and treatment outcomes for gender dysphoria in childhood is based on a case-mix of predominantly birth-registered males presenting in early childhood. There is much less data on the more recent case-mix of predominantly birth-registered females presenting in early teens, particularly in relation to treatment and outcomes (para. 1.28).

Secondly, the cohort that the original Dutch Approach was based on is different from the current

more complex NHS cohort, and also from the current case-mix internationally, and therefore it is

difficult to extrapolate from older literature to this current group (para. 5.10).

The Cass Review interim report highlights the difficulties faced by clinicians responsible for making diagnoses and recommending treatment. Teachers are neither qualified nor capable of

critically evaluating existing evidence. They must carry out their duties within statutory and non-

statutory frameworks. This included ensuring that any necessary referrals are made as specified by their schools' safeguarding protocols.

Diagnostic overshadowing

Another significant issue raised with us is one of diagnostic overshadowing – many of the children and young people presenting have complex needs, but once they are identified as having gender-related distress, other important healthcare issues that would normally be managed by local services can sometimes be subsumed by the label of gender dysphoria (para. 4.10).

School staff must be clear that they are not qualified to offer students advice in this area. Moreover, the promotion of specific beliefs about the source(s) of gender-related distress could

influence children's attitudes toward the diagnostic process before meeting with a clinically trained professional. Guidance from the Department for Education states that teachers "are in a

position of authority and will typically be respected and trusted by the pupils they teach, giving

their personal opinions greater weight and credibility. As a general principle, they should avoid

expressing their own personal political views to pupils unless they are confident this will not amount to promoting that view to pupils [4]."

Affirmative vs developmental models

Broadly speaking, there are two approaches to treating children with gender-related distress: the

gender-affirmative approach and the developmentally-informed approach. The gender-affirmative approach is based on the theory that a child's gender identity is innate. The developmentally-informed approach is based on the theory that a complex interaction of multiple

factors underlie gender-related distress. The Cass Review interim report acknowledges that some clinicians report being under pressure to adopt a gender-affirmative approach.

Following directly from this is a spectrum of opinion about the correct clinical approach, ranging

broadly between those who take a more gender-affirmative approach to those who take a more

cautious, developmentally-informed approach (para. 4.15).

Some secondary care providers told us that their training and professional standards dictate that

when working with a child or young person they should be taking a mental health approach to

formulating a differential diagnosis of the child or young person's problems. However, they

are
afraid of the consequences of doing so in relation to gender distress because of the
pressure to
take a purely affirmative approach (para 4.20).
There is a spectrum of academic, clinical and societal opinion on this. At one end are those
who
believe that gender identity can fluctuate over time and be highly mutable and that,
because
gender incongruence or gender-related distress may be a response to many psychosocial
factors, identity may sometimes change or the distress may resolve in later adolescence or
early adulthood, even in those whose early incongruence or distress was quite marked. At
the other end are those who believe that gender incongruence or dysphoria in childhood or
adolescence is generally a clear indicator of that child or young person being transgender
and question the methodology of some of the desistance studies (para. 5.8).
School staff are unqualified to evaluate the merits of these approaches. Moreover, they
have an
obligation to remain politically impartial. This means not supporting one approach over
another.

Social transition

Social transitions (the act of treating children as if belonging to the opposite sex) are
performed
by some schools in England. A social transition is a powerful psychological treatment that
affects a child's psychological development. Not only are school staff unqualified to judge
the
appropriateness of such interventions, the outcomes are poorly understood.
Social transition – this may not be thought of as an intervention or treatment, because it is
not
something that happens within health services. However, it is important to view it as an
active
intervention because it may have significant effects on the child or young person in terms of
their psychological functioning. There are different views on the benefits versus the harms
of early social transition. Whatever position one takes, it is important to acknowledge that it
is not a
neutral act, and better information is needed about outcomes (para. 5.19).

Pressure

The Cass Review interim report acknowledges the pressures clinicians are under to adopt
an
unquestioning affirmative approach. Similarly, there is an acknowledgement that children
are
under pressure to identify with societal stereotyping. Schools cannot erase the pressures

that

children are under from, for example, social media and peers. However, teachers should promote acceptance for children's non-stereotypical behaviour (boys and girls exhibiting stereotypically 'feminine' and 'masculine' behaviour, respectively) and avoid reinforcing harmful stereotypes.

Primary and secondary care staff have told us that they feel under pressure to adopt an unquestioning affirmative approach and that this is at odds with the standard process of clinical

assessment and diagnosis that they have been trained to undertake in all other clinical encounters

(para. 1.14).

From the point of entry to GIDS there appears to be predominantly an affirmative, non-exploratory approach, often driven by child and parent expectations and the extent of social transition that has developed due to the delay in service provision (para. 1.18).

It is not the role of this Review to take any position on the cultural and societal debates relating

to transgender adults. However, in achieving its objectives there is a need to consider the information and support that children and young people access from whatever source, as well as any pressures that they are subject to, before they access clinical services (para. 2.5).

We have heard that distress may be exacerbated by pressure to identify with societal stereotyping and concerns over the influence of social media, which can be seen to perpetuate unrealistic images of gender and set unhealthy expectations, especially given how long children and young people are waiting to access services (para 4.13).

These will be considered further during the lifetime of the Review and include: . . . The complex

interaction between sexuality and gender identity, and societal responses to both; for example,

we have heard from young lesbians who felt pressured to identify as transgender male, and conversely transgender males who felt pressured to come out as gay rather than transgender. We have also heard from adults who identified as transgender through childhood, and then reverted to their birth-registered gender in teen years (para. 4.14).

Safeguarding

Children with gender-related distress may pose specific safeguarding concerns. They have a

higher incidence of comorbid psychiatric and/or developmental difficulties. They are also more

likely to be looked after children. Teachers need to be aware of possible harms such as breast

binding or tucking (of male genitals). Children may also be subjected to grooming and/or

coaching, and encouraged to deceive parents, clinicians and teachers in order to secure particular outcomes such as clinical diagnoses of gender dysphoria. They may also be receiving cross-sex hormones from unregulated sources.

In addition, approximately one third of children and young people referred to GIDS have autism

or other types of neurodiversity. There is also an over-representation percentage wise (compared to the national percentage) of looked after children (para. 3.11).

We have also heard about the distress experienced by birth-registered females as they reach

puberty, including the use of painful, and potentially harmful, binding processes to conceal their

breasts (para. 4.3).

Most children and young people seeking help do not see themselves as having a medical condition; yet to achieve their desired intervention they need to engage with clinical services and

receive a medical diagnosis of gender dysphoria (para. 4.4).

We have heard that some young people learn through peers and social media what they should

and should not say to therapy staff in order to access hormone treatment; for example, that they

are advised not to admit to previous abuse or trauma, or uncertainty about their sexual orientation

(para. 4.5).

We have heard about families trying to balance the risks of obtaining unregulated and potentially

dangerous hormone supplies over the internet or from private providers versus the ongoing trauma of prolonged waits for assessment (para. 4.7).

Summary

There has been a huge increase in the number of children (predominantly female teenagers)

seeking help for distress in relation to their biological sex. Research into this new phenomenon is limited. The lack of high-quality data from longitudinal studies together with the changing

epidemiology means that no consensus exists about the possible causes for this recent surge in children wanting to change sex. Clinically trained professionals face difficulties in making

diagnoses and recommending treatment. School staff who now affirm are neither qualified to evaluate existing research nor clinically trained. Therefore, they cannot judge the

appropriateness of, for example, socially transitioning children. It is an intervention with poorly understood outcomes that affects children's psychological development. The Cass Review interim report outlines some of the specific safeguarding issues that surround gender-questioning children.

Thank you most sincerely for your time and consideration.

Yours sincerely,

Sara Stultz

I am an academic researcher at a top U.S. university. Let me start by saying that I am a lifelong, staunch supporter of LGB rights. Like most progressives, when “T” was added to the acronym, I assumed that represented something good. The little I knew suggested that transsexuals (at the time) were a tiny, marginalized group treated poorly by society. I still believe that, in a way, but over the past three years I have discovered that the issue is much more complex in 2022 than I had previously understood.

My daughter, a highly intelligent, sensitive, creative child, was always lost in her own fantasy world. She loved stuffed animals, Angelina Ballerina, Fancy Nancy, Calico Critters, My Little Ponies, American Girl dolls and books, Disney princesses, books about fairies and elves and dragons, and horses. She was obsessed with horses – real ones, figurines, stories of horses – and still takes lessons. She begged to take ballet because she loved the pink tutu and the slippers. She loved to play dress-up, and I would have to talk her out of wearing her holiday dress with sequins to a family picnic at the park. As a female scientist, I would try unsuccessfully to interest her in STEM topics. I would sign her up for soccer and science camp and outdoor adventure camp. She liked some of those things, but creative, artsy, and imaginative activities were always her favorites. She was young for her age.

When she was 11, my daughter hit puberty. Her chest blossomed, and she kept outgrowing bras every few months. Also at 13, she received her first smart phone for her birthday. At age 14, she came to us and said she was *literally not a girl* but rather identified as “nonbinary”. My husband and I were taken aback. The idea that someone with a female body as well as lifelong adherence to all the stereotypical “girly” attributes and interests was “not a girl” was puzzling. She asked for and got a very short haircut. She was upset coming home because it wasn’t short enough in her view. I was finally able to get a little clarity: she told me it was her hope that a very short haircut could help offset the very obviously female shape of the rest of her.

My daughter is, as I said, highly sensitive, which is a [common characteristic of gifted kids](#). Asynchronous development, which is a mismatch between cognitive, emotional, and physical development, [is also common](#). So I don’t doubt she was feeling agony at the effects of puberty, which catapulted her into the body of an 18-year-old when she was struggling to hold on to childhood. But what happens when such a girl goes online and searches “I hate my breasts”? The answer she found was to label herself “nonbinary.” My daughter, [immature like so many modern adolescents](#), and seeking a definitive solution to her social anxiety, swiftly got pulled into this narrative. It seemed to solve everything, especially since one key step for a nonbinary or trans-identified natal female is to get a double mastectomy – something that is euphemistically known as “top surgery” – and to which my daughter aspired.

I found this solution quite extreme, and I started doing some research. Adolescence, from age 12 to 25, is a period of life in which [the brain is entirely rewired](#). Synapses are pruned, neural pathways that are often used are strengthened, and the [brain is bathed in pubescent hormones](#). The [developmental goal](#) is to emerge at the end of the process having formed an occupational identity and a sexual identity. Part of a fulfilling adulthood is a sense of self-actualization: having a set of goals and a drive to pursue them. When a person spends the better part of adolescence pondering and performing gender and expending energy getting others to validate it, it seems likely that this activity could replace any more concrete goal. I worry about this for my daughter and for all of the teens caught up in this narrative who have a similar story of [adolescent awkwardness](#) pathologized. This, more than anything, is why I do believe those who draw the association between adolescent transgender identification and internet use: social media encourages us to perform to others rather than to just live our lives.

The internet, along with academia, our school district, and most other mainstream sources, was very clear about what my husband and I should have done as parents: affirm our daughter as a nonbinary person, start using different pronouns and another name, buy her a binder to squeeze her breast tissue, and start working

on reducing our bigotry. We should agree that yes, there is something missing in you, a “female” feeling that you apparently lack. But I found that idea disturbing and regressive, and I dug further for answers that made more sense to me. So I can tell you that this advice is not the only advice out there. Other thoughtful, nuanced advice says to acknowledge that your child is truly experiencing extreme distress, and to ask questions, listen carefully and empathetically, and work on identifying the true source of that distress.

In my daughter’s case, the answers weren’t hard to identify. She is extremely self-conscious, socially anxious, and a perfectionist. That last trait, in adolescents, often causes them to resist trying new things in case of failure; how much more problematic to have a new sexualized body that you didn’t ask for, and how tempting to opt out of it with a trendy label and a checklist of steps to complete to rid yourself of the problem. I will never forget that when I first took my daughter to a therapist specializing in gifted kids, the therapist told me that about half her caseload had some type of gender issue. Think about that for a minute. A therapist who sees only gifted kids, which are the top 2-3% of the population according to IQ, says *half her caseload* is questioning their gender. There is a lot of overlap between giftedness and autism spectrum, including what used to be called Asperger’s Syndrome. Interestingly, one well-known fact about autistic people is that they tend to be confused by or impatient with gender norms.

We have been working on building my daughter’s self-esteem and providing more real-life experiences that can help her become comfortable inhabiting her body. These things are working. She is much happier and is slowly maturing, and she no longer fixates on gender.

I do not pretend to know what’s best for other families and other kids, but I have spent a lot of time in parent support groups online and I can tell you that there are many, many kids like my daughter, who have been swept up into the trans narrative for other reasons but then cling to it hard for a long time. I personally know of two of my daughter’s friends and three of my older son’s friends, all natal girls and all academically gifted, who believe they are nonbinary or trans. And I know that there are many parents who swallow feelings of whiplash and disorientation because the “experts” say that this is what they must do.

Nothing that I have read gives me confidence that the clinicians at gender clinics are willing to recognize this, that essentially it is now their job to try to sort out who are the very few kids with such extreme gender dysphoria that arose organically and cannot be remedied in some other way than to sign up for a lifetime as a medical patient, versus all of the kids with sundry other mental health and neurodevelopmental issues who have read on the internet that gender services are the solution to their distress. And once they are 18, there appears to be no care taken *at all* to get to root causes in any of the cases that I personally know about.

I heard that there was a question about this being a made-up issue, that Republicans are being hateful and stirring up political controversy where there is no real concern, so I decided to write. I don’t know their motives, but I am very grateful that this issue is now getting public scrutiny. There *is* real concern. I have shared my story with many friends and relatives, and even a few colleagues, and the concern is uniform. Most people know a kid like my daughter and are dubious about the whole idea of gender identity being helpful to kids. Several people confessed that they had always thought it made no sense, but felt guilty saying so. Outside of politics, people do understand that childhood and adolescence are times of imagination, experimentation, rejection of cultural norms, and identity formation, and they tend to agree that permanent, irreversible changes to the body with lifelong health implications should not be made on the basis of what a child or adolescent believes at a point in time along that developmental journey.

Florida Board of Medicine Committee testimony

I am the mother of a daughter, who as of recently identified as transgender. It started suddenly a few months shy of her 15th birthday, out of the blue and with no prior manifestation of gender dysphoria or incongruence. At least 2 years prior to the transgender announcement she was suffering from social anxiety and depression. In 9th grade she was introduced to gender concepts at school and then on the internet. She became withdrawn, isolated herself and suicidal. We sought help for her in the form of psychotherapy from a psychologist and psychiatrist. Both immediately affirmed her trans identity without any exploration of her prior co-morbidities or issues. We (her parents) were shut out of all conversations surrounding this sudden onset of gender incongruence. We were told that this was her "authentic self" and that we needed to be on board with her new identity and if we didn't the chances of suicide were exceptionally high.

Our daughter at the age of 16 expressed a desire for "top surgery" and was exploring the route of opposite sex hormones. My husband and I were absolutely opposed to this and expressed our concern. Her therapist continued to affirm and the affirmation model of gender care was the only model employed. We were shut out of sessions and communication with the therapist so we decided to take our daughter out of therapy because of the lack of communication and the fact that we were becoming the enemy. We told our daughter that at this age we would not consent to these irreversible surgeries and treatments but that we understood that at 18 she could make her own decisions. We counseled her to wait until she was at least 25 years old to make these decision and we talked about the science of brain development and how the frontal lobe was not fully mature until at least 25 and sometimes later. She agreed to take a wait and see approach until at least 18. We told her that no matter what we would always love and care for her and if at 25 she still felt this way that we would cross that bridge and be there for her.

She is now 18 years of age and no longer identifies as transgender. During the years that she identified as transgender we let her have time and space to explore her feelings and to present as masculine as she wanted. She cut her hair and took her senior pictures in a tuxedo. We did not allow for social transition as a teenager knowing full well that when a child socially transitions it is very hard to walk back and can confirm and cement gender incongruence. We wanted to give her space and time to explore without anything becoming permanent at this young age. I recently posed the question of "what if we had agreed to the double mastectomy and testosterone that you wanted? Do you think it would have helped or hurt you?" She expressed that she was glad that we let her take her time to get more comfortable with her body and herself and that she knows that it would have hurt and not helped and most likely would have made her worse.

As I write this, I look back and am thankful for the group of parents I found that are going through this. Almost all our stories are the same and the only model of care we and these kids are offered is the affirmative care model. I can think of no other mental health diagnosis where the only model offered is to affirm. This is a completely new, unstudied cohort of teenagers and young adults that are being affirmed and being told that they are born in the wrong body and that surgery and hormone treatment will "fix" them. We ask ourselves daily, what if we had followed the professionals advice? What if we allowed our underage, suffering from depression and anxiety, highly gifted, sensitive daughter to cut off her breasts and take testosterone?

I urge you all to consider the ramifications of allowing underage children who cannot possibly understand or consent to irreversible surgeries and hormone treatments. Please give these kids the gift of time and help that will allow them to explore, without the permanence that takes place with gender affirming care only. Gender affirming

care is a one way street than does not allow for questions, reflexion, exploration or space in which to safely investigate feelings and expression.

Thank you for your time and consideration,
Stephanie and Jeff O'Brien

Dear Mr Vazquez

I'm writing out of concern for young people who are considering surgical or hormonal gender transition and the ease of which it seems, they can currently access this. I believe it is important to consider that for many this is happening during a period of their lives where so many things are confusing, in a world where there is so much turmoil around them and in an era where they can access all sorts of highly influential information, some credible, but much non-credible and possibly damaging while not even having complete brain development yet. I am also concerned about the possible negative impacts long term for these teenagers. I am aware of some who realise a few years after transitioning that their choice to transition they regret due to the permanency of many of the physical and chemical changes to their body.

I have a daughter who is 17 years old. Following 15 years of being a very content child to teenager she began showing signs of severe mental illness. A number of factors including grief of a well-loved pet, long-term low-level bullying by a close friend and increasing school pressure seemed to trigger this. In the last 8 months she has revealed that she feels that "she is in the wrong body" but thankfully at this stage she has no intention of making physical or hormonal changes. I am very grateful that we have a very caring and alert psychiatrist who recognises that Gender Dysphoria is becoming increasingly common and often exists in patients who are displaying signs of mental illness. She has spent a good number of hours talking to myself and my daughter and asking questions relating to her childhood and has recognised Obsessive Compulsive Disorder (OCD) as one of the main underlying illnesses which is impacting my daughter.

An illness such as OCD can play a major part in something such as gender dysphoria as the patient spends a lot of time ruminating on things that bother them. I expect that other illnesses such as Autism Spectrum Disorder, Post Traumatic Stress Disorder and even Anxiety and Depression could play a significant part in the lives of many experiencing Gender Dysphoria. It is very easy to blame the way we feel, particularly dissatisfaction with ourselves and our bodies on a problem that we can come up with a quick fix solution for.

I am concerned that many young patients who are undergoing gender transitioning procedures are not receiving the medical investigations they need to help them identify possibly underlying causes of their dissatisfaction in themselves or the counselling which they deserve to adequately inform them of the likely impacts the changes may have on their adult lives.

I personally suffered 8 years of infertility and had the best treatment available at the time to enable me to conceive a baby. I would not wish that suffering on anyone else but gender transitioning procedures I understand could *cause* problems such as this. The last thing that a gender dysphoric

patient needs is to be given a quick fix solution when they are possibly too young to know if they will still feel the same way once their brain has fully developed and which will likely predisposition them to impacts such as infertility, inability to breastfeed, certain cancers, hair loss and other impacts; all ramifications which they may need medical help and/or counselling for in the future and which will potentially lead to mental illness if they are not already experiencing this.

I believe the best use of financial resources and best care for gender dysphoric patients is that they are listened to and cared for, that they are given opportunities to have mental illnesses diagnosed and treated and that they and their carers are given extensive and thorough counselling on how to best help them manage the difficulties that they are dealing with. I believe that this should be available to them until the time when their brain has fully developed. If at that stage they completely understand the consequences of transitioning their bodies, then they are in a much better position to choose to go ahead with this.

Dear Sirs:

There is a lack of quality evidence supporting efforts to medically alter secondary sexual characteristics in minors with gender dysphoria. The Florida Medical Board needs to consider proper evidence-based medicine standards in all decisions and defer decisions on issues without such proper evidence. Expert opinions on a medical issue such as this are best evaluate at the individual practice/practitioner level and should not enter into the state arena of decisionmaking.

Sincerely,

-RM

Dear Florida Board of Medicine,

Thank you for considering young people's health regarding hormone treatments and surgeries. The use of hormones, if administered according to the Endocrine Society's recommendations, will sterilize young people in a distressed state.

In many places in our country, older adolescents can easily get both hormones and life-altering surgeries. They are told that these interventions will solve their distress; however, the data does not support this claim.

In addition, many parents are seeking exploratory therapy for their children. I have spoken to clinicians who want to offer this service but face obstacles. Families deserve safe alternatives to the current model of medical experimentation.

Please protect our youth.

Would encourage you to vote against gender transitioning treatment for children and adolescents. These treatments harm children. Gender dysphoria is a treatable condition. No state funding should be used to encourage this condition.

Sincerely,

Michael H. Jaquith, M.D.

To whom it may concern:

I am writing to express my concerns regarding the transgender medical treatment of minors. It seems that the treatment of these minors is done very quickly with no concern to the long-term effects either physically or psychologically. Seeing that many of these children come from broken homes and have endured some form of trauma in their short lives, I think it would be prudent to first have them go through a series of counseling sessions to help them think through their feelings before making such a drastic and life changing decision. What are the possibilities of increased risk of cancer given that the natural function (DNA) of the sexual organs have been altered? The bodies DNA knows the true sex of the child and how will artificial hormones react in the body long term? Again, possible cancer risks because of the artificial hormones. I do hope the oath of "Do no harm," is still the number one priority. With that in mind there should be no rush to permanently alter a child's sex when the appropriate research of the physical and psychological health of the child has not been extensively researched.

Sincerely,
Rachel Murphy

Children are in our care and we need to ensure a cautious slow approach that takes medicalization out of the picture.

The options being pushed are unethical with no scientific backing.

The risk of harm is huge when there is an absolute lack of knowledge about the outcomes of our future generation.

Please protect our children.

To be brief, I do not feel that this is a good or ethical idea for the following reasons.

1. although transgenderism is present in only a minority of the population, there has recently been a huge increase in the number of school children claiming to be transgender, up to 30% in some schools. This is thought to be because this is the current “in” thing to do and a way to stand out and get attention, even though gender dysphoria has not been present since a very young age.
 2. There is data indicating that a large percentage of people who do transition regret it, and have to live with this decision, or find a way to transition back. Since they often do not return to the original surgeon, who participated in their transition, this is not well documented.
 3. Although much has been said about gender, dysphoria, causing people to commit suicide, I believe that there is an equal amount of suicide after transitioning when the person finds that this does not solve their problems.
 4. About 80% of children who do say they want to change their gender change their minds by the time they become an adult. I think many of us can remember, wanting to belong to the other gender for various superficial reasons when we were children But this was transient and luckily, our parents did not take it seriously. Before drastic measures are taken there needs to be in-depth counseling of the child and the parent to determine what is at the root of this desire and in most cases surgery should wait until the child is an adult and can make more informed decisions.
 5. Children are not capable of foreseeing the long range consequences of such a decision.

I write to you as the parent of a trans-identifying teen, aged 17, from the UK. A girl who says she is a boy and who requested the use of male pronouns and a male name at school two years ago (when only 15), a request to which the school agreed without the knowledge of us, her parents. In fact, they hid the fact from us for two months, and paid no heed to my pleas when we did find out, to consider reversing the change. They - without any specialist knowledge in this field - seemed to believe that 'social transition' was a harmless concept. It is not.

Luckily, we live in the UK and my child has not requested any hormones to transition, or any surgery. Of course, this may all change when she becomes an adult (age 18) , next July. But for the time being we are 'safe'.

I have talked to my daughter extensively about this and said, "If you still feel this way when your brain has matured, around your mid-20s, then lets talk again.

But in the meantime, you are a biological female (a fact that, to be fair, she acknowledges) and you cannot ever BE male. All you can do is take opposite sex hormones and 'pass' as the opposite sex and have body-altering surgeries, should you so wish. I have emphasized to her the side-effects of cross-hormone therapy, many irreversible, and the obvious irreversibility of any surgeries. I have said, "You'd better be damn sure before you do any of this, that it's what you really want. And that you will be able to sustain this life-long adherence to such medical treatment."

I do not believe that the vast majority of 'gender experts' in the world are acting in the best interests of children. They are 'affirming' a self-diagnosis of 'being trans' which they would not DO in any other condition (eg anorexia). I believe that gender dysphoria is first and foremost a body dysmorphia. My daughter was incredibly girly growing up, but after she started her period, that's when she became uncomfortable in her female body. I do not believe that she wants to 'be' a male, rather I'm convinced that she is just not ready yet to be a woman.

I would strongly urge you, at the Florida Board of Medicine, to severely restrict all prescribing of puberty blockers, or cross-sex hormones, to under 18s. In cases where parents truly believe such treatment would be in the best interest of their child, I would suggest the conduct of a proper clinical trial, where the children are followed long-term (most youth receiving hormones and getting 'gender' affirmative surgeries are not followed anywhere in the world).

Also, in the case of youth aged 18 to 25, I would strongly implore you to look at the 'informed consent' model used to justify 'gender-affirming' care - again, I don't believe these young people are sufficiently mature to understand the implications of what they are undertaking. Surgeons have not historically performed hysterectomies on young women under 25 - even if they have begged for them for example due to severely painful endometriosis. The young woman claiming that she doesn't want children at that age is deemed not reliable, as they may change their mind as they get older. Why should this be any different for a young woman who wants her womb removed because she wants to pass as male??

Thanks for considering my submission

Dear Board of Medicine members,

As a physician dealing with patients of all walks of life, including transgender patients, I would like to remind you that we all have a most important responsibility: Protect our children from “well meant” but utterly misguided attempts to change their gender and feed into their “gender confusion”.

Children are NOT mature enough to make these decisions on surgeries and drugs. Just because we can do a thing doesn't mean we should. I have seen many several adult patients with previous gender changing measures and their lives have been misery. I will refer you to an article that does make it real of what we do not want:

<https://thefederalist.com/2019/10/24/it-should-be-illegal-to-give-children-transgender-hormones-and-surgery/>

Scientifically, I just want to reference the recent extensive review of the literature in the United Kingdom by Dr. Hilary Cass. The conclusion was that the quality of evidence supporting medical transition was deficient. Just to remind you that these findings have caused the UK, Sweden and Finland to change their approach to minors with gender dysphoria. Certainly, Florida should also undertake a slow and cautious approach to gender dysphoria in minors, emphasizing mental health evaluations rather than jumping quickly to medical transition. (<https://cass.independent-review.uk/publications/interim-report/>)

It is your and our societal responsibility to not allow treatments that are “experiments” on minors.

Thank you,

Siegfried O.F. Schmidt M.D., Ph.D., FAAFP

Dear Sir -

I am writing to you both as a parent and a trauma informed healing practitioner as you consider regulating gender care.

I strongly urge you and the Florida government to set an important precedent by

- regulating medicalized gender care, especially for minors
- bringing focus back to science-based, holistic methods.

As a mother raising two teenagers, I understand how difficult it is for young people growing up and going through puberty at a time when so much is changing socially, economically, politically and globally.

Many young people from different backgrounds are struggling with their well being post lockdown, and have depression, anxiety, and various mental health challenges.

As a trauma specialist, I have learned that trauma can alienate us from our bodies, which is why so many young people begin to hate their bodies and self harm (cutting, anorexia, identifying as trans). The pathway to healing trauma is to work with our autonomic nervous systems in order to find ease in ourselves again (see references below signature line). Children in distress need somatic, body based therapy in order to heal the trauma from the inside out. They need to have their bodies as whole and as healthy as possible so that they have someplace to come home to when they are ready to heal.

Medicalizing an otherwise healthy body, poisoning it with wrong sex hormones and removing healthy body parts increases trauma rather than relieves it. It also creates medical problems that will continue to compound the existing trauma.

It is hard for me to comprehend, given what we know about children's development, teens, and trauma, that we are even entertaining any other pathway than psychotherapy and holistic care for young people.

I urge you to do the right thing by young people and the parents who are desperate to protect them. Please bring sanity into gender care and put a stop to knee-jerk 'affirmation' and medical harm.

Sincerely,
Lana A. Harel, ScD, PCC, SEP
Mountain View, CA

Dear Dr. Vazquez,

The clinical research in support of youth transition uniformly falls into the lowest rank order of reliability. Given that these interventions are often being performed in patients who, because of their age, are unable to give full informed consent, these practices should be limited to strictly controlled studies under IRB review only. Thank you for your time and attention to this matter.

Dear Mr. Vazquez:

There is a lack of quality evidence supporting efforts to medically or surgically alter secondary sexual characteristics in minors with gender dysphoria. In a recent extensive review of the literature in the United Kingdom by Dr. Hilary Cass, the conclusion was that the quality of evidence supporting medical transition was deficient. These findings have caused the UK, Sweden and Finland to change their approach to minors with gender dysphoria. Florida should also undertake a slow and cautious approach to gender dysphoria in minors, emphasizing mental health evaluations rather than jumping quickly to medical transition.

To perform surgeries or other procedures, the issue of informed consent in minors comes up. There is no way that these minors or their parents can fully comprehend the long-term impact that utilizing these experimental drugs or surgeries will be. There is an increasing number of persons who are attempting to undo what was done to them medically or surgically at an earlier point in their lives. Contrary to what some say, many of the changes brought about medically or surgically can never be adequately undone.

Please protect our children.

Hello,

It has come to my attention that there is a bill that will be considered regarding whether or not to affirm the choices of transgender youth, and that the Florida government is looking for input from medical professionals. Feel free to share the statement below.

I am a registered nurse and I work in an Emergency Department. I have cared for numerous individuals who identify as transgender. It is my experience that they do not have a healthy view of themselves. When we consider the actual biology of a human, it is impossible to change from a male to a female, or vice versa. Each cell of the body codes for XX or XY, regardless of what hormones are used to flood the body, or what surgeries are performed. Transgenderism views the body as the problem, but bodies cannot lie. Perhaps the problem is with the thinking of the one who cannot accept his or her birth assigned gender. To try to change this is to damage the body severely. Healthcare providers would do better to explore why such a person has this level of self-hatred, and try to treat that, rather than permanently mutilate bodies. I do not believe a person will ever be at peace or be able to accept himself or herself, if he or she cannot accept who and what they are on this very fundamental level.

Thank you very much for your consideration.

Christina Miller, BSN, RN

Dear Dr. Vazquez, I hope this email finds you well and in good health.

My name is Alfred Cioffi. Academically, I have a Doctorate in Bioethics (Gregorian U, Rome) and a Doctorate in Genetics (Purdue U). I am an Associate Professor of Biology and Bioethics at St. Thomas University, Miami Gardens, Florida.

In re. teenagers and gender transitioning, a few points to consider:

First, it is well known that the vast majority of gender questioning self-resolves as children transition through the teen years into adulthood. This is within the range of normal psycho-sexual development.

Second, teens -like any of us- are also influenceable by peer pressures and beliefs; but teens generally more influenceable, due to their immature mind.

Third, many parents do not necessarily possess in-depth knowledge of human psycho-sexual development. Therefore, when one of their children tells them that they want to "transition" -perhaps because his/her best friend at school is transitioning-, parents may feel pressured to allow their child to transition too, but without realizing the full life-long implications of this.

Fourth, it has also been published that the suicide rate of transitioned people is at least 15x higher than those who do not transition. I know that Drs. Mayer and McHugh's data (Johns Hopkins) has been challenged and disputed -it starts getting ideological. Even so, even if it's only twice or three times the background suicide rate, that is sufficient reason for pause. And, we can't just keep blaming societal non-acceptance for the discontent, since there's plenty of acceptance in society today.

Fifth, since a full transition is essentially irreversible (loss of genitalia and therefore fertility), we really should wait at least until adulthood, when the person, on average, will have a more mature mind to make this drastic decision. Repressing puberty artificially on teens is cruel, abusive and ethically unjustifiable. Teens deserve at least the chance to finish their biological sexual development before considering this issue.

In sum, I ask you to please refrain from allowing teens to transition, and from parents consenting to their children's transition. This is an extremely serious decision, and should be strictly adult fare.

Respectfully submitted,

Alfred Cioffi, SThD, PhD

I believe that there is insufficient evidence to support altering secondary sexual characteristics in minors with gender dysphoria. The extensive literature review of the issue performed by Dr. Hilary Cass concluded that the quality of evidence supporting medical transition was deficient.

Furthermore, I do not believe that minors have the experience or maturity to make gender altering decisions, with or without parental support.

I urge the Board to recommend against making medical transition available to minors suffering from gender dysphoria.

Dear Dr. Vasquez and Florida Medical Board,
I would like to comment on medical intervention for gender dysphoria and its regulation, for your upcoming hearings.

Normally, I would not want the government to interfere between the physician-patient relationship. However, in spite of the medical interventions for gender dysphoria not being demonstrated to help (as in your own evidence review and those in Sweden, the UK, Finland and even the Endocrine Society finding low quality evidence behind recommendations), the US has adopted the affirmative model for treatment, recklessly and without evidence to back it.

I'm sure you'll get lots of letters saying that major (US) medical societies agree that the affirmative model is appropriate, but I'm sure you also know that the AAP adoption was not based upon evidence ("Remarkably, not only did the AAP statement fail to include any of the actual outcomes literature on such cases, but it also misrepresented the contents of its citations, which repeatedly said the very opposite of what AAP attributed to them.", Cantor, Journal of Sex and Marital Therapy, 2020) and the Endocrine Society's current position statement also departs from the evidence (claiming gender identity does not respond to external influences, that medical intervention has been established to help, etc., see one rebuttal by Malone et al., 2021). This area of medical practice is full of misinformation (e.g., see Levine et al, 2022), with many clinicians, patients and their families completely unaware that trans identification can be temporary. Treating a temporary condition with interventions which are serious, irreversible and inappropriate once the condition resolves is iatrogenic harm. There is no clear test to determine when trans identification is not the temporary, so caution is crucial. It is also known that many comorbidities might be contributing to a transgender identification, which is why several countries recommend or have put into policy that mental health support should be first line. The misinformation in the US is so bad that even some American clinicians who are supposedly expert, e.g. a new UCSF gender professor, don't know therapy can help gender dysphoria resolve for some (<https://www.gendergp.com/exploring-detransition-with-dr-jack-turban/>). Most people don't seem to realize that long term outcomes are unknown, that even the number of detransitioners are unknown! (The commonly quoted < 4% or < 1% numbers are either from measuring regret too soon, losing track of people who were likely to regret, and/or measuring something besides regret and calling it regret, no one is really keeping track right now, again, how is large scale serious intervention like this happening when even this most basic information is missing??) There is a honeymoon period, regret studies find regret happening at 4,8, even 10 years on average, depending upon the study, so many of the people who will write you saying it is helping them...check back with them later. I believe there is going to be a horrifying flood of detransitioners shortly.

Given the enormous ignorance found in yours and other reviews, it is unclear why these drastic (including interruption of puberty, sterilization of young people and removal of healthy body parts, some of them key parts of the endocrine and reproductive systems) are being done outside of research studies, being done without extensive informed consent and oversight.

By informed consent, I mean factual informed consent, rather than what many young people and even some clinicians believe. In particular, many clinicians follow the affirmative model, which assumes that mental health issues are likely due to minority stress, and which assumes that medical intervention will be beneficial for mental health, gender dysphoria and quality of life, long term. This has not been shown to be true. The model's stance of quickly providing medical intervention as "care" instead of starting with exploratory therapy is also not supported by the evidence, but instead in conflict with it, given that many variants of gender dysphoria resolve with mental health support alone. The "informed consent" model where no mental health evaluation is also used in the US for people over the age of consent; it is appallingly irresponsible as well.

I know many clinicians are aware and afraid to speak up, I know journalists who have tried to speak up and have either been cancelled or gagged. I know many well meaning but misinformed people who think they are supporting trans-identified individuals by trying to get them medical intervention, not realizing that they are in fact working hard to provide inappropriate care which will recklessly interfere with the bodies of many distressed young people in irreversible and damaging ways which will cause them lifelong harm. It is horrifying that this has gone on so long.

The medical profession is not regulating itself on these interventions, so I think it is absolutely appropriate that the state do so instead.

Please support these young people with evidence based care. These interventions should be treated as experimental for people under 25 or who are for other reasons developmentally immature, and be restricted to only extreme cases in highly regulated research studies. It is a travesty that the medical profession is not doing this already, but if they won't do their job, please step in--regulate the medical treatments until the medical profession treats these young people's bodies and futures with respect! Right now, instead, terrible harm is being done.

Thank you for looking into this serious and important medical question,
Joanne

First off, thank you for being willing to examine the extremely nuanced issue of transgender medicine in a non-political forum.

I would like to express my deep concern for the current trend in “affirmation care” for transgender youth. Recently our 13 year-old daughter suddenly told us that she feels like a boy. She showed no signs of gender dysphoria prior to her declaration. Since her announcement I have learned that 80% of the girls in her friend group claim a trans-ID and a review of her social media activity revealed an almost exclusive interest in the trans community. To us, there is an obvious social contagion aspect to the explosive rise in transgender identified youth.

In an effort to seek assistance in identifying the root cause of our daughter’s sudden discomfort, we immediately sought professional medical guidance. We were aware of many external influences that were affecting the overall mental health of our daughter and explained these to the professionals assuming they would ask deep questions and address all relevant factors contributing to our daughter’s distress. Unfortunately that was not the case. Once gender is mentioned the child is identified as exceptional and the pathways to healing narrow to ‘affirmation care’ only. The first professional we visited was an adolescent specialist MD who explained to our child that if she “felt trans, then she was trans” and began to explain the steps toward medical transition. All this was covered in our first visit. The second professional we visited was a counselor who immediately labeled our child as gender dysphoric and advised that we support social transition by using her preferred name and pronouns in order to reduce the risk of suicide.

My concern is that we are pathologizing and medicalizing puberty without sufficiently addressing serious mental health concerns. Yes, puberty is a most unpleasant phase of life, but nonetheless it is a very natural phase. We do our children a great disservice when we encourage them to ignore or run away from discomfort rather than teaching them ways to cope and accept themselves. I understand the allure of thinking that a medical intervention will take away one’s feelings of discomfort, but I find it unlikely that a radical physical change will ever satisfy a mental stress. These young people are hurting. It is a strange and complicated world they are growing up in. But what they need from us is encouragement to accept themselves and reality, not pills and surgeries. Please examine robust, peer reviewed data and seriously consider implementing safeguards to protect minor children.

Thank you for your time and consideration,
Susan Albon

ATTN: Paul A. Vazquez, J.D. Executive Director Florida Board of Medicine

Dear Director Vazquez,

My 26 year old daughter was caught in the web of social contagion that emerged insidiously into our society while she was an easily influenced adolescent. The influence continued into her late teens and early twenties, and there was little support for any parents to stop it. In fact, most professionals and anyone I spoke with didn't seem alarmed, let her find herself, she is going to be who she is intended to be. Fortunately, although she is socially transitioned, she has not gone any further. My hope is that she will go no further down this road. She never wanted to be a boy/man, and of this I am certain.

This social contagion has caused a tremendous amount of undue pain and anguish for our family, and it continues each and every day of my life. I know this is the case for many many more families with adult children of this generation who were influenced and supported in the most insidious ways by teachers and medical professionals. It will go down as the single most devastating and dangerous social contagion to ever plague our children. It needs to stop and I plead with you and all government leaders within your influence to put a stop to it now.

I am deeply troubled by the continued promotion and advocacy of this insanity from media and professionals who think it is a perfectly sound idea to follow the whims of a child and allow them to make permanent and irreversible decisions to mutilate their bodies to assuage typical adolescent insecurities. Very very few people truly are "born in the wrong body." Very very few...

We need your help to stand up against this social contagion and prohibit medical and educational professionals from pushing this agenda any further. Big money is promoting it and there is no concern for children, their welfare, nor the destruction to so many families.

Please help.

Regards,
Kay Biltucci

Dear Paul A. Vazquez, J.D.
Executive Director Florida Board of Medicine

I am a parent of a 16 year old girl, who identifies as transgender.
Our daughter is not transgender: she has struggled since she was 11 with mental health challenges and
with her social anxiety, not to mention low self esteem.
We are constitutionally opposed to the affirmation model and with hormonal and surgical interventions. These are not based on science or ethics for this new population of teenage girls. A very vulnerable population.
Great Britain recently commissioned a highly distinguished public health and pediatric expert to
reconsider the affirmative model in the United Kingdom.
Please consider with care the findings of the Cass Review interim report.
What is the Cass Review interim report?
The Cass Review is an Independent Review of Gender Identity Services for Children and Young People. It was 'commissioned by NHS England and NHS Improvement in Autumn 2020 to make recommendations about the services provided by the NHS to children and young people who are questioning their gender identity or experiencing gender incongruence [1].' In March 2022, the Cass Review submitted an interim report to NHS England. This interim report '[set] out [the] work to date, what [had] been learnt so far and the approach going forward [2].'

Who is Dr. Hilary Cass

Dr Hilary Cass was appointed by NHS England and NHS Improvement to chair the Independent Review of Gender Identity Services for children and young people in late 2020.

A former President of the Royal College of Paediatrics and Child Health from 2012-2015, Dr Cass recently finished a term as Chair of the British Academy of Childhood Disability (2017-2020).

Although retired from clinical practice, she remains an honorary Consultant Paediatrician at Evelina London Children's Hospital, Guy's & St Thomas's NHS Foundation Trust, where

she was also previously Director of Education and Workforce.

Dr Cass is currently Chair of Together for Short Lives, and a Trustee for Noah's Ark Children's Hospice. She is also leading work on how to address the challenges for both families and professionals in supporting the rising numbers of children with complex medical conditions and disability.

Other recent roles include acting as the Senior Clinical Advisor for Child Health for Health Education England.

Prior to this Dr Cass held a range of senior education and management roles in NHS hospital trusts and was previously Head of School of Paediatrics in London. Her consultant clinical practice was as a tertiary neurodisability consultant from 1992 to 2018 in three very different specialist centres and she has published widely in this area.

In addition to her neurodisability practice, Dr Cass was closely involved in the development of paediatric palliative care services at Evelina London Children's Hospital.

Dr Cass was awarded the OBE for services to child health in 2015. She was also awarded an honorary fellowship by the Royal College of Nursing in 2015, and by RCGP in 2016.

Background

The United Kingdom has seen a significant increase in the number of children seeking help for distress in relation to their biological sex. Many school staff first started noticing the phenomenon of children – predominantly teenaged girls – wanting to change sex during the last decade.

In recent years, there has been a significant increase in the number of referrals to the Gender Identity Development Service (GIDS) at the Tavistock and Portman NHS Foundation Trust (para. 1.1).

From a baseline of approximately 50 referrals per annum in 2009, there was a steep increase from 2014-15, and at the time of the CQC inspection of the Tavistock and Portman NHS Foundation Trust in October 2020 there were 2,500 children and young people being referred per annum, 4,600 children and young people on the waiting list, and a waiting time of over two years to first appointment (para 3.10).

This surge in children seeking help for distress in relation to their sex is occurring in the context of an ongoing public debate around issues relating to sex, gender and gender identity.

Over the last few years, broader discussions about transgender issues have been played out in public, with discussions becoming increasingly polarised and adversarial. This polarisation is such that it undermines safe debate and creates difficulties in building consensus (para. 2.4).

No consensus

This being a new phenomenon, research is limited and no consensus exists (within the scientific community) about possible causes and most appropriate treatment options.

At primary, secondary and specialist level, there is a lack of agreement, and in many instances a lack of open discussion, about the extent to which gender incongruence in

childhood and adolescence can be an inherent and immutable phenomenon for which transition is the best option for the individual (para. 1.7).

We must secure a balanced treatment of political issues, they must take a child-centred, evidence-based approach, and take care not to express personal beliefs in ways which could exploit pupils' vulnerabilities. We should not for example, present, as fact, childhood gender incongruence as an inherent and immutable phenomenon as this is a contested idea rather than an established evidence-based fact.

Low quality evidence

The Cass Review interim report acknowledges that '[over] the last few years, broader discussions about transgender issues have been played out in public, with discussions becoming increasingly polarised and adversarial' (para. 2.4). Many of us feel confused or conflicted about approaching the issues of sex and gender identity with adolescents. The above-mentioned rise in referrals to GIDS has been accompanied by an increasing number of news reports claiming that some teachers and/or schools are promoting the idea that gender identity supersedes sex. However, there is insufficient high quality, longitudinal data (relating to gender-questioning children) from which to draw robust conclusions. There is a notable gap in the evidence base pertaining to the surge in female teenagers seeking support from gender identity services.

Aspects of the literature are open to interpretation in multiple ways, and there is a risk that some authors interpret their data from a particular ideological and/or theoretical standpoint (para. 1.29).

Decisions need to be informed by long-term data on the range of outcomes, from satisfaction with transition, through a range of positive and negative mental health outcomes, through to regret and/or a decision to detransition. The NICE evidence review demonstrates the poor quality of these data, both nationally and internationally (para. 3.21). It is also important to note that any data that are available do not relate to the current predominant cohort of later-presenting birth-registered female teenagers. This is because the rapid increase in this subgroup only began from around 2014-15. Since young people may not reach a settled gender expression until their mid-20s, it is too early to assess the longer-term outcomes of this group (para. 3.23).

Since the rapid increase in this group began around 2015, they will not reach late 20s for another 5+ years, which would be the best time to assess longer-term wellbeing (para. 5.10).

This is an area of research where no scientific consensus exists. Schools must be aware that any claims made about the reasons behind the increase in gender-questioning children are speculative and cannot be treated as established evidence-based facts.

Changing epidemiology

Early childhood gender dysphoria is not a new phenomenon. However, the existing literature on treatment and outcomes is largely based on early childhood gender dysphoria in male children. It may not apply to the current cohort of gender-questioning children who are older, predominantly female and often presenting with a range of neurodevelopmental

and mental health co-morbidities.

In the last few years, there has been a significant change in the numbers and case-mix of children and young people being referred to GIDS (para 3.10).

This increase in referrals has been accompanied by a change in the case-mix from predominantly birth-registered males presenting with gender incongruence from an early age, to predominantly birth-registered females presenting with later onset of reported gender incongruence in early teen years (para. 3.11).

The mix of young people presenting to the service is more complex than seen previously, with many being neurodiverse and/or having a wide range of psychosocial and mental health needs. The largest group currently comprises birth-registered females first presenting in adolescence with gender-related distress (para. 1.10).

Much of the existing literature about natural history and treatment outcomes for gender dysphoria in childhood is based on a case-mix of predominantly birth-registered males presenting in early childhood. There is much less data on the more recent case-mix of predominantly birth-registered females presenting in early teens, particularly in relation to treatment and outcomes (para. 1.28).

Secondly, the cohort that the original Dutch Approach was based on is different from the current more complex NHS cohort, and also from the current case-mix internationally, and therefore it is difficult to extrapolate from older literature to this current group (para. 5.10).

The Cass Review interim report highlights the difficulties faced by clinicians responsible for making diagnoses and recommending treatment. Teachers are neither qualified nor capable of critically evaluating existing evidence. They must carry out their duties within statutory and non-statutory frameworks. This included ensuring that any necessary referrals are made as specified by their schools' safeguarding protocols.

Diagnostic overshadowing

Another significant issue raised with us is one of diagnostic overshadowing – many of the children and young people presenting have complex needs, but once they are identified as having gender-related distress, other important healthcare issues that would normally be managed by local services can sometimes be subsumed by the label of gender dysphoria (para. 4.10).

School staff must be clear that they are not qualified to offer students advice in this area. Moreover, the promotion of specific beliefs about the source(s) of gender-related distress could influence children's attitudes toward the diagnostic process before meeting with a clinically trained professional. Guidance from the Department for Education states that teachers "are in a position of authority and will typically be respected and trusted by the pupils they teach, giving their personal opinions greater weight and credibility. As a general principle, they should avoid expressing their own personal political views to pupils unless they are confident this will not amount to promoting that view to pupils [4]."

Affirmative vs developmental models

Broadly speaking, there are two approaches to treating children with gender-related distress: the gender-affirmative approach and the developmentally-informed approach. The

gender-affirmative approach is based on the theory that a child's gender identity is innate. The developmentally-informed approach is based on the theory that a complex interaction of multiple factors underlie gender-related distress. The Cass Review interim report acknowledges that some clinicians report being under pressure to adopt a gender-affirmative approach.

Following directly from this is a spectrum of opinion about the correct clinical approach, ranging broadly between those who take a more gender-affirmative approach to those who take a more cautious, developmentally-informed approach (para. 4.15).

Some secondary care providers told us that their training and professional standards dictate that when working with a child or young person they should be taking a mental health approach to formulating a differential diagnosis of the child or young person's problems. However, they are afraid of the consequences of doing so in relation to gender distress because of the pressure to take a purely affirmative approach (para 4.20).

There is a spectrum of academic, clinical and societal opinion on this. At one end are those who believe that gender identity can fluctuate over time and be highly mutable and that, because gender incongruence or gender-related distress may be a response to many psychosocial factors, identity may sometimes change or the distress may resolve in later adolescence or early adulthood, even in those whose early incongruence or distress was quite marked. At the other end are those who believe that gender incongruence or dysphoria in childhood or adolescence is generally a clear indicator of that child or young person being transgender and question the methodology of some of the desistance studies (para. 5.8).

School staff are unqualified to evaluate the merits of these approaches. Moreover, they have an obligation to remain politically impartial. This means not supporting one approach over another.

Social transition

Social transitions (the act of treating children as if belonging to the opposite sex) are performed by some schools in England. A social transition is a powerful psychological treatment that affects a child's psychological development. Not only are school staff unqualified to judge the appropriateness of such interventions, the outcomes are poorly understood.

Social transition – this may not be thought of as an intervention or treatment, because it is not something that happens within health services. However, it is important to view it as an active intervention because it may have significant effects on the child or young person in terms of their psychological functioning. There are different views on the benefits versus the harms of early social transition. Whatever position one takes, it is important to acknowledge that it is not a neutral act, and better information is needed about outcomes (para. 5.19).

Pressure

The Cass Review interim report acknowledges the pressures clinicians are under to adopt an unquestioning affirmative approach. Similarly, there is an acknowledgement that children are under pressure to identify with societal stereotyping. Schools cannot erase the

pressures that children are under from, for example, social media and peers. However, teachers should promote acceptance for children's non-stereotypical behaviour (boys and girls exhibiting stereotypically 'feminine' and 'masculine' behaviour, respectively) and avoid reinforcing harmful stereotypes.

Primary and secondary care staff have told us that they feel under pressure to adopt an unquestioning affirmative approach and that this is at odds with the standard process of clinical assessment and diagnosis that they have been trained to undertake in all other clinical encounters (para. 1.14).

From the point of entry to GIDS there appears to be predominantly an affirmative, non-exploratory approach, often driven by child and parent expectations and the extent of social transition that has developed due to the delay in service provision (para. 1.18).

It is not the role of this Review to take any position on the cultural and societal debates relating to transgender adults. However, in achieving its objectives there is a need to consider the information and support that children and young people access from whatever source, as well as any pressures that they are subject to, before they access clinical services (para. 2.5).

We have heard that distress may be exacerbated by pressure to identify with societal stereotyping and concerns over the influence of social media, which can be seen to perpetuate unrealistic images of gender and set unhealthy expectations, especially given how long children and young people are waiting to access services (para 4.13).

These will be considered further during the lifetime of the Review and include: . . . The complex interaction between sexuality and gender identity, and societal responses to both; for example, we have heard from young lesbians who felt pressured to identify as transgender male, and conversely transgender males who felt pressured to come out as gay rather than transgender. We have also heard from adults who identified as transgender through childhood, and then reverted to their birth-registered gender in teen years (para. 4.14).

Safeguarding

Children with gender-related distress may pose specific safeguarding concerns. They have a higher incidence of comorbid psychiatric and/or developmental difficulties. They are also more likely to be looked after children. Teachers need to be aware of possible harms such as breast binding or tucking (of male genitals). Children may also be subjected to grooming and/or coaching, and encouraged to deceive parents, clinicians and teachers in order to secure particular outcomes such as clinical diagnoses of gender dysphoria. They may also be receiving cross-sex hormones from unregulated sources.

In addition, approximately one third of children and young people referred to GIDS have autism or other types of neurodiversity. There is also an over-representation percentage wise (compared to the national percentage) of looked after children (para. 3.11).

We have also heard about the distress experienced by birth-registered females as they reach puberty, including the use of painful, and potentially harmful, binding processes to conceal their breasts (para. 4.3).

Most children and young people seeking help do not see themselves as having a medical condition; yet to achieve their desired intervention they need to engage with clinical services and receive a medical diagnosis of gender dysphoria (para. 4.4).

We have heard that some young people learn through peers and social media what they should and should not say to therapy staff in order to access hormone treatment; for example, that they are advised not to admit to previous abuse or trauma, or uncertainty about their sexual orientation (para. 4.5).

We have heard about families trying to balance the risks of obtaining unregulated and potentially dangerous hormone supplies over the internet or from private providers versus the ongoing trauma of prolonged waits for assessment (para. 4.7).

Summary

There has been a huge increase in the number of children (predominantly female teenagers) seeking help for distress in relation to their biological sex. Research into this new phenomenon is limited. The lack of high-quality data from longitudinal studies together with the changing epidemiology means that no consensus exists about the possible causes for this recent surge in children wanting to change sex. Clinically trained professionals face difficulties in making diagnoses and recommending treatment. School staff who now affirm my daughter are neither qualified to evaluate existing research nor clinically trained.

Therefore, they cannot judge the appropriateness of, for example, socially transitioning children. It is an intervention with poorly understood outcomes that affects children's psychological development. The Cass Review interim report outlines some of the specific safeguarding issues that surround gender-questioning children.

Thank you most sincerely for your time and consideration.

Kind regards,
JackalynnLopez

Please, please, please do NOT consider gender affirming CARE. It's not care; it's destructive. Please don't buy into the Transgender ideology that has trapped many youth including my daughter who are so vulnerable. They are too young to be making harmful medical decisions. And medical gender affirming treatment is harm, long lasting harm, destructive harm that can't be taken back.

Stop gender affirming for youth and children!!!
Please !!!!

Florida Medical Board Affirmative Therapy Submission

We are an Australian family. We love and respect our 23 year old daughter who identifies as a transgender male and is in the process of transitioning. She was prescribed testosterone injections by a medical practitioner, which she is now self administering and will be doing so for the rest of her life. It is difficult to express the heartache that this has caused her father and myself. We are not satisfied that the path that she is currently on is the best way for her to deal with her gender issues and we are worried about her future health both physically and mentally.

At no stage in the process of gender identification and transition has she consulted with a psychologist, something that has been of great concern for us. We have urged her to seek psychological counselling to deal with underlying mental health issues that may be associated with the body dysmorphia and gender dysphoria she has been experiencing.

As deeply concerned parents, we researched transgenderism and found that not only is gender dysphoria included as a mental disorder in the DSM4, studies have shown that there is a potential higher prevalence of ADHD and ASD among transgender individuals. It is clear that transgenderism is a psychological disorder. Our belief is that surgery and hormone therapy is not the way to properly treat the problem. There is nothing wrong with the body of a transgender person, there is a disconnect with the person's perceptions of their body and this is where treatment should be first directed.

Our daughter has symptoms of ADHD and has through adolescence experienced trichotillomania (compulsive hair pulling) and tics, therefore, it appears that our daughter's anxiety regarding her gender may be ameliorated by rational psychological approaches instead of the life altering and potentially dangerous avenue of gender affirmation treatment. To our thinking, it makes sense that treatment for associated conditions such as ADHD or OCD and anxiety/depression, should be the first strategy in treating transgender individuals; hormone therapy and surgery should be considered only after a careful psychological and complete medical evaluation.

Another concern we have as parents is that the long term negative impact of testosterone on the body of female to male transitioners has not been evaluated, especially in cases of polycystic ovary syndrome. Transgender males have a higher than average rate of polycystic ovary syndrome and a case has occurred where a transgender male developed ovarian cancer while receiving testosterone as part of their transition. While this is only one reported case, there is little evidence to show that long term testosterone injections have a benign impact on ovarian tissue. The five year survival rate for ovarian cancer is 45.7 percent, an alarming statistic that should not be ignored when it is clear that testosterone is being indiscriminantly injected into healthy female bodies, and all that an individual has to do to have this hormone prescribed is to state that they have a belief that they have been assigned the incorrect gender at birth.

Testosterone was prescribed to our daughter by a practitioner without any other medical or psychological evaluation having been presented. We find this highly irresponsible and frankly,

dangerous to her future health and well being.

As parents of a daughter who is transgender, our worries revolve around the activity of those members of the medical profession who see fit to, and profit from, indiscriminantly prescribing gender affirming drugs, as well as performing life altering surgeries on transgender individuals, who research has shown are suffering from a mental disorder that is being allowed to go unevaluated and untreated.

Diane and John,

Adelaide (South Australia)

EXTERNAL EMAIL: DO NOT CLICK links or open attachments unless you recognize the sender and know the content is safe.

Dear Paul A. Vazquez, J.D. ,

I am the parent of a teen who became confused about his gender a few months after covid first hit. However, we did not find out about his "new" identity until last year. My child never showed any signs of gender confusion in his childhood. He was what we call the typical boy who loved everything that had to do with boys. He loved playing outdoor and getting dirty. Never showed any distress with the clothes he wore and always loved playing with boy toys (cars, trucks, trains, etc). His gender confusion came after the amount of time he spent on the internet during covid lockdown.

In the last year we have tried helping our child by removing social media and blocking certain sites from his phone and computer. We also tried finding him a therapist. However, after doing some research and speaking with other parents who are in this same situation as us, we came to the conclusion that no therapist is better than a bad one. You see, once the gender topic comes up, therapist and other specialists now put everything else aside and just focus on that. Then they send kids/young adults to a gender clinic where they are placed on crossed-sex hormones and then have irreversible surgeries. But of course you know all that. That is now what these children and young adults need. We need stop putting them into a path of irreversible damages.

A lot of this children suffer from anxiety, depression, ADHD, autism, and bullying. Some were sexually assaulted and have not been able to speak about it.

Our child, for example, was a victim of bullying while he was in middle school. Sadly we did not find about it until he no longer attended the school and he refuses to tell us what happened to him.

Although we do not affirm his new identity, we love our child and nothing will ever change that. We worry about him and his future if he continues on this path. For now, he has only come out to his closed friends at school who celebrate his new identity and affirm him. Friends of which most are also calling themselves trans or non-binary.

I don't understand how professionals like yourself are blinded by what is happening out there. In the past few years, we have seen an enormous increase of children identifying as trans, specially after covid lockdown. Children are being told that if they feel a certain way, it is because they were born in the wrong body. What kind of nonsense is that? This ideology makes it seem like we walk into a store that sells infant parts and we put them together just like we do with the Mr. Potato Head toy. It's ridiculous. We all know no child is born in the wrong body.

I ask you, actually I beg you to please put a stop to this medical malpractice happening with children and young adults. We need you to create a rule that will prevent doctors from bring able to prescribe experimental puberty blockers, cross sex hormones and perform any type of gender affirming surgeries such as double mastectomies, vaginoplasty or phalloplasty on minors. Below you will find reasons why we need to put a stop to this.

- There is a lack of high-quality rigorous evidence surrounding these treatment procedures, which make them experimental in nature since the long-term consequences of these drugs being used on children/teens are relatively unknown. There is also a lack of debate among medical professionals in this area because doctors that speak out against these treatments being used on children are silenced. Alternate treatment options are not being considered or even presented at this point in medicine. It appears activism has infiltrated our medical community on this issue and biological reality is being ignored.
- The side effects we are aware of often times lead to the sterilization of these individuals and the loss of any future sexual function when puberty blockers are used.
- Children and teen brains are not fully developed until age 25 and therefore they cannot give informed consent because they don't have the ability to fully understand the consequences of these treatments. Parents are also not

being given the full picture and all treatment options available to them like the watchful waiting approach. They are being told to only affirm or their child will commit suicide. They are also not told that through the watchful waiting treatment approach, many of these children, upwards of 80%, would resolve their distress during or shortly after puberty. There is also no evidence that medical transitioning children actual improves mental health outcomes.

- Proper assessments are not being done and there is little to no safeguarding in place before a child is placed on a medical pathway. Many of this new cohort of children/teens do not even meet criteria for gender dysphoria, yet they are being treated medically for the “feeling” in their mind that they should be the opposite sex. They are experiencing normal discomfort with their pubescent body, but are being convinced that any amount of discomfort with their body is an indication that they are “transgender.” There is currently no coherent definition of the word transgender in the medical field.

- Co-morbid issues are being unchecked and unresolved in the name of gender affirming care and patients and parents are being told that medical transitioning will fix their child’s distress.

- We are now seeing the population of detransitioners increase every day because they come to the realization that medical transitioning did not fix their pain and many are stating their co-occurring mental health issues were ignored or not explored.

- Medical organizations and associations are blindly adopting guidelines from WPATH without doing a proper review of the evidence being used for these guidelines. These guidelines are being pushed as actual standards of care, which is a gross misrepresentation of what these guidelines are. Further, professionals that are speaking out against these guidelines or advocating for a review of existing literature are silenced through gaslighting or simply ignored as in the case of the American Academy of Pediatrics.

- Other countries like the UK, Sweden, Finland and France are re-evaluating these medical treatments for children because they have done a rigorous review of existing literature and research and have come to the conclusion that the risks do not outweigh the benefits in children and there is just so much we don’t know about the long-term consequences of these irreversible interventions. These countries have either stopped medical transitioning minors or are advocating for great caution when medically treating children for gender dysphoria. They are all stating mental health treatment should be the first line of defense, which is not currently happening in the US.

- Despite what the media reports, these surgeries are occurring on children. Many hospitals state openly they are performing double mastectomies on children ages 16 and up and sometimes as young as 15, as stated in the new WPATH guidelines that were set to be released this month. In addition to the pediatric gender clinics in Florida hospitals providing these medical interventions, there are many private plastic surgeons, OBGYN offices, private endocrinologist offices and pediatricians prescribing puberty blockers, cross sex hormones and operating on minors. They claim parents give consent, but should a parent be allowed to consent to experimental medical treatments for their child for a mental health issue? Should parents be able to consent to amputating healthy body parts for their children and taking away their fertility and ability to have a child as an adult?

Again, I ask you to please help put a stop to this by creating a rule that will protect our children from being used as experiments.

Sincerely,

J.C.

September 18, 2022

Paul Vazquez,
Executive Director of the Florida Board of Medicine
Tallahassee, Florida

Subject: Necessary Regulations on “Gender-Affirming” Care

Dear Mr. Vazquez,

I am writing to provide input to the Florida Board of Medicine as it considers regulations around so-called “gender-affirming” care, especially as it pertains to minors and intersects with parental rights.

I am the father of two sons, including a now-18-year-old who is being seen by Dr. Stephen Rosenthal and Dr. Diane Ehrensaft, the co-directors of UCSF Child and Adolescent Gender Center (CAGC). My family’s story was the subject of investigative journalism stories earlier during 2022 that went viral worldwide:

- <https://www.city-journal.org/child-custody-gender-gauntlet>
- <https://www.dailymail.co.uk/news/article-10489717/California-father-denied-custody-trans-son-wouldnt-consent-therapy.html>

Dr. Rosenthal also is an expert witness retained by the Plaintiffs in *Eknes-Tucker v. Marshall* federal lawsuit challenging Alabama’s Vulnerable Child Compassion and Protection Act (VCCAP).

I have read Dr. Rosenthal’s Declaration against VCCAP. I can testify that his statements regarding the standard of care for transgender children, and particularly his claims that parents have the opportunity to exercise informed consent regarding medical interventions for their child are not true with regard to my son when he was a minor.

Dr. Rosenthal claims that medical treatment is done in consultation with the patient's family. In my case this is not true. Dr. Rosenthal's institution (UCSF CAGC) has actively worked to prevent my son's care to the point of providing information to the attorney representing my son in family court aimed at stripping me of custody because I would not affirm my son in a discordant gender identity. Some of the information provided was untrue.

In fact, I knew nothing about my son receiving life-altering medical interventions until I received a statement from my insurance carrier showing that it had paid more than \$200,000 to a child and adolescent gender clinic at UCSF. Even then, I did not know what the payment was for until I asked my ex-wife. She emailed me that she was "happy" to report that our son had been given an implant of Supprelin (used to suppress testosterone) and was receiving estradiol (estrogen) pills.

My research on these substances showed that they chemically castrate patients and are even used specifically for that purpose in some cases for sex offenders. Yet here my 17-year-old son was receiving these drugs from Dr. Rosenthal ostensibly to improve his health and well-being.

I have learned that Supprelin is Dr. Rosenthal's preferred method for administering puberty blockers for adolescents like my son. Supprelin requires surgical implantation, meaning that it is a surgical intervention administered to children under the age of 18, which is contrary to Dr. Rosenthal's testimony that surgical interventions are not prescribed to minors and not recommended by the "Standards of Care."

According to Breitbart News, Dr. Rosenthal has received more money from pharmaceutical manufacturers of the puberty blockers he dispenses than any other doctor: <https://www.breitbart.com/health/2022/07/26/childrens-gender-clinic-founder-was-consultant-puberty-blocker-manufacturers/>

Dr. Rosenthal's testimony also contradicts his actions with my son in that after UCSF implanted my 17-year-old son with Supprelin LA (without my knowledge or consent but paid for by my health insurance), Dr. Rosenthal discussed follow-up surgical options with him without at least one parent present. Dr. Rosenthal discussed breast implants, facial feminization, and bottom surgery with my son at age 17 years and 5 months.

Rosenthal claims to "provide the patient and their family the information they need to make an informed decision about whether to proceed with the treatment." Again that is not true regarding the treatment prescribed for my son. When I sought

information about alternatives, such as “watchful waiting,” and whether patients are assessed by Ray Blanchard’s typology of transsexuals, instead of receiving an answer I was subjected to actions in the family court aimed at stripping me of custody because of my questioning of the protocols at UCSF.

Similarly, when I provided Dr. Rosenthal with research that I had found which suggests that puberty blockers can cause cognitive harm and asked questions I received no response, contrary to his testimony that parents are involved to ensure everyone involved has the information they need to make an informed decision.

Further contradicting his claim of “informed” decision-making is seen in the form presented to and discussed with my then 16-year-old son. The form did not indicate that permanent and irreversible sterility is a potential and likely outcome of the recommended treatment, particularly when puberty blockers are combined with estrogen.

Dr. Rosenthal’s actions with regard to the treatment of my son differ significantly from the “safe and effective” protocols that he claims are part of “gender-affirming” treatments. His refusal to respond to my questions as the concerned father of his patient belie his testimony about the information-rich and collaborative environment he claims is part of the “gender-affirming” care he provides.

My experiences with Dr. Rosenthal instead point to an ideologically-driven conveyor belt onto which vulnerable children like my son are placed and processed without the safeguards usually inherent in medical procedures.

Parental participation is tolerated only so long as it is affirming of the ideology. If, as in my case, the parent asks questions instead of immediately affirming the agenda, then that parent is disregarded even to the point, as in my case, of having their rights stripped away.

The availability of “gender-affirming” medical interventions for vulnerable children experiencing distress about changes in their bodies enables the ideological conveyor belt to proceed unhindered, leaving in its wake sterilized, drug-dependent and dysfunctional young adults, shattered relationships, and distrust in the medical profession.

The Florida Medical Board’s efforts to ban these treatments for minors is necessary to prevent the irreversible and incalculable harms caused by the unchecked gender medicine machine and save Florida families from similar devastation.

Sincerely yours,

A handwritten signature in black ink, appearing to read "Edward H. Hudacko".

To the Florida Board of Medicine:

My name is Torren Danowski and I am a 33 year old male who has desisted from a transgender identity. I prefer the term desisted because thankfully, I never "completed" a full transition process. I am grateful that at my age, I had the self-awareness and introspection to see that affirmative care for my gender dysphoria was nothing more than treating a symptom of much deeper issues. It was as though I was being given morphine for the pain of a broken leg, without the leg itself being treated.

I write to urge your consideration that the current informed consent model being touted by trans activists is incredibly dangerous, especially for younger children. The medical codes used during my treatment that allowed for my prescription for cross-sex hormones indicated that I had a, "disorder of the endocrine system." No such disorder existed. My endocrine system was producing the correct sex hormones based on my biology. However, the informed consent model allowed me to self-diagnose a physical condition that did not exist and be administered drugs that needlessly altered an otherwise healthy body.

I am thankful that because of my age and my community, I was able to continue wrestling with my decisions until I found freedom from the real underlying condition- my mental health and my own self-hatred. Had I not continued to wrestle with my decision, I would have never gotten healing from what actually ailed me and would have continued on trying to live life as transwoman when what I really needed was to learn to love myself as I was.

Informed consent implies that the individual undergoing treatment understands the costs and benefits of the desired treatment. I would argue that under no circumstances can an individual truly know all the costs of attempting a gender transition. I desisted when I realized I had a desire for biological children. I'm 33. No youth will be able to accurately assess their desire for such things until they are much older. This is why doctors often rightfully will not perform sterilization surgeries on young adults. In no circumstances should sterilization, chemical or surgical, be performed on someone not even old enough to vote.

Instead of either supporting or blanket-banning gender-affirmative care such as youth transition or informed consent, I would humbly ask that the board of medicine and all doctors and scientists involved would do more research on what actually causes gender dysphoria as well as potential alternative treatments. There is quite a bit of anecdotal evidence that both Cognitive Behavioral Therapy and psychedelic-assisted therapy can go a long way towards easing and even eliminating gender dysphoria.

Seeking to treat and cure the cause of dysphoria should always be the first option, with transition only being a last resort. If seeking to treat the cause is the first step, that leaves very

little room for an informed consent model, especially for youth.

Thank you,

Torren Danowski

Dear Mr. Vazquez,

I understand Florida is considering regulating gender medicine. I know that every story is different, but I feel that you need to hear our perspective. We are a Military Family stationed in Seoul, South Korea (residents of Florida). When we arrived in Seoul she was gender conforming. Always wore skirts to school, did her nails, wore dresses most of the time out of school. She liked singing and art. She's academically gifted. It was a hard transition. Girls in Korea are super thin with no curves. Our daughter struggled with puberty, growing into her adult female body was painful. She started hanging out with some kids in our neighborhood and suddenly the whole group was identifying as trans. It didn't sit right with me, this child at this point it just didn't make sense. We decided as her parents to take a loving, but stern approach. We did not allow binders, we did not allow social transition at school, we did allow haircuts (shaved head), and she could choose her own clothes. She got very sad, she hated us, she often wrote in her journal that we were bigots and horrible people. We talked about life, that it's long and teenagers don't always have the answers, we talked about medical complications from transition, we got her involved in activities that didn't allow her to wallow in self pity. We also said we accept whoever you become as an adult but now is the time to play with your clothes, your hair, your hobbies, your schoolwork, and everything with sexuality (and gender) will fall into place eventually.

I won't lie the 18 months were terribly difficult, we were often at odds with each other. Friends questioned whether we were being supportive enough. Luckily, schools in Korea are quite conservative so she didn't get much validation at school of this "identity". Living in Korea is not easy for any of us because of various circumstances, but I am grateful every day that my child didn't have an adult concretizing her teenage

"identity". In the past adults never really got involved in a kid's life. There was a separation that I think is healthy. Our teachers didn't obsess over our personal lives. We were free to try things to experiment and grow and learn without the

pressure of an adult cheering or jeering our social choices. My teen did have validation from friends and I feel that she knows that we accept her no matter what but, happened to be skeptical that medical care was necessary for her current situation.

The friends moved away, as they do in military life, and my daughter came back to us. She came to me and said she felt like she woke up from a bad dream, that the trans things she had dedicated her life too didn't sit well with her, she said she felt like she was leaving a cult and that she felt better and happier then she had in the last two years. That's what can happen when you sit with something for a while, when you aren't pushed, when you have time and perspective.

I read the stories of other parents who are not so lucky. The "Glitter Family" grabs these kids and tells them x will make you better, then it does for a while, until you need more and more and in a lot of cases it's never enough. You have to come to peace with who you are. No one should be affirming children especially Counselors and Therapists. If anything they should ask them to question everything and saying that stereotypes don't matter. They shouldn't tell them they aren't trans either, that's not the job of a counselor or therapist. They should only explore and allow the person to make their own decisions. I truly believe that most cases of gender dysphoria resolve naturally after adulthood. Some kids will end up gay, some won't and a very few will have to take further steps to relieve this dysphoria, but what's the rush?

Please take steps to save our children, to let them have time and perspective before they do irreversible damage to their perfect bodies.

Thanks for your time,
Yiotula Shilland

Dear Chairman Diamond,

Thank you and the Board of
medicine for protecting minors from
"gender affirming" treatment. It's
even hard to think that children
would be put through such
treatments and schools, counselors, et
encourage such. We're killing + injuring
our greatest assets with experimental vaccine
and crazy treatments - all due to politics.
Thank you for standing firm - Kent + Cathy Seland

Dear Board Members,

I would like to tell you about why I believe a slower approach should be taken in regards to gender transition versus affirmative care.

My 21 year old son, "B" went to Planned Parenthood and was prescribed male to female hormones on his first visit.

B has a genetic mutation; SDHB which is called c.287-1g>c. This type of SDHB mutation can cause renal and papillary thyroid cancers, pituitary adenomas and also, an increased risk of developing paragangliomas or pheochromocytomas. These types of tumors are more likely to be malignant. Studies have shown that there is a **77-100% chance** of B **developing cancer** between 30-50 years of age. *See attached for additional information in regards to this mutation.*
